Sweet peas may be sown in 3- to 4-inch pots (Fig. 3747). A suitable potting-soil made of well-rotted sod, with a little leaf-mold and sand, is best. Four or five seeds are sown in each pot and covered with an inch of clean sand. The sowing should be made six to eight weeks prior to the usual time sweet peas can be sown. The pots are placed in a cool greenhouse or a well-protected coldframe and given plenty of light and air so as to keep the plants short and sturdy. When the plants begin to produce tendrils, insert some small twigs in the pots to support the plants. The plants are gradually “hardened off” so that they may be set out in the open ground. One great advantage of this system is that the grower is independent, to a certain extent, of weather conditions as he can wait until the soil is in the best possible condition before planting. The pots may be set 12 to 15 inches apart, using care to keep the ball of earth intact and without intermixing with the supports. Good twiggy brush will make the best supports for sweet peas, but when not obtainable, wire netting makes an excellent support. The latter is durable and looks neat when not covered with vines. The soil should be frequently stirred, and in hot weather a mulch of straw or lawn-clippings will serve to conserve moisture. If waterings are given in dry weather, they should be copious. The quality of the flowers improves by watering with weak manure water, but other liquid fertilizers are seldom used. The prompt removal of all withered flowers and pods is essential in preserving a long period of bloom.

Sweet peas in greenhouses (Figs. 3748, 3749).

The winter-flowering varieties are the most important type yet developed from the garden form, and this type has attained its greatest perfection in the United States. This range of sweet peas is distinct in habit of growth and early-flowering character. Unlike the garden type which apparently ceases growing for a time when the plants are a few inches high while the side shoots develop, the winter-flowering sweet peas grow rapidly until they attain a height of 2 to 4 feet. Then they begin to flower freely, after which time side branches are developed. Winter-flowering varieties planted in September begin to flower between Thanksgiving and Christmas, while varieties of the garden type planted at the same time do not flower until April or May. A knowledge of these characteristics of the early stage of growth will enable a grower to guard against considerable loss from getting the wrong seed.

Soon after the introduction of Blanche Ferry, florists began to grow that variety in boxes placed across the ends of the greenhouse where the plants were near the glass, or small clumps were grown on carnation benches and trained round the purlin posts. With such methods of culture, and with the varieties then available, the flowers were not received on the market in sufficient quantity to be quoted until March or April.

Anton C. Zvolanek, in 1892, found a chance seedling among the variety Lottie Eckford which was much earlier and dwarfer in habit. This was crossed with Blanche Ferry, and the result of this line of crossing was the variety Christmas Pink, sent out in 1899. Miss Florence E. Denzer, a white variety, was introduced in 1902. Since the latter date many varieties have been sent out. The first varieties had flowers of the open or hooded form, but as soon as the waved sweet peas were introduced, Zvolanek made crosses with the winter-flowering varieties. It was not until 1912 that this class was ready to introduce to the trade, but in 1913 twelve varieties were offered. At present waved varieties of all the colors known among winter-flowering sweet peas are grown, and the older varieties are rapidly disappearing in the competition.

Another group of the early-flowering sweet peas is the Telemly, originated in Algeria in 1900. These varieties are an adaptation of the climate of northern Africa where the varieties of the garden type planted in the latter part of September do not flower until May. An exception to this was Blanche Ferry which flowered about the first of April. An early sport was found flowering in February, and from this have been developed a number of varieties which flower from Christmas until after the garden varieties come into bloom. Recently waved-flowered varieties have been introduced by Ada Wright, the originator of this strain. This group is better known in Australia or England, and in the latter country these varieties are grown to some extent in winter under glass.

The culture of sweet peas under glass has increased rapidly since 1902, when William Slim began to grow this flower extensively and has developed the modern methods. Today large greenhouses are specially constructed for the purpose of growing this flower, and the amount thus invested represents considerable capital.

Low or dark greenhouses are not suitable for raising sweet peas. Large, wide houses with side walls at least 6 feet high and with good top and side ventilation, are now built for sweet-pea growing. No beds or benches are required. If the soil in the greenhouse is not naturally good, it is removed to a depth of 2 or 3 feet and replaced with better earth. The soil is trenched 2 feet deep or deep trenches are dug in which to place composted soil in preparing to sow sweet peas. The soil should be made sweet by the addition of lime, and enriched by liberal applications of bone-meal. Each year the soil should be deeply prepared and manure worked into it before sowing.

The colors most in demand on the market are pink and white, pink, lavender and white. The reds and orange colors are usually grown in less quantity. The
varieties chosen should be those possessing good, clear, well-defined colors. The Grandiflora varieties are more productive, but do not bring so good a price in the larger cities as the waved or short-stalked flowers.

The early crop is sown about August 15, and the later crop during the latter half of September. The seeds are sown in drills where the plants are to stand, except the white-seeded varieties which are sown in sand and transplanted. The latter do not germinate well in soil, as a rule, but when treated in this way a good stand is secured. When the rows run east and west they should be 9 feet apart, and if they run north and south they may be placed as close as 3 feet.

The plants should be thinned to four plants to a lineal foot of row whether grown in single or double drills, and in planting from pots this rule should be observed.

Sweet peas are often grown after chrysanthemums, and for this purpose the plants should be started in 2-by-2-inch pots. Two seeds may be planted in deep rose pots or in paper pots. The soil should be fibrous loam with the addition of fine old manure and sharp sand. The seeds are covered 1 inch deep, and the pots placed in a temperature of 55° to 60° F. for germination, after which the plants must be placed in a lower temperature to prevent them from becoming drawn.

The plants must soon have supports, and the best material to use under glass is string. If the rows are in line with the purlin posts a binder twine can be stretched from post to post on either side of the row thus inclosing the plants. These tiers of string will need to be as close as 6 to 8 inches apart at the bottom, but later as the vines grow may be as much as a foot apart. When the purlin posts are not in the row, temporary posts of iron pipe or 2-by-2-inch strips may be used. Wire netting is generally condemned by commercial growers, owing to the labor and expense connected with its erection and removal, and also because they think more crooked-stemmed flowers result.

The vines supported by string can be easily removed at a minimum expense and the house for dry made ready for another crop.

The temperature in the autumn is often too high for sweet peas, and under such conditions the plants often show a tendency to flower when only 2 feet high; but, as a rule, it is usually better to remove all such flowers until the plants gain more strength. As far as possible, the night temperature should be from 40° to 45°, for if a higher temperature is given the plants flower too soon and before they have made a good root-system. When the plants are from 30 inches to 4 feet high and showing buds, the temperature should be gradually raised to 52°. This is the highest temperature required for the Grandiflora varieties. When in bloom, the temperature should be 60° on cloudy days, and 68° on bright ones. The waved, or orchid-flowering, or Grandiflora varieties require the same treatment previous to flowering, after which the night temperature should be 55°, 60° to 65° on cloudy, and 70° to 72° on sunny days.

Picking and packing.

Sweet pea flowers should be picked when the top flower is at least half open, unless the flowers are to be shipped a long distance, when they may be cut in a less fully developed state. The proper time to cut the flowers is in the morning, although this will depend upon the time the shipments can be made. The flowers should be kept two to three hours in water before packing, and this will govern the hour of picking for the florist. The flowers must be packed dry, and if the outdoor flowers must be picked wet, they should be placed while in water in a warm current of air to dry the blooms. The flowers are made into bunches of nineteen to twenty-six spikes, according to quality. These are tied near the base of the stems, which are wrapped with waxed paper. The bunches are packed in shallow boxes with one, or at most two, layers of bunches packed in each box thus preventing the bruising of the flowers. The boxes often employed are 4 by 10 by 12 or 5 by 12 by 24 inches in depth, width, and length. The amount of wrapping on the boxes will depend on the temperature and other conditions at the time of shipment.

Exhibiting.

Exhibitors should keep the flowers off their vines until four or five days before the exhibition, and three days before this event a shade of cheesecloth should be erected over the orange-, scarlet-, and blue-flowered varieties to prevent the scorching of the blooms. This shading must be removed after the exhibition flowers are cut. The spikes are cut so that all the flowers are fully open when they are judged. The ideal spike has a stem 12 to 18 inches long with four flowers. Twenty spikes loosely arranged so that each may be easily seen, is the proper number for a vase. The stems may be kept in the proper position by placing in the vases some 2-inch pieces of stiff reeds or grass stems. Some gypsophila may be used in the vases if permitted by the rules of the competition. Arrange the vases of a collection of varieties so that colors do not clash and the rules of the competition. Arrange the vases of a collection of varieties so that colors do not clash and so as best to exhibit the merit of the blooms. The educational value of the exhibit is enhanced if each vase is neatly labeled with the name of the variety.

Insects and other pests.

Snails sometimes destroy sweet pea seedlings in frames or greenhouses, but can be prevented by scattering lime under the pots. The red-spider is sometimes troublesome in the greenhouse and outdoors, and can be controlled by the usual methods. The green aphis, or "green-fly" attacks sweet peas under glass, but is easily controlled by regular fumigations of tobacco preparations. In the garden a larger green aphis, the clover aphis, is not infrequently found, but spraying with tobacco extract, nicotine, or kerosene emulsion should be carried out as in the greenhouse.
will usually destroy them. Plants that are frequently syringed with cold water are seldom infested with insects.

Fungal pests:

The most prevalent fungal pest affecting sweet peas under glass appears to be *Thielanecia basoica*, or root-rot. Infected plants have little or no root-system, due to the fact that new roots are constantly destroyed. The leaves often turn yellow with white edges, finally dying and falling to the ground. Sometimes one portion of the plant may be dry and dead while the remainder is green, although it does not grow or produce flowers. In fact, it is sometimes a mystery how a diseased plant can continue to live with its very limited root-system. There are several other organisms, but their action is similar and the method of control is the same for all—the removal of infected soil or sterilizing it.

The powdery mildew attacks greenhouse sweet peas at any stage of growth. If the proper temperature is not maintained. The application of sulfur to the heating-pipes will check this disease. Care must be taken not to use the sulfur too strong or the flowers will be injured. Outdoor mildew usually does not appear until late in the season when the plants are in the flowering stage. The disease, which may be allied to or identical with the trouble known as streak in the tobacco, is a rather baffling disease to the growers. When first noticed, the leaves turn yellow with white edges, finally turning brown and stems of the plant. This is often accompanied by a curling of the leaves. The plants become stunted and stunted. The disease can be carried over winter upon the seeds. The prompt destruction of the diseased plant can continue to live with its very limited root-system. It is distinguished by a yellow mottling of the leaves and stems of the plant. This is often accompanied by a curling of the leaves. The plants become stunted in growth and case flowering if they have reached the flowering stage. It is a disputed point whether it is a bacterial disease or not, but it seems certain that the trouble is transmissible by the feeding of aphides. No remedy is known except the obvious one of keeping insects in check and destroying affected plants by fire.

The dropping of the young flower-buds either in the open or under glass is usually due to physiological conditions. Low temperature, lack or excess of plant-food, too much nitrogenous fertilizer, lack or excess of water are among the causes of this trouble. A. C. BEAL.

Growing sweet pea seed in California:

Up to about the year 1885, most of the sweet pea seed was grown in England, France, and Germany, and imported to this country; at that time the first attempt was made to grow the seed in California. This resulted in almost immediate success, and in 1900 more than 600 acres were devoted to the growing of the crop. Most of the sweet peas grown at this time were of the Grandiflora type and yielded an average of 1,100 pounds to the acre, sometimes in a good year even as much as 2,500 pounds. With the introduction of the Countess Spencer type of sweet pea, about 1904, however, the waved forms supplanted the Grandiflora type, the larger part of the acreage being now devoted to the Spencer type. Approximately 2,500 acres are now planted to the sweet pea.

The original Countess Spencer sweet pea was of a shell-pink color, but it was not fixed and many color sports were produced. At present there are about 150 distinct varieties of the Spencer type under about 400 different names, resulting from different growers finding, the same sports, or from varieties which were not improvements on existing varieties of the same colors. The yield of seed to the acre of the Spencer type is much less than from the Grandiflora type, only about 250 pounds to the acre; these being obtained. The yield is due to the structure of the flowers: in the Grandiflora type the keel is closed, not allowing the pollen to escape so that each variety must pollinate itself, and the varieties can be grown close together and the flowers will remain true to color and type. In the Spencer type, however, the keel is open, allowing the pollen to be blown out, and, as a consequence, about 75 per cent of the flowers do not set seed; also the plants must be set far apart in order to keep them true to color and type.

A cross was made between the Spencer sweet pea and the winter-flowering sweet pea, resulting in the winter orchid-flowering sweet pea. This is a shyer seedling than the Spencer, yielding only about seventy-five pounds to the acre. The flowers resemble the summer Spencer except that the growth is dwarf and the foliage more point. If sown in August under glass in the eastern states, they will bloom from November until late in spring. If sown outdoors, they will bloom three to four weeks earlier than the summer type, just before the extreme hot weather.

There are four types of sweet pea now grown in California: the summer Grandiflora, the winter Grandiflora, both of these being grown only on a small scale; the summer Spencer, and the winter orchid-flowering. In addition, the Cupid, which grows 5 to 6 inches high, is occasionally grown, about 30 acres a season being devoted to it.

The raising of the sweet pea seed is usually on a large scale. Large tracts of land are plowed in autumn about 10 inches deep, either by horse-power or large tractors, before the beginning of the rainy season. The field is then carefully disced and pulverized and left to settle. If the rainy season begins as early as October, the fields should be harrowed again after the rain and the seeds planted. However, if the rains do not come until late, the seed must be sown in the dry soil, although they will not germinate so evenly. The most successful sowing is done between November and January. The seed is sown mostly by four- or two-row horse planters, being planted 30 inches apart and 3 inches apart in the rows, and 2 inches deep. Between each named variety, at least 10 feet must be left to prevent crossing.

After the seed is planted, the field must be kept in good condition by hoeing. After each rain the ground between the rows must be broken up. As soon as the plants are up, a horse cultivator may be used which breaks the crust 2 or 3 inches deep and a small scale from the plants; but hand labor must be used to cultivate nearer the plants. This must be done after each heavy rain, sometimes five times being necessary. Irrigation is seldom practised, as 10 inches rainfall is sufficient for a good crop of sweet peas.

By the latter part of March and April the winter or early sweet pea will be in flower, and the summer or late sweet pea begins to bloom in May. Now must begin the process of thinning. No matter how carefully the seeds have been selected, there will be some 'rogues' and these must all be removed. The best among these may be tagged and kept for stock seed to grow later on. All novelties and the stock seed for the next year are usually planted and taken care of by hand.

After the thinning has been done, the plants are left to themselves, no supports being given them, until the seed is ripe. These seeds are not evenly ripened and the cutting must be left to prevent crossing. After the seed is ripe, the cutting must be done when the larger part of the seed is ready to be harvested. The cutting is performed by a specially constructed ripper drawn by two horses and cutting two rows at once. As soon as cut,
the plants are piled in small heaps and left for several
days to dry. They are then put in large piles to cure
which takes from three to four weeks. As soon as all
the seed is perfectly cured and sufficiently dry, the
threshing begins. This is usually performed by gasoline
power, and the clean seed is run directly from the
thrasher into the sacks.

SWEET POTATO. The plant Ipomoea Batatas,
grown for its large edible root-tubers (Fig. 3750). The
origin is not definitely known (see page 1662, Vol. III),
but it is probably tropical American. It is a widely
variable plant in foliage, as shown by the leaf-forms in
Fig. 3751. The top is herbaceous, form a running vine.
Flowers and fruits are rarely seen.

Neither the acreage, production, nor the money value
of the sweet potato crop give an adequate idea of the
economic importance. In those parts of the earth's
surface where it thrives, it forms an important food
staple for the inhabitants, and thus occupies a position
not accorded crops which, though of great money worth,
do not contribute directly to the food-supply of the
territory in which they are grown.

The sweet potato, being native to tropical and sub-
tropical regions, is restricted in its range of cultivation

3750. A good hill of sweet potatoes.

more by climatic than by soil conditions, although its
commercial cultivation is confined almost exclusively
to sandy or loamy soils. It is, in fact, one of the staples
of the southern states which thrives well on lands that
have been considerably depleted by cropping with
other plants, and one which can be made to produce a
profitable return on light sandy soils carrying little
humus, provided an adequate supply of plant-food in the
form of commercial fertilizer is available. The ability
of this plant to thrive and produce under such condi-
tions, together with its great food value, which is con-
siderably higher than that of the Irish potato, has served
to advance it to the position of second 'place among
the truck crops grown in the South and to seventh place
among the standard agricultural crops of the nation.

Botanically the sweet potato belongs to the Con-
volvulace or morning-glory family. The edible part is
the thickened root. It does not possess eyes or scars
as do some other roots and tubers, but it possesses the
ability to develop adventitious buds, which character is
taken advantage of in reproducing the crop by vege-
tative means.

Roots to be used for seed purposes, selected at the
time of harvest, are usually small, from 1 to 1½ inches
in diameter, of uniform shape, and characteristic of the
variety. These roots are cured and stored under con-
ditions most certain to insure an adequate supply of
seed material, which, at the northern limit of the culti-
vation of the crop, is needed for bedding in April to
insure a supply of "draws" for planting during the
second and third weeks in May.
The curing of sweet potatoes at harvest-time is of equal importance with a proper storage room, good ventilation, and the maintenance of a proper storage temperature subsequently. As the sweet potatoes come from the field, they should be placed in the bins in layers distributed evenly over the surface, and during the time the house is being filled and for a period of ten days or more thereafter the temperature of the storage house should be maintained at 85° to 90° F, both night and day. After this drying or curing period, the temperature should be gradually reduced, but at no time during the storage period should it fall below 45° F. The temperature which has proved most satisfactory for holding the roots after the curing period is 50° F. While sweet potatoes can be successfully stored in hampers or crates, most commercial storages are economical, are more convenient for handling than crates or hampers, and during the curing period is 50° F. While sweet potatoes come from the field, they should be placed in the bins in layers distributed evenly over the surface, and during the time the house is being filled and for a period of ten days or more thereafter the temperature of the storage house should be maintained at 85° to 90° F. Both night and day. After this drying or curing period, the temperature should be gradually reduced, but at no time during the storage period should it fall below 45° F. greenish yellow, dark-spotted; corolla-segments membranaceous, lanceolate, rather obdurate, pubescent in 2's, oblong, crested and fringed. S. E. Eu., Caucasus.

**SYMBEGÔNIA*** (name refers to the union of parts of the flower). *Begonia nodosa*. A few small herbs, all natives of New Guinea (Afr.), differing from Begonia in the tubular female fls.; the male fls. have the parts distinct. *B, falco-ellisii*, Warb., for some time the only known member of the genus, appears to be the only species that has appeared in cult., but is apparently not in the trade: erect herb 8 in. or less high, with red-tinged st. and oblique lance-oblong strongly double-serrate green lvs.; female fls. pale yellow, with 5 spreading deciduous lobes and 3 stamens; male fls. of 2 separate sepals, and 12–20 stamens. B.M. 8409. L. H. B.

**SYMBIOSIS** is the intimate association of two or more distinct organisms, with benefit to one only, or to both; commensalism; consorship; copartnership. In this association each organism is called a symbiont. According to the character of the union, several kinds of symbiosis have been recognized: (1) Mutual antagonistic symbiosis (mutual parasitism), when two organisms are foes of each other, as certain bacteria and animals, the latter showing a “natural resistance;” also the mycophytes of certain lichens with higher organisms. (2) Mutualistic symbiosis (true parasitism), when the host is partly or completely killed by the parasite, as the potato and the root fungus (*Phytophthora infestans*); or galls (Myxosporites) produced in the heart of the tree, a knot of plums; and in higher plants, which live at the expense of others, as the mistletoe (green) and the dodder (chlorophyllus). (3) Mutual symbiosis, when there is often reciprocal advantage; (a) nutrition, when one symbiont nourishes the other without apparently receiving any return, as the mycorrhiza and the roots of forest trees (mycosymbiosis); (b) mutualism, when a mutual benefit results from the union of two organisms capable of living separately, as the bacteroid and the roots of the Leguminosae; (c) individualism, when the symbionts are so intimately connected in their growth as to suggest a single individual, as the union of alga and fungus to form a lichen. By some this relationship of alga and fungus in the lichen thallus is regarded as holism, or slavery, where the alga lives entirely indifferent to the fungus. The views of Bruce Fink, who considers the lichen to be a fungus associated with an alga, are widely different from the usually accepted views on the subject. (4) Prototrophy, the wet-nurse relationship, as in the lichen *Lecidein unilocensis*, which eventually gets its nourishment by means of a lodger, a different lichen. (5) Contingent symbiosis, when one symbiont lives in the interior of another for shelter, as *Nostoc* in the tissues of Hepaticae, Lemna, Cycas, Gunnera; and *Amanita* in *Azolla*. Green plants live symbiotically with animals such as *Spongilla*, Hydra, and Convolvula. In Hydra, the green alga, known as *Chlorella*, is found in the endodermal layer and when the colorless eggs of the fresh-water polyp are almost mature a few of the green cells are found migrating into the protoplasm of the egg-cells.

**SYN**...
The snowberries are low or medium-sized shrubs, with slender upright or decumbent stems, spreading more or less by suckers, with small generally oval or ovate leaves and small clustered, rarely solitary, white or pink flowers followed by attractive usually white, rarely pink, dark red or bluish black berries. The flowers are rather insignificant in most species except in *S. oreophilus*, *S. microphyllus* and allied species which bear larger tubular nodding flowers and are rather attractive when in bloom. The chief ornamental feature is the fruits which are usually white and retained far into the winter; among the handsomest are *S. albus* var. *liretus* with heavy clusters of snowy white fruits at the tips of the arching branches, and *S. orbiculatus* with dark red fruits densely clustered along the slender branches and remaining plump and fresh far into the winter, its foliage also remaining unchanged until severe frost sets in. Some species, as *S. albus*, *S. orbiculatus*, and *S. occidentalis*, are quite hardy North, while *S. mollis*, *S. rotundifolius*, and *S. oreophilus* are hardly as far north as Massachusetts; *S. microphyllus* is tender. They are excellent plants for borders of shrubberies and for covering the ground under trees, spreading more or less by suckers; they will thrive in almost any soil from heavy clay to dry gravelly banks. Propagation is readily effected by hardwood and by greenwood cuttings, by division, and also by seeds.

- **S. Heyeri**, Dipp. (var. *aurco-retilcatus*, Zabel). Variegated with yellow.—One of the most desirable species on account of the long-persisting fr. and foliage.
SYMPHYTA (Greek, to grow together, in reference to the supposed healing virtues). Boraginaceae. Comfrey. Erect often hispid herbs, usually hardy in all but the far North, sometimes grown for the variegated foliage of some species.

Roots sometimes tuberous: lvs. alternate or semiterete; the cauline sometimes decurrent; the upper sometimes strongly approximate, almost opposite: cymes terminal, usually single or twice bifid or simple unilateral racemes: fls. yellowish, blue, or purplish, pedicellate; calyx glabrous, tubular-campanulate: lvs. acutely double-dentate; radical long-attenuate to the petiole; fls. generally numerous.

A. St. branched: lvs. singly racemose. 
B. Calyx divided to or below the middle.

C. Lvs. decurrent at or on the st. officinale, Linn. (S. bohemicum, F. W. Schmidt). Perennial, about 3 ft. high: root thick: st. branched, white-pilose: branches decumbent: lvs. slightly pilose, basal and lower cauline ovate-lanceolate, upper oblong-lanceolate, all broadly decurrent at base: fls. white, yellowish, purple, or rose, in drooping cymes. Eu., Asia. Var. argenteum, Hort., is offered in the trade as growing 2 ft. high, with silver-variegated foliage and drooping blue fls. Var. aureum, Hort., is offered in the trade as a golden variegated form growing 2 ft. high. Var. coccineum, Hort. (S. coccineum, Hort. ex Schlecht.), is offered in the trade as a scarlet-feld form. Var. lilacinum, Hort., is offered in the trade. Var. purpureum, Pers. (S. officinale var. bohemicum, Don), has reddish purple fls. Eu. Var. variegatum, Hort., has lvs. widely margined with creamy white. F.S. 18:1901-1902.

cc. Lvs. not decurrent.

D. Calyx-segments obtuse: upper lvs. subpetiolate.

asperum, Lepech. (S. asperrum, Donn.) Packly Comrey. Fig. 3753. Perennial, 2½-5 ft. or even more high: root thick: st. branched, uncinate: lvs. hispid or prickly on both surfaces, ovate or elliptical, acuminate; lower petioled base cordate or subcordate; upper subpetiolate, base cuneate: fls. at first rose then blue, smaller than those of S. officinale. Russia, Caucasus. Pers. B.M. 929.—Has some forage value.

There are horticultural forms with yellow-variegated or -margined lvs. known as S. asperum aureovariegatum and S. asperrum var. variegatum.

Dd. Calyx-segments acute: upper lvs. sessile.

peregrinum, Ledeb. Perennial, about 3½ ft. high: st. erect, tall, branched, prickly, prickles slightly retronse: lower lvs. long-petiolated, elliptic-lanceolate, acuminate, about 10 x 4½ in.; upper lvs. sessile, all

3753. Symphytum asperum. (X 10)

F. Tracy Hubbard.
SYMPHYTUM

softly hispid; petals deciduous: fls. sky-blue; buds pinkish; calyx 5-parted almost to the base, segments triangular-lanceolate; corolla-tube angled, constricted at the middle, upper part somewhat campanulate, mouth 5-cleft. Caucasus. G.C. III. 50: 127.—Closely related to S. officinale, may be a hybrid.

bb. Calyx not divided to the middle.

SYMPLOCOS

oblong, attenuate to the petiole; upper lvs. narrowly and shortly deciduous: fls. paniculate-corymbose, blue; calyx viscidulus and setulose; corolla tubular-funnelform, lobes shortly and broadly ovate. Caucasus.

AA. St. simple or nearly so: fls. generally few.

bb. Lvs. nearly glabrous.

grandiflorum. DC. Perennial, about 1 ft. high: st. rather simple, base glabrate, otherwise reflex-spreading, hispid: lower lvs. long-petioled, subcordate-ovate, acute, deciduous along the petiole; uppermost lvs. opposite, oval, decurrent on the st.: fls. yellowish white, in a few-flowered raceme; calyx lobed below the middle, lobes lanceolate; corolla-lobes broadly adnate at the base. Caucasus.

SYMPLOCÁRPUS (Greek, referring to the aggregate fruit). Aráceae. Spathyzma. Ornamental woody plants grown chiefly for their attractive flowers and fruits.

Deciduous or evergreen trees or shrubs: lvs. alternate, entire or serrate, exstipulate: fls. perfect or sometimes polygamous, in terminal or axillary racemes or panicles, rarely solitary; calyx 5-lobed, imbricate, corolla 5-lobed or 5-parted, often split almost to the base, rarely consisting of 2 whorls; stamens numerous, rarely few, usually connate at the base, and often more or less adnate to the corolla; style filiform; ovary 2-5-loculed, inferior: fr. a drupe with a long 1-5-seeded stone.—About 285 species, widely distributed through the tropical regions except Afr.; only a few outside the tropics. Monograph by Brand in Engler’s Pflanzenreich, hft. 30 (IV. 241), 1907. Several species have medicinal properties; S. tinctoria yields a yellow dye. Of the numerous species only S. paniculata which is

mens generally out in February or March. The buds retain their beauty for months. In April or May they decay and the strong-growing leaves soon attain a height of 1 to 3 feet and a breadth of 1 foot or more. All parts of the plant give a strong skunk-like odor, but only when bruised. Skunk cabbage is offered by dealers in hardy plants, as also by collectors. Its hardiness and bravery have been celebrated by outdoor writers from Thoreau to the present day. The question of its pollination has been much discussed. It was long supposed to be pollinated by the action of the carrion flies which are attracted by its odor. However, Trelease has shown that the bees are busy with the pollen while the plant is in flower and that the carrion flies mostly come later.

S. officinale, Linn. (Spathyzma fétida, Nutt.) SKUNK CABBAGE. Fig. 3754. Lvs. numerous, 1–3 ft. long, 1 ft. wide, ovate, strongly cordate: spathe preceding the lvs., colored as described above: fr. ripe Aug., Sept. Nova Scotia to Minn., south to Fl. and Iowa; also in Asia. B.M. 896 (as Pothos fétida); 324A. V. 23: 186. A.G. 14:367.

WILHELM MILLER.
SYMPOCOS

hardy as far north as Massachusetts, is generally cultivated; it is a shrub or small tree with abundant white flowers in small panicules, appearing in spring, and with bright blue berry-like fruits in autumn. It thrives in well-drained soil and sunny position. The half-evergreen S. tinctoria, which seems not hardy north of its natural habitat, prefers neutral soil and shady situation. The evergreen species are all tender and little known in cultivation. Propagation is by seeds, which usually do not germinate until the second year, and by Greenwood cuttings under glass; also by layers.

SYNADENIUM, Wall. (S. crategoïdes, Buch.-Ham. Lodd. crategoïdes, Deene.). Fig. 3755. Evergreen succulent shrub or small tree, attaining 40 ft., with spreading branches, forming an irregular open head: young branches pubescent: lvs. short-petioled, oval or ovate to oblong-ovate, acute or acuminate, sharply serrate, distinctly veined beneath and more or less pubescent at the veins, rarely glabrous, 1½–3 in. long; fls. white, fragrant, ½–1½ in. across, with spreading, oblong-ovate petals in panicules 1½–3 in. long; fr. usually 1-seeded, oval, blue, about ½ in. long. June. Himalayas to China and Japan. G. F. 5: 59 (adapted in Fig. 3755). M.D.G. 1901: 100, 101. S. I. F. 2: 85. G. 33: 425.

SYNDESMON

3756. Syndesium Grantii. (Xyw).

SYNÉNTRIUM (Greek name, indicating the united involucral glands). Euphorbiaceæ. Thick-branched tropical shrubs, sometimes oll. in collections of succulents, having the generic characters of Euphorbia, except that the glands of the involucre are united so as to form a ring around the lobes.—About 10 species, chiefly in Trop. Afr. Prop. and treated similarly to the succulent euphorbias.

arboréscens, Bois. A shrub, up to 4 ft. high, the st. unbranched: lvs. obovate-ovate, obscurely crenate; midrib keeled and often denticulate: bracts puberulent: involucre yellow. S. Afr. B. M. 7184.

Gréntii, Hook. AFRICAN MILK BUSH. Fig. 3756. A shrub 10 ft. or less high, branched: lvs. obovate-spatulate, 3–4 in. long, obtuse; midrib rounded: cymes dichotomous, with tomentose bracts and red involucral glands. Trop. Afr. B. M. 5633.

SYNÁNTRA (Greek, together and anther, referring to the comate anthers). Labiatae. Hardy fibrous-rooted biennial herb, with the habit of Lamium, suitable for border planting: calyx campanulate, inflated; corolla-tube long, much expanded above and at the throat, the upper lip slightly arched, entire, the lower spreading and 3-dect, with ovate lobes, the middle one broadest and notched; anthers approximate, in pairs under the upper lip, the 2 upper each with 1 fertile and 1 smaller sterile cell, the latter cells cohering together. One species—Anemone thalictroides, Brit. (S. grandiflora, Nutt.). Hairy biennial, 1–2 ft. high, lvs. long-petioled, broadly ovate, cordate, crenate, thin; the floral lvs. gradually reduced to bracts, each with a single, sessile fl.: corolla 1½ in. long, yellowish white. Shady banks of streams, Ohio to Ill., Tenn., and Va.

SYNÁRCRIA (Greek, together and fruit, referring to the head-like clusters of caps.). Myrtaceae. Trees, one of which is intro. into Calif.: lvs. opposite, ovate, evergreen: fls. gathered in globose heads: peduncles 1-headed, lateral axillary or paniculate at the ends of the branches, rather small, white; calyx-tube adnate at base of ovary, turbinate or campanulate, sepal. 4, rarely 5, persistent; petals 4, rarely 5; stamens many, free; ovary inferior, 2–3-celled: caps. adnate to the calyx and inclosed in it.—Two species, Austr.

SYNGLUMIFERA, Niedenzu (S. laurifolia, Ten.). TROP. AMERICAN TREE. Lvs. broadly ovate to elliptic-oblong, obtuse or obtusely acuminate, 2–3 in. long, often appearing as if in whorls of 4: fls. 6–10 in a head, with 2–4 bracts of variable size under the head; calices connate at the base; petals broadly ovate or orbicular, less than 2 lines long; ovary 3-loculed: ovules several to each locale.—According to Von Mueller’s Select Extra-tropical Plants, this tree attains a height of 200 ft., with a trunk often 30 ft. in circumference; it is of quick growth and well adapted for a shade tree. The wood is very durable and almost fireproof and is valuable for piles, railway sleepers, and shipbuilding. It takes a high polish and is used for flooring and cabinetwork. Offered in S. Calif.

F. TRACY HUBBARD.

SYNDÉSMEON (Greek, bound together, because the plant unites characters of Thalictrum and Anemone). Ranunculaceae. ANEMONE. Dainty perennial herb grown in wild borders for its carpet of beautiful leaves and attractive spring flowers.

Glabrous, from a cluster of tuberous roots: basal lvs. 2–3-ternately compound: involucre similar but sessile, the lfts. being stalked: fls. white or pink in an umbel; pedicels slender; sepalis thin, 5–10, petal-like; petals none; stigma sessile, truncate: achenes terete, deeply grooved.—A monotypic genus of E. N. Amer. Under the International Rules, Anemolla was the tenable name (Anemolla thalictroides). Syndesium was used earlier (1832 as against 1839), but in such a way as not to constitute publication as defined by those Rules, although it is tenable under the American Code. The plant should have been treated under Anemolla in this work.

The plants should be grown in partial shade. The soil should be rich and light or sandy. They should be left undisturbed for years. They will then form a carpet of great beauty. Propagation is by division of roots in spring or fall, but such division greatly weakens them and the plants for propagation should be taken from the edges of the beds.

thalictroides, Hoffmg. (Anemolla thalictroides, Linn. Thalictrum anemonoides, Michx. Anemolla thalictroides, Spach). Fig. 3757. Plant 3–6 in. high: lvs. much like those of thalictrum: fls. resembling those of Ane-
SYNESMON

K. C. DAVIS.

SYNECHANTHUS (Greek, continuous and flower, alluding to the arrangement of the infl.). Palmaeae. Unarmed gregarious palms, grown in the warmhouse: trunk slender, an- nulate, often stoloniferous; lvs. terminal, equally pinnati- sect, segms. broad or narrow; membranaceous, acuminate, plicately nerved: spadices several, long- and slender: pendent, the floricere erect; spathes several, tubular, membranaceous, persistent: fls. green or the upper purplish, minute, arranged in 1-2 rows in alternate elongated groups, the superior in the groups male, the inferior female: fr. reddish yellow, shining, ellipsoid, 1-seeded. The three species, Cent. Amer. and Colombia. S. fibrosus, Wendl.

SYNGONIUM (Greek name, said to refer to the cohesion of the ovaries). Araceae. Tropical American woody climbing or creeping plants, with milky juice and at. rooting and fl-bearing at the nodes: lvs. sagittate, becoming with age pedately 5-parted, racemose on long petioles, with a persistent appressed sheath; peduncles short: spathe yellowish or whitish green; tube small, ovoid, persistent; spadix shorter than the spathe: staminodes fls. with 3-4 stamens, pistillate fls. with oblong-ovoid 2- or abortively 1-loculed ovary: seeds in each locule. (Fig. 3757.) In S. persicaria the caps. are %in. across; pedicels slender and short: calyx-lobes lanceolate. Ore. and Wash. Gn. 74, p. 105.

In England this plant is considered a winter bloomer; it flowers there in Feb. or March, occasionally Nov.

SYRINGA (of doubtful meaning; probably from syrinx, pipe, because pipes are made from the straight stems of Philadelphus by removing the pith, and the name Syringa had been originally applied to Philadelphus but was transferred to the lilac. Philadelphus is still popularly called Syringa). Oleaceae. Lilac. Ornamental woody plants grown chiefly for beautiful and showy often fragrant flowers.

Deciduous, rarely evergreen (S. sempervirens), shrubs or small trees: lvs. opposite, entire or rarely pinnate, exoptilulate; fls. in panicles, the superior in the branches many, very slender, forked: fr. orange-red. Cent. Amer. B.M. 6572.

Trunk 4 ft. high, green; lvs. 4 ft. long, erect and spread- ing; lfts. numerous, 1-1½ in. long, spreading and rather pendulous, linear-lanceolate: spadices one-third as long as the lvs., the branches many, very slender, forked: fr. orange-red. Cent. Amer. B.M. 6572.

SYRINA (Greek, together and little door or valve, the valves of the capsule long adhering below to the short placentiferous axis). Scrophulariaceae. Hardy herbaceous perennials, glabrous or pilose: rhizome thick: lvs. radical, petioled, ovate or ovate-lanceolate, or incisely pinnatisect, peduncles scape-like, ample; fls. racemose or spicate, blue or reddish; calyx 4-parted, segms. narrow; corolla-tube very short or almost none. subrotate-campanulate, 4-lobed or none; stamens 2: caps. compressed, obtuse or emarginate, 2-4-veined. About 15 species, natives of W. N. Amer. Syrinx is nearly related to Wulfenia of S. E. Eu. and the Himalayas, but the anther-cells are not confluent and the seeds are discolored in their native region they are summer-blooming plants with small purplish or flesh-colored spikes or racemes. Border plants.

reniformis, Benth. (Wulfenia cordata, Greene). A tufted plant about 1 ft. high: lvs. glabrous, orbicular-reniform, crenately incised, the small lobes sharply toothed, 1-3 in. diam.; petioles 3-6 in. long: infl. a raceme about 5 in. long with about 40 purple-blue fls. which are ¾in. across; pedicels slender and short; calyx-lobes lanceolate. Ore. and Wash. Gn. 74, p. 105.

In England this plant is considered a winter bloomer; it flowers there in Feb. or March, occasionally Nov.

rotundifolia, Gray. Nearly or quite stemless; lvs. tufted, cordate-ovibracular, 1-2 in. diam., long-petioled, densely crenate or crenate-crenate, slightly pubescent: scape 4-6 in.: fls. few in a terminal raceme, blue or purple; calyx-lobes ovate, acute. Shady coniferous woods, Ore.

F. TRACY HUBBARD.

SYRINGA (of doubtful meaning; probably from syrinx, pipe, because pipes are made from the straight stems of Philadelphus by removing the pith, and the name Syringa had been originally applied to Philadelphus but was transferred to the lilac. Philadelphus is still popularly called Syringa). Oleaceae. Lilac. Ornamental woody plants grown chiefly for beautiful and showy often fragrant flowers.

Deciduous, rarely evergreen (S. sempervirens), shrubs or small trees: lvs. opposite, entire or rarely pinnate, exoptilulate; fls. in panicles, the superior in the branches many, very slender, forked: fr. orange-red. Cent. Amer. B.M. 6572.

Trunk 4 ft. high, green; lvs. 4 ft. long, erect and spread- ing; lfts. numerous, 1-1½ in. long, spreading and rather pendulous, linear-lanceolate: spadices one-third as long as the lvs., the branches many, very slender, forked: fr. orange-red. Cent. Amer. B.M. 6572.

SYNDESMON

Trunk 4 ft. high, green; lvs. 4 ft. long, erect and spread- ing; lfts. numerous, 1-1½ in. long, spreading and rather pendulous, linear-lanceolate: spadices one-third as long as the lvs., the branches many, very slender, forked: fr. orange-red. Cent. Amer. B.M. 6572.

SYRINA (of doubtful meaning; probably from syrinx, pipe, because pipes are made from the straight stems of Philadelphus by removing the pith, and the name Syringa had been originally applied to Philadelphus but was transferred to the lilac. Philadelphus is still popularly called Syringa). Oleaceae. Lilac. Ornamental woody plants grown chiefly for beautiful and showy often fragrant flowers.

Deciduous, rarely evergreen (S. sempervirens), shrubs or small trees: lvs. opposite, entire or rarely pinnate, exoptilulate; fls. in panicles, the superior in the branches many, very slender, forked: fr. orange-red. Cent. Amer. B.M. 6572.

Trunk 4 ft. high, green; lvs. 4 ft. long, erect and spread- ing; lfts. numerous, 1-1½ in. long, spreading and rather pendulous, linear-lanceolate: spadices one-third as long as the lvs., the branches many, very slender, forked: fr. orange-red. Cent. Amer. B.M. 6572.
The foliage is not much attacked by insects, but a fungus, *Microcortica alni*, late in summer often covers the whole foliage of *S. vulgaris* and also of *S. chinensis* and *S. pekinensis* with a white mealy coat, while *S. oblata* is but rarely troubled with this fungus and the other species never. Much damage is sometimes done by a borer, *Trocchitum denudatum*, which lives in the stems and branches of *S. vulgaris*, but is rarely found in any other species.

After blooming, the inflorescence should be removed if possible and the pruning be done as far as necessary. Pruning in winter or spring would destroy a large part of the flower-buds for the coming season. Lilacs grow in almost any kind of soil, but a rich and moderately moist one is the most suitable. They are easily transplanted at any time from fall to spring. *S. vulgaris* and its numerous varieties are the most popular of the lilacs of our gardens because of their early blooming and profuse blooming; their sweet fragrance, and the variety of colors ranging from dark purple to lilac, pink, and white. The double-flowered varieties keep the blooms longer, but the panicles are less graceful and they usually do not bloom so profusely as the single ones; they also remain mostly dwarfer and have a more compact habit. The faded flowers do not fall off, but remain on the inflorescence; this gives the plant a very unsightly appearance if the faded panicles are not removed. W. J. Stewart suggests a word of warning against lilacs not on their own roots, because of the attacks of borers and the bad habit of suckering in some cases.

Some of the best single-flowered varieties are the following:

**Single-flowered Lilacs.**—White: *Alba* grandiflora; *Alba pyramidalis*; Frau Bertha Dammann, A.F. 12: 1078; Madame Moser; Marie Legraye, one of the very best, B.H. 28: 174; Princess Alexcen; *Alba pyramidalis* is a favorite variety of this class in America.—Blue, lilac, or pink: Ambrose Verschaffelt, pale pink; Dr. Lindley, pinkish lilac, F.S. 14: 1451; Géant de Los batailles, bluish lilac; Geheimrath Heyder, light lilac; Gigantea, bluish red; Glorie des Moulin, pale pink, G.M. 44: 490; Goliath, purplish lilac; Lovaniama, light pink; Macrostachys, light pink; Sibiras, purplish lilac; Trianoniana, bluish lilac.—Red: Aline Moequers, dark red; Charles X (Carol), dark lilac-red, A.F. 12: 1076. F. 1875, p. 70; Marlyensis, sometimes called Rubra de Marley, lilac-red; Rubra insignis, purplish red.—Dark purple: Philémon; Ludwig Spaeth (Andenken an Ludwig Spaeth, Louis Spaeth), very large panicles, the best of the dark varieties; Negro, deep violet-purple; Congo, deep wine red.

**Double-flowered Lilacs.**—White: Madame Abel Châtenay, compact panicles; Madame Casimir-Perier, large graceful panicles, one of the best; Madame Lemoine, large fis. in dense panicles; Obléisque; Virginité, white and pink.—Blue, lilac, or pink: Alphonse Lavallé, bluish lilac, A.F. 12: 1077; Belle de Nancy, fis. pink with white center; Charles Baltet, lilac-pink; Condorcet, blue, A.F. 12: 1074; Doyen Keteleer, lilac-blue; Jean Bart, pinkish violet; Lamarck, pale lilac, large, rather loose panicles; Lemoinei, lilac-pink, B. H. 28: 174; Léon Simon, changing from pinkish to bluish lilac. Gt. 43: 1407; Maxime Cornu, pinkish lilac; Michel Buchner, pale lilac, large and very double fis.; President Carnot, pale blue.—Purple: Charles Joly, dark purplish red, one of the darkest; Comte Horace de Choiseul, lilac-purple; La Tour d'Avenguire, violet-purple.

The lilacs have been favorite forcing plants in France for more than a century and are nowadays among the most important cut-flowers during the winter season in France as well as in Germany and England. They are on the market from the end of September until they bloom outdoors. Charles X is considered one of the very best for forcing. *Marlyensis*, Marie Legraye, *Alba chinensis duplex*, Ludvig Spaeth, and other varieties are also good for forcing. Of the double-flowered varieties the following have proved adapted for forcing: Madame Casimir-Perier, Madame Lemoine, Charles Baltet, Jean Bart, Léon Simon, *S. chinensis duplex*, and others. Either grafted plants or plants on their own roots are used. Both force equally well, but grafted lilacs can be grown into plants well set with flower-buds and suited for forcing in two or three years, while plants grown from cuttings require four to six years. *Marlyensis* is always used on its own roots and propagated either by seeds, cuttings, or division. Special attention must be given to pruning in order to have well-branched plants of good compact habit (see Fig. 15, Vol. III, p. 1295). The lilac has nothing like the commercial importance for forcing in America that it has in Europe, but the appreciation of it for winter bloom is on the increase in this country.

Lilacs are generally forced in pots, being potted usually in July or in the fore part of August, that they may fill the pots with new roots before winter. Some growers pot the plants in spring or in the preceding fall. This practice is of especial advantage if the plants are intended for very early forcing. These early potted plants are then plunged into the ground outdoors, mulched, well watered and regularly manured; after June, when the young growth is almost finished, only enough water is given to prevent withering. When the flower-buds have been formed, more water is given until they have reached their full size. It is essential to keep the plants rather dry in fall, so that the wood may ripen thoroughly and early. When the leaves have fallen off, the plants are shielded away in convenient places, where they are sheltered from severe frost. Sometimes the lilac, especially *S. marlyensis*, is forced from balls of earth which are not potted, but this does not always give satisfactory results.
About three to four weeks is required to force the plants into bloom with the temperature recommended below. The first days after bringing the plants into the forcing-room, a temperature of 65° to 70° may be given, gradually rising to 75° to 80° and maintained as equally as possible until the panicles are fully developed and the first flowers begin to expand; then the temperature is lowered to 60° to 66°, and when the panicles are about half open the plants are transferred to a cool greenhouse. Hardening-off is essential to ensure good keeping qualities of the flowers. The red-flowered varieties are often forced in darkened rooms in order to have the flowers blanched or only slightly colored. The shade of color depends entirely on the time when full light is given and also on the temperature. Show plants in pots should be grown in full light to have the foliage well developed. When the temperature is higher than 76°, frequent syringing is necessary. It is, of course, possible to force lilacs in a lower temperature, and this should be grown in full light to have the foliage well frequent syringing is necessary.

Developed. When the temperature is higher than 76°, not count. Full advice for commercial lilac-forcing will even be advisable if the longer time required does not count. Full advice for commercial lilac-forcing is given by Fr. Harms in "Flieder und Asparagus," a book devoted almost exclusively to lilac-forcing. When the temperature is higher than 76°, not count. Full advice for commercial lilac-forcing will even be advisable if the longer time required does not count. Full advice for commercial lilac-forcing is given by Fr. Harms in "Flieder und Asparagus," a book devoted almost exclusively to lilac-forcing.

interesting experiments recently conducted have shown that the lilac is more readily forced when the temperature is higher than 76°, not count. Full advice for commercial lilac-forcing will even be advisable if the longer time required does not count. Full advice for commercial lilac-forcing is given by Fr. Harms in "Flieder und Asparagus," a book devoted almost exclusively to lilac-forcing.

of these experiments by W. Johannsen is entitled "DasEtherverfahren beim Frühtreiben mit besonderer Berücksichtigung des Flieders." That the ether has a tendency of the albuminoids in the plant has been stated recently by other botanists also.

The ether has a tendency of the albuminoids in the plant has been stated recently by other botanists also.

Forcing lilacs.—Most of the lilacs used by American commercial florists for forcing are imported. Care should always be taken to procure pot-grown plants, that is, plants that have been grown in pots the previous summer. The florist who wishes to grow his own plants should lift them in the field in April or before the growth starts and pot them without losing much root. Plunge them out-of-doors during summer and give them plenty of water. This treatment will insure a good growth and the check the plants receive from lifting will induce them to form new flower-buds. These plants will force with the greatest certainty. It is well to allow five weeks for the earliest forcing. A strong heat is necessary, beginning at 60° for the first few days and increasing to 75° to 80°, with a daily watering and syringing several times. After the flowers begin to open, the syringing can be discontinued and when fully expedient the plants are better removed to a coolhouse, where they will harden off and be much more serviceable when cut. As the season advances, say March and April, less heat is needed. They will then force in any ordinary house where the night temperature is about 60°. The Persian lilac, on account of its abundance of bloom and delicate truss, is very desirable, but this must be forced almost in the dark to produce white flowers. Marie Legrave is for all purposes the most useful lilac which has been used for forcing. (Wm. Scott.)
Section EUSYRINGA.

Group VILLOSE.

1. Josikrea, Jacq. Shrubb, attaining 12 ft., with upright, stout, terete branches: lvs. broadly elliptic to elliptic-oblong, acute at both ends, finely ciliate, dark green and shining above, glabrous or pubescent on the midrib beneath, 2½-5 in. long: fls. violet, inserted much below the mouth, ½-3 in. long, with nearly upright lobes: fruiting panicles pendulous or nodding, somewhat large, with handsome dark foliage.

2. villosa, Vahl (S. Bretschneideri, Lemoine. S. emodi var. rosea, Cornu.). Figs. 3759, 3760. Bushy shrub, 8 ft. high, with rather stout, upright, terete and warly branches: lvs. broadly elliptic to oblong, acute at both ends, finely ciliate, bright green and dull above, pubescent usually or only near the midrib, rather glabrous beneath, 3-7 in. long: fls. pinkish lilac or whitish, short-pedicelled, in broad or somewhat narrow usually pubescent panicles, 3-7 in. long, rather loose; rachis terete; lobes spreading, tube about ½ in. long: infructescence, tube 3½ in. long, pale violet-purple, with the stamens just below the mouth. May. Japan. 

3. emodi, Wall. (S. villosa var. emodi, Rehbn.). Shrubb, to 15 ft.: branchlets brownish or dark olive-green, dotted with pale lenticles: lvs. elliptic to oblong, acute at both ends, white and glabrous beneath, 6-8 in. long: fls. narrow, 3-6 in. long, with leafy bracts; racemes drooping, with rachis angular; corolla pale lilac or whitish, not pleasantly scented, tube ½ in. long; anthers partly exserted; calyx obscurely lobed. Himalayas. Grass. 31:6. R.H. 1876, p. 308. Gn. 39, p. 106. RB. 28:193. Not quite hardy in Mass. There are varieties with yellow lvs., var. aurea, Simon-Listous, and with yellow-variegated lvs., var. aureo-variegata, Hort.

4. reflexa, Schneid. Shrubb, to 12 ft.: branches gray or purplish gray, dotted with lenticles: lvs. ovate-oblong to lance-oblong, sometimes elliptic-obovate, acuminate, ciliate at the base, glabrous above, villos beneath chiefly along the veins, 3-5 in. long: fls. nearly cylindrical, nonning or pendulous, 5-7 in. long and ½-2 in. across; rachis, pedicels, and calyx sparingly villous or calyx nearly glabrous; corolla pinkish, ½-3 in. long, or nearly upright lobes: fruiting panicles reflexed, slightly warty oblong caps. W. China.

A remarkable species very distinct from all others by the pendulous panicles and particularly handsome before the fls. open because of the carmine color of the buds.

Group VULGARS.

5. pubescens, Turcz. (S. villosa, Deene, not Vahl. S. villosa var. ovatifolia, DC.). Shrubb, 6 ft. high, with slender, somewhat quadran-gangular branches: lvs. roundish ovate to rhombic-ovate or ovate, shortly acuminate, ciliate, dark green and glabrous above, 1-3 in. long: fls. pale lilac, fragrant, short-pedicelled, in ovate, not very large, but numerous panicles; lvs. very slender; anthers violet, inserted much below the mouth. May. N. China. Grass. 1:415; 376. B.R. 1907, p. 262. A remarkable species—Free-flowering shrub of graceful habit, with handsome dark foliage.

6. Julianna, Schneid. Spreading shrub, to 6 ft.: branchlets villous: lvs. elliptic-ovate, acute or acuminate, cuneate at the base, pubescent above, pale and more villous-pubescent beneath, particularly on the veins, 1-2 in. long; fls. pinkish lilac or whitish, not precisely scented, tube ½ in. long, pale violet-purple outside, fragrant, small, the spreading lobes white inside; anthers inserted a little below the mouth. May,
June. W. China. B.M. 8423.—A handsome and distinct species similar to S. pubescens; the deeper color of the fls. is heightened by the purplish violet color of the whole inflo.

7. affinis, L. Henry (S. oblata var. albiflora, Hort.). Slender, loosely branched shrub; lvs. broadly ovate, acuminate, truncate at the base, finely pubescent while young, particularly on vigorous shoots, on flowering branches sometimes glabrous or nearly so, 1/4-1/2 in. long and 1/4-1/2 in. broad; infl. slender and rather loose, 4-5 in. long; calyx distinctly 4-toothed; corolla white, tube 1/2 in. long. May. N. China. Var. Giraldii, Schneid. (S. Giraldii, Lemoine, not S. Giraldiana, Schneid.). Lvs. usually more densely pubescent while young: infl. 5-6 in. long, lvs. purplish-lilac; racich, pedicels, andpyx. green; blooms a week earlier than the other varieties of S. vulgaris; such are "Lamartine" with rose-mauve fls. and "Mirabeau" with rosy lilac fls.

8. oblata, Lindl. Shrub or small tree, 12 ft. high, rather compact: lvs. roundish ovate or reniform, often broader than long, cordate, short-acuminate, bright green, their margins usually reddish while young, 2/1-4/3 in. across: fls. pale lilac to purple-lilac, in dense subglobose or pyramidal panicles, 3-5 in. long; pedicels about as long as the distinctly toothed calyx. May. N. China. G.F. 1:221. A.G. 22:183. G.W. 5, p. 549. B.M. 7896. G. 38:355.—Next to the preceding species the earliest to bloom and handsome in fall with its vinous or russet-red foliage. A hybrid with the following species is S. hyacinthiflora, Rehd. Intermediate between the parents, with broadly ovate lvs. turning purplish in fall. Only known in the double form, var. plena, Lemoine. Many or perhaps most of the newer double-flowered varieties have originated by recurrent crossing of these two varieties of S. vulgaris.

9. vulgaris, Lindl. Figs. 3758, 3761, 3762. Upright shrub or small tree, 20 ft. high: lvs. ovate, truncate or slightly cordate, acuminate, bright green, 2-4 in. long: fls. lilac, blue, purplish, or white, in large panicles. May. S. E. Eu. to Caucasus and Afghanistan; sometimes escaped from gardens in the eastern states. B.M. 183. Gn. 53, p. 156. M.D.G. 1899:205. F.E. 22:5. R.H. 1903, pp. 126-128.—The most important of the older original varieties are the following: Var. albiflora, Hort., branchlets yellowish gray: lvs. white; buds yellowish green; blooms a week earlier than the other varieties. A.F. 12:801. Var. cerulea, Ait. Fls. blue, in rather loose panicles. Var. rubra, Loud. Fls. purplish red, in large and rather dense panicles. Here belong also var. maysiana, Hort., and Charles X. Var. violacea, Ait. Fls. violet-lilac, in rather loose panicles. Var. plena, Hort. With double fls. There are several varieties with variegated lvs., but these are hardly worth cultivating.

11. persica, Lindl. Fig. 3763. Shrub, attaining 5-10 ft., with slender, arching branches: lvs. lanceolate, acuminate, 1 1/2-3 in. long: fls. pale lilac or white, in rather loose, broad panicles, about 4-6 in. long; pedicels as long or longer than calyx. May. June. Caucasus to Afghanistan. B.M. 486. Var. albiflora, Loud. (S. steerei, Hort.). Fls. white. Var. rubra, Hort. Fls. red. Var. laciniata, Valth (S. filifolia, S. filicifolia, and S. pinata, Hort.). With pinnately lobed or pinnatifid lvs., of dwarfer habit and with smaller panicles. R.H. 1877, pp. 452, 453; 1883, p. 80; 1901, pp. 40, 41.

Section LIGUSTRINA.

12. pektinensis, Rupe. (Ligustrina amurensis var. pektinensis, Maxim. Ligustrina pektinensis, Regel). Large shrub, attaining 15 ft., with slender, spreading branches, brownish red when young: lvs. ovate to oвate-lanceolate, usually narrowed at the base, acuminate, rather dark green above, pale or grayish green and glabrous beneath, 2-4 in. long, 1 1/2-2 1/2 in. broad; fls. yellowish white in large glabrous panicles, usually in pairs at the ends of branches; stamens about as long as limb. June. N. China. G.F. 3:165; 7:385. M.D.G. 1899:425.—Large shrub, of excellent habit, with handsome foliage retained until late in fall; flowers profusely only when older. Var. pendula, Hort. With very slender, pendulous branches.

13. amurensis, Rupe. (Ligustrina amurensis var. mandshurica, Maxim. Ligustrina amurensis, Regel). Shrub, attaining 12 ft., with spreading or upright branches: lvs. broadly ovate to ovate-lanceolate, usually rounded at the base, acuminate, dark green above, pale or grayish green and glabrous beneath, 2-6 in. long, 1 1/2-2 1/2 in. broad; fls. yellowish white, in large, rather loose glabrous panicles; stamens almost twice as long as limb. June. Manchuria. Gh. 12:396; 45, p. 64. G.F. 3:271. Gn. 12, pp. 629, 642. R.H. 1877, pp. 453-455.—Sometimes cult. under the name of S. sibirica or S. sibirica dōba.

14. japónica, Decne. (Ligustrina amurensis var. japónica, Maxim.). Fig. 3764. Pyramidal tree. attain-
SYRINGA

ing 30 ft., with upright branches; Ivs. broadly ovate to broadly elliptic, rounded or slightly cordate at the base shortly acuminate, pale green beneath, and usually pubescent when young, 3–7 in. long; fls. yellowish white, in very large pubescent panicles often 1 ft. or more long; stamens little longer than limb. June, July.

Very desirable free-flowering tree and quite hardy N. var. argentea, Temple, var. as the Ivs. variegated with silvery white.

SYZYGIUM

(Sym. from the Greek, united, referring to the calyptrae petals). Myrtaceae. Trees and shrubs of the tropics of the Old World, variously defined and by some authors made a section of Eugenia: from Eugenia proper the group differs in the united petals, the calyx truncate or with a 4–5-lobed limb and no staminal disk: fls. small, in compact clusters: fr. small 1- or 2-seeded berries. As defined by Niedenzu, the genus has about 140 species. One or two names under this genus appear in the trade. For S. jambolana, see Eugenia jambolana, p. 1103, Vol. II.

operculatum, Nied. (S. nervosum, DC. Eugenia operculata, Roxbg.). A large evergreen tree with 4-angled or nearly terete branches; Ivs. opposite, broad-ovate or elliptic, rounded or somewhat acuminate at apex and narrowed at base, 3–6 in. long, dark green and glossy, the primary lateral nerves few and separated; fls. in 3's and collected into a more or less thyrsoïd infl. greenish: berry 3⁄4 in. or less diam., juicy, edible. Himalaya.—This name appears recently in Calif.: young plants described as having handsome foliage; said to be an acquisition.

L. H. B.
TABEBUIA (Brazilian name). Bignoniaceae. Ornamental trees grown chiefly for their showy flowers.
Evergreen: lvs. opposite, simple or digitate, entire or serrate; fls. in terminal panicles or racemes, rarely solitary; calyx regularly splitting or unequally 3-5-lobed; corolla funnelform-camppanulate; stamens included; disk annular or cupulate; ovary with the ovules in many series: caps. more or less compressed, usually elongated, glabrous or nearly so. — About 90 species in Trop. and Sub-trop. C. Amer. By Bureau and by Schumann, Tabebuia is limited to the 5 or 6 species with simple lvs., and the species with digitate lvs. are referred to Tecoma, while the Tecoma of this work is called Stenolobium by these authors. See, also, Bignonia.

The tabebuias are upright trees with large evergreen foliage simple or digitate and with large pink, white, or yellow flowers in terminal, usually few-flowered panicles or racemes or sometimes solitary.

They are suited for cultivation in tropical or subtropical countries only and are sometimes grown in southern California and Florida. They grow luxuriantly in rich or well-manured soil and are easily propagated by cuttings and also by air-layers.

a. Lvs. simple.
leucoxyla, DC. (Bignonia leucoxyla, Veill. B. pallida, Lindl.). Fig. 3765. Evergreen tree or shrub: lvs. elliptic-oblong to obovate-oblong, obtuse or sometimes marginal at the apex, glabrous, dark green, with distinct pale midrib, 4-7 in. long; fls. in few-fl. terminal racemes; corolla funnel-shaped, about 2 in. long, with yellow tube and pale lilac limb. Brazil. B.R. 965.

b. Lvs. digitate.

b. Fls. pink.

triphylla, DC. (Bignonia tripaphylla, Linn. Tecoma tripaphylla, Mart.). Evergreen tree: lvs. long-petioled, digitate; lfts. 3-7, usually 5, stalked, oblong-lanceolate, entire, glabrous, 1-2½ in. long; fls. in usually few-fl., loose panicles or 1 or 2; corolla funnelform, with large, spreading limb, rose to pink or nearly white, suffused with pink, 2½ in. long; calyx 2-lipped: caps. linear, 6-8 in. long. W. Indies, Guiana.

rosea, DC. (Tecoma rosea, Bertol.). Evergreen tree: lvs. digitate; lfts. 5, rarely 3, long-stalked, ovate to oblong, acuminate, entire; fls. in many-fl. terminal panicles; corolla funnelform-camppanulate, with short tube and large spreading lobes, rosy pink; calyx camppanulate, obscurely 2-lobed, almost truncate. Guatemala.

b. Fls. yellow.

chrysantha, Nichols. (Tecoma chrysantha, DC.). Evergreen tree: lvs. digitate; lfts. 5, ovate, acuminate, entire, tomentose, 4-7 in. long, long-tailed; fls. in terminal dense racemes, yellow, funnelform, 2 in. long. Caracas.

T. zeillii, Hems!. (Tecoma zeillii, DC. Bignonia zeillii, Humb. & Bonpl.). Evergreen tree; about 20 ft. high; lvs. digitate, with 7 oblong-obovate lfts., pubescent above, tomentose beneath; fls. in terminal panicles, subcampanulate, orange-red, with yellow spots on the lower lower lobes. Mex.—T. deutschen-Bornhardt, Rose, Known in Mexico as "Primavera" and so called to be one of the most beautiful trees, sometimes 4 ft. diam., and the wood very valuable; fls. beautiful golden yellow, in great abundance, usually appraising before the palmette compound lvs.; lfts. 7, oblong to ovate, acuminate, rounded or truncate at base, serrate.—T. pulcher, Rose. Tree, 18-25 ft., bearing rose; low like-like lvs.: lvs. opposite; lfts. 4, about 2-2½ in. long, oblong, somewhat acuminate, obtuse at base; fls. white and purple, with yellow spots, in close clusters at ends of naked branches; corolla 1½-2 in. long. Mex.—T. pentaphylla, Hems!. (Tecoma pentaphylla, Juss.). Closely related to T. tripaphylla. Tree, to 50 ft.: lfts. usually 5, elliptic, oblong-obovate, obtuse or acute; fls. rosy pink, larger. W. Indies, Cent. Amer., Venezuela. The plant intro. under this name by the Dept. of Agric. under No. 38649 is said to have orange-colored fls., and belongs probably to some other species.—T. serratifolia, Nichols (Tecoma serratifolia, Don). Evergreen tree: lvs. digitate, with 4-5 oblong-obovate acuminate lfts. serrate at the apex, 3-5 in. long; fls. in terminal panicles, tubular-funnelform, yellow. W. Indies.—T. spectabilis, Nichols. (Tecoma spectabilis, Fitch & Lindl.). Evergreen tree: lvs. digitate, with 5-stalked ovate to oblong-obovate, cretately serrate lfts.; fls. in terminal panicles, orange-yellow, funnelform-camppanulate. Colombia. E.S. 9:948.

ALFRED REHDER.

TABERNANETUMANA (named for J. T. Tabernemontanus of Heidelberg, physician and botanist; died 1590). Apocynaceae. Evergreen usually glabrous trees or shrubs, grown in the greenhouse.

Leaves opposite, thin or leathery: cymes rather branched, terminal or dichotomously arranged; fls. white or yellowish, small or rather large; calyx usually short, deep or to the middle 5-lobed or parted; corolla salver-shaped, tube cylindrical, lobes twisted; disk various; ovary with 2 distinct carpels: berries or follicles, 2, globose, oblong, ovoid or recurved-reniform, smooth or 3-ribbed. — About 160 species, widely distributed throughout the tropics. See Gonion for distinctions from that genus.

The East Indian rosebay, T. coronaria, is one of the
best ornamental shrubs for subtropical gardens. This species and *T. Camassi*, referred in this work to *Convolvulaceae*, is grown everywhere in Florida from Jacksonville southward. If they receive proper attention, tiny cuttings soon develop into dense, bushy plants 3 to 5 feet high, covered with delicately scented flowers throughout the summer. Indeed the plants are so densely covered with buds and flowers that it is often difficult to find a sufficient supply of cuttings for propagation. *T. coronaria* has larger leaves than *T. Camassi* and the flowers are much like those of the double white oleander, while *T. Camassi* resembles the shed flowers of the old-fashioned Madonna lilies. Both do well under the same treatment. In order to enjoy the beauty of the East Indian rosebay to its fullest extent, it must be planted in rich, sandy soil, not too wet and not too dry, and in places fully exposed to the sun. Only very strong pot-grown plants should be set out in the garden. This should be done during the rainy season. Avoid breaking the ball in transplanting. It is useless to transplant in November, the time when most evergreens and other plants are most successfully set out. The plants at this season have not time to become established before the first sharp frost comes, and a weakened tabernamontana is usually killed outright by even a slight frost. Just before Christmas all the plants of this nature (bauhinias, eucalypti, and so on) are banked about 18 inches to 2 feet high with dry sand, and they always come through without much damage. In April or even earlier, the banking is taken away and the plants cut back to sound wood. The tabernamontanas look best in groups by themselves or in front of other glossy leaved evergreens. (H. Nehring.)

*a Fls. white.*

**coronaria,** Wild. **Crape Jasmine. Nero's Crown.** A tender shrub, 6-8 ft. high; lvs. glossy green, oblong to oblanceolate; fls. white, fragrant, 1-2 in. across, in 1-8-fld. clusters in the forks of the branches; petals crimped on the margin, whence the common name. Cult. in India but native country unknown. Var. fibro-plena, with double, somewhat larger, very sweet-scented fls., seems to be far more common in cult. P.M. 16:354. B.M. 1865 (as *Nerium coronarium*).—Cult. in the more southern states and also in greenhouses. Also known as Adam's apple and East Indian rosebay.

**aa Fls. yellow.**

**grandiflora,** Jacq. A small, tender shrub; lvs. oblong-ovate, sharply acuminate, 2-3 in. long, thick: fls. from a tuberous or creeping rhizome, adapted to the warmhouse. **A tender shrub, 6-8 ft. high:** lvs. glossy green, oblong to oblanceolate, 2-3 in. long, thick: fls. white, fragrant, 1-2 in. across, in 1-8-fld. clusters in the forks of the branches; petals crimped on the margin, whence the common name. Cult. in India but native country unknown. Var. fibro-plena, with double, somewhat larger, very sweet-scented fls., seems to be far more common in cult. P.M. 16:354. B.M. 1865 (as *Nerium coronarium*).—Cult. in the more southern states and also in greenhouses. Also known as Adam's apple and East Indian rosebay.

TACSONIA (from the Peruvian name of one of the species). *Passifloraceae.* From Passiflora, *Taconia* differs in having a long-tubular calyx, stamens and petals usually 5, the latter never wanting, corona of tuber; or very short threads, and in a short reflexed crown near the base of the fl.-tube. However, the line of demarcation between the two groups is not well marked and Harms (Engler & Prantl's Pflanzenfamilien) unites *Taconia* with *Passiflora.* Masters (Trans. Linn. Soc. 27) accepts 25 species of true *Taconia*, relegating the intermediate forms largely to *Passiflora*. Other species have been discovered subsequently. The *Taconias* are all S. American, inhabiting the Andes. They are tendril-climbing shrubs or herbs, requiring the treatment given passiflora. *T. manicata* is cult. freely in the open in Cent. and N. Calif. *T. manicata* (Passiflora manicata) is a common and striking red-fls. tall climber in S. Calif. In this work, following Engler & Prantl and also Hooker, the *Taconias* are described under *Passiflora.*

TACCA (Malayan name). Syn., *Adictiox Taccodes,* a family allied to the Dioscorea tribe. Perennial herbs from a tuberous or creeping rhizome, adapted to the warmhouse.

Leaves radical, large, petiolate, sometimes unilobed and palmately lobed; veins variously branched; petioles 8-10 in. long: bracts narrowly ovate to lanceolate, 1 in. long, indescent, rarely finally double. Fls. from the very thin leafy stems, small: pedicels 8-10 in. long: involucral bracts 4, conspicuous, the 2 inner elliptical, narrowed to a petiole, the 2 outer revolute. Malaya. B.M. 4588. F.S. 9:860–861. Gn. 45, p. 418; 49, p. 423.—According to Gn. 45, p. 418 it requires rich, good, open soil, with ample drainage, plenty of water, and a stove temperature. In the winter season the plant should be kept in a state of partial rest.

**aa Lvs. not lobed.**

**crisirita,** Jack. **Adictiox crisirita,** Kunth. Rootstock a short conic caudex, marked with f.-sears: lvs. 1-2 ft. long, oblong acuminate, dark purplish green: scape longer than the lvs.; fls. dark purple, ½ in. across, in a somewhat 1-sided umbel, with numerous pale sterile pedicels 8-10 in. long: involucral bracts 4, conspicuous, the 2 inner elliptical, narrowed to a petiole, the 2 outer revolute. Malaya. B.M. 4588. F.S. 9:860–861. Gn. 45, p. 418; 49, p. 423.—According to Gn. 45, p. 418 it requires rich, good, open soil, with ample drainage, plenty of water, and a stove temperature. In the winter season the plant should be kept in a state of partial rest.

**cc Lvs. much lobed.**

**pinnatifida,** Jack. **Tender perennial herb, about 2 ft. high:** rootstock globose, becoming 1 ft. through; lvs. large, usually 3-branched, the divisions pinnately cut or divided, the ultimate lobes sometimes irregular and unequal but usually ovate to lanceolate; fls. greenish, 8 lines across, many with the sterile pedicels purplish; berry nearly globular, 1 in. through. Afr., India, and Austral. L.B.C. 7:692. B.M. 7299, 7300.—According to Von Mueller’s Select Extra-tropical Plants, the Fiji arrowroot is prepared from the tubers of this species. The plant thrives even on the sand-shores of tropical countries, and it is not unlikely that it will endure a temperate climate.

TENONIA (Greek, making reference to the very small ribs of the fr.). *Umbelliferae,* One species, a slender smooth glaucous perennial of E. Canada and U.S. *P. integerrima,* known as *P. pinellina integerrima,* Gray, and *Zizia integerrima,* DC. It has little value to the horticulturist, although interesting to the collector of native plants for the hardy border. It is erect, 2-3 ft., slender, open-branched, with long-rayed umbels of small yellow fls. in spring and early summer: lvs. ternately 2-compound, the fls. oval to lanceolate, entire, nearly or quite obtuse.
TAGETES

(TAGetes, an Etruscan god, or perhaps of other derivation). Compositae. MARIGOLD. American perennial and annual flower-garden herb.

Leaves opposite or alternate, pinnately cut or rarely simply serrate; fl.-heads of various sizes, yellow or orange, marked in some species with red: strong-scented plants with opposite or alternate mostly pinnately divided lvs. that bear oil-glands; involucre of united parts forming a cup or tube, naked at base; achene angled or flattened, the pappus of a few entire mostly unequal bristles or scales; rays pistillate; disk-fls. perfect.—Species about 20, from New Mex. and Ariz. to Argentina, mostly annuals. The popular annual species known as “African” and “French” marigolds have been derived respectively from T. erecta and T. patula, both of which are native to Mex. According to Sweet’s Hortus Britannicus, these two species were intro. into cult. in 1596 and 1573.

For garden purposes Tagetes may be divided into two groups, based upon habit of growth. T. erecta and T. lucida are of upright and somewhat open growth; while T. patula and T. signata are spreading and bushy, the lower branches lying close to the ground and often rooting. The French marigolds, T. patula, are valuable bedding plants. Good garden forms are of even height and bushy compact growth, with a mass of good foliage and well-colored flowers appearing continuously from June until frost. In raising plants, it is preferable to grow them in pots, as this practice seems to check the plants sufficiently to cause them to bloom at a small size and more plentifully during the early summer months than if they were raised with unlimited root room. They should be planted about 1 ft. apart.

This species also makes attractive specimens in small pots in a few weeks from seed. Mixed seed of the double sorts will give a large percentage of good double flowers, while the seed of special named double sorts is remarkably good. Some of the single forms are very fine in full bloom. The African marigolds, T. erecta, are not well suited to bedding purposes, the growth being too open, but for the mixed border or shrubbery they are excellent late-blooming subjects. This species should be grown with plenty of root room, air, and rich soil from start to finish if the largest and most double flowers are desired. The African marigolds are very useful as cut-flowers except under circumstances where their odor is objectionable.

For pot marigold, see Calendula.

A. Fls. generally marked with red.

pátula, Linn. FRENCH MARIGOLD. Fig. 3766. A hardy annual, usually about 1 ft. high and much branched from near the base, forming a compact, bushy plant: lvs. darker green than in T. erecta, pinnately divided; lobes linear-lanceolate, serrate; fls. smaller than in T. erecta and borne on proportionately longer peduncles. Mex. B.M. 150; 3830 (as T. compropinum).—Both the single and double forms are grown. The species is very variable as to the color-markings of the fls. which range from almost pure yellow to nearly pure red. A dwarf variety, nana, Hort., is known. Gn. 65, p. 24; 73, p. 127.

cc. Rays few, usually 5.

signátá, Bartl. An annual branching species: lvs. pinnately divided into usually 12 oblong, linear, sharply serrate segms., the lower teeth awned; rays 5, yellow, roundish-ovate. Mex. R.H. 1896, p. 505. Var. pámula, Hort., a dwarf, bushy form, usually less than 1 ft. high, seems to be the only form in the trade. The fls. are bright yellow and small but numerous.—The species is suited for massing or for borders.

cc. Rays numerous.

erécta, Linn. AFRICAN MARIGOLD. Fig. 3767. A hardy annual growing about 2 ft. high, erect, branched: lvs. pinnately divided, segms. lanceolate-serrate; fls. 2-4 times as large as in T. patula and of one solid color, the typical color, according to DeCandolle, being a lemon-yellow. Mex.—The rays are sometimes rather 2-lipped and in one of the garden forms they are quilled. The color ranges from a light sulfur-yellow to a deep orange, many of the light yellow shades being rare amongst fl. colors. This is the common marigold of old gardens in Amer. Foliage very strong-scented.

bb. Lvs. lanceolate, simply serrate.

Ricída, Cav. SWEET-SCENTED MARIGOLD. A tender perennial plant, entirely distinct from the foregoing annuals in the sessile, lanceolate lvs. and small, usually 2-3-rayed fls. in dense, terminal corymbs. The fls. have a much more agreeable odor than the other species cult. Mex. B.M. 740. R.H. 1895, p. 505. Sometimes used as a substitute for tarragon, which sees.

T. lucida is a species discovered about 1896 by T. S. Brandegee in Calif. It makes a compact bush 4-5 ft. high, bearing a profusion of yellow fls. in winter. Small plants flower well in pots. See G.F. 9:67.

—T. Lémmonii, Gray, also a shrubby nearly smooth plant about 2 ft. high, seems to be grown in Calif. It is distinctly woody but rather slender; lvs. all opposite. 3-7-foliate, the serrulate fls. about 1 in. long; heads about 1 in. diam., showy. Ariz. G. C. III. 37:21.

F. W. BARCLAY.

TAINIA (Greek, hand or fillet, alluding to the shape of the lip). Orchidáceae. Terrestrial warm-house orchids. Sterile st. from a many-sheathed rhizome finally thickened into a pseudobulb; fl. single, terminal, large, long-petioled; flowering scape arising from the rhizome, tall, leafless, base few-sheathed, bearing a simple terminal raceme: fls. pedicellate, sparse, rather large or medium-
TAINIA

 sized; sepals about the same length, narrow, acutish to acuminate; petals similar to the sepals or narrower; labelium affixed to the foot of the column, erect, gibbous at the base, erect and parallel or clasping the column, the middle lobe spreading, short, broad; pollinia 8.—About 14 species, India, S. China, and Malay.

Fuerstenthieliana, Schlecht. Tall: pseudobulbs ovate, about 2 in. long, 1-fld.: if. erect, petiolol, lanceolate, about 2 ft. long; scape slender, erect, 2½–3 ft. tall, bearing a lax 10–15-fld. raceme: fls. about 2 in. across; sepals and petals oblong-ligulate; lip oblong, 3-lobed. Habitat?—Closely allied to T. penangiana.

penangiana, Hook. f. Not pseudobulbs: fls. 8–12 x 1½–2 in., about equaling the slender pedicel: scape twice as long; sepals linear-lanceolate, 2½ in. long, acuminate; petals narrow, 5–7-nerved, spurred shortly conical, obtuse; lip oblong, side lobes subacute, incurved, overlapping the orbicular, acuminate, crispaped midlobe; Penang, Malay Penins. F. TRACY HUBBARD.

TAINIOPSIS (like Tainia). Orchidaceae. Epiphytic plants, probably adapted to the coolhouse. Roots rather stout, with a short decumbent rhizome: pseudobulbs ovoid, slightly 4-angled, finally rugose, at apex 2-fld.: lvs. elliptic-lanceolate, acuminate, narrowed to the petiole, lightly plicate, 1 ft. or more long; scape lateral from near the base of the pseudobulb, erect, slender, more or less exceeding the lvs.: inf. simple or slightly branched, laxy several- or many-fld.: sepals ringent, ligulate, rather obtuse, minutely puberulent outside, glabrous inside, lateral recurved, falcate, base broadened; petals obliquely linear, obtuse, recurved, glabrous, as long as the sepals; labelium curved, mobile, lanceolate-tongue-shaped, apex hastately dilate with the margins incurved; column medium-sized, broadened toward the apex; pollinia 8. One species, Xhassia Mts. and Burma, T. barbata, Schlect. O. 1915:11. F. TRACY HUBBARD.

TALAIMA (S. American name). Magnoliaceae. Evergreen trees, grown occasionally in the greenhouse. Lvs., inf., and seeds as in Magnolia: sepals 3; petals 6 to many, imbricate in 2 rows; stamens numerous; carpels numerous, capitate or spicate, indehiscent; ovary many-ovuled: caps. globose or ovoid, chartaceous, 3-valved.—About 15 species, India, S. China; both hemispheres, being grown both as an ornamental and for its acid fruits, which have many uses. The tamarind became known in Europe during the Middle Ages, doubtless through the Arabs. It is said to have been introduced into Europe by Europeans to be produced by an Indian palm (Dymock). Leaves alternate, equally pinnate, the Ifs. small, indeterminate in number; stipules minute, caducous; fls. irregular, produced in racemes at the ends of the branches; bracts and bracteoles ovate-oblong, colored, caduceous; calyx-tube turbinate, narrow, the segments 4, imbricate, membranaceous, colored; 3 superior petals imbricate, yellowish, veined with red, 2 inferior reduced to bristles hidden at the base of the staminal tube; fertile stamens 3, connate in a sheath, opening above with short, free filaments, anthers oblong, longitudinally dehiscent; ovary many-ovuled, with a stall adnate to the calyx-tube, the style filiform, stigma terminal, subcapitate: fr. an oblong or linear, compressed, indehiscent pod, with a thick, crustaceous epicarp, pulpy mesocarp, and coriaceous endocarp seat between the ovulate-ovulate seeds, compressed and exalbaceous. The genus is distinguished from Schotiaia, the only ally which seems to be cult. in Amer., by its floral characters.

indica, Linn. TAMARIND. TAMARINDO. Fig. 3708. A large tree, attaining to 80 ft. in height when grown on deep soils, with a trunk 25 ft. in circumference; bark brownish gray, somewhat shaggy: lvs. abruptly pin

TAMARINDUS (from the Arabic tamar-Hindi, meaning "Indian date"). Loganiaceae. A tropical genus containing but one species, the well-known tamarind. It is considered to be indigenous to tropical Africa (the upper Nile region) and possibly southern Asia as well. It has long been cultivated throughout the tropics of both hemispheres, being grown both as an ornamental and for its acid fruits, which have many uses. The tamarind became known in Europe during the Middle Ages, doubtless through the Arabs. It is said to have been introduced into Europe by Europeans to be produced by an Indian palm (Dymock). Leaves alternate, equally pinnate, the Ifs. small, indeterminate in number; stipules minute, caducous; fls. irregular, produced in racemes at the ends of the branches; bracts and bracteoles ovate-oblong, colored, caduceous; calyx-tube turbinate, narrow, the segments 4, imbricate, membranaceous, colored; 3 superior petals imbricate, yellowish, veined with red, 2 inferior reduced to bristles hidden at the base of the staminal tube; fertile stamens 3, connate in a sheath, opening above with short, free filaments, anthers oblong, longitudinally dehiscent; ovary many-ovuled, with a stall adnate to the calyx-tube, the style filiform, stigma terminal, subcapitate: fr. an oblong or linear, compressed, indehiscent pod, with a thick, crustaceous epicarp, pulpy mesocarp, and coriaceous endocarp seat between the ovulate-ovulate seeds, compressed and exalbaceous. The genus is distinguished from Schotiaia, the only ally which seems to be cult. in Amer., by its floral characters.

TAMARINDUS

...a refrigerant, digestive, carminative, laxative, and antiscorbutic, for which latter purpose it is sometimes used in place of lime juice. With the addition of sugar and water, it makes a cooling drink or refresco, especially well known in Latin America. For the preparation of this drink, a sirup is often made from the pulp which can be bottled and used as desired. In some countries tamarinds are an important article of export. In Jamaica the fruit is prepared for shipment by stripping it of its outer shell, and then packing it in sacks, with alternate layers of coarse sugar. When the cask is nearly full, boiling sirup is poured over all, after which the cask is headed up. In the Orient, the pulp, containing the seeds, is pressed into large cakes, which are packed for shipment in sacks made from palm leaves. This product is a familiar sight in the bazaars. It seems to be greatly esteemed as an article of diet by the Indians. As also by the Arabs, large quantities being shipped to Arabia from India.

According to Watt, the natives of India have an aversion to sleeping under the shade of the tree because of the supposed acid exhalation from the leaves. Pittier states, however, that he has slept under a tamarind tree for weeks without suffering the least inconvenience. Gamble writes that the leaves cause the cloth of tents pitched in the shade of the tree. This happens, he says, in wet weather; the leaves fall on the tents, and within a day or two the cloth is decomposed in holes.

The tree is easily propagated by means of seeds, which is the only method commonly used. Seeds can be transported without difficulty, as they retain their viability for a considerable length of time if kept dry. They are best germinated by planting them \( \frac{1}{2} \) inch deep in light, sandy loam. The young plants are rather delicate and must be handled carefully to prevent damping-off. In India, the yield of a mature tree is said to be about 350 pounds of fruit per annum. Little is known of the insect pests which attack the tree; Maxwell-Leffroy mentions two, Cargoborus gonagra, a large gray-brown chrysomelid beetle found in tamarind seeds, and Charaxes Fabius, a large black yellow-spotted butterfly whose larvae feed on the leaves. Both these insects occur in India.

Firminger mentions three varieties of tamarind grown in India, but does not know whether they can be depended on to come true from seed. Masters, in the "Treasury of Botany," states that the East Indian variety has long pods, with six to twelve seeds, while the West Indian variety has shorter pods, containing one to four seeds. Seedlings undoubtedly show considerable variation in the size and quality of their fruit, which accounts for the different varieties which have been noted by many writers. Firminger recommends that seedlings which produce unusually choice fruit be propagated by gootee, or stem-layering, a method which is described under Litchi. More recently (1913) Wester has reported that the tree can be shield-budded successfully the method being similar to that used with avocado. F. W. POPPENOE.

TAMARIS: Tamarind

TAMARIS (ancient Latin name). Tamaricaceae. Tamarisk. Ornamental woody plants, grown chiefly for their showy panicles or racemes of pink or whitish flowers; and also for their very fine graceful foliage.

Deciduous shrubs or trees; lvs. alternate, sessile, often sheathing, small, and scale-like; fls. small, short-pedicelled or sessile, in rather dense racemes, usually collected into terminal panicles; sepals and petals 4-5; stamens usually 4-5, rarely 8-12, sometimes slightly connate at the base; ovary 1-celled, surrounded at the base by a more or less deeply 5- or 10-lobed disk; styles 2-5, clavate or short and thick; fr. a caps., dehiscent into 3-5 valves; seeds many, minute, with a tuft of hairs at the apex. About 75 species from the Medit. region to...
TAMARIX

E. India and Japan. Several species have medicinal properties and yield dye-stuffs. The punctures of an insect, Coccus marnipennis, cause T. marniura to produce "manna."

The tamarisks are very graceful shrubs or small trees with slender branches clothed with minute scale-like leaves. They are good inhabitants of warmer arid regions, and are adapted to dry and alkaline soil. They are excellent for seaside planting and thrive in the very spray of the salt water. Propagation is by seeds, which are very fine and should be only slightly covered, or usually by cuttings of ripened wood in the open ground or by greenwood cuttings under glass.

KEY TO THE SPECIES.

A. Fls. 4-merous: racemes lateral on last year's branches.
   B. Petals spreading, persistent; styles usually 3
      1. parviflora
   B. Petals deciduous; styles 1
      4. tetrandra

A. Fls. 5-merous.
B. Racemes lateral on last year’s branches.
   B. Racemes forming large terminal panicles, rarely lateral on the current year’s branches.
   C. Lvs. glabrous.
   D. Petals persistent.
   E. Bracts ovate-lanceolate
      4. pentandra
   E. Bracts subulate.
   F. Infl. nodding: tree with spreading branches.
      5. chinensis
   F. Infl. upright: erect shrub.
   G. odsessana
   D. Petals deciduous
      7. gallica
   Cc. Lvs. finely pubescent
      8. hispida

1. parviflora, DC. (T. tetrandra var. parviflora, Boiss. & Kohtsency). Fig. 3769. Shrub or small tree, 15 ft. high, with reddish brown bark and slender spreading branches; lvs. ovate, acuminate, semi-amplexicaul, scarios at the apex when older; fls. pink, very short-pedicelled, in slender racemes about 1 in. long along last year’s branches; petals spreading, persistent; calyx very small, sometimes only 3-parted; styles usually 3, much shorter than ovary. April, May. S. Eu. F.S. B:885. H.1855-401. Gn. 61, p. 273; 71, p. 398.
   - Often confused with the T. tetrandra, also with T. africana and T. gallica and cult. under those names. T. tetrandra var. purpurea probably belongs here.

2. tetrandra, Pall. Shrub or small tree, attaining 12 ft., with stamens in equal, ovate-lanceolate, some-
   what narrowed at the base, with diaphanous margin: fls. light pink or almost white, in racemes 1–2 in. long along last year’s branches; disk purple, deeply 4-lobed; styles usually 4, about as long as ovary. April, May. S. Eu. W. Asia. Doubtful whether in cult. in this country; all plants seen under this name by the writer belong to the preceding species.

3. juniperina, Bunge (T. japonica and T. plumbea, Hort.). Shrub or small tree, attaining 15 ft., with
   slender spreading branches; lvs. green, oblong-lanceolate, acuminate, scarious at the apex; fls. pinkish, in lateral racemes 1½–2½ in. long on last year’s branches; petals slender, shorter than calyx; sepals ovate-lanceolate, little shorter than the persistent petals; disk 5-lobed, with emarginate lobes. Japan, N. China. S.Z. 1:71 (as T. chinensis).

4. pentandra, Pall. (T. Pallast, Desv. T. hispida austrosia, Hort.). Shrub or small tree with usually purple branches; lvs. lanceolate to ovate, acute, gla­
cous or pale green; fls. pink, in large panicles, the racemose dense, 1–2 ft. long; bracts ovate-lanceolate, 
   -ne or acuminate, as long or slightly longer than petals; petals broadly elliptic-oblong, convivent, disk 5-
   lobed, with emarginate lobes; styles slender, about 1 in. long, on short, naked peduncles, spreading and disposed in ample loose panicles; petals about as long as calyx; sepals ovate, much shorter than the persistent petals; disk deeply 10-lobed. July–Sept. China.

5. chinensis, Lour. Shrub or small tree, attaining 15 ft., with slender spreading, often drooping branches; lvs. bluish green, lanceolate, acuminate, keeled; fls. pink, in large and loose usually nodding panicles, pedicels as long as calyx; sepals ovate, much shorter than the persistent petals; disk slightly spreading; disk 5-lobed, with rounded lobes. July–Sept. Caspian region.

6. odsessana, Stev. Shrub, 4–6 ft. high, with upright, slen­
der branches; lvs. lanceolate, subululate, deciduous; fls. pink; racemes slender, about 1 in. long, on short, naked peduncles, spreading and disposed in ample loose panicles; petals about as long as calyx; sepals oblanceolate; disk 5-lobed, with rounded lobes. July–Sept. Caspian region.

7. gallica, Linn. (T. arborea, Sieber, not Ehrenb. T. canar­
   ine, Willd.). Shrub, or small tree with slender spreading branches; lvs. dull to bluish green, closely imbricated, rhom­bic-ovate, acute or acuminate, keeled, semi-amplexicaul, with scarious margin; fls. white or pinkish, globose in bud, almost sessile, in slender, panicled racemes; petals deciduous; filaments somewhat dilated at the base, inserted between the rounded lobes of the 10-lobed disk; styles 3. May. S. Eu. Medit. region to Himalaya; naturalized in S. Texas and N. Mex. Gn. 34, p. 329. Var. indica, Ehrenb. (T. indica, Willd.). With slender, upright branches; lvs. dull green; racemes longer and slenderer; fls. pink, disk obscurely and nutate 10-lobed. July–Sept. Caspian region.

8. hispida, Willd. (T. kashgaria, Hort.). Shrub, with slender upright branches; lvs. bluish green, cordate and subauriculate at the base, acuminate, somewhat spreading, finely pubescent; fls. pink, almost sessile, in dense racemes 2–5 in. long, disposed in terminal panicles;
**TAMARIX**

**ALFRED REHDER.**

**TAMONEA** (native name). *Melastoma cauliflorum.* This name was revived to cover the names *Cyanophyllum,* *Miconia,* and others from *Cyanophyllum* to *Tamonea,* the other from *Eu., N. Afr., and Temp. Asia.* About 2 species, 1 from Canary Is., the other from *Eu., N. Afr., and Temp. Asia.*

**TANACETUM** (name of doubtful derivation). *Compsas.* Annual or perennial herbs which are odorous: Fls. alternate, variously cut: heads of small to medium-sized yellow fls. disposed in corymbs, or rarely solitary, heterogamous, disk-shaped; female fls. with 3-5-toothed, tubular corollas: achene 5-ribbed or 3-5-angular, with a broad truncate summit, bearing a coroniform pappus or none.—Thirty-five species scattered about the northern hemisphere, of which about 7 are native to *N. Amer.* For cult., see *Tanacetoidea,* 261.—*T. annua, Linn.—*T. brachystyla, Gay, T. africana, Forr.—*T. Boudourea, Gay, T. rubida, Hassen, T. paucosinuata, Gay, and T. articulata, Vahl.—*T. dolica, Webb. Allied to *T. gallica. Shrub, 10 ft. fls. bluish green, somewhat constricted at the base; fls. ovate or in bud; filaments minute, at the base, attached to the acute lobes of the 5-angled disk, W. E., B.E. 2:61.—*T. articulata, Vahl. Tree, attaining 30 ft., with, slender, pointed branches. Fls. glaucous, minute, sheathing; fls. 5-merous, pink, sessile, in terminal pedicels. W. Asia. Not hardy. N.—*T. subtilis, Willd.—*Myricaria dahurica.—*T. gallica, Linn.—*Myricaria germana.—*T. rubida, Batsch. Allied to *T. parviflora. Tree or shrub with red cored branches; lvs. minute, imbricate; bracts ovate, acute, almost as long as calyx; calyx-segms. 4; petals 4, rose; stamens 4, with long filaments and dark purple anthers. Algerian.

**TANAGA (named in honor of M. Tanaka).** *Saxifragaceae.* Herb probably hardy and perennial: plant dicocious, perhaps sometimes monocious, stoloniferous; stolons slender, leafy and rooting: lvs. basal, long-petioled, thick or somewhat fleshy, finally leathery, including the petioles 4-8 in. long; blade oblong-lanceolate or ovate-lanceolate, rounded or somewhat cordinate at base, acute, doubly serrate; scapes very slender, branched, pyramidal, 6-8 in. high: fls. very small, greenish white, shortly pedicelled, solitary in the axis of the bracts; sepalas 5, almost free, oblong-lanceolate; petals none; stamens 10, alternate ones shorter; ovary glabrous, almost entirely free, 2-celled.—One species, Japan, T. radicans, Franch. & Sav. B.M. 7943. G. 33:376; 36:515.

**TANSELO** (from tangerine and pummelo; by syn­
copation: tange-ri.ne [pum­melo]. A new group of cit­
rous fruits originated in 1897 by the writer by cross­
ing the Dancy tangerine with the Bowen grapefruit.

**TANGELO 3309**

The resulting hybrid, named Sampson tangelo by H. J. Webber and the writer (United States Department of Agriculture Yearbook, 1904) does not closely resemble either parent in its fruit characters, being a slightly pear-shaped thin-skinned smooth and shining fruit of medium to large size, pale orange in color, and with a rather acid sprightly flavored very soft and juicy orange-colored pulp. It ripens very late, several months after it begins to color, and sometimes becomes partly dry before complete maturity. When properly grown it is a delicious fruit. It is being grown commercially on a small scale, but its delicate okin and commercial value is being ripened for a special market.

The Thornton is another tangelo, a hybrid of tangerine with a Florida grapefruit. It is a rough thick-skinned round fruit with very pale orange-colored juice and sprightly flavored pulp. It ripens earlier than the Tangelo and is less acid. It is very like a tender good-flavored orange in character. It is beginning to be grown commercially on a small scale.

The success of the first two tangelos produced by artificial hybridization has led to the creation of hun­
dreds of additional hybrids between all the mandarin types of orange (Citrus nobilis) such as the tangerine, willow-leaf mandarin, King, Satsuma, and the like, and the better sorts of grapefruit and pummelo (Citrus grandis). These fruits in general resemble round oranges (Citrus sinensis) more than either of their parents and are exceedingly variable. Sister fruits from seeds of a single cross-pollinated fruit often being very unlike. Among the tangelos there are some of much promise because of their superior flavor and juiciness.

The spread of citrus canker (a bacterial disease caused by Pseudomonas citri) to many of the hot moist orange-growing regions of the world makes it desirable to breed new types of tangelos by hybridizing the canker-resistant mandarin oranges with canker-resistant pummelos such as can be found in the Orient. Such tangelos, if canker-resistant, could perhaps be grown in place of the more susceptible round oranges, just as limequats can be grown in place of the common lime, which is very susceptible to canker.

WALTER T. SWINGLE.

TANGERINE: Orange and Citrus.

TANSY (Tanacetum vulgare, Linn.). A coarse-growing herbaceous perennial naturalized from middle Europe, and a familiar occupant of old gardens, waste places, and roadsides. Its common name is said to be derived from athanasia, immortality, an idea suggested to the ancient Greeks by the characteristic permanent possession it takes of the soil. Its annual upright usually unbranched stems, which rise about 3 feet from the perennial root, bear greatly divided deeply cut compound bitter aromatic leaves and rather dense corymbs of numerous small yellow flower-heads which appear in midsummer. The seed, which is small, is marked by five rather prominent grayish ribs and retains its vitality for about two years. Formerly its leaves were in great favor as a seasoning for various culinary preparations, especially puddings and omelettes, and it is now almost obsolete. By the medical profession, its tonic and stimulant properties and its efficacy in hysterical and dropsical disorders are still recognized, although other medicines are more popular.

In domestic practice it played an early rôle as an anthelmintic and stomachic and is still somewhat popular as a local agent to relieve the pain of muscular rheumatism, bruises, and chronic ulcers. The wild plants usually satisfy all demands, but when no wild supply is at hand seed may be used to start the half-dozen specimens that a family should need. Easily started, readily transplanted or divided, tansy requires no special care in cultivation except to keep it clear of weeds and to prevent its spreading and thus becoming troublesome. It will thrive in almost all soils and situations that are not too wet. For botanical account, see Tanacetum.

M. G. KAINS.

TAPEINOTES (from the Greek, referring to its low stature). Gesneriaceae. Under this generic name, one species is listed abroad, T. Caroliniana, Wawra. The genus is now included in Sinningia and the current name is S. Caroliniana, Benthi, & Hook. (S. barbata, Nichols.). It is a Brazilian plant, adapted to the warmhouse: decumbent or ascending, with oblong to lanceolate-cuneate-serrate lvs. 1 ft. or less long and red beneath; fls. white, red-marked inside, with a contracted and hairy throat and tube swollen at base. B.M. 5823, which represents a striking plant with lvs. brilliant red-purple beneath and curved hairy deflexed white corollas 1½ in. long; described as a small under-shrub.

TAPIoca: Manihot.

TAPIRIPA (from a native name in Guiana). Also spelled Taphra. Anacardiaceae. A name of disputed application. The plant likely to interest horticulturists in this relationship is Cyrtocarpa procera, from Mex., described on p. 945, Vol. II. Of Tapirira itself, distinguished by 4-5 styles, those in the pistillate fls. short, none is probably regularly in cult. As formerly defined, the species are S. American, with a few in Afr. and Asia, 8 or 10 in number. Later authors restrict the genus to S. Amer., mostly to Brazil. Under any definition, the genus is probably adapted to cult. only on our southernmost borders.

TAPIScia (anagram of Pistacia, to which it bears a strong resemblance, though not closely related).
**TAPISCA**

*Staphyleaceae.* An ornamental deciduous tree from China with large alternate odd-pinnate lvs., deciduous stipules and with small yellow fragrant fls. in axillary panicles; calyx tubular-campanulate, 5-lobed; petals 5, spatulate-ovate, little longer than the calyx; stamens 5, exerted; style slender, longer than stamens; ovary superior: fr. a 1-seeded ovoid drupe. It is as yet little known in cult., but probably can be grown successfully in the S. only; it may be recommended chiefly for its bold pinnate foliage and the honey-scented fls. Prop. can probably be effected by cuttings besides by intro. seeds. *T. sinensis,* Oliver. Small tree, to 30 ft., occasionally to 90 ft.: lfts. 5-7, ovate to ovate-oblong, acuminate, cordate at the base, sericulate, glaucescent and nearly glabrous beneath, 3-5 in. long; panicles broad, 2-3 in. long; fls. 1/4 in. long, yellow, fragrant: fr. ovoid, black, 1/2 in. long. June, July. Vent.

**TARAXACUM** (name probably associated with supposed medicinal properties). *Leontodon* of some authors. **Compositae. Dandelion.** Low nearly or quite stemless herbs of cold and temperate regions, mostly of the northern hemisphere. Distinguished by having posed medicinal properties).

3774. Variation in foliage of the common dandelion. (All leaves drawn to the same scale.)

**TARO.** A group of tuberous-rooted edible aroids, of the genus *Colocasia,* scattered throughout the tropics and subtropics of the world; cultivated also in many warm regions of the temperate zones, as Egypt, Syria, China, Japan, and New Zealand, and lately in the southern United States.

The taro has been cultivated from very early times and the Egyptian variety, under the name "colocasia," is mentioned by Pliny as being of great importance in Egypt at that time. The culture of it was said to have been already introduced into Italy. The Egyptian variety, now called qolqas, is *Colocasia antiquorum* (*Arum Colocasia*), Fig. 3775, a quite different plant from that of the varieties most commonly grown in southeastern Asia and the islands of the Pacific. The qolqas is of very inferior quality and is said to be eaten in Egypt only by the laboring classes.

The botany of the taros of the Pacific regions is in an unsatisfactory state, owing largely to the infrequency with which many varieties flower, but most of them evidently belong to *Colocasia esculenta* (by some considered to be a variety of *C. antiquorum* and so treated in Vol. II, page 830). See Fig. 3776.

The culture of taro has probably reached its highest development in the Hawaiian Islands and it is largely through its extensive use there that the plant has become so widely known among travelers and others. The large number of varieties despite the fact that the plants seldom, if ever, set seed, testifies to the antiquity of the culture of this type of taro. MacCaughey and Emerson, in the Hawaiian Forester and Agriculturist
TARO

(vols. 10, 11, 1913–1914), record a list of 262 named varieties of taro, or "kalo," which are said to have been grown on the islands. But few of these are of commercial importance, and many are no doubt lost.

In Hawaii, taro is eaten mostly in the form of poi, a sticky paste made by steaming or boiling the taro, then peeling and "pounding" or grinding it with the addition of a little water. It is usually allowed to ferment for a day or two before being eaten, and is considered to be a very easily digested, wholesome, and nutritious food. The organisms involved in the fermenting process are probably not always the same, but they appear to include a yeast and one or more bacteria. Fermented or sour poi is not alcoholic, but acid. Poi frequently constitutes an important part of the diet of invalids. By others it is usually eaten with meat, especially fish. Taro is also eaten boiled, or parboiled and baked, and in many other ways like the potato. Most varieties are acid in the raw state, however, and these often require longer cooking in order to destroy this property. When properly cooked and served, the better varieties of taro are highly palatable and constitute a most valuable food. The young leaves, before they open, are prized as greens and are called "laau." They are parboiled with baking soda or cooked with fat meat to destroy the acridity.

The cultivation and use of taro in Hawaii appears to be slowing decreasing, although in 1913 it was estimated that the total planting was some what greater than 1,500 acres. It is reckoned as fourth in importance among the crops cultivated, sugar-cane, rice, and pine-apple exceeding it.

Taro-culture is of two general types, water and upland, and a different set of varieties is grown for each. The length of season required to grow a crop is about one year, although some varieties require longer and some mature in less time. Propagation is by a "huli," which consists of the top of a corn or cornel with 7 or 8 inches of the inner pedicels still attached. Planting is undertaken at any time of the year.

In water culture the hulis are placed rather close together, often no more than a square foot being allowed for each plant. The cultural treatment varies greatly and is doubtless influenced by the water-supply, water being often scarce. The soil is pullded in order to prevent too rapid seepage. In some cases the land is rested for several weeks between crops, but more often replanting is made at once. Again, water is sometimes withheld for two to four weeks after planting, while at others the ground is not allowed to dry. At harvest-time the laborers wade into the mud and water and pull up the taro plants by the roots. The roots are then removed from the corms, the outer leaves stripped off, and hulis made from the tops as already described.

The practice in growing upland taro in Hawaii also varies considerably in the spacing of the plants, they being sometimes planted in small groups, at regular intervals, though more commonly in regular rows. The harvesting is performed by hand in much the same manner as described for water taro, a simple tool being used, however, in lifting the plants. Upland taro can be grown only where the rainfall is abundant and well distributed throughout the year, hence its culture is limited to certain localities.

The dasheen.

A variety of this same species of taro, Colocasia esculenta, known as the Trinidad dasheen (Fig. 3777), was introduced into the United States for culture in the South, in 1905, having been previously brought from the island of Trinidad to Porto Rico by O. W. Barrett. This variety, which has come to be known simply as 'dasheen,' is thought to have come originally from China, as its name, a corruption from "de la Chine" or "da Chine," indicates. Varieties similar in appearance but inferior in quality exist, some of them known to be of Chinese origin.

The Trinidad dasheen is considered to be one of the most promising crop plants introduced into the United States in recent years, as it is thoroughly adapted for culture in the moist sandy loams of the South Atlantic and Gulf states and, as grown on such soils, of excellent quality. The crop from each hill when well grown, consists of one or more large central corms, with a large number of lateral cormels or "tubers" (Fig. 3778). The total yield from one hill in good soil ranges from four pounds to as high as thirty pounds in rare cases. These are cooked for table use like potatoes. They are somewhat drier and have a delicate nutty flavor when they have been grown under suitable conditions and are properly prepared. The color of cooked dasheens varies from white or cream to gray or violet. When grown in heavy or poorly drained lands, however, the quality is usually inferior, in both texture and flavor. An average of eleven analyses of the dasheen gives 27.5% per cent of starch and sugars and 3 per cent of protein. The sugar-content is a little higher than in

3775. Taro—Colocasia antiquorum var. esculenta. a, Inflorescence, showing wide-open limb of spathe and long sterile appendage of spadix characteristic of this species. b, Spadix, showing the following areas, beginning above the base: 1, pistillate flowers; 2, abortive flowers which were compressed by the neck of tube of spathe; 3, staminate flowers; 4, sterile appendage.
the white potato, making the dasheen seem slightly sweet by comparison. Like other taros, it is held by many to be easy of digestion as compared with most other starchy foods.

In the United States, the dasheen is at present grown exclusively as an upland crop, that is, not under flooded conditions as other taros are usually grown in Hawaii. The crop requires about seven months of warm frostless weather fully to mature. It has been grown with best results in a moist, but well-drained rich sandy loam. Heavy soils produce a low quality of corm and tuber, and often a poor yield. Muck soils, if they contain a moderate amount of moisture, usually produce a heavy crop of dasheens but of poor quality for table use. Dry soils of any kind are useless for dasheens.

Planting should be made in the early spring, just so that the last spring frost will be past before the plants are up. In central Florida, it is made about the middle of March and farther north, up to early April. Cormels, or "tubers," two to four ounces in weight, are generally used for planting, although smaller ones may be used. Larger tubers, small corms, or the upper parts of larger corms may also be planted when available. The character of soil is of greater importance than the size of tuber planted. The tuber is planted about 2 inches below the surface. The plants are spaced 4 by 3 or 3½ by 3½ feet, on level ground except where there is danger from standing water, when planting should be done on ridges. With level planting the soil is gradually drawn toward the plants in cultivating during the latter half of the season. The large leaves shade the ground almost completely by midseason if the soil conditions are good.

The crop matures in late October and early November in the southern United States. Harvesting is performed with a spade or with team and plow. Dasheens keep well when properly handled and stored. The entire subject is treated at length in bulletins of the United States Department of Agriculture.

ROBERT A. YOUNG.

TARRAGON (Artemisia Dracunculus, which see) is a close relative of wormwood (A. Absinthium). It is a perennial composite herb native of the Caspian Sea region and Siberia, and is cultivated as a culinary herb in western Europe. Its lanceolate entire leaves and small inconspicuous and generally sterile blossoms are borne upon numerous branching stems, 2 to 3 feet tall. Its green parts, which possess a delicate aromatic flavor resembling anise, are widely used for seasoning salads and for flavoring vinegar, pickles, and mustard. The essential oil of tarragon and tarragon vinegar are articles of commerce, the crop being grown extensively in southern France for this purpose. The

TASMANNIA (named after Abel Jansen Tasman, navigator, for whom the island Tasmania is named). Now considered a synonym of Drimys. One species, Drimys aromatica, Moell. (Tasmannia aromatica, R. Br.), is sometimes mentioned in horticultural literature: small tree or a bushy shrub with pinkish fins, elliptic-oblong or oblong-lanceolate lvs. and aromatic pea-size berries. Victoria, Tasmania. B.R. 31:43.

3777. Full-grown plant of dasheen, the variety of taro grown in the United States.

3778. A hill of dasheen. The large central corm, with part of leaf-stems still attached, is surrounded by the cormels, or tubers, just as they grow.
TAVARESIA (derivation unexplained). Aeciphedaceae. Succulent stapelia-like perennials, branching at the base: sts. 6–12-angled, angles tuberculate, toothed, each tuber with 3 bristles: fls. large and showy, in sessile cymes at base of young sts.; calyx 3-parted; corolla large, tubular-funnel-shaped, 5-lobed; crown double, outer shortly tubular at base, then divided into 10 long filiform segms., each terminated by a knob, inner crown of 5 narrow lobes; staminal column arising from base of corolla. Two species. T. and S. Afr. T. Banklyi, N. E. Br. G. W. 15, p. 117.

TAXODIUM (alluding to the similarity of the foliage to that of Taxus). Syn., Glyptostrobus, Schuerbertia. Nothofagus. Ornamental woody plants, grown chiefly for their graceful feathery foliage and wood.

Deciduous or evergreen trees or shrubs: lvs. alternate, linear, usually 2-ranked, falling off in autumn or the second year together with the short lateral branchlets; fls. monocious, small; staminate fls. catkin-like, consisting of spirally arranged anthers, with 4–9 anther-cells and forming terminal panicles; pistillate fls. solitary or in pairs at the ends of branchlets of the previous year, composed of imbricated scales bearing 2 ovules inside at the base; cone globose or nearly so, maturing the first year, consisting of spirally arranged woody scales enlarged at the apex into an irregularly 4-sided disk with a mucro in the middle and toward the base, then divided into 10 short branches: lvs. narrowly linear, acute, thin, light green, usually in N. Am. and 1 in China.

Of the three species, the only one well known in cultivation is the bald cypress. T. distichum, a tall pyramidal deciduous tree with small linear two-ranked leaves and small globose cones. It is hardy as far north as New England and is a very desirable tree for park planting. Its light green feathery foliage and the narrow pyramidal habit which it usually retains in cultivation give it a very distinct appearance. In its native habitat it forms in old age a broad round-topped head sometimes 100 feet across and has the trunk much enlarged at the base by huge often hollow buttresses projecting in all directions and terminating in long horizontal roots. From these roots spring the peculiar cypress knees, pyramidal protuberances composed of a very light, soft, spongy wood and spongy bark. These sometimes attain a height of 10 feet and with age usually become hollow. From the under side of the horizontal roots large anchor-roots are sent perpendicularly into the earth and help to anchor the tree firmly in the swampy yielding soil. The knees are thought by some to be formed for the purpose of strengthening this root-system, since they are chiefly found opposite to the anchor-roots, but their main purpose is probably to bring air to the roots during the several weeks or months when the swamps are covered with water. The knees always grow high enough to rise above the surface of the water (see, also, G. F. 3, pp. 21, 22, 27).

The bald cypress is one of the most valuable timber trees of North America. The wood is brown, light and soft, close and straight-grained, but not strong; it is easily worked, durable in the soil and much used for construction. The bald cypress thrives best in moist sandy soil, but also does well in drier situations. The habit seems to depend somewhat on the degree of moisture; in drier soil the head is more narrow-pyramidal, in moist soil broader and more spreading. Propagated by seeds sown in spring and the varieties by grafting on seedling stock early in spring in the greenhouse; also by cuttings in sand constantly saturated with water or grown in water alone, under glass.

of reddish color. They are particularly beautiful in autumn when loaded with scarlet berries. They are well suited for hedges and easily trimmed into any desired shape. They were formerly much used for fantastic topiary work (see e. g., G.C. II. 3:264, 265).

The best-known species is

**TAXUS** (ancient Latin name of the yew). Taxaceae, formerly named in the Conifera. Yew. Ornamental woody plants, grown for their dark green foliage and the scarlet berry-like fruits.

Evergreen trees or shrubs. Lvs. linear, without resin-dots, pale or yellowish green beneath, usually 2-ranked: fls. usually dioecious, solitary and axillary, rarely terminal, small, appearing in early spring; staminate globose, composed of 4-8 stamens each, with 8 anther-cells attached to the peltate connective for pistillate consisting of a single terminal ovule with several bracts at the base: seed a bony nut surrounded by a fleshy cup-shaped scarlet disk; cotyledons 2.—Six species are known. They are distributed throughout the northern hemisphere and in America south to Mex. They are all very closely allied and have been considered geographical varieties of a single species. The wood is heavy, hard, close-grained, strong, and cattle, but the berries are not.

The yews are evergreen, usually small slow-growing trees or shrubs, with 2-ranked linear dark green leaves, insignificant flowers and showy berry-like red fruits. The best-known species is **T. baccata**, which is hardly as far north as Rhode Island and northwestern New York, and in some forms as far as Massachusetts, while **T. cuspidata** and **T. canadensis** are considerably hardier and thrive as far north as Canada; the other species are little known in cultivation. The yews are very desirable evergreens for park planting; they are densely clothed with dark green foliage and the pistillate plants are particularly beautiful in autumn when loaded with scarlet fruits. They are well suited for hedges and easily trimmed into any desired shape. They were formerly much used for fantastic topiary work (see e. g., C.C. II. 2:264, 265).

That the typical tree-like form of the yew is nowadays not much planted is chiefly due to its slow growth, but its numerous mostly shrubby garden forms are popular plants for small gardens. The yews thrive best in a moderately moist sandy loam and endure shade well. Large plants may be successfully transplanted if it is possible to secure a sufficient ball of earth with the roots. Propagation is by seeds, which do not germinate until the second year, and by cuttings taken early in autumn and kept during the winter in a cool greenhouse or frame; the varieties also often by grafting on the type in early spring in the greenhouse, or sometimes by layers. Plants raised from cuttings grow more slowly than grafted ones and cuttings of the type rarely grow into trees but usually into low-spreading shrubs (see M.D.G. 1898:565).

cuspidata, Sieb. & Zucc. (T. baccata var. cuspidata, Carr.). Tree, attaining 50 ft., with a trunk usually 2 ft. diam.; bark bright red; branches ascending; lvs. usually falcate, thickish, distinctly and abruptly mucronate, dark green above, pale fulvous green or pale green beneath. 3/4-1 in. long: fr. with ovoid seed slightly 3-4-angled and 3/4 in. long. Japan. S.I.F. 1:115. Very similar to T. baccata, but branches stouter and lvs. denser and more crowded and of a lighter, more yel-low and W. China.-This variety fruits very profusely.

The plant offered as var. capitata, Rehd. Low form making a dense sometimes almost hemispherical bush with ascending branch-lets: lvs. somewhat shorter and duller, ascending and not or scarcely 2-ranked: slow-growing, rather compact while young, but with age becoming more open. C.L.A. 11:308. F.E. 29:409. Gn.M. 2:111. Var. densa, Rehd. Low form making a dense sometimes almost hemispherical bush with ascending branch-lets: lvs. like those of the preceding form. Var. chinensis, Rehd. & Wilson (T. bac tata var. chinensis, Pilger). Lvs. more falcate, lighter green, 3/4-3/2 in. long, convex above with the midrib very slightly raised: seeds broadly ovoid, slightly compressed, slightly 2-angled. Cent. and W. China.—This variety fruits very profusely. The plant offered as var. cuspidata does not differ from typical T. cuspidata.

canadensis, Marsh. (T. baccata var. minor, Michx. T. baccata var. canadensis, Gray. T. minor, Brit.). Fig. 3781. Prostrate shrub, with wide-spreading slender branches, rarely more than 3 ft. high: lvs. shorter and narrower, less crowded and of a lighter, more yel-lowish green than those of T. baccata, assuming in winter usually a reddish tint: fr. ripens about 2 months earlier than that of T. baccata; seeds depressed, broader than long: fls. monocious (at least usually). Newfoundland to Man., south to Va. and Iowa. B.B. (ed. 2) 1:167. V. 14:252. Gn.M. 2:22.—In cult. it becomes usually a more upright and less straggling shrub.

brevifolia, Nutt. Fig. 3782 (adapted from Pacific R. R. Report). Tree, 40-50 or occasionally 80 ft. high, with slender horizontal or somewhat pendulous branches forming a broad, open, pyramidal head: lvs. distinctly 2-ranked, sharply pointed, dark yellowish green, 7/10 in. long: seeds ovoid, 2-angled. Brit. Col. to Calif. S.S. 10:514.—Probably as hardy as T. baccata.

—T. karinna, Hort. = Ephedrataxus Harringtonia var. instigatorii.

—T. Wallachiana, Zucc. Tree, to 100 ft.: lvs. gradually long-acuminate, 1-1 1/2 in. long. Himalayas, Malay Archipelago, Philippine Isls. Apparently not in cult. ALFRED REHDER.

TEAK: Tectona.

TEASEL: Species of Dipsacus.

TÉCÓMA (abridged from the Mexican name Tecomaxochitl). Including Stenolobium, Bismarckia. Ornamental shrubs, grown for their showy flowers.

Upright plants with herbaceous shoots: lvs. opposite, odd-pinnate, rarely simple; lfts. serrate, membranous: fls. in terminal panicles or racemes; calyx tubular-campanulate; corolla campanulate; stamens included, with diverging anther-claws: disk cupulate, crenate: caps. linear, with leathery valves; seeds narrow-elliptic, with 2 large thin wings.—About 3 species from Fla. and Texas to Argentina. The trumpet-vine, commonly referred to Tecoma, will now be found under Campsis.

The tecomas are upright shrubs with pinnate deciduous or subpersistent foliage and large and showy usually yellow flowers in terminal clusters. They stand but little frost and are well suited for cultivation in Florida and southern California. Propagation is by seeds which are usually freely produced and by green-wood cuttings under glass.

The yellow elder, T. stans, grows exceedingly well on high pine-land and is perfectly at home in Florida, attaining an immense size if well fertilized and mulched, dense masses 15 to 25 feet high and as much through being not at all rare. This tecoma is the glory of the south Florida gardens in autumn, as is the beautiful Bauhinia purpurea in April. No shrub is better adapted for the new settlers in the sandy pine-land gardens. When covered with its large fragrant flowers it is visited by numberless hummingbirds and insects. Owing to its rapid growth and dense foliage from the ground, the yellow elder is highly valued as screen for
TECOMA

TECOMARIA 3317

unsightly fences and buildings. This tecoma ripens its seed so abundantly that hundreds of seedlings come up around the old plant. The value of this shrub, blooming so late in autumn, cannot be overestimated. T. mollis, incorrectly known to the trade as T. stans var. velutina, also does well, but being a native of Guatemala it is much less hardy than the former. The growth is more upright and stiff, the leaflets are much larger, less serrate, and much darker green and the flowers, which are borne in terminal panicles, are smaller and without fragrance and the color is a much lighter yellow. It also flowers several weeks earlier than T. stans. The foliage looks crimped and often blackish, being attacked by a kind of aphid and by several fungi. T. Smithii is said to be a hybrid between T. mollis and Tecoma capensis, raised near Melbourne, Australia, by Edwin Smith. The plant comes true from seed, and seedlings flower when about a year old, beginning to open their large clusters of yellow and reddish trumpets in April and continuing with short intervals until cut down by frost in December. (H. Nehrling.)

A. Fls. pure yellow, funnel-form-campanulate, abruptly contracted above the base.
B. Lvs. glabrous or nearly so.

T. stans, Jess. (Stenolobium stans, Seem.). YELLOW EKAZA. Upright shrub: lvs. odd-pinnate; lfts. 5-11, almost sessile, oblong-ovate to lanceolate, acuminated, serrate, glabrous, 2-5 in. long and ¾-1 ¼ in. broad: fls. in large, terminal racemes or panicles; corolla funnel-form-campanulate, yellow, 1½ in. long; anthers pubescent; calyx with 5 short teeth; caps. linear, 5-7 in. long. Sept.-Dec. S. Fla. to W. Indies and S. Afr. EXOT. T. mollis, Humb. & Bonpl. (T. velutina, Lindl.). Similar to the preceding, but pubescent: lfts. 5-9, oblong-ovate to lanceolate, acuminate, less deeply serrate or almost entire, villous-pubescent on both sides or only beneath, 2-4 in. long: fls. like those of the preceding, but smaller and paler and not fragrant: lfts. obtuse or acutish, serrate, glabrous, 2-5 in. long; calyx with 5 short teeth: caps. linear, 5-7 in. long. Sept.-Dec. S. Fla. to W. Indies and S. Afr. EXOT.

Smithii, W. Wats. Fig. 3783 (adapted from The Garden). Upright shrub: lvs. odd-pinnate; lfts. 11-17, oblong, obtuse or acutish, serrate, 1-2 in. long: fls. in large, compound panicles, sometimes 8 in. long and as broad; corolla tubular-funnel-form, with 5 reflexed rounded lobes, bright yellow tinged with orange, 1½-2 in. long. Sept.-Jan. Intro. from Austral and supposed to be a hybrid of T. mollis and Tecoma capensis. G.C. I1. 14:169. Gn. 48:23. I.H. 43:55, 107. Gt. 44, p. 52. G. M. 36:627. J.H. III. 42:371. Blooming in the greenhouse in winter and well suited for culture in pots. It has been said that it comes true from seed, but plants raised by Franceschi from seed received from the originator had mostly pure yellow fls.

Garrócha, Hieron. Glabrous small shrub: lvs. 3½-5 in. long; rachis narrowly winged; lfts. 7-11, short-stalked, oblong-ovate, acuminate, serrate, 1-2 in. long: fls. in slender racemes forming terminal panicles 4-6 in. long; calyx with long-acuminate teeth; corolla about 2 in. long, yellow with scarlet tube, slender, very gradually narrowed toward the base, limb ¾-1 in. across; anthers slightly exceeding the mouth: caps. 2½-4 in. long. July-Aug. Argentina. A smaller and more graceful plant than T. stans, strikingly handsome with its bright yellow and scarlet fls.

ALFRED REHDER.

TECOMARIA (name derived from Tecoma, alluding to its affinity). Bigmondeaceae. Warm-country plants, grown for their showy bloom. Evergreen shrubs with slender, often serar ominous branches: lvs. opposite, odd-pinnate; lfts. sessile; fls. in terminal panicles or racemes; calyx campanulate, regularly 5-toothed; corolla funnel-form, slightly curved; stamens mostly exerted, with pendulous diverging filaments; disk cupulate; capsules linear, compressed. Five species in Cent. and S. Amer. and in S. Afr.

The tecomarias are half-climbing or nearly upright
shrub with handsome pinnate foliage and yellow, orange, or scarlet flowers in rather dense terminal clusters. They can be grown outdoors only in tropical regions. Of the several species in cultivation only *T. capensis* seems to be planted in southern California and Florida. Moderate pruning in spring insures a more profuse blooming. Propagation is by seeds and by cuttings under glass in spring or in midsummer.

The cape honeysuckle, *T. capensis*, grows most luxuriantly in Florida gardens and in those all along the Gulf coast. It is usually grown on trellises on verandas and piazzas with a southern exposure. Of all the species this is the best and most suitable for verandas, being a dense and compact grower, evergreen, almost constantly in flower, easily kept in health and readily trained into shapely specimens. If the long shoots are cut back severely, the plant can be easily trained into shrub form. These long shoots, usually lying flat on the ground, readily strike root and form an excellent material for propagation. *T. capensis* and *Tecoma Smithii* are the only ones which grow and flower fairly well as pot-plants in northern greenhouses. They need good soil and rather large pots to do well. If not well cared for they lose most of their foliage and look poor and unsightly. (H. Nehrling.)

*capensis*, Scem. (*Tecoma capensis*, Lindl.). *Cape Honeysuckle*. Half-climbing or nearly upright shrub: lvs. odd-pinnate; lfts. 7-9, broadly oval to ovate, acute, serrate, glabrous, ½-2 in. long; fls. in peduncled terminal clusters; corolla tubular, curved, with 4-parted spreading limb, the upper lip emarginate, orange-red to scarlet, about 2 in. long; calyx 5-toothed: caps. 4-5:1, ovate, acuminate, 1-2 in. long, with a narrow tube and obovate segments. India, Malaya, and the Philippines. *T. smithii*, Baker (not known to be in the trade), has longer peduncles, longer and narrower scarcely undulate lvs., and narrow oblong segments. Species largely at New York City in protected places, but usually the plants do not thrive more than a year or two; they ought to do better farther south. Blooms very early in spring. Fls. violet-scented.

F. TRACY HUBBARD.

**TECÔRIA** (Latin for cover, the indusium having shield-shaped coverings). *Polyopodaceae*. A group of ferns, mostly of large and coarse habit, with superior form, often heart-shaped indusia fixed by the sinus, as in Dryopteris, but with veins uniting freely to form arcsides with free included veinlets. About 25 species are known, largely from the E. Indies, a few from Trop. Amer. By some included in Polystichum.

decícrens, Copeland. 1-fl.-stalks narrowly winged from a creeping rootstock: lvs. 2-4 ft. long, 1 ft. or more wide, cut down to a winged rachis and with 4-8 pairs of pinnae 5-12 in. long, 1-2 in. wide; sori large, in 2 regular rows between the principal veins. India to Polynesia.

cícutária, Copeland. Fig. 3784. Caudex stout, erect, scaly above; lvs. 6-8 in. to 1½ ft. long; pinnae horizontal, suboblong, suboblong from a rather broad truncate base, 2-3 in. long; sori on disk of larger pinnae in 2 rows, oblong, those on terminal narrow segments solitary, quite marginal. Trop. Amer.

**TECÔNA** (derived from Tekka, the Malabar name of *T. grandis*). *Symplocos*. Tall trees, stellately tomentose, including the well-known teakwood, sometimes grown in the warmhouse as a curiosity. Lvs. opposite or ternately verticillate, large and entire; cymes dichotomous, many-fl., arranged in a large terminal panicle: lvs. small, white or bluish, sessile; corolla-campanulate, shortly 5-6-cleft, inflated in fr.; corolla-tube short, limb spreading, 5-6-cleft; stamens 5-6; ovary fleshy, 4-celled, each cell 4-seeded, included in the calyx, 4-celled; endocarp bony. —Three species, Asia, India, Burma, Malaya, and Philippines.

*grandis*, Linn. *Teak*. Tree, 80-150 ft. high; branchlets quadrangular: lvs. 8-12 in. (of seedlings sometimes 3 ft.), ovate, cuneate at both ends, close tomentose beneath: fls. white or bluish, numerous, but only a few fertile, in pinicles 18 in. diam.; calyx stellately white-tomentose, 1 in. diam. in fr. when it is ovoid or sub-spherical; corolla scarcely ¼ in. long. India, Malaya.

——The timber of this important tree is much used in ship-building because of its durability, great strength, and the ease with which it can be worked. Not planted in this country except experimentally.

F. TRACY HUBBARD.

**TEEDIA** (named for Teophila Billoiti, daughter of a botanist). *Amaryllidaceae*. *Chilean Crocus*. Bulbous plants, useful for blooming in pots indoors early in the spring. Lvs. radical, few or 1, inclosed in a long scarious sheath at the base; blade spreading, linear or lanceolate; scape included with the lvs. at base in the sheath, otherwise leafless, 1-fl., or laxly few-fl.: fls. blue; perianth campanulate, 6 segments; stamens 3 perfect and 3 staminodia; ovary 3-celled: caps. ovate conical toward the top, loculicidally dehiscent. —Two species, Chile. The botanical position of *Teochilina* is open to discussion, but the inferior ovary seems to take it out of the Liliaceae, with which it has been placed by some writers. The plants are useful for blooming in pots indoors early in spring. *T. violiflora*, Bent., does not appear to be introduced.

[Image 50x42 to 480x714]

**TEÊNÔSIA** (named for J. G. Teede, German botanist). *Scrophulariaceae*. *Glauabrous or pubescent shrubs, grown in the greenhouse. Lvs. opposite, ovate, entire; peduncles in the upper axils, bearing a few-fl. cymose infl.: fls. rose, rather small; calyx deeply 5-cleft, lobes narrow; corolla-tube cylindrical, limb spreading, 5-lobed, lobes subequal, rostrate; stamens 4: berry subglobose, indehiscent. —Two species, S. Afr. The foliage of both species has an objectionable odor.

icida, Rud. *Glauabrous*: at. 4-cornered: lvs. oblong-ovate, acuminate, 2 in. long, decussate; petioles winged
Alternanthera the tube is short or almost none, the anther-bearing stamens sometimes less than 5, and the staminodia much shorter than stamens, 2-3-cuspid at apex.—To this variable species appear to belong the garden names picta, tricolor, aurea, aurana compacta, paronychoides, versicolor aurea, magnifica, and others. Var. typica, Regel (Alternanthera paronychoides, Hort.), is low, 2-3 in. tall, with olive-colored lvs. and the upper ones red at apex. Var. spathulata, Regel (A. spathulata, Lem.), is 6-8 in. tall, the st. and lvs. red. I.H. 12:445.

versicolor, Regel. Fig. 3785. Usually becoming taller, much branched, and apparently less used for carpet-bedding than the others; lvs. round-spatulate, narrowed into a short petiole, the colors mostly in shades of copper-red or blood-red, with patches of green between the veins: fl.-heads sessile, single or in pairs. I.H. 12:449.

ficioidea, Moq. St. herbaceous, repent at base and ascending, angled and striate, glabrous, or puberulent above and in the fl.-axils: lvs. spreading or deflexed, short-stalked, broadly lanceolate, attenuate and some­what mucronate: fl.-heads sessile, single, in pairs or 3's, terminal and axillary; bracts ovate-lanceolate, acu­minate, nearly or quite entire; staminodia much shorter than stamens, 2-3-cuspid at apex.—To this apparently belong the garden names amabilis, spectabilis, sessilis, roezel, Reinhardii.

A. Lvs. essentially spatulate.

Bettzickiana, Regel (originally, in 1862, spelled as here, but changed by the author in 1862 to Bettzichiana). Fig. 3785. Plant described as suffruticose and erect, the st. branched at base and terete, adpressed-pilose but becoming glabrous: lvs. narrow, spatulate, narrowed into long petiole, apex acuminate and some­what mucronate: fl.-heads sessile, single, in pairs or 3's, terminal and axillary; bracts ovate-lanceolate, acu­minate, nearly or quite entire; staminodia much shorter than stamens, 2-3-cuspid at apex. —To this variable species appear to belong the garden names picta, tricolor, aurea, aurana compacta, paronychoides, versicolor aurea, magnifica, and others. Var. typica, Regel (Alternanthera paronychoides, Hort.), is low, 2-3 in. tall, with olive-colored lvs. and the upper ones red at apex. Var. spathulata, Regel (A. spathulata, Lem.), is 6-8 in. tall, the st. and lvs. red. I.H. 12:445.

versicolor, Regel. Fig. 3785. Usually becoming taller, much branched, and apparently less used for carpet-bedding than the others; lvs. round-spatulate, narrowed into a short petiole, the colors mostly in shades of copper-red or blood-red, with patches of green between the veins: fl.-heads sessile, single or in pairs. I.H. 12:449.

ficioidea, Moq. St. herbaceous, repent at base and ascending, angled and striate, glabrous, or puberulent above and in the fl.-axils: lvs. spreading or deflexed, short-stalked, broadly lanceolate, attenuate and some­what acute, mucronulate, the margin undulate-repand: heads 3/4-3/4 in. long, sessile, solitary or in 2's; bracts

3785. Spray of Telanthera ammata; also leaf-outlines of a, T. ammata; b, T. Bettzickiana; c, T. versicolor. (XI)
TELENTHERA

acuminatesubciliate, much longer than outer sepals. Brazil.—The T. ficoides, Hort., may be a form of one of the other species.

TÉLÉKIA: Buphthalmum.

TELEPHIUM (an old Greek name). Carvophyllo-
äsæ, in Engler & Prantl; Die Natürelchen Pflanzen-
-familien, Ficoidæ, in Bentham & Hooker, Genera
Planae, Order. One species, T. Imperati, Linn., is listed abroad as a hardy perennial but it has little to commend it to the cultivator: it is a low plant with woody base and slender prostrate sts., with erect or ascending branches: lvs. many, ½ in. long, alternate or scattered, oval or elliptic, entire: fls. several and inoperculous, in small compact clusters. Perhaps valuable on banks or as a carpet.

The genus Telephium comprises 2 or 3 species in the Medit. region, being diffusely branched and glau-
cous herbs: lvs. alternate, paired or opposite, without distinct midrib or nerves: fls. small, in compact terminal clusters, the 5 petals white but not showy; sepals 5, persistent; stamens 5; ovary ovoid, 3-angled and usually 3-celled, the styles 3 and short: fr. a dry capsule, included in the calyx.

TELFÁRIA (named after Charles Telfair, 1778–
1833). Cucurbitaceæ. Climbing shrubs, occasionally
grown in the warmhouse, of economic value in the tropics. Lvs. digitately compound; lfts. 3–5, oblong,
acuiulate at the base on the outside; tendril lateral and 2-cleft: fls. dicious, medium or large, male pedicels bracteate, pale purple; male raceme, calyx tubinate, lobes lanceolate; corolla rotate, 3-parted, segments obvate-cuneate, elongated, filiform-tendrilled; stamens 3; female solitary, calyx and corolla like male; stamens rudimentary or none; ovary oblong, 3–5-

pedátæ, Hook. (Fenúlla pedítæ, Sims). Root stout, fleshly: st. perennial, 50–100 ft. long: lvs. long-petioled; lfts. 3–5 in. long, acuminate, repand-toothed, glabrous except nerves beneath: fls. pale purple, fringed, male 2
in. across; petals obvate-cuneate; female fls. about 4 in. across; ovary obtusely 10-ribbed: fr. fleshy, sometimes weighs 60 lbs., 200–300-seeded; seed 1 in. broad. Zanibar. B.M. 2851; 2751, 2732.—Intro. into S. Calif. but not successful. The seeds are roundish, about an inch across, and the kernels are sweet to the taste, and are said to be as good as almonds. The negroes of Trop. Afr. boil and eat them. These seeds also yield an abundance of oil which has been said to be equal to olive oil. The fr. becomes 1½–3 ft. long and 8
in. wide. It is oblong in shape, has 10–12 deep furrows, and is always green. Both male and female fls. are 5-
lobed, copiously fringed and purple in color, the females somewhat brownish, with a circular green throat, while the males have a 5-pointed star of green in the middle. The male fls. are about 2 in. across, females 4 in. across, with an ovary 2 in. long. The foliage has an unpleasant smell when bruised.

T. occidentalis. Hook. var. is very similar to T. pedata, but the lfts. are all triple-nerved from near the base (those of T. pedata all at an angle of 45° from the midrib): fls. smaller. Upper Guiana. Said to be cult. for the seeds which the negroes boil and eat.

TÉLLIMA (anagram of Mitella). Saxifragaceæ. Erect rather simple hardy herbaceous perennials, the western American representatives of Mitella, well adapted to the wild-garden.

Plants pilose or glandular: lvs. petioled, subrotund-
cordate, lobed, dentate; stipules none or adnate to the base of the pedicels: fls. pedicelled, nodding, greenish or white; petals red-calyx-tube large, dilated or inflated, campanulate, 5-toothed or 5-lobed; petals 5, usually elongate, entire, 3-fid or pinnatifid, sessile or clawed; stamens 10; ovary semi-superior, conical, 1-
celled: caps. membranaceous, 1-celled, many-seeded.—About 10–12 species, W. N. Amer. Tellima differs from Mitella mainly in the caps., which is 2-beaked in Tellima, not beaked in Mitella.

a. Petals privately cut into long, thread-like segms.

b. Fls. not fragrant.

rhíba, Hort., grows 1 ft. high, has red foliage and yellow fls.

bb. Fls. fragrant.

donátà, Howel. Height 1–2 ft.: lvs. broadly cordate, obscurely lobed and crenately toothed: fls. red. Wet
places near Columbia River.

AA. Petals palmately 3–7-lobed or -parted.

b. Basal lvs. not divided to the base.

affinis, Gray (Lithophryna affinis, Gray). Sts. stout, 1–2 ft. high: lvs. radicil, roundish in outline, crenately lobed, varying into the calyce; calyx mostly parted into 3 broad divisions, which are deeply incised or merely toothed: calyx turbinate; petals 3-lobed at the apex. Orc. to S. Calif.

BB. Basal lvs. divided to near the base.

parviflóra, Hook. (Lithophryna parviflóra, Nutt.). Height ⅛–1 ft.: lvs. mostly 3–parted or -divided, the divisions narrowly cuneate and once or twice 3-lobed into narrow lobes: fls. pink or sometimes white; petals with a slender claw, the limb palmately 3–7-parted. Brit. Col. to Utah and Colo.

T. rubrotín, Hort., is offered in the trade abroad, as a plant growing 1 ft. high with beautiful foliage and very pretty fls. Probably it is T. grandiflóra var. rhíba. F. TRACY HUBBARD.

TELÔPEA (Greek, seen at a distance, of fanciful application). Proteaceæ. Tall shrubs, occasionally
grown in the greenhouse and one species has been experimented with in S. Calif., but so far has not proved very successful. Lvs. alternate, entire or dentate: fls. white; petals red, hermannifolia, 3–7-parted, densely racemose; racemes terminal, subglobose or ovoid; bracts exterior, membranaceous, colored; perianth-
tube elongate, segms. at length more or less separated; disk fleshy, strongly oblique but almost perfectly anu-
late; ovary long-stipitate, fr. oblong, 3–7-celled: fr. elongate, base swollen, many-seeded: seeds edible.—One species, 2
Australian, 1 Tasmanian. An earlier name of the genus is Hylogyne, but Telopæa

speciosissíma, R. Br. (Embothrium speciosissimum, Smith). WARATAH. WARRATAH. Stout glabrous
shrub 6–8 ft. high: lvs. cuneate-oblong, 5–10 in. long, mostly toothed in the upper part, coriaceous: fls. crimson, in a dense ovoid or globular head 3 in. across; involucral bracts colored, the inner ones 2–3 in. long. New S. Wales. B.M. 1128. G.C. II. 17:677; III.
55:348. Gn. 22:400. I.H. 34:29.—One of the showiest
flowers of the southern S. Wales. The heads are 3 in. across and 3–4 in. deep and bear a rough resemblance to a florist’s chrysanthemum. The showiest parts, however, are involucral bracts. This plant is known as waratah. It is one of the most distinct members of its family, for a horticultural account of which see Protea. Seeds of this species are imported into Calif. frequently, but although they germinate readily, the seedlings damping-off still more readily. Probably if the plant were once established it could be easily prop. by layering or by cuttings.

F. TRACY HUBBARD.
TEMPLETONIA

(Templetonia) (J. Templeton, botanist of Belfast, early part of 19th century). *Leguminosae*. Coral Bush. Shrub or rarely subshrub, cultivated in the greenhouse abroad and hardy outdoors in the extreme S., where they may be used as ornamentals. Lvs. alternate, simple, entire or reduced to minute scales; stipules small or none; fls. red, yellow, or purple, axillary, solitary or 2 or 3 together; calyx 5-lobed, lobes unequal; standard obovate or obovate-lanceolate, rarely ovate; petals long, broad teeth, the lowest longest; pod sessile or stipitate, much flattened, ovate-oblong or linear, completely dehiscent.—About 8 species, Austral. Said to do best in a mixture of sandy loam and peat. Prop. by cuttings.

T.EOSINTE: *Fuchsia.*

TEPHROSIA (Greek, *tephros*, ash-colored, hoary; referring to the foliage). *Leguminosae*. Hardy or half-hardy perennial herbs, subshrubs, or rarely shrubs, of low horticultural value.

Leaves uneven-pinnate; lfts. numerous, rarely 1-3, linear; stipules bristle-like or broader and striate; racemes terminal, opposite the lvs. or in the upper axes; fls. in fascicles of 2-6, red, purple, or white; calyx-lobes subequal or the 2 upper longer; petals clawed, standard suborbiculate, outside more or less silky-villous; wings obliquely obovate or oblong; keel incurved, obtuse or rather acute; ovary sessile, many-ovuled; pod linear, rarely ovate, compressed 2-valved.

—About 170 species, natives of the warmer regions of the world.

grandiflora: Pers. (*Galega grandiflora*, Vahl). Rigid shrub 1-2 ft. high, pubescent or nearly glabrous; lvs. short-petioled; lfts. 5-7 pairs, cuneate-oblong or linear-oblong, variably pubescent on both surfaces; fls. fasciculate-corymbose, red, pubescent on the outside 8-10 lines long; pod broad, linear, plano-compressed. S. Afr. B.R. 769.

macrantha, Rob. & Greenm. Fig. 3786. Shrub, 6-10 ft. tall; lvs. odd-pinnate; lfts. about 10-12 pairs, oblong-linear, entire, short-acute or cuspidate; fls. in loose terminal panicles 1 ft. long, shaded purple and white, nearly as large as sweet peas; standard very large, erect, oblong-obovate. Mex. G.F. 7:175 (reduced in Fig. 3736).—A very showy plant, deserving of planting where hardy. Pringle writes that “for weeks it lights up the thickets of hillside ravines with masses of pleasing color.”

F. TRACY HUBBARD.†

TERMINALIA (alluding to the leaves being borne upon the terminus of the shoot). *Combretaceae*. Only one species, *T. Catappa*, the Indian almond or tropical almond, is well known in American horticulture, but several others are important in the Orient, principally for their fruits, known as myrobalans, which are used in dyeing, tanning, and in medicine.

Leaves alternate, or rarely opposite, often crowded toward the ends of the branchlets, usually petiolate and entire; fls. sessile or nearly so, small, hermaphrodite or polygamo-dioecious, usually in elongated spikes but sometimes in heads; calyx-tube ovoid or cylindrical, constricted above the ovary, the limb urn-shaped or campanulate, 5-toothed, usually deciduous; petals none; stamens 10, in 2 series, the 5 inferior opposite the teeth; filaments exserted, subulate or filiform; anthers oblong-linear, entire, short-acute or cuspidate: fls. sessile or nearly so, small, hermaphrodite or polygamo-dioecious, usually in elongated spikes but sometimes in heads; calyx-tube ovoid or cylindrical, constricted above the ovary, the limb urn-shaped or campanulate, 5-toothed, usually deciduous; petals none; stamens 10, in 2 series, the 5 inferior opposite the teeth; filaments exserted, subulate or filiform; anthers oblong-linear, entire, short-acute or cuspidate; pod sessile or stipitate, much flattened, ovate-oblong or linear, completely dehiscent.—About 100 species distributed throughout the tropics, principally in S. Asia, with only a few in Amer.

Catappa, Lindl. TROPICAL ALMOND. INDIAN ALMOND. MYROBALAN. ALMENDRO. AMENDOEIRA. Fig. 3787. A tall, stately tree, up to 80 ft. high, with horizontal branches arising from the primary axis in whorls 3-6 ft. apart; bark smooth, brownish gray; lvs. clustered at the ends of the young branchlets, alternate, entire, oblongate, obtuse to subacuminate at the apex, alternate toward the slightly aeated base, 6-12 in. long, 3-6 in. broad, coriaceous, glabrous above, very finely pubescent below, venation slightly raised on both surfaces but most prominent below; petiole stout, under 1 in. long, flattened above, rusty-pubescent; fls. whitish, upper ones staminate and lower ones perfect, in finely pubescent spikes up to 6 in. long; calyx-segments acute, slightly concave, valvate in bud, finely pubescent; filaments subulate, inserted upon the hairy disk; anthers coriaceous: fls. red, yellow, or purple, axillary, solitary or 2 or 3 together; calyx 5-lobed, lobes unequal; standard very long, emarginate or mucronate, inserted upon the hairy disk; anthers cordate: fls. red (or rarely white); calyx with 4 very short, broad teeth, the lowest longest; pod sessile or stipitate, much flattened, ovate-oblong or linear, completely dehiscent.—About 170 species, natives of the warmer regions of the world.

3786. Tephrosia macrantha. (×½)

3787. Nut of tropical almond. —Terminalia Catappa. (×3½)
winged in transverse section, 11/2-2 in. long, indehiscent, greenish or reddish, glabrous, with a firm, fleshy exocarp and a hard endocarp inclosing the oblong-elliptical seed; testa membranous, the cotyledons with spiral grooves. 

T. orientalis, indigenous to beach forests of the Andaman Isl., but now cult. widely throughout the tropics; Schimper points out that the frs. are adapted for dispersal by ocean currents, the thick husk containing air-cells enabling them to float for a long time. The tropical almond (so-called, but not related to the true almond) is extensively planted in S. Fla., the W. Indies, Cent. and S. Amer., as a street and ornamental tree. Its greatest disadvantage seems to be that it is deciduous during the cold season (shedding its lvs. in November) in Ceylon; according to Macmillan, it is not grown in Calif., but is probably too tender for most locations in that state. Prop. seems to be exclusively by seed.

T. Arjuna, Bedd., a large tree indigenous to Cent. and S. India, and parts of the country, has recently been intro. to the U. S. and is doing finely in S. Fla. The bark is sometimes used in dying and tanning, according to Watt. T. javanica, Thunb., not Sieb., is the best known. Its heads have only 4 fls. They are modified into spines. The original species, T. canescens, Oliver, is a tree with narrow lvs. indigenous to Malayas. Under the name of T. elongata, Blanco, a plant has recently been intro. to the U. S. from the Philippines which is probably T. javanica. It is doing well in S. Fla. and promises to be an unusually handsome ornamental. Barrows says of it "this magnificent large forest tree occurs very commonly, in the provinces of Bataan and Cavite (Philippines). In the rainy season abundant crops of cherry-like frs., about the size of plums, are produced. Each fr. contains 1-3 seeds. The pulp of the fr. or some other acid juice makes a beautifully colored jelly.'" The tree is known as "kalumpit" in the Philippines.

T. edulis, Bedd., a large tree indigenous to Malaya.-Under the name of T. amblycostatum, Lour., is the best known. Its heads have only 4 fls. They are modified into spines. The original species, T. laciniata, Bedd., a large tree indigenous to Cent. and S. India, and parts of the country, has recently been intro. to S. Fla., the W. Indies, Cent. and S. Amer., as a street and ornamental tree. The plant is of easy cult. in a cool greenhouse. No method of prop. by the bulb is known.

T. sinense, Oliver. Tall tree with smooth pale or somewhat greenish-brown lvs. very commonly in the provinces of Bataan and Cavite (Philippines). The tropical almond, although not closely related, but it is easily distinguished by the alternate lvs., solitary, not in clusters; petals 5; stamens numerous; ovary 2-3-celled (sometimes imperfectly so); fr. indehiscent. About 45 species, warmer Asia, Indian Archipelago and Trop. Amer.

T. japonica (from testudo a tortoise, alluding to the supposed resemblance to a tortoise of the above-ground roots). Dioscoridès. The Hottentot's Bread, Tortoise Plant, or Elephant's Foot. Perennial plants bearing a slender twining vine from a large hemispherical rhizome or caudex which is above ground and solid-fleshy or woody; sometimes grown in the greenhouse as curiosities or for illustration to students of botany, but not in common cultivation.

T. orientalis, from Greek words, lvs. alternate, short-stalked, entire, ovate-oblong or oblong, glabrous, feather-veined; fr. clustered; berries about the size of peas. Japan. S. Z. 1:81.

TESTUDINÄR (from testudo a tortoise, alluding to the supposed resemblance to a tortoise of the above-ground roots). Dioscoridès. The Hottentot's Bread, Tortoise Plant, or Elephant's Foot. Perennial plants bearing a slender twining vine from a large hemispherical rhizome or caudex which is above ground and solid-fleshy or woody; sometimes grown in the greenhouse as curiosities or for illustration to students of botany, but not in common cultivation.

T. orientalis, from Greek words, lvs. alternate, short-stalked, entire, ovate-oblong or oblong, glabrous, feather-veined; fr. clustered; berries about the size of peas. Japan. S. Z. 1:81.
TETRAGONIA

TETRAGONIA (Greek, four-angled, referring to the usually four-angled fruit). Aizoaceae. Here is included a garden vegetable of minor importance.

Herbs or subshrubs from the southern hemisphere and Japan; usually decumbent; lvs. alternate, short-petioled, somewhat fleshy; fls. yellow, green, or reddish, axillary, apetalous; calyx 3-5-lobed. — Only 1 species in cult., but 20 or more species are known in E. Asia and the southern hemisphere.

TETRAGONIA expansa, Thunb. New Zealand Spinach. New Zealand Ice-Plant. Fig. 3788. A hardy or half-hardy annual 4-8 in. high, often spreading 4-6 ft.; lvs. triangular, larger ones 4-5 in. long by 2-3 in. broad; fls. small, yellowish green. New Zeal. B.M. 2962.

New Zealand spinach is chiefly useful for furnishing greens during the summer when the common spinach cannot be grown. It tastes something like spinach but is somewhat tougher, as a rule. It is grown to some extent in California both for man and sheep. It readily self-sows. For an early outdoor crop, fresh seed should be sown in rich soil in a warm room in January or early February. The seed may germinate in a week or ten days but frequently requires a month to start. After growing about two weeks the seedlings should be transplanted to thumb-pots and about a month later to 4-inch pots. Growing vigorously in this condition they will be good-sized plants to move into the garden toward the end of April, where they should be set 3 to 4 feet apart each way, and the plants, when grown, will entirely cover the ground. They should be handled with great care in transplanting, otherwise growth will be so checked that it will require several weeks to recuperate. Again, plants should never be allowed to become pot-bound, as this will immediately bring them into flower and fruit and stunt their further growth, as well as greatly shorten their period of productiveness. Well-grown plants should be ready for use by June 1 and, if vigorous growth continues, nearly a peck of greens can be gathered from each plant once a week until heavy autumn frosts. In gathering, only 4 or 5 wecks of the tip ends of the larger plants should be taken. In the South, it is usually dwarf, not generally exceeding 6 to 8 inches. There is another and somewhat easier method of growing the crop, although a given area will be less productive. Inasmuch as the plant is a hardy annual, many seeds which ripen late in autumn will fall to the ground and germinate early in spring, though not early enough for the plants to be injured by spring frosts. These will be large enough for use toward the end of June. Annual crops are thus grown on the same ground several successive seasons with no care except removing old plants and keeping the ground free from weeds.

For the forcing-house crop, seed should be sown during July in seed-beds where the plants remain until the latter part of September, when they should be taken directly to the benches and will be ready for use early in November. It is best to set the plants about 18 inches apart in benches at least 6 inches deep. No further attention is necessary except to give plenty of water, and under good conditions a peck of greens will be produced once a week on 4 square feet from November to May inclusive. A crop may also be grown beneath the benches near the walks, as well as in the grapeviny borders. Space that cannot be used for other purposes may thus be utilized to very good advantage, although the plants will not produce so abundantly.

This crop may also be grown in houses with portable roofs by starting the plants in summer in houses with the roofs removed, the roofs being replaced on the approach of cold weather. The plants will continue producing the entire winter and following spring, when they should be uncovered and will reproduce themselves in the same way as the summer crop.

F. H. C. Ireland.

TETRAGONOLOBUS: Lotus. The following species now in cult. was not treated in Vol. IV, p. 1917. Lotus siliquosus, Linn. (Tetragonolobus siliquosus, Roth). Perennial, trailing, hirsute: rhizome slender, branched: roots spreading: lvs. oblong or oblanceolate; petioles with the stipules shortly adnate: peduncles 1-fld., much longer than the fls.; fls. pale yellow; calyx-segms. lanceolate; pod with straight wings much narrower than the body. Medit. region.

TETRAMICRA: Leptotes.

TETRANEMÁ (Greek, four and filament; the genus is characterized by having 4 stamens). Scrophulariaceae. Perennial herbs, grown in the greenhouse. St. very short or in cult. slightly elongated, ascending: lvs. nearly radical, opposite, obovate or oblong, slightly crenate-dentate, base angulate, glabrous; peduncles axillary, scape-like, longer than the lvs., bearing an umbel-like cyme at the top: fls. short-pedicelled, nodding, purple-violet, variegated paler; calyx 3-parted; corolla declinate, posterior lip shortly 2-lobed, anterior larger, 3-lipped; stamens 4: caps. rather compressed, loculicidally dehiscent.—Two species, Mex. and Guatemal. T. mexicanum, Benth., is the only species cult., known as the "Mexican foxglove" and formerly as Pentaster mexicanus. The pretty fls. are borne in profusion on the summits of slender purple scapes 6-8 in. high. Although essentially a summer bloomer, with good care it may be made to flower most of the year. It is usually regarded as a greenhouse subject, but it makes a good window-plant and is easy to grow. Plants continue to bloom year after year. Prop. by seeds. B.M. 4070. B.R. 29:52. H.U. 6, p. 71.

F. TRACY HUBBARD.

TETRAPANAX (four and parax, referring to the four-merous flower structure). Araliaceae. By Bentham & Hooker (Gnetum Plantarium) this genus is included in Fatsia, and is so treated in Vol. III, page 1204. By others, however, it is kept distinct, and the plant known as Fatsia japonica then becomes T. papyrifera, Koch, the only species. The reader may take his choice whether to name the plant in one genus or the other;
the preference probably lies with placing it in Tetrapanax. This genus, if accepted, differs from Fuchsia in its four-merous rather than mostly five-merous flowers, with the numerous ovary, the tomentose-lanate character, and other features. T. papyrifera is an excellent subtropical subject.

Patsia japonica, Deane & Planch., remains in that genus, as treated on page 1294.

TETRASTIGMA (Greek, four and stigma, in reference to the 4-lobed or 4-parted stigma). Viáceae. About 40 species in Trop. and Subtrop. Asia of shrubs climbing by tendrils: lfts. alternate, digitate or pedate; petals 3-5, sometimes reduced to 1; tendrils with adhesive disks or twining; fls. polygamo-dioecious, in axillary cymes or umbels, 4-merous; petals spreading; disk adnate to the base of the ovary; stigma sessile, 4-lobed or 4-parted: berry 2-seeded; seeds ovoid-globose, sulcate on the inner surface. Allied to Cissus and Parthenocissus but easily distinguished by the sessile 4-lobed stigma and from the latter by the 4-merous fls. Of the numerous species only the following are occasionally cult.: T. obtectum and T. serrulatum are probably the hardiest, but tender in the N., and are graceful small-lvd. vines which may be used where vines of more delicate character are desired; the first species clings to walls, the second has twining tendrils. T. Hármandii is a tall-growing vine with larger lvs. and edible berries, suitable only for tropical or subtropical countries. For cult. and prop., see Cissus and Parthenocissus. T. obtectum, Planch. (Cissus obtéca, Wall.). Climbing with disciferous tendrils: branchlets hirsute: lvs. long-stalked, persistent or subpersistent; petioles pubescent; lfts. 5, digitate, sessile, cuneate-obovate to elliptic, acute, remotely crenate-serrate with mucronate teeth, glabrous, or in var. pilosa, Gagnep., pubescent beneath, 4½ in. long: fls. in axillary short-stalked cymes: fls. purple; petals ovate, oblique, not reflexed; ovary glabrous or rarely pubescent with 2 superposed ovules: caps. obovate-elliptic. R.B. 28:121.

bb. Lvs. rarely somewhat verticillate.

TETRATHECA (Greek, four and cell; the anthers are sometimes four-celled). Tremandracem. Slender glabrous or stellate-pubescent, heat-like little shrubs, grown in the greenhouse and out-of-doors in the far 4S. About 20 species, all from Austral. In European greenhouses all the plants of this family are considered difficult of cult. They are treated like many other Australian heat-like plants, being potted in fibrous peat and silver sand and watered carefully at all times. It is said that only soft rain-water should be used.

A. Lvs. terete, leafy.

b. Lvs. mostly verticillate.

thymifolia, Smith. Lvs. almost all verticillate in 3's or 4's, ovate-elliptical or lanceolate: fls. purple; sepals ovate-lanceolate, acute or acuminate, seldom reflexed; ovary glabrous or rarely pubescent, with 2 superposed ovules. B.M. 8028.

TETRATHECA (Greek, four and cell; the anthers are sometimes four-celled). Tremandracem. Slender glabrous or stellate-pubescent, heat-like little shrubs, grown in the greenhouse and out-of-doors in the far 4S.

Leaves alternate, verticillate or scattered, heat-like, entire, flat and toothed or reduced to minute scales: fls. 4-5-merous; stamens apparently in a single series; disk inconspicuous: caps. opening only at the edges.

A. Lvs. entire or the lower somewhat dentate.

b. Lvs. entire or the lower somewhat dentate.

Key to the Species.

A. Floras' whorls condensed into a terminal subglobose head.

b. Lvs. entire....................... 1 montanum

bb. Lvs. crenate.

C. Blades oblong or oblong-linear................ 2 Polium

cc. Blades roundate.................. 3 pyreanum

AA. Floras' whorls not condensed into a terminal head.

b. Calyx erect.

c. Lvs. entire or the lower somewhat dentate.

C. Lvs. entire or the lower somewhat dentate.

dd. Petals shorter than the floral lvs.

bb. Calyx dentate.

INDEX.

acuminatum, 1

fruticans, 11

bicolor, 9

karrnianum, 8

pyreanum, 3

Scordonia, 6

The teucriums are little known in cultivation. They probably present no special difficulties to the gardener.
CXL. *Syringa* (lilac), Madame Lemoine.
Section I. Polium.

1. montanum, Linn. Low subshrub, prostrate, hoary or pubescent; stts., much branched at base, summit shortly ascending or rarely suberect and 2–4 in. high; lvs. oblong-linear, entire, base narrowed to a very short petiole, beneath or both surfaces hoary; floral whors few, condensed into a terminal head, which is hemispherical; fls. white becoming yellow; calyx tubular-campanulate; corolla small. S. Eu. and Orient. — A deciduous shrub. Var. flavescens, Benth. CT.

2. Polium, Linn. Low canescent-tomentose, lanate or rarely pilose-hispid shrubs, 2–6, rarely 12 in. high; basal branches procumbent, ascending or rarely suberect; lvs. cuneate-oblong or linear, sessile, crenate, margin revolute, upper surface very short-tomentose, densely lanate or pilose, color, especially above, yellowish hoary, golden or rarely green; floral lvs. similar; floral whors few, 2–6–fld., condensed in a globose or oblong head, which is solitary or often several corymbose globose-leaves; fls. white, yellow, or purple; calyx tubular-campanulate; corolla-acuminate. S. Eu. and Orient. — A deciduous shrub.

Section II. Chamaedrys.

4. Chamaedrys, Linn. Perennial or shrubby, 1–2 ft. high, base decumbent, branching, pubescent or villos: lvs. short-petioled, ovate or oblong, incised-crenate, base cuneate, both surfaces green and hirsute, especially near the margins and nerves; floral lvs. pilose, oblong-linear, entire, acute; floral whors few, condensed in a small terminal head; fls. yellow (or white); calyx campanulate; corolla-lobe, teeth acuminate-acute; corolla-tube included. S. Eu.

Section III. Scorodonia.

6. Scorodonia, Linn. Erect, hispid perennial, 1–2 ft. high, pubescent or subglabrous: lvs. ovate, 1–2 in. long, obtusely crenate, short-petioled, base rounded or cordate, both surfaces green; floral lvs. minute: raceme somewhat branched, rather paniculate above: fls. yellow; calyx rather villous, broad-campanulate; corolla-tube exserted, pubescent outside, the tube as long as the calyx. Eu. and adventitiously in E. N. Amer.

Section IV. Stachybotrys.

7. canadense, Linn. Erect, perennial herb, 1–3 ft. high, soft-pubescent or canescent; lvs. ovate-lanceolate to oblong-ovate, 2–3 in. long, serrate, base rounded, somewhat canescent beneath, short-petioled; floral lvs. sessile or on short branches, few, condensate and hispid; lvs. base truncate, rounded or cuneate, much branched, villous, sterile branches whip-like; calyx simple: fls. purple to cream-color; calyx short-pedicelled, campanulate, hoary and somewhat villous; corolla-tube elongated. Low ground, Maine to Brit. Col., southward to Pa., Ohio, Mo., New Mex., and Calif. — Useful for low grounds and moist borders.

8. hircanicum, Linn.; also spelled hyrcanicum. Erect perennial herb 1–2 ft. high, slightly branched, pubescent: lvs. ovate-cordate, 1–3 in. long, obtuse, coarsely crenate, base deeply cordate, scarcely pubescent above, softly somewhat canescent beneath; floral lvs. as subulate bracts; spike simple, 3–8 in. long, dense; fls. purple or red; calyx 2–lipped, corolla vines outside. Cau­casus and Persia.

Section V. Teucris.

9. bicolor, Smith. Dwarf, herbaceous, glabrous: lvs. ovate, olanceolate or suberect, about 1 in. in long, obtuse, entire or incised, both surfaces green; floral lvs. usually exceeding the fls.: peduncles axillary, 1–fl., short, upper subraccmose: fls. blue and white; calyx broadly campanulate, green, teeth broad-lanceolate, acute; corolla-tube included. Peru and Chile.—Offered in Calif. at one time, but apparently not successful.

10. orientale, Linn. Erect perennial herb, about 1 ft. high, branched at base, green and glabrous or pubescent, canescent: lvs. 1–2-pinnatisect, lower 1½–2 in. long, segments, linear, entire or incised, both surfaces pale or green; upper lvs. smaller; floral lvs. minute: peduncles lacy racemose, irregularly 1–3–fl.; pedicles much longer than floral lvs.: fls. violet or blue; calyx campanulate, teeth lanceolate; corolla 3 times longer than calyx. Caucasus and Asia Minor.

11. fruticans, Linn. Shrub 2–3 ft. high, divaricate branching: lvs. ovate, entire, obtuse, glabrous above, white or reddish brown, tomentose beneath, petiolated; floral lvs. similar, smaller: racemes terminal or lateral on short branches, few-fl.; pedicules 1–fl., shorter than the calyx: fls. blue; calyx campanulate, tomentose; corolla-lip twice longer than the calyx. Eu. —Recommended for dry places S. It has a long blooming season.

Section VI. Teucrophis.

T. fruticans, Hort., is offered in the trade as a shrub for the rockery, with downy foliage and heads of pale blue fls.; not known botanically; possibly it is an error for T. frutescens, Benth. (Teysmann).}

minute; calyx cup-shaped, 3-toothed; petals thick; stamens 6; ovary of 3 carpels, rarely 1 or 2, free or saccate, with or without fr. globose or depressed-globose, 1-seeded, 1-seeded. One species, Sumatra. T. diltitifrons, Reichb. f. & Zoll. Lvs. 6-7 x 1½ ft., folded; petioles carinate dorsally, obtusely conoid in front, the angles rounded and uminate-prickly: spathes sheathing the tomentose peduncle: fr. as large as an apple. Sumatra.

**Thalictrum** (named after Johann Thabius, a German naturalist; died 1588). *Ranunculaceae*. Perennial marsh or aquatic herbs, some of them hardy, others suitable for the warm- or greenhouse.

Leaves few, large, long-petioled, often canna-like: panicles terminal; fls. in pairs along the branches forming lax spikes, the pairs in a 2-valved spathe; sepals 3, free, equal, membranaceous; petals 3, free or very shortly connate; lobes of the androecium petaloid, very irregular; lip broad, crested within; anthers 1-celled; ovary I-celled, l-ovuled, stigma 2-lipped: caps. oblong-ovoid or globose.—Schumann (Das Pflanzenreich, hft. 11) accepts 7 species in Trop. and warm Temp. America.

_A. Plant covered with a white powder._

**T. aquilegifolium**, Linn., may be a synonym of this, and _T._ _cornutum_, Fras. Stem less; petals longer than in _T._ _dealbata_: lvs. banana-like, 1-3 ft. long, oblong-ovate: scape 5-10 ft. high: panicles 2-4 ft. wide: spikes zigzag, pendulous. Sept., Oct. Ponds, Fla.—This native ornamental-lvd. marsh-plant thrives in garden soil with canna-like and like plants. Does well under cultivation in S. Calif.

obtuse: achenes many, long-stalked, reticulate, with an incurved style. Himalayas, 8,000-12,000 ft. G.C. III. 28:167.—A handsome plant.

4. Delavayi, Franch. Slender. 2-3 ft. high, glabrous; lower lvs. on long, slender petioles, 2-3 times 3-5-parted; lfts. long-stalked, 3-5-lobed, base cuneate, rounded or cordate; fls. pendulous, dichotous; sepals purple or lilac, 3-lobed, long equaling the slender stamens; anthers linear: carpels 10-12; fr. winged at the 3 angles, stipitate. Summer. Mountains of E. China. B.M. 7152. G.C. III. 8:125; 35:450. G. 35:793.

aa. Fr. striate edged or ribbed rather than winged, sessile or essentially so in most species.  

b. Fls. probably perfect.  
c. Filaments widened near the anthers, the latter ovate and obtuse.

d. Achenes sessile on a head, ovate-oblong.

nn. Achenes somewhat stalked, widely spreading, straight on the dorsal margin.

6. sparsiflorum, Turcz. St. erect, sulcate, 2-4 ft. high, branching, usually glabrous: lvs. trinerved, upper ones sessile; lfts. short-stalked, round or ovate, variable in size and shape of base, round-oblong or toothed: fls. in leafy panicles on slender pedicles, perfect; sepals oblong, white, soon reflexed; filaments somewhat widened; anthers very short: achenes short-stalked, obliquely obovate, flattened, dorsal margin straight, 8-10-nerved; styles persistent. N. Asia, through Alaska to Hudson Bay, in mountains to Colo. and Calif.

c. Filaments filiform or at least very slender; anthers linear, acute or mucronate.

d. Stigma hastate or spurred.

7. minus, Linn. (T. purpureum, Schang. T. ozothile, Vill.). Sts. smooth, naked or 1-lvd., only 4-8 in. high, from a sealy rootstock: lvs. tufted at the base, twice 3-5-parted; lfts. coriaceous, orbicular or cuneate at the base, lobed, revolute: fls. in a raceme, perfect; sepals greenish, equaling the yellow stamens; stigma linear: achenes small, obliquely obovoid. Northern and Arctic, and alpine regions of both Old and New Worlds. B.M. 2207.

dd. Stigma not hastate or spurred.

8. minus, Linn. (T. purpureum, Schang. T. ozothile, Vill.). Sts. round, sulcate, 1-2 ft. high; lvs. variable, acute or obtusely lobed, often glaucous; fls. drooping, in loose panicles, perfect; sepals yellow or greenish; fr. ovate-oblong, sessile, striated. Summer. Eu., Asia, N. Afr.—A polymorphic species in the variation of the lfts.

Var. adiantifolium, Hort. (T. adiantifolium, Hort. T. adiantifolium, Bess.). Lfts. resembling those of adiantum fern.—A form much used and admired.

9. Púrdomi, J. J. Clark. Much like T. minus, but fls. larger, sepals acute or acuminate, the pedicels longer and somewhat capillary: glabrous, the branches reddish green: lvs. 2- or 3-pinnate, about 8 in. long, the pinnae 2-3 pairs; lfts. ovate, 3-lobed, membranaceous; fls. small, greenish, pendulous, in lax panicles; sepals 4, ovate-lanceolate, 3-nerved, acute or acuminate; stamens about 14: carpels 5, sessile, 8-ribbed. N. China; very recently described; cult. abroad.

10. flavum, Linn. Stout, 2-4 ft., with furrowed stem; leaves and creeping stoloniferous rootstock; lvs. large, 2-3-compound; lfts. to 1½ in. long, 3-lobed, ovate or obovate: infl. compact and compact, the fls. erect and pale yellow (the anthers bright yellow); sepals small: achenes 6-10, small, 8-ribbed. Eu.

11. glaucum, Desf. (T. spectabile, Hort.). Sts. erect, round, glaucous, 2-5 ft. high: lfs. ovate-orbicular, 3-lobed; lobes deeply toothed: fls. in an erect panicle, perfect; sepals and stamens yellow: frs. 4-6, ovate, striated, sessile. June, July. S. Eu.

nn. Fls. ducious or polygam-o-dioscious.

c. Achenes somewhat inflated, obovoid, and short-stalked.

12. polygamum, Wats. Aromatic, to 3 ft. high, glabrous throughout: lfts. long-stalked, ovate or roundish, serrate, cut or divided, veined beneath: fls. dioecious, in rather close panicles; sepals elliptic or ovate; stamens 15-25, with yellowish anthers: achenes larger, in a dense globose head, short-stalked, obovoid, turbid, tapering into reflexed styles. Sandy streams, coast ranges of Calif. to Columbia River.

cc. Achenes flattened and 2-edged, nearly or quite sessile.

13. occidentale, Gray. St. to 3½ ft. high, bearing 2 or 3 lvs. which are 2-4-ternate and glandular-pubescent: lfs. thin and glaucous, with rounded lobes: achenes long, slender, thin-walled, 2-edged, ribbed, not furrowed. Colo., northward and westward.

14. Fendleri, Engelm. Fig. 3790. Plant 1-3½ ft. high, rather stout and leafy: lvs. 4-5 times pinnatid, on st. lvs. sessile; lfts. rather firm, ovate to orbicular, usually with many shallow rounded or acuminate lobes; bases variable: fls. dioecious, in rather compact panicles; stamens many; anthers long: achenes nearly sessile, obliquely ovate, flattened and 4-edged gibbous, 3-5 ribs on each face. July, Aug. S. Colo., westward and southward.

ccc. Achenes ovoid, sessile or nearly so, striate or ribbed.

dd. Filaments club-shaped or dilated to nearly or quite the width of the anthers.

15. polygamum, Mühl. (T. Cornuti, Auth., not Linn.). Tall Meadow Rue. Erect, 3-8 ft. (or more) high, branching and leafy, smooth or pubescent, not glandular; lvs. 3-4 times ternate or terminally pinnate; lfts. oblong to orbicular, bases variable, 3-5 apical lobes: fls. in a long, leafy panicle, polygamo-dioscious; sepals white; filaments broadened when young; anthers short: achenes ovoid, stipitate, 6-8-nerved, flat, 2-edged, reticulate, with stigmas as long, which become curled. July, Aug. Low or wet grounds, Newfoundland and Canada to Fla., westward to Ohio.

dd. Filaments very slender, usually filiform.

16. dasycarpum, Fisch. & Lall. (T. purpurácens, Auth., not Linn.). Stout and erect with purplish st., 3-7 ft. tall, leafy and branching: lvs. 3-4-ternate; lfts. short-stolon and mostly 3-toothed, pubescent beneath but not waxy or glaucous; fls. mostly dioecious but perhaps in some cases polygamous, with purplish
sepalis and filaments: achenes ovoid, with 6–8 prominent ribs. N. J. to N. D. and S. Dak. and far southwest. — An attractive plant.

14. **Venusia**, Trib. **(T. confine, Fern.)** St. simple, erect, 10–20 in. high, glabrous, glaucous, bearing 2–3 long-petioled lvs. above the base: lvs. 3–4 times 3-parted; lfts. short-stalked, rather firm, rounded and lobed at the apex, veiny beneath: fls. in a simple panicle, dolicious, small; sepalis ovate; stamens 10–20, on slender filaments; anthers oblong, slender-pointed: achenes nearly sessile, 2 lines long, ovoid tapering to a straight base, thick-walled and 2-edged. S. W. S. and Southward in the mountains.

18. **Dioica**, Linn. Rather slender, 1–2 ft. high, glabrous: lvs. 3–4 times 3-parted; lfts. thin, orbicular, several-lobed or revolute, bases variable: fls. in a loose, leafy panicle with slender pedicels, dolicious; stamens much longer than the greenish sepalis; anthers linear, obtuse, exceeding their filaments in length: achenes ovoid, nearly or quite sessile, longer than their styles, with about 10 longitudinal grooves. Early spring.

**MEADOW** *THAMNOPTERIS* (Greek, *busby fern*). **Poly-podiaceae.** A generic name for a small group of simple-leaved ferns which cannot properly be separated from Asplenium, to which they are here referred (page 414). One species (and a probable variety) is all that is known in this country and require about the same treatment as camellia, which see for culture and propagation.

**sinensis**, Linn. *(Camellia Thaë, Link. Camellia the-féra, Griff.)*. **THEA.** Fig. 3791. Shrub, sometimes tree, to 30 ft.: lvs. elliptic-lanceolate or obovate-lanceolate, acuminate, serrate, glabrous, sometimes pubescent beneath, 2–3 in. long: fls. white, fragrant, 1–1 3/4 in. broad; petals usually 5. China, India.—Several varieties have been distinguished, of which the following are the most important: Var. *Bohea, Pierre (T. Bohea, Linn.)*. Lvs. elliptic-oblong, obtuse, flat, dark green, 2 1/2 in. long: fls. usually solitary; sepalis pubescent inside or glabrous, ciliate, petals 5–6; styles conuate below: branches erect. B.M. 998. L.B.C. 3: 226. Var. *viridiss, Pierre (T. viridis, Linn.)*. Lvs. oblong-lanceolate, acute, often concave, light green, 5 in. long: fls. 1–4; sepalis pubescent, ciliate; petals 5–9; styles free: branches spreading. B.M. 3148. L.B.C. 3: 227; 19: 1828. Var. *cantonensis, Pierre (T. cantonensis, Lour.)*. Lvs. oblong-lanceolate; fls. usually terminal, solitary; sepalis pubescent inside; petals 7–9; styles free only near the apex. Var. *assamica, Pierre (T. assamica, Mast.)*. Lvs. oblong-lanceolate, acuminate: fls. 1–4; sepalis glabrous inside; petals 7–9; styles free only at the apex.—The black tea, however, and green tea of commerce are not derived from certain varieties, but are the result of different treatment of the lvs. after gathering. For the cult. of tea in N. Amer., see Vol. II. Cyclo. of Amer. Agric.

**THEA** (the Latinized Chinese name of the tea plant). **Thapsiaceae.** **Thea.** Woody plants; one species grown for its leaves which yield the tea, the others grown for their attractive flowers and foliage.

Evergreen shrubs or small trees: lvs. alternate, short-petioled, serrate: fls. axillary or sometimes terminal, usually solitary, stalked, nodding; sepalis 5–7, persistent; petals 5–7, rarely 9, stamens numerous, more or less connate below; ovary 3–5-celled; styles 3–5, filiform, connate below: fl. a dehiscent capsule with 1 large globose or ovoid seed in each cell.—About 14 species in Trop. and Subtrop. Asia. Camellia, differing in its sessile upright lvs. with many deciduous sepalis, in often united with Thea, but from a horticultural point of view it seems desirable to keep the two separate.

The most important member of the genus is *T. sinensis*, cultivated in nearly all subtropical countries, and in the mountainous regions of the tropics for its leaves which yield the well-known tea and are an article of great commercial importance. The other members of the genus are ornamental shrubs occasionally grown for their handsome white or pink flowers and the attractive evergreen foliage. They are but little
THEOBROMA (Greek, food of the gods). Sterculiaceae. Here belong the trees that produce the seed from which chocolate and cocoa are derived. About a score of small trees in Trop. Amer., with large simple thick and strongly nervèd entire Ivs., and small fls. which in at least some species are borne laterally on the branches rather than in axils: calyx deeply 5-parted or -lobed; petals 5, mostly clawed or narrowed below; fertile stamens 5, opposite the sepals; ovary sessile and 5-celled, many-ovuled, the style filiform: fr. a large woody drupe or pod, with seeds imbedded in the pulp. The species of prime economic importance is T. Cacao, but other species are probably concerned in the production of cocoa, and the natural history of the group is yet confused. The word "cacao" (pronounced "ka-kow") is the name of the plant and the unmanufactured product of it; "cocoa" is the manufactured product, produced from the bean-like seeds, chocolate being the chief commercial commodity. (Coco is a
The common cacao is *Theobroma cacao*, Linn., native apparently in Cent. and S. Amer. It is a wide-branching evergreen tree, reaching 20-25 ft. in height (or somewhat more in the wild), with pubescent twigs and alternate oblong-ovate or elliptic-oblong, entire short-petioled lvs., the blade 6 in. long more or less, rounded at base and abruptly acuminate at apex, with strong midrib and paired or somewhat alternate arching side veins: fls. small, in fascicled directly on the bark of the trunk and main branches, about ¼ in. across when expanded, on slender pedicels ½ in. or more long; calyx rose-colored, with acuminate segments; corolla yellowish, the long petals with a stalk-like claw and expanded blade: fr. or "pod" 1 ft. or less long and mostly 4 in. or less in diam., about 10-ribbed, red, yellow, purplish, or brown, elliptic-ovoid in form, the rind thick, hard, and leathery: cells 5, each with 5-12 "beans" in a row imbedded in a white or pinkish acid pulp; the pods will average about 20-40 good beans; these flat brown or purple beans or seeds, each an inch or more across; constitute the commercial cacao, from which the products are manufactured. For an account of the cult. of cacao, see Cyclo. Amer. Agric., Vol. II, pp. 224-6. There is a large literature on the subject.

The estates devoted to the culture of the plant are usually known as "cacao plantations" and are largely on the increase in all suitable climates, owing to the increased demand for the manufactured article in the different forms in which it is now prepared for consumption. The larger proportion of commercial cacao is produced by *Theobroma Cacao* (Fig. 3793). Other species native to Central America and the West Indies are *T. pentagona*, *T. speciosa*, *T. angustifolia*, and the closely related *Triobroma bicolor*.

In vigor of growth and productive capacity, *Theobroma pentagona* resembles to a very large degree the generally cultivated varieties of *T. Cacao*, but it differs in the flowers, in the size of the beans, and especially in the shape of the pods. The beans are larger in size than those of *T. Cacao*, fully equal if not superior in flavor, and are capable of being worked up in the same way as the commoner species. This kind is known on the mainland as "Alligator" cacao, from the fancied resemblance of its skin to that of an alligator. The outside of the pod is soft and easily broken, and does not afford such good protection to the interior as the harder shell possessed by *T. Cacao*. In Nicaragua, *T. Cacao* and *T. pentagona* are grown together, and the produce is mostly a mixture of the two species. From the presence of *T. pentagona*, it is possible that hybridization has taken place between two species. It has been noted that the pods of *T. Cacao* produce much larger seeds or beans in Nicaragua than in countries where this species is not growing in company with *T. pentagona*: and the beans of the two species are almost impossible to distinguish when cured together. The product of Nicaraguan plantations also requires much less time for fermentation than the produce of Grenada, Trinidad, or Venezuela, some forty-eight hours being the usual period, while more than four times that number of hours will be required for the proper fermentation of the produce of the last-mentioned countries.

The "Monkey cacao" of the mainland is produced by *Theobroma speciosa*. This is never made into market cacao, as it is very inferior in quality and has a disagreeable flavor. The pods are hard, much corrugated, warty, and of a dirty brown color when ripe.

Many names have arisen for the varieties of *Theobroma Cacao* which are in cultivation, as many as forty having been listed by a Trinidad cultivator of large experience. Looking at the matter from a practical point of view, all these are merely strains of the one species, produced by natural cross-fertilization of the older types. According to Batt, Trinidad, 1900, there are but three major strains or classes of *T. Cacao*, respectively, "Criollo," "Forastero," and "Calabacillo." The type of the first is found indigenous in Trinidad and various places on the mainland, its distinctive character being its bottle-necked pod, with a thin skin and finely ribbed exterior, together with its white or whitish seeds or beans, which are mild in flavor and somewhat rounded in form.

The characters of "Forastero" are its roughly corrugated or verrucose pod, containing large flattish seeds of a purplish color. It is a tree having greater vitality than "Criollo," and gives a much larger crop. "Forastero" means foreign, and this type is said to have been found on the mainland of South America, whence it was imported to Trinidad by Arragonese Capuchin Fathers about 1757. (De Vertical, "History of Trinidad," 1884.)

"Calabacillo" is the third form, its chief characteristics being the vigor of its growth and its small flat and strongly flavored bean. By some it is considered as a degraded form of Forastero. While the above gives a brief sketch of the chief characters of the principal types, it must be understood that there are varieties intermediate between the forms; in fact, on the larger number of estates it is impossible to find any two trees exactly alike in all their botanical characters, occurring, without doubt, from the unappreciated cross-fertilization which has taken place. Still, each country appears to maintain certain characters more permanent than others, and thus secures for itself a name upon the markets of the world. It is probable that this is due, in a measure, to the unconscious preference taken by some to distinctive features of the produce by the continuous cultivation of a fairly
fixed strain which has arisen. It may also be due in some measure to the influence of climate and environment. Certain it is, however, that there are today strains of cacao which are possessed of distinctive characters, not readily produced by any process of preparation in places other than that in which they are grown. A fine set of illustrations of varieties common to different countries has been published in a work by Huiz, who traveled in the cacao-producing countries on behalf of the German government.

These different brands are bought by manufacturers and blended to suit their particular market, but there are certain kinds possessing special flavor which are readily sold at high prices. The value of the commercial product fluctuates and the price has marked variations due to many causes. Whether this results from increased production or from a deterioration in the quality cannot be ascertained. It is clear that if cultivators grow cacao for seed without regard to the best rules of selection, the quality must deteriorate. What mitigates this fact is that all the cacao world has, up to a recent date, followed the same practice. The process of grafting, to which the cacao tree readily submits, as has been proved in Trinidad, will enable operators to make large fields of the choicer varieties, and it may confidently be expected that in a few years a great improvement will be shown in the various grades placed upon the market. (For further reading, see Wester, Philippine Agric. Rev., 1914, p. 27.) But little cacao is manufactured in the countries where it is grown.

The word "cocoa" is a market corruption of the original Spanish "Cacao," which was adopted by Linnaeus in 1753 and placed by the Linnaean Theobroma. This species is very widely distinct from any of the varieties of T. Cacao and T. pentagona, and assumes the mature or oblong form only on reaching the third or fourth year of growth. The pods are oval, ribbed and netted, hard and woody, with an outer shell 1/4 inch in thickness which can be cut only with a saw. The seeds are oval, much flattened, with a dark, hard, and smooth exterior. The interior is white, and has a somewhat nutty flavor. They are used in sweetmeats in the same way as almonds, but cannot be made into commercial cacao, suitable for the manufacture of chocolates. This species is very widely distinct from any of the varieties of T. Cacao which produce commercial cacao. The produce of T. pentagona which is possessed of distinctive parts of Central America by the names of "Wariba," "Tiger," and "Patashte" cacao. See also Cont. Nat. Herb., vol. 17, pt. 8, for branching and flowering habits of cacao and patashte.

THEOBROMA (probably a personal name). Orchidaceae. One Brazilian orchid, T. gomezoides, Rodr., of botanical interest but very little known in cult. By some it is referred to Gomezia. Rolfe describes it as having "the general habit of some small slender oncidium, about 5-6 in. high, but the fls. are borne in slender arching racemes of about 6-12 each. The sepals and petals are subomnivent, lanceolate, acute, 4-5 lines long, and light green in color, with a broad dark brown line toward the base. The lip is oblong-ovate, acute, somewhat reflexed at the apex, and white, with an orange-buff blotch in the center. It appears to be a free-growing little plant, and its appearance in cult. is interesting.

THEOPHRÁSTÁ (named for Theophrastus, a Greek naturalist and philosopher, 370-285 B.C.). Myrsináceas; by Mex separated in the family Theophrástaceae. Glabrous shrubs, ephedroid.-P. Schott, 1915. (For further reading, see Wester, Philippine Agric. Rev., 1914, p. 27.) But little cacao is manufactured in the countries where it is grown.

Chocolate is the term used for sweetened andhardened preparations of the roasted and ground cacao bean, with the larger proportion of the original fat retained, while the so-called "cocoa" preparations are the same material in fine powder, sweetened or unsweetened, but with a smaller proportion of the cacao fat extracted. This fat, when clarified, is a pure white substance, almost as hard as beeswax, and is used in many pharmaceutical preparations. Chocolate and cocoa are both made from the beans or seeds of Theobroma Cacao and T. pentagona, and differ only in the method of preparation.

The word "cocoa" is a market corruption of the original Spanish "Cacao," which was adopted by Linnaeus in 1753 and placed by the Linnaean Theobroma. The plant known as Theobroma biocolor has recently been made the type of a new genus (Triobroma bicolor, Cook) on account of distinctly different habits of fruiting and flowering and structural differences in the flowers (q.v., F. Cook, Journ. Wash. Acad. 5:287-289, 1915). The leaves are large, and in the juvenile stages of growth are broadly cordate in form, and assume the mature or oblong form only on reaching the third or fourth year of growth. The pods are oval, ribbed and netted, hard and woody, with an outer shell 1/4 inch in thickness which can be cut only with a saw. The seeds are oval, much flattened, with a dark, hard, and smooth exterior. The interior is white, and has a somewhat nutty flavor. They are used in sweetmeats in the same way as almonds, but cannot be made into commercial cacao, suitable for the manufacture of chocolates. This species is very widely distinct from any of the varieties of T. Cacao which produce commercial cacao. The produce of T. pentagona which is possessed of distinctive parts of Central America by the names of "Wariba," "Tiger," and "Patashte" cacao. See also Cont. Nat. Herb., vol. 17, pt. 8, for branching and flowering habits of cacao and patashte.

laceolata, R. Br. (Podalia lupinoides, Willd.). Sts. 6-12 in. high; Ivs. nearly evergreen, the lower and uppermost ones often simple; Ifts. oblong-lanceolate, silky-puberulent on both surfaces; stipules lanceolate, half as long as Ifts.: fls. geminate or somewhat verticillate, bright yellow. Siberia and Alaska. B.M. 1389.

AA. Pod straight or only slightly curved at the apex.

BB. Plant 3-5 ft. high.

c. Stipules longer than the petiole.

d. Racemes terminal.

mollis, Curtis. St. erect, branched, 2-3 ft. high, pubescent: Ifts. obovate-oblong, 1-2 in. long; fls. in long spikes; pod straight, erect, pubescent. May, June. Western states. B.M. 2811. B.B. 1272 (both erroneously as T. falacca).—Sometimes called "buffalo pen" in the West.

c. Stipules shorter than the petiole.

d. Racemes axillary.

fabacea, DC. Resembles T. montana and has possibly been confused with it in the trade. It differs in having more spreading pods and larger and more compressed seeds. May, June. Siberia.

AA. Racemes terminal.

BB. Plant 1-3 ft. high.

c. Stipules large, clasping: racemes 6-12 ft. high, with Ivs. 3-4 in. long and oval-oblong, pubescent: leaves narrowed at the base, somewhat silky-puberulent. June, July. Mountains of N. C.

BBB. Plant 1-3 ft. high.

c. Stipules shorter than the petiole.

d. Racemes axillary.

THBHÁDÚUSIA (named for Thiebaud de Berneaud, a French botanist). Ericeæ. Shrubs with the stem, sometimes tall-climbing: Ivs. alternate, persistent and leathery; fls. in numerous many-flowered axillary racemes, scarlet; calyx 5-lobed or 5-toothed; corolla tubular, 5-lobed; stamens 3-4 in. long; pod falcate, linear, pubescent, 2-4 in. long. Mountains of N. C. and Ga. F. W. Barclay. F. Tracy Hubbard.†

THESPÉSIA (Greek, divine; application doubtful). Malaceæ. Trees or tall hedges, grown in the warm-house, and planted in warm regions.

nereftóla, Juss. Known locally in Fla. as "trumpet-flower" and incorrectly as "yellow oleander." A tender shrub: fls. linear, shining, margins revolute; fls. in large clusters; pod 2-4 in. long, yellow, fragrant. W. Indies, Mex. B.M. 2900 (as Cerbera Thevetia).—Cult. in S. Fla. and S. Calif.

F. Tracy Hubbard.†

THLADIANTHA (Greek, Thalassa, sea; 

flora).—T. pulcherrima, Wall., which equals Agapetes variegata.—T. subrufa, Wall.—Agapetes setigera. F. Tracy Hubbard.

THLLÁDÁNÝTHA (Greek, to crush and flower; the author of the genus is said to have named it from pressed specimens). Cucurbitacæ. Herbaceous softly pubescent vines with tuberous roots, some of which are hardy, others adapted to the greenhouse. May be either annuals or perennials.

Leaves ovate-cordate, denticulate, sinuous deep; tendrils simple: fls. dioscorious, rather large, golden yellow; male fls. solitary or racemose, calyx-tube short-campanulate, 5-lobed, corolla rather irregularly campanulate, 5-parted, stamens 5. ovary rudimentary; female fls. solitary, calyx and corolla in the same, stamens rudimentary or none; ovary obovate, pubescent, with 3 placenta: fr. obovate, chesty, indehiscent, many-seeded.

**THLADIA** (Greek, crushed, referring to the strongly flattened pods and seeds). *Cruciferae*. Annual or perennial herbs which are glabrous or glaucous, rarely pilose, some of which are cultivated now and then.

Leaves basally, rosulate, entire or dentate; cauline obovate to oblong, hastate-auriculate; fls. white, rose, or pale purple; sepals with a white margin. Mound species, including Amer.

alpestre, Linn. Perennial, 2-12 in. high but usually glabrous, somewhat glaucous, habit tufted, forming rather thick mats: basal lvs. in a rosette, petioled, obovate; cauline lvs. elongated-lanceolate, base cordate, entire or dentate: peduncle unbranched, terete: fls. white, sometimes somewhat reddish; sepals purplish. Alpine Eu.—Has been offered as a neat little rock plant. It should be given shade and a cool moist soil. The material growing in Colo. and formerly called *T. bellidifolium* is now considered a distinct species, *T. coloratum*, Sargent.

TRHYLLIS (old Greek name, transferred to these plants). Malpighiaceae. Confusion in practice has arisen in the application of this name and Gal­phimia. As expressed by J. N. Rose, "the genus Thryallis was published by Linnaeus in the second edition of his Species Plantarum, basing it upon a single species, T. brasiliensis. In 1829 Martius described two additional species, T. longifolia and T. totofolia. These two species, however, were soon found not to be congeneric with the original species, but instead of being taken out as a new generic type, were allowed to remain as Thryallis, while the true type of that genus was transferred to Galphimia." Kuntze gave the name Thryallis to the Hernaelea to the plants of Martius, and this was restored to its original application, with its legit­mate extension, then the plants described under Gal­phimia, page 1312, become T. brasiliensis, Linn. (G. brasiliensis, Juss.); T. hirsuta, Kuntze (G. hirsuta, Cav.); T. grauea, Kuntze (G. grauea, Cav.). It appears to us that the true type of the genus was never transferred to Thryallis, but to Galphimia, and the generic name Thryallis was published by Linn. in 1753. Since then it has been used by such authors as Sturt and others as a popular name for these plants. Had Kuntze given the name Thryallis, the above plants would have been included in this genus.

TRHYTÔMENE (Greek word said to refer to the low heat-like appearance of the plant). Myrtacea. Glabrous heat-like shrubs, which were at one time popular greenhouse plants, now apparently not so com­monly in cult. Lvs. opposite, small; entire: fls. small, sessile or pedicelled, solitary at the base, becoming racemes at the top. Seeds one, usually con­spicuous above the base, with a resinous tree or shrub). Also spelled

larly reticulate, tomentose: young lvs. white woolly­tomentose; blade equaling the petiole, silvery gray beneath, making one of the

margin, 6–8 ft. high: sheaths ragged, fibrous, irres­

hair-like extension, then the plants described under Gal­phimia, page 1312, become T. brasiliensis, Linn. (G. brasiliensis, Juss.); T. hirsuta, Kuntze (G. hirsuta, Cav.); T. grauea, Kuntze (G. grauea, Cav.). It appears to us that the true type of the genus was never transferred to Thryallis, but to Galphimia, and the generic name Thryallis was published by Linn. in 1753. Since then it has been used by such authors as Sturt and others as a popular name for these plants. Had Kuntze given the name Thryallis, the above plants would have been included in this genus.

THUJA

THYIA

THYIUM

THUIA

THUJITA
grained, durable in the soil; it is much used for construction, cabinet-making, and in cooperage. *T. occidentalis* contains a volatile oil, and thuja and is sometimes used medicinally.

1 inch in length. The well-known *T. occidentalis* is hardy North; and also *T. Standishii*, *T. plicata*, and several forms of *T. orientalis* are hardy as far north as Massachusetts. Thujas are favorites for formal gardens. They are all of regular symmetrical habit. Their numerous garden forms vary greatly in habit and in color of foliage. For planting as single specimens in parks they are mostly too stiff and formal, but they are well suited for massing on borders of streams or lakes. The most beautiful and the most rapidly growing species is *T. plicata*. Thuja are well adapted for hedges and windbreaks (see Gn.M. 2:15). They bear pruning well and soon form a dense hedge. They thrive best in somewhat moist, loamy soil and are easily transplanted. Propagation is by seeds sown in spring. The varieties, especially those of *T. occidentalis*, are usually propagated by cuttings taken late in summer and kept during the winter in a cool greenhouse or frame; also by grafting on seedling stock in summer or early in spring in the greenhouse. The varieties of *T. plicata* and *T. orientalis* are usually grafted, since they do not grow readily from cuttings, except the juvenile forms of the latter, as *var. decussata* and *var. maldenii*. Consult *Retinispora*.

A. Cones pendulous, with thin scales apiculate below the apex; seeds winged, compressed; branchlets ramified more or less horizontally, with a distinct upper and under side.

B. Lvs. yellowish or bluish green beneath, glandular; leading shoots compressed.

*occidentalis*, Linn. COMMON ARBOR-VITAE. Erroneously but commonly called *White Cedar* (which is properly *Chamaecyparis*). Figs. 3795-3797. Tree, attaining 60 ft. and more, with short horizontal branches ascending at the end and forming a narrow pyramidal rather compact head; lvs. ovate, acute, usually glandular, bright green above, yellowish green beneath, changing in winter usually to dull brownish green; cones ovate to oval-oblong, about $\frac{1}{3}$ in. long, brownish yellow with

3795. Typical form of Thuja occidentalis. (X 3/5)
THUJA

Ständishii, Carr. (T. japonica, Maxim. T. gigantea var. japonica, Franch. & Sav. Thujaépsis Ständishii, Gord.). Fig. 3801. Similar to the preceding but lower, usually only 20-30 ft. high: branchlets more irregularly set, thicker and less compressed: lvs. of vigorous shoots closely placed together, ending in short rigid points spreading outward, of the lateral branchlets ovate, obtuse, thickish, lighter green above, darker beneath and with whitish, triangular spots, without gland: cones oval, little over ½ in. long; scales 8, oval, usually the 2 middle pairs fertile. Japan. G.C. III. 21:238 (adapted in Fig. 3801). R.H. 1896:160. C.I.A. 11:311. S.I.P. 1:11.

AA. Comes upright, the thickened scales with a prominent horn-like process below the apex; seeds wingless; branchlets ramified in a vertical plane with both sides nearly alike. (Biota. orientalis, Linn. (Biotá orientális, Endl.). Pyramidal or bushy tree, attaining 25 ft., with spreading and ascending branches: branchlets thin: lvs. rhombic-ovate, acute, bright green, with a small gland on the back: cones globose-ovate, 3⁄4-1 in. long; usually 6 ovate scales, each with a horn-like process, the uppermost pair sterile. From Persia to E. Asia, in Japan probably only cult. There are many garden forms, of which the following are the best known: Var. athrotaxoideae, Carr. Dwarf, irregularly and not frond-like branching; branchlets nearly quadrangular, slender, dark green. R.H. 1861:1 p. 239. Var. aurea, Hort. Low,

THUOJPSIS (Greek, Thuja-like). Also spelled Thuyopsis. Pinaceae. Ornamental tree or shrub grown chiefly for its handsome evergreen foliage and the formal habit.

A tree closely related to Thuja and chiefly distinguished by the broader much flattened 'branchlets and branchlets irregularly whorled or scant, wd, horizontally spreading and often nodding at the base; branchlets 4–6 in. broad; lvs. glossy green above, marked with a broad white band beneath, those of the upper and under side obovate-oblong, obtuse, anaticher in appearing than the lateral ones spreading, ovate-lanceolate and curved (hatchet-shaped), obtuse; cone globose-ovoid, about 3/8 in. long; scales 6–10, much thickened at the obtuse pointed apex, the middle ones fertile and with 3–5-winged seeds under each scale. Japan. S.Z. 2:119, 120. G.C. II. 18:556. Gn. M. 2:23. G.Z. 25, p. 139. F.E. 10:517. C.L.A. 7:364. S.I.F. 1:11. Var. atitissima, Ansorge. Vigorous and of almost columnar habit. Var. crisata, Ansorge. Branches compact, very full and somewhat crisped. Var. nana, Sieb. & Zucc. (T. leuconeira, Lindl.). Dwarf form, with more slender and narrower branchlets of a lighter green. Var. picata, Ansorge. Very vigorous with heavy branches which hang over and appear folded. Var. variegata, Fortune. Tips of branchlets creamy white. Var. Hondoai, Makino(T. Hondoai, Henry). Tall tree to 100 ft.; branches more densely ramified; lvs. smaller and whiter beneath; cone sub-globose, with the scales not thickened at the apex. This is the more northern form and probably harder than the type which has been called var. australis by Henry. Recently intro. and now growing at the Arnold Arboretum.

THUNBERGIA (after Karl Peter Thunberg, professor of botany at Upsala and successor to Rudbeck and Linnaeus; died 1828). Acanthaceae. Mostly tall perennial climbers producing flowers in great profusion; greenhouse, and in the open far South.

Leaves opposite: fls. blue, yellow, purple, or white, solitary and axillary or in racemes; calyx annular and scarcely lobed or toothed or 10–15-toothed, surrounded by 2 large brachts which often inclose also the corolla-tube; corolla trumpet-shaped, with a spreading limb, tube curved or oblique, often compressed, enlarged toward the mouth; stamens 4, didynamous, fixed near the base of the tube, filaments thickened at the base, separate; anther-cells parallel, equal, mostly mucronate at the base; ovary seated on a fleshy disk, 2-loculed, each cell with 2 ovules (rarely only 1). The Thunbergias are distinguished by the contorted corolla, the 4-seeded caps., and the globose seeds. About 25 species, in the tropics of the world, particularly in Afr.
THUNBERGIA

The thunbergias are nearly all vigorous greenhouse climbers resembling amaranthas in habit. In large conservatories where they are not cramped for room they flower freely and display their flowers to the best advantage. Severe pruning, which is necessary in small greenhouses, prevents the production of flowers. The larger species, *T. laurifolia*, *T. affinis*, *T. grandiflora*, *T. mysorensis*, and *T. cocinea* are rapid growers, requiring plenty of feeding and root-room. All do better in open beds than in pots. They may be propagated either from seeds or by cuttings which are taken from the young wood which starts into growth after the plants have been cut back during winter. These produce few flowers the following autumn, but bloom freely the second season. As a rule, the plants flower in late summer or autumn, but the time of flowering may be made to vary according to treatment in some species. *T. alata* and its varieties and *T. fragrans* are often treated as annual garden plants, flowering in late summer. *T. erecta* and *T. affinis*, when grown in pots, form rather compact shrubby plants (see G. 24, p. 314; 30, p. 292; 47, p. 150). In Porto Rico *T. alata* has escaped and is common. Cook writes that there are two forms, one with corolla-limb cream-yellow and other white.

Thunbergias and amaranthas are great favorites in central and southern Florida, being used on verandas, arbors, small trellises, and buildings. Of the blue-flowered kinds *T. grandiflora* is hardiest and commonest. It has large heart-shaped leaves which overlap one another in a charming manner. It blooms from September until Christmas, the flowers being light blue and rather dull. The form of *T. laurifolia* known to the trade as *T. Harrisii*, has nearly sky-blue flowers, of a deeper but brighter hue than the preceding. It is a tall-growing and choice plant, and has ten or more flowers in a raceme, while those of *T. grandiflora* are solitary in the axils. *T. fragrans* is the common white-flowered kind. The form cultivated in Florida is probably *var. vestita*, as the blossoms are not fragrant. *T. alata* is a general favorite. The flowers range from buff and white to orange with a deep purplish brown throat, the last form being the most popular. This species is killed to the ground by sharp frost every winter but sprouts vigorously the following spring. It also comes up from self-sown seed. This species grows only 7 to 8 feet high. All the thunbergias mentioned above are easily raised from cuttings or layers in summer. *T. erecta* is not a climber but has a somewhat straggling habit. It has small dark green leaves and large deep purplish blue gloxinia-like flowers, which are white at the base. There is a pure white variety of it. It blooms all summer and autumn. It is readily raised from cuttings during the rainy season. (H. Nehrling.)

3802. *Thunbergia alata*. (X 3/4)

s. thunbergii, S. Moore. Sts. prostrate; lvs. about 1 in. long, triangular, glossy green; peduncles axillary, erect, 3 in. long; fls. solitary, about 1 in. across, yellow, each with a pair of inflated and united crimson-stained bracts. British E. Afr. B.M. 9904. — *T. primulina*, Hems. Perennial. silky hairy at first:

3803. Thunbergia grandiflora. (X3)

Var. lutea, Hort. (*Hexacentris lutea*, Hort., Veitch. G.C. 1854, p. 151, not *T. lutea*, T. Anders.), has the fls. pure yellow; a variety with a crimson limb and yellow tube is figured in Paxton’s Flower Garden, 3:88.

10. cocinea, Wall. (*Hexacentris cocinea*, Nees). A very tall climber: st. much branched, 4-angled; lvs. short-petiolate, variously shaped, the lower broadly ovate, with a hastate or cuneate angled base, the upper ovate, cordate, all angularly toothed or the upper entire; fls. in terminal or axillary racemes, 1-3 ft. long; bracts large, inflated, as long as the tube; limb scarlet, of 5 reflexed emarginate lobes; throat orange. Autumn and winter. India. B.M. 5124. L.B.C. 12:1193. F.S. 23:2447-48. R.H. 1890, p. 197. G.W. 3, p. 44.

11. elegans, Borzì. *T. cocinea*. The fls. are said to vary from red to intense yellow. Known only from plants in the Palermo Botanic Garden, to which it is supposed to have been intro. from a nursery at Genoa.

THUNIA (Count Thun-Tetschen, who had an important collection of orchids about the middle of the nineteenth century). *Orchidaceae*. Tall plants with annual leafy stems terminating in a raceme of showy flowers. Formerly united with *Phaius* from which it differs by the terminal inf.: sepals and petals similar, spreading; labellum convolute over the column, spurred, ornamented with several c. columns consisting of lines of fleshy hairs; pollinia 8: fl. subtended by large membranous bracts.—About 6 species in N. India, Burma, and in the S. Himalaya region ascending to a height of 6,000 ft.
The culture of the thunias is very simple. They begin growth naturally at the end of February or early in March. As soon as new growth is visible the plants should be given new material, consisting of fibrous peat or fern-root and sphagnum mixed with loam and some sand and potsherds for drainage. In their native home the plants are said to be epiphytic, and when treated as terrestrial orchids the native habit may be imitated by setting them well above the pot, which should not be too large. For the first four to six weeks until the young roots have made good growth, it is necessary to apply water sparingly. Thunias are very rapid-growing orchids and may be liberally supplied with liquid manure until the end of the flowering season, which occurs about the middle of August. Soon after this the leaves fall. The old stems winter in this condition and serve as food reservoirs for the young growth of the next season, but although they remain on the plant two years they form no leaves the second season. During the resting-period they should be kept in a rather dry atmosphere and be given only enough water to prevent the stems (pseudobulbs) from shriveling. This is one of the few orchids which can be profitably propagated by cutting the old stems into lengths of about 6 inches and rooting them in sand or sphagnum. When rooted the young plants may be potted in the usual way. A temperature of 60° to 65° is favorable during the growing season.

alba, Reichb.f. (Phaius albus, Lindl.). Fig. 3804. Suberect, 2-3 ft., clothed with sheathing, oblong-lanceolate, striate lvs. 6 in. long; raceme drooping at the end of the st., 6-12-fld.: fls. white, 3-4 in. across when fully open; sepals and petals oblong-lanceolate, acuminate; labelium shorter than the segms., not manifestly 3-lobed, lateral lobes convolute over the column, apex spreading, wavy and finely crisp; color of labelllum white veined with purple in the throat, with 5-9 purple or yellow fringed keels; wings of the column entire. In long; fls. like those of T. alba but of a pale purple color; labelllum large, 3-lobed, deep purple in front, with a yellow crested disk, with 6-7 rows of fringe-like golden yellow hairs; spur short, slender. India, July-Sept. B.M. 6594. G.M. 195:137. F.W. 1871:161. — The most showy species of the genus.

Marshalliana, Reichb. f. (Phaius Marshallii, Nichols.). Closely related to T. alba. Sts. somewhat stronger: segms. pure white, acuminate; labelium evidently 3-lobed, with the lateral lobes surrounding the column, middle lobe wavy and crisp; color of labelllum yellowish white, with 5 orange-fringed keels in the throat; wings of the column toothed. May-Aug. India. R.B. 21:229. S.H. 2, p. 335. Var. ionophila, Reichb. f., has the center of the labelllum bright yellow, paler toward the margin. Var. albula, Reichb. f., has white fls. with sulfur-yellow disk to the lip.

T. Veitchiana = T. Bensoniae × T. Marshalliana. Sepals and petals white, flushed light mauve at tips; front of lip mauve-purple, the base white, purple-lined. Heinrich Hassetering.

_Thymus_ (the old Greek name used by Theophrastus either for this plant or for savory). _Labiate_. _Thymus._ Small shrubs or subshrubs, mostly hardy, and excellently adapted for edging the rockery or fern-root and sphagnum mixed With loam and some sand or potsherds. Small hardy shrub, wholly silky-canescent, whitish or pale yellow, oblong or prostrate habit, ability to persist in dry places and withstand the strong summer sun. Excellent ground cover on banks, in borders, or rockwork. The creeping or prostrate habit, ability to persist in dry places and poor soils, and the colored or wooly foliage of some species make them adaptable to a variety of uses. The common _T. Serpyllum_ is evergreen. _T. vulgaris_ is the thyme of sweet-herb gardens, being prized in cookery. _Thymus_ is easily propagated by means of division, although seedlings may sometimes be used to renew plantations of some of the species, particularly of _T. vulgaris_. Several names occur in American catalogues, all of which seem to be referable to three species, one of
INDEX.

1. vulgaris, Linn. COMMON THYME. Subshrub, erect, 6 in. high: sts. sometimes decumbent at base: branches stiff and woody, usually white-pubescent: lvs. sessile, 3-6 lines long, linear-ovate-lanceolate, fascicled at the axis; floral lvs. lanceolate, oblong, obtuse: floral lvs. smaller than the type.

3. Chamädrys, Fries. Subshrub, low, forming a tuft: sts. diffuse, ascending: lvs. broad-oblong; petiole usually heart-shaped: flowers white or capitate, purpureus; calyx-teeth of upper lip 3, triangular, of lower lip 2, subulate. N. Eu.—Similar to T. Serpyllum and by most considered a form of that species, but said to differ in having the lvs. less narrowed to the petiole and only the pedestal ciliate; also the lvs. are less prominently veined.

4. Serpyllum, Linn.; also spelled Serpyllus (T. azorícus, Lodd. T. hispátus, Auth. not Bieb. T. micans, LOW). MOTHER OF THYME. CREEPING THYME. Perennial or subshrub, caespitose or creeping: sts. wiry, prostrate and rooting below, ascending-erect above, slightly puberulent: lvs. elliptic, oblong or oblongate, obtuse or acute, base more or less attenuate, seldom shorter than long, short-petioled: floral-whorls sessile, congested into a head of the lower more or less raceme, of upper subulate, teeth of lower lip triangular, glabrous or ciliate, of upper lip 2, lanceolate-subulate, ciliate; corolla-tube rather included. Temperate parts of Eu., Asia, and N. Afr. G.M. 57:807. L.B.C. 16:1550.—A common plant in old gardens, prized as an evergreen edging and as cover for rockwork and waste places; also run wild. The lvs. are sometimes used for seasoning, as are those of T. vulgaris. The nodes are short, making it a very leafy plant. Variable. Var. vulgaris, Hort., is a white-flld. form. G. 45, p. 108. Var. argenteus, Hort., is a form with silver variegated lvs. commonly known in the trade as T. citriodorus argenteus. Var. aureus, Hort., is a form with golden variegated lvs. growing about 8-12 in. high; usually known in the trade as T. aureus, Hort., or T. citriodorus aureus, Hort.; there is also a minor varia­tion known in the trade as T. Serpyllum aureus marginatus. Var. Chambdréi, Boiss. & Heldr., see T. heterotrichus, Var. aureus, Hort., see var. vulgaris. Var. caucasicus, Hort. (T. caucasicus, Hort.), grows about 1%-3 in. high, has dark green lvs. and bright crimson fls. Var. lanuginosus, Hort. (T. lanuginosus, Mill. T. Chamädrys lanuginosus, Hort.), is a low form, about 3 in. high with small roundish lvs. which are gray-pubescent; a good edging plant. Var. montánus, Benth. (T. montánus, Waldet. & Kit. T. Chamädrys, Auth., not Fries), is a form with the branches more erect and the lvs. larger than the type. Var. pulchellus, Hort., has the upper part of the calyx and its teeth purple. G.M. 56:83. Var. splêndens, Hort., is a form with brilliant red (according to some bright purplish red) fls. Var. variegatus, Hort., has white-variegated lvs. possivly the same as var. argenteus. Var. vulgaris, Benth. (T. Serpyllum var. citriodorus, Hort. T. citriodorus, Schreb.). LEMON THYME. Lvs. smaller than the type and strongly veined; the plant has a decided lemon odor.

5. hispátus, Bieb. Perennial or subshrub, cespitose and cushioned or procumbent: flowering branches ascending, hoary-pubescent: lvs. not punctate, sessile or nearly so, linear-subulate, obtuse, both surfaces hoary-tomentose, margins ciliate: fls. closely approximated in an oblong head, rose; calyx subulate, 2-lipped below the middle, teeth of upper lip lanceolate, acuminate, of lower subulate; corolla-tube included. S. E. Eu. and Caucasus.

7. heterotrichus, Griseb. Subshrub, 3-6 in. high: branches ascending, puberulent: lvs. 6-8 lines long, linear-lanceolate, rather obtuse, fascicled in the axis, flat, glabrous; floral lvs. similar: floral whorls approximate in a head-like raceme: fls. violet; calyx pilose, upper lip triform to the middle, its segms. lanceolate-acuminate. Greece and Macedonia. G.W. 12, p. 461.—Treated by some authors as T. Serpyllum var. Chambdréi, Boiss. & Heldr.

8. carnatus, Boiss. Subshrub, about 9 in. high; sts. decumbent at base, otherwise erect, white-pubescent: lvs. minute, fascicled, strongly revolute, fleshy, subterete, oblong, obtuse, glandular-punctate, glabrous,
glauous; floral lvs. ovate, with revolute margins, hirsutellos: heads dense, ovate: fls. white; calyx hirtellous, upper lip 3-toothed to hardly the middle, margin revolute; lower lip with bristle-like teeth. Portugal.

9. villibus, Linn. Subshrub, about 3 in. high: sts. rough branched, erect, pubescent: lvs. narrow-linear, acute, ciliate, fascicated at the axis; floral lvs. broadly ovate, acuminate, villous: floral whorls in an ovate-globose spike; fls. purple; calyx-crimson; calyx villous, teeth of upper lip short, ovate-lanceolate, of lower subulate. Portugal.—Some of the material offered in the trade under this name may be of T. Serpulium.

F. TRACY HUBBARD.

THYRSOPTERIS (Greek, bunch or raceme and fern); the fructification is disposed in racemose bunches). Polypodiaceae. Tree-like fern: lvs. 3 compound, the fertile portions appearing like bunches of stipitate acorn-cups, the sterile portions twice-pinnae and then deeply pinnatifid. One species, Jsl. Juan Fernandez, T. elegans, Kunze. Tree fern about 15 ft. high: lvs. compound, reaching a length of 5-6 ft., one-third of which is naked; sterile portions bipinnate, with lanceolate incised pinnae; fertile parts tripinnae, each pinna becoming a raceme of stalked involucres: sori globose; involucres cup-shaped.

THYRSOSTACHYS (Greek, thyrse and spike). Gramineae. A genus of 2 species of arborescent bamboos native to Upper Burma and Siam, which has been referred to Rothboelia but is probably sufficiently distinct. The st.-sheaths are very broad and persistent, with a long narrow blade. The lvs. are small or moderate-sized. T. siamensis, Gamble, is a tender, deciduous, giant bamboo, with very graceful tufted sts. 25-30 ft. high and 1½-2 in. thick: st.-sheaths waved and truncate at the top, 9-11 x 1½-3 in.; articles short-triangular: blade narrowly triangular: lvs. small, narrow, linear, 3-6 x ½-1½ in. Siam.—Once intro. in S. Calif., but it did not persist. Probably not-now in cult. in this country outside test-garounds.

THYSANOTHUS (Greek, fringed and ear, alluding to the 3 inner perianth-segments, which are fringed). Liliaceae. Perennials, suitable for the rhizome house. Rhizomes sometimes very short, sometimes stout and horizontal: lvs. radical, grass-like, flat or terete: scape leaves, now erect and simple or paniculate above, now much branched or in one species twining: fls. sometimes densely fascicled, with 1 terminal fascicle or few at the top of the scape, sometimes variously panicled; perianth withering, persistent, segments distinct, outer shorter; lanceolate, margin, beautifully fimbriate-ciliate; stamens 6; ovary sessile or short-stipitate, 3-celled: capsules glbose or ovoid.—About 21 species, Austral., one of which is also found in the Philippines and China. The difference in the inner and outer stamens and the absence of the latter in some species may not always be as constant as it would appear at first sight. The following species have been occasionally cult. They thrive in sandy loam and may be increased by offsets.

THYRSACANTHUS (Greek, thyrse and flower). Acanthaceae. Erect, glabrous, pubescent or villous herbs, which are adapted to the warm house. Lvs. opposite, entire, usually large: fls. red, fascicled at the bract-axis, peduncled; fasciciles or cymes arranged in a terminal thyrse, simple raceme or paniculate branched: calyx short, rather 5-parted, segments narrow, acute or acuminate; corolla-tube elongate, straight or somewhat incurved, limb sometimes what 2-lipped, 4-cleft; stamens 2, staminodia 2; disk rather thick: caps. oblong; seeds 4 or fewer by abortion.—About 25 species, Trop. Amer. The oldest and now accepted name of the genus is Odontonema.

F. TRACY HUBBARD.
TIARELLA

TIARELLA (Latin, a little tiara or turban; in reference to the form of the pistil). Saxifragaceae. False Miterwort. Slender erect, hardy perennial herbs, useful for the wild-garden or any shaded spot.

Leaves several, radical, long-petioled, simple or 3-foliolate; stipules small, adnate to the petiole; raceme terminal, somewhat bracteate, simple or compound; fls. white or reddish; calyx-tube short, lobes 5, ovate; petals 5, entire; stamens 10; ovary superior, compressed, 1-celled: caps. membranaceous, 1-celled, 2-valved.—About 8 species, mostly from Japan, 1 from the Himalayas, the remainder from N. Amer. These plants are little grown, but they are useful for colonizing or perhaps for the rock-garden and are particularly attractive in the autumn on account of their brilliant leaf-coloring. Prop. by division.

A. Lvs. simple.

b. Petals oblong.

unifoliata, Hook. Hardy perennial: lvs. thin, rounded or triangular, 3-5-lobed, the lobes crenate-toothed; st-lvs. usually only 1, rarely 2-3: panicle loose; petals small. W. Amer.—The lobing of the lvs., according to Bot. of Calif., varies so that it may pass into the next species.

TIBOUCHINA

trifoliata, Linn. Resembling T. unifoliata except in having 3-foliolate lvs. Ore. to Alaska, also N. W. Asia. T. biternata, Vent.—Astilbe biternata. F. W. BARCLAY. F. TRACY HUBBARD.

TIBOUCHINA (native name in Guiana). Including Plerôma. Metastacoseae. Shrubs or subshrubs, rarely herbs, sometimes climbing, usually strigose-pilose or hispid, adapted to the greenhouse or to out-of-doors in the extreme South.

Leaves usually large, leathery, petiolid, ovate or oblong, entire, 3-7-nerved: fls. generally in trichotomous terminal panicles, large, violet or purple, rarely numerous; calyx hirsute or strigose, tube ovoid, campanulate, urn-shaped or elongated, lobes 5, subulate, lanceolate or oblong; petals 5, obovate; stamens 10; ovary free or adhering toward the base to the 5 calyx-lobes, 5-celled: caps. 5-valved.—About 215 species, Trop. Amer., but chiefly from Brazil.

Tibouchinas are among the handsomest of our intermediate greenhouse plants, and can be readily trained in bush form, probably with the exception of T. semidecandra, which is better adapted as a pillar or trellis plant. These plants may be propagated at any time of the year, but early spring is the best season. Small pots should be half filled with sandy loam, the remainder being all sand and the cuttings inserted singly. They should be kept quite close and fairly moist, and they will root in a few weeks. After they are rooted, place them in a greenhouse with a night temperature of about 55°, allowing a rise of 20° in the middle of the day. Pinch the heart out as soon as they begin to grow, and a few days after they have been cut back, move them into a pot about 3 inches larger. A good fibrous loam may now be used for all future pottings, and as the plants get stronger about a third of sheep-manure may be added, also a little sharp sand and charcoal, to keep the soil sweet and porous. Give plenty of light at all times, but avoid strong sunshine. Give plenty of water, and syringe the under side of the foliage to prevent red-spider, which is about the only insect that is trouble-
some. Never allow the plants to become pot-bound until the size desired for flowering is attained. Give strict attention to keeping the plants in shape, by pinching the strong shoots, and tying them to the outer edge of the plants, allowing the weaker ones to grow, and fill up the middle of the plant. In general the plants may be placed out-of-doors, and plunged to the rim of the pot, in a bed of ashes; but never allow the sun to strike them directly, as it will disfigure the foliage. Those plants are excellent for exhibition purposes and consequently decoration. The species T. elegans and T. semidecandra are worthy of general cultivation. (George F. Stewart.)

**semidecandra**, Cogn. (*Lasidandra maculata*, Lind. et Seem. *Pierrotma maculatum*, Hook.). Fig. 3807. A tender shrub: lvs. ovate or oblong-ovate, 2–6 in. long, round at the base, short-petioled, densely setose above, villous beneath, not foveolate, 5-nerved or 3-nerved: bracts broadly suborbicular, somewhat rounded at the apex and shortly apiculate, margin not translucent; fls. reddish purple to violet, often 5 in. across, solitary or terminal and 1 in the upper axils on the branchlet; stamens purple, style setulose. Brazil. B.M. 4412 (as *P. Kunthiana*); F. 23:2430. G. 15:4. G. W. 23: 209. 24: 259. C. Z. 20: 151. J. L. H. 11:42219. H. 10:72. Var. floribunda is more suited to pot culture and flowers more freely than the type when small. *Lasidandra* or *Pierrotma splendens*, Horta., should be compared with this. The fls. of *T. semidecandra* last but a day or so, but the flowering season lasts for several weeks. Plants may also be used for summer bedding. They are seldom out of bloom. The species is much esteemed in Fla., where it makes a showy shrub 8 ft. high. Plants may also be used for summer bedding. They endure a few degrees of frost with impunity, and even if cut down sprouts readily.

There is a plant offered in the trade under the name of *Pierrotma edulis*, Horta. Bull, described as being a shrub with dark green ovate-lanceolate lvs., densely silky-hairy, the 5 longitudinal veins very prominent beneath. Fls. white, about 13/4 in. across, borne in loose terminal heads. Said to have been intro. from S. Amur. As there are no Tibouchinas known outside of S. Amur, it is not likely that this is correctly placed in *Pierrotma*; the proper identification of the plants is at present impossible.—*T. lepidota*, Hook. (Lasidandra lepidota, Naud.), is a plant which has been much confused. A. 1864: 209.—There is a plant at least formerly cult. under the name of *Pierrotma sarmentosa*, Hook. Small villous shrub with the branches and branchlets serrate: lvs. 3-5 m. long, 2-6 in. across, yellow, or red-spotted on the claw; inner segms. pan­

**TIGRIDIA**

**TIGRIDIA** *(tiger-like, referring to the peculiarly marked flowers). *Iridaceae.* Bulbous plants, grown in the greenhouse and also making very showy summer-blooming subjects.

Bulbs tunicated: st. erect, mostly branched, 1–2½ ft. tall, with a few narrow plicate lvs. at the base and 2 or 3 smaller ones higher up: spathes 1 or 2, leaf-like, being bearing 1 or few blossoms. F. Stewart.

A long cylindrical tube including the style; pistil with 3-loculed ovary, long style with 3 2-parted branches.—About 13 species from Mex., Cent. Amer., Peru, and Chile. *T. Pavonia*, from S. Mex., was in cult. in Eu. in the 16th century. L’Obel described it in 1576. The younger Linneus referred it to the genus Ferraria, and some of the tigridias are yet cult. under that name. Ferraria, however, is a S. African genus, and all the parts of the perianth are nearly equal. *T. Pavonia* is cult. in many forms, and is the only common species in garden. The fls. of all tigridias are fugitive, lasting only for a day.

Tigridias are tender “bulbs” requiring the treatment given gladiolus. Plant in well-prepared soil when set­
ed water comes, 2 to 3 inches deep and 4 to 6 inches apart. The principal blooming fls. is in July and August. Allow the corms to remain in the ground until danger of frost approaches, then store in a dry place where dahlias or gladioli will keep. See that the corms are dry before being placed in storage. Propagation is by cormels and seeds. The best colors are secured in warm weather.

**T. semidecandra**, Cogn. (Lasiandra semidecandra, Lind. & Seem. *Pierrotma maculatum*, Hook.). Fig. 3807. A tender shrub: lvs. ovate or oblong-ovate, 2–6 in. long, round at the base, short-petioled, densely setose above, villous beneath, not foveolate, 5-nerved or 3-nerved: bracts broadly suborbicular, somewhat rounded at the apex and shortly apiculate, margin not translucent; fls. reddish purple to violet, often 5 in. across, solitary or terminal and 1 in the upper axils on the branchlet; stamens purple, style setulose. Brazil. B.M. 4412 (as *P. Kunthiana*); F. 23:2430. G. 15:4. G. W. 23:209. C. Z. 20:151. J. L. H. 11:42219. H. 10:72. Var. floribunda is more suited to pot culture and flowers more freely than the type when small. *Lasidandra* or *Pierrotma splendens*, Horta., should be compared with this. The fls. of *T. semidecandra* last but a day or so, but the flowering season lasts for several weeks. Plants may also be used for summer bedding. They are seldom out of bloom. The species is much esteemed in Fla., where it makes a showy shrub 8 ft. high. Plants may also be used for summer bedding. They endure a few degrees of frost with impunity, and even if cut down sprouts readily.

There is a plant offered in the trade under the name of *Pierrotma edulis*, Horta. Bull, described as being a shrub with dark green ovate-lanceolate lvs., densely silky-hairy, the 5 longitudinal veins very prominent beneath. Fls. white, about 13/4 in. across, borne in loose terminal heads. Said to have been intro. from S. Amur. As there are no Tibouchinas known outside of S. Amur, it is not likely that this is correctly placed in *Pierrotma*; the proper identification of the plants is at present impossible.—*T. lepidota*, Hook. (Lasidandra lepidota, Naud.), is a plant which has been much confused. A. 1864:209.—There is a plant at least formerly cult. under the name of *Pierrotma sarmentosa*, Hook. Small villous shrub with the branches and branchlets serrate: lvs. 3-5 m. long, 2-6 in. across, yellow, or red-spotted on the claw; inner segms. par­nately or narrowly obovate-cuneate. Brazil. F. Tracy Hubbard.
26:128 (as T. alba). Var. alba immaculata, Hort., is a spotless white variety, a sport from var. alba. Gn. 40, p. 361. Var. flava, Hort., has pale yellow fls., with red-spotted center. Gn. 50:22. Var. canariensis, Hort., is also a pale yellow-flowered form, but named as if an inhabitant of the Canaries. Var. idaea immaculata, Hort., has pure yellow spotless fls. Var. rosea, Hort., has rose-colored fls. with yellow variegated center. Var. lilacea, Hort., has lilac-flowered, spotless center. Gn. 45:28. Var. speciosa, Hort., is a partially dwarf form with deeper red color, the interior of the cup being similar in color to the limb. Described in 1843. G. 36:359. Var. grandiflora, Hort., has fls. much like those of T. Pavonia itself except that they are larger and brighter colored. Gn. 45, p. 263. G. 1:20; 6:263 (as T. grandiflora). Identical with this, or subtypes of it, are the forms known as Wheeleri, coccinea, splendens. Most of the marked departures in colors of T. Pavonia are recent. In catalogues the above names often appear as if they were species names.

3809. Tigridia Pringlei. (X3½)

Distinguished by Sereno Watson, the author of the species, as follows: "Very closely related to T. Pavonia, and if color alone were to decide, it might be considered a variety of it, though differing markedly even in that respect from the old species. The base of the sepals is blotched (rather than spotted) with crimson, with a border of orange, the reflexed blade being of a bright scarlet-red. The petals have the base blotched and coarsely spotted with crimson, with a well-defined, deeper-colored, brownish margin, the blade orange, tinged with scarlet, but not at all spotted as in T. Pavonia. The more essential difference is in the form of the petals, which have a broadly cordate or reniform base, with a much narrower triangular-ovate acute blade. The sepals are also smaller and more oblong in outline."* N. Mex. G. F. 1:389 (adapted in Fig. 3890). B.M. 7089.

AA. Fls. relatively small; the 2 rows of segms. differing less in size; stigmas capitate, or at least not strongly decurrent. (Subgenus Beatonia.)

buccifera, Wats. Fig. 3810. About 1 ft. high, slender, branching, glaucous: lvs. very narrow, strongly plicate; fl. 2 in. across, the cup pale greenish yellow, dotted with purple, the obovate obtuse blade of the outer segms. light purple; inner segms. "folded together in such a manner as to form a sunken longitudinal tube down the center, the dilated sides at the oes- end of the tube approaching each other in the form of 2 check-like prominences.—these are ovoid, white, purple, and yellow, while the small rounded terminal blade is a deep purple." Mountains of Jolisco, Mex. G. F. 2:413 (adapted in Fig. 3810).—Offered in 1889 by Horsford.

T. albina, Hort., is Cypella plumbea.—T. axillata, Hort., is Cypella plumbea.—T. Houtties, Rein. in Hydrogenia Van Houtte.—T. Meligyna, Hort., is also a Hydrogenia (H. Meligyna, Lindl.), but is not in the American trade. B. H. 28:39.——T. oxyloba, Schleid. & Schl. One of the Beatonia section: slender, narrow-leaved; fls. 2 in. across, violet, spotted at the base; inner segm. small, cup-shaped, Mex. B. M. 725. H. U. 3, p. 301. Other kinds of Tigris are likely to appear in cult.

3810. Tigridia buccifera. (Xearly 3½)

TILIA (the classical Latin name). Tiliaceae.—Linden. Lime. Basswood. Whitewood. Ornamental trees, grown for their handsome foliage, good habit, and also for their fragrant flowers.

Deciduous: winter buds large, obtuse, with several imbricate scales, terminal bud wanting: lvs. alternate, petiolate, usually cordate, serrate, with caducous stipules; fls. small, in long-peduncled drooping cymes; the peduncle for about half its length adnate to a membranous ligulate bract; sepals 5; petals 5, often with 5 opposite petaloid staminodes; stamens many, with the filaments forked at the apex; ovary superior, 5-celled; style slender, with 5-lobed stigma: fr. globose or ovoid, nut-like, usually with 1–3 seeds.—About 25 species throughout the temperate regions of the northern hemisphere, in N. Amer. south to the highlands of Mex., except W. N. Amer., and in Asia south to Cent. China. The names of the lindens, and particularly of those in cul., have been much confused, owing to the great variability of some species, the rather slight differences between many of the species and to the presence of many hybrids originated spontaneously and in cult. The light-colored soft and light wood is easily worked and much used for the interior finish of houses, for wood-carving, wooden baskets and other small wooden ware. The tough inner bark is used as a tying material and, particularly in Russia, in the manufac-

T. albina (H. L. B.)
drooping clusters followed by small inconspicuous nutlets. The species in cultivation are nearly all hardy North and not particular as to the soil, but do not thrive well in dry locations or in dry climates. They are much planted as shade and ornamental trees and, particularly in Europe, are favorite avenue and street trees. The best for avenue planting are T. tomentosa, T. euchlora, T. americana, T. cordata; T. tomentosa stands heat and drought better than any of the others, while T. platyphyllos, although often planted for its rapid growth, is likely to suffer in dry seasons or in dry localities.

Propagation is by seed which must be sown soon after ripening or stratified, as it does not germinate until the second year if kept dry and sown in spring. Also increased by layers; in layering usually the method of

"stooling" is employed; this consists of cutting a younger tree close to the ground and of laying down and covering partly with earth the numerous shoots which will appear. Varieties or rarer species are often grafted in spring or budded in August on common stock. Plants raised from layers or grafts remain often one-sided for many years, as the lateral branches usually employed will appear. Varieties or rarer species are often grafted covering partly with earth the numerous shoots which younger tree close to the ground and of laying down and "stooling" is employed; this consists of cutting a

second year if kept dry and sown in spring. Also ripening or stratified, as it does notgerminate until the second year if kept dry and sown in spring. Also increased by layers; in layering usually the method of

INDEX.

AA. Tilia, with stellate hairs or stellate tomentose beneath; fls. with staminodes.

BB. Branchlets glabrous.

CC. Axillary tufts present on the lvs. beneath.

DD. Axillary tufts wanting on the lvs. beneath.

EE. Tomentum of branchlets, buds, and petioles yellowish or brownish: margin of the lvs. coarsely serrate with short-pointed teeth.

FF. Habit upright; petioles shorter than half the blade: fr. slightly 6-angled.

GG. Habit pendulous; petioles longer than half the blade: fr. 5-furrowed.

HH. Tomentum of branchlets, buds, and petioles yellowish or brownish; margin of the lvs. coarsely serrate with short-pointed teeth, often glabreanct with age.

II. Miqueliana

JJ. With axillary tufts of hairs; lvs. orbicular-ovate, grayish, tomentose beneath, brownish on midribs and nerves.

KEY TO THE SPECIES.

A. Lvs. green or glaucous beneath, glabrous or pubescent with simple hairs.

B. Under side of lvs. and branchlets pubescent: fls. without staminodes... 1. platyphyllos

BB. Under side of lvs. glabrous except axillary tufts of hairs.

CC. Axillary tufts present at the base of the lvs. and elsewhere.

D. Margin of the lvs. finely serrate: fls. without staminodes... 1. platyphyllos

EE. Lvs. green beneath; the tertiary veins prominent.

F. Upper surface of lvs. dull green, margin with short-pointed teeth... 2. vulgaris

FF. Upper surface glossy dark green, margin with long-pointed teeth... 3. euchlora

GG. Lvs. glaucous beneath; the tertiary veins not tomentose.

HH. Cyanes 6–11-fid.: fls. without staminodes... 4. cordata

II. Cyanes 8–10-fid.: fls. with staminodes... 5. japonica

JJ. Axillary tufts of hairs wanting at the base, present elsewhere; lvs. 3–6-in. long: fls. with staminodes... 6. mongolica

KK. Margin of lvs. coarsely serrate, lvs. often 3-lobed: fls. with staminodes... 7. americana

LL. Margin of lvs. finely serrate with short-pointed teeth.

MM. Petioles longer than half the blade: fr. 5-furrowed.

NN. Petioles shorter than half the blade:

HH. Habit pendulous; petioles longer than half the blade: fr. 5-furrowed.

II. Miqueliana

JJ. With axillary tufts of hairs; lvs. orbicular-ovate, grayish, tomentose beneath, brownish on midribs and nerves.

1. platyphyllos, Scop. (T. grandijalial, Ehhr. T. europaea, Link, in part). LARGE-LEAVED LIME. Fig. 3811. Trec, to 120 ft.; young branchlets pubescent, older glabrous: lvs. orbicular-ovate, abruptly acuminate, obliquely cordate at the base, regularly serrate, dull green and short-pubescent or glabrous above, light green and pubescent beneath, 3–4 in. long; petioles stout, hairy: fls. in usually 3-fld. pendulous cymes; petals obovate, longer than sepals; stamens 30; style glabrous; fr. globose, ovoid or pyriform, 3–5-ribbed, apiculate, tomentose, thick-shelled. June; the earliest species to bloom. Eu. G.F. 2:256 (adapted in Fig. 3811). H.W. 3:24, 25. R.F.G. 6:316, 317, 318.—Very variable; some of the most important varie-
ties are the following: Var. pyramidalis, Kirchn. (X
narrow pyramidal habit. M.D.G. 1898:101. Var. concolor, Dipp. (var. rubra, Hort.). Young branches red. Var. aurea, Kirchn. Young branches golden yellow. Var. lacinata, Henry (var. asplenifolia, Kirchn. var. blaesifolia, Hort. T. europaea var. lacinata, Loud.). Lvs. deeply and irregularly cut. G.W. 15, p. 662. Var. vitifolia, Simomkai. Lvs. slightly 3-lobed or indistinctly lobed.—This species is the strongest grower and in this country often sold as T. europaea. It is more impotent of drought than most other species and therefore not to be recommended as a street tree.

2. vulgaris, Hayne (T. intermedia, DC. T. europaea, Linn., in part). COMMON LINDEN. Fig. 3812. Tree, to 120 ft.; young branchlets glabrous; lvs. broadly ovate, abruptly acuminate, obliquely cordate or truncate at the base, serrate with short-pointed teeth, dark green above, light green beneath, glabrous except auxiliary tufts of hairs, 3-4 in. long; petiole about half as long as the blade: fls. 5-10, similar to those of the preceding species: fr. ovoid or globose, apiculate, tomentose, thick-shelled. June, July; a week or 10 days later than the preceding species. G.F. 2:257 (adapted in Fig. 3813). H.W 3:41, pp. 21, 22. R.F.G. 6:311, 312. M.D.G. 1904: 188. Var. pyramidalis, Wittm. Of narrow pyramidal habit.

3. euchlora, Koch (T. dasystyla, Kirchn., not Stev. T. rubra var. euchlora, Dipp.). CRIMEAN LINDEN. Tree, to 50 ft.; young branchlets glabrous; green: lvs. orbicular-ovate, abruptly acuminate, obliquely cordate at the base, regularly serrate, the teeth with slender points, dark green above, paler beneath and glabrous except auxiliary tufts of brown hairs, 2-3 in. long; petiole slender, more than half as long as the blade: fls. 3-7, in pendulous cymes; style glabrous: fr. globose, slightly ribbed, apiculate, tomentose, with thin fragile shell. July. Eu. G.F. 2:257 (adapted in Fig. 3813). H.W 3:41, pp. 21, 22. R.F.G. 6:311, 312. M.D.G. 1904: 188. Var. pyramidalis, Wittm. Of narrow pyramidal habit.

5. japónica, Simonkai (T. cordata var. japónica, Miq.). Tree, to 60 ft.; young branchlets slightly pubescent at first: lvs. suborbicular, almost like those of the preceding species, 2-3 in. long; petioles usually longer than half the blade: fls. 7-10, in pendulous cymes; staminodes present: fr. ovoid, not ribbed, tomentose, thin-shelled. July. Japan. S.I.F. 1:72.

6. mongolica, Maxim. Small tree, to 30 ft.; young branchlets glabrous, reddish: lvs. suborbicular, or ovate, acuminate, subcordate or truncate at the base, coarsely serrate and usually 3-lobed, dark green and shining above, glaucous beneath, glabrous except axillary tufts, 1½-2½ in. long; fls. 6-12 in a cyme; the bract stalked; staminodes present; style glabrous: fr. ovoid, mucronulate, tomentose, thick-walled. July. Mongolia, N. China. R.H. 1902, p. 476. S.T.B. 1:61.

—Very distinct with its small coarsely serrate, birch-like lvs. reddish when unfolding; it flows when only a few feet high.

7. americana, Linn. (T. glabra, Vent.). Fig. 3814. Tree, to 120 ft.; young branchlets glabrous, green: lvs. broadly ovate, abruptly acuminate, cordate or truncate at the base, coarsely serrate, the teeth long-pointed, dark green above, light green beneath with tufts of hairs in the axis of the lateral veins, but wanting at the base, 4-6 in. long, turning yellow in autumn; cymes pendulous, many-fld.; bract stalked, tapering toward the base; staminodes present: fr. ovoid or globose, without ribs, tomentose, thick-shelled. July. Canada, south to Va. and Ala., west to N. Dak., Kans., and E. Texas. S.S. 1:24. Mn. 6:153. Var. macrophylla, Hort. (var. mississippiensis, Hort.). A large-lvd. form.

—This species is frequently planted as an avenue tree. Its wood is much used in the manufacture of wooden-
ware, cheap furniture, panels of carriages, and also of paper pulp.

8. neglécia, Spach (T. Michaëzi, Sarg., not Nutt. T. pubescens, Hort., not Vent.). Tree, to 80 ft.: branchlets freely ovate or ovate, acuminate, obliquely coriaceous at the base, rarely truncate, coarsely serrate, with long-pointed, usually incurved teeth, dark green and glabrous or sparingly pubescent above, more or less stellate-pubescent and grayish green beneath with conspicuous axillary tufts, 6-6 in. long, turning yellow in autumn: cymes many-fld.; bract deciduous nearly to the base, tomentulose above; peduncle glabrous: fr. subglobose or ovoid, slightly furrowed, tomentose. July. E. Canada to Ga. and Texas west to Ohio. S.M. 676. — This species has often been confused with T. pubescens and with T. heterophylla.

9. heterophylla, Vent. (T. alba, Michx. T. Michæzi, Nutt.). Tree, to 60 ft.: young branchlets glabrous and red; lvs. broadly ovate to oval-ovate, short-acuminate, obliquely truncate or coriaceous at the base, finely serrate with rather short-pointed teeth, dark green and glabrous above, white-tomentose beneath without axillary tufts, 4-7 in. long; fls. in many-flowered pendulous cymes; bract deciduous often nearly to the flower, rather large; fr. subglobose, tomentulose. June. W. N. Y. to Ala. and Ill. S.S. 1:27. — This is a very handsome linden with its large lvs. silvery white below and is sometimes sold as T. macrophylla.

10. Olivieri, Sakszylovicz. Tree, to 50 ft.: young branchlets reddish brown, glabrous; lvs. ovate, short-acuminate, coriaceous or truncate at the base, supinately dentate, with short gland-tipped teeth, dark green and glabrous above, white-tomentose beneath, with long hairs on the veins, without axillary tufts, 5-5 in. long; petals glabrous; fls. about 20, in pendulous cymes; bract sessile; pedicels short, thickened: fr. globose, tomentose and tuberculate, apiculate, thick-shelled. Cent. China. — This recently intro. species promises to be a handsome ornamental tree.

11. spectabilis, Dipp. (T. alba spectabilis, Hort. T. Blechiana, Hort.). Hybrid of T. americana and T. petiolaris or T. tomentosa. Tree of vigorous growth; branchlets glabrous or slightly pubescent at first; buds pubescent toward the top: lvs. similar to those of T. americana, ovate, slightly grayish tomentose beneath, with long hairs on the veins, without axillary tufts, 4-6 in. long, 3-5 in. wide: inf. and size of fls. like those of T. americana, but petals though less densely than T. tomentosa. Blooms 2 or 3 weeks earlier than T. tomentosa. Of unknown origin; a similar form was raised from seed of T. petiolaris at the Arnold Arboretum in 1900. Var. Möltkei, Reich. (T. Möltkei, Spach). Branchlets and buds quite glabrous; lvs. often without long hairs on the veins, 5-7 in. long. Originated at Spaeth's nursery near Berlin, Germany.

12. tomentosa, Moench (T. argentea, DC. T. alba, Ait. T. alba pyramidalis, Hort.). WHITE LINN. Tree, to 100 ft. with upright branches; young branchlets stellate-tomentose: lvs. nearly orbicular, abruptly acuminate, truncate or coriaceous at the base, serrate or doubly serrate, often lobulate, with short-pointed teeth, sparingly pubescent above, white-tomentose beneath, 3-5 in. across; petals pubescent, less than half of the length of the blade; fls. 7-10, in pendulous tomentose cymes: fr. ovoid, slightly 5-angled, tomentose; shell woody. July. E. Eu., Asia Minor. R.F.G. 6:259-331. H.W. 5:3-43, p. 36. F.E. 14:1154, pl. 38. G.W. 8, p. 617. S.A. 1903:190, 1904:189. — This is a very handsome tree of dense habit with upright branches; it stands heat and drought better than any of the other species. Its fls. and those of the following species have proved poisonous to bees.

14. mandshurica, Rupr. & Maxim. Tree, to about 60 ft.: young branchlets and buds with brownish tomentum: lvs. orbicular-ovate, short-acuminate, usually coriaceous at the base, coarsely serrate with long-pointed teeth, sparingly pubescent above, white-tomentose beneath, 4-6 in. long; petiole about half as long as the blade, tomentose: fls. 7-10, in pendulous cymes covered with brownish tomentum: fr. globose, tomentose, with 5 distinct ribs toward the base or without ribs. N. China, Manchuria, Korea. — Similar to T. tomentosa, from which it differs in the larger lvs. with long-pointed teeth and in the fr. Like the two following species still rare in cult.

15. Miqueliana, Maxim. Tree, to 40 ft.: young branchlets finely tomentose: lvs. ovate or deltoid-ovate, usually much longer than broad, acute or acuminate, obliquely coriaceous at the base, coarsely serrate with broad mucronate teeth, dark green and glabrous or nearly so above, grayish tomentose beneath, without axillary tufts of hairs, 2½-5 in. long; fls. 10-20 in pendulous tomentose cymes; stamina 60-75; style shorter than petals, hairy at the base: fr. subglobose, tomentose, 5-ribbed at the base. Cult. in Japan; native habitat unknown. S.I.F. 1:72.

16. Maximowicziana, Shirasawa (T. Miyabe, Jack. T. Miqueliana, Sarg., not Maxim.). Fig. 3815. Tree, to 100 ft.: young branchlets tomentose: lvs. broadly ovate or orbicular-ovate, abruptly acuminate, obliquely coriaceous at the base, coarsely serrate with broad mucro-
nate teeth, dark green above and pubescent at first, finally glabrous or nearly so, grayish tomentose beneath with brownish axillary tufts of hairs, finally often becoming partly glabrous, 3-6 in. long; petioles less than 1/5 in. of the length of the blade long, 10-15 in. long, pendulous tomentose cymes; style exerted: fr. globose, 5-ribbed, tomentose, thick-walled. *Japan.* S.I.P. 2:50. G.F. 6:113 (adapted in Fig. 3815).

The modern conceptions of tillage probably date from Tull's time, but his was erroneous, nevertheless Tull showed that tillage is necessary to make the soil thrifty and productive wholly aside from its use for killing weeds. He supposed that tillage benefited plants by making the soil so fine that the minute particles could be put into the land, weeds killed, and the crop taken out.

Tillage improves land in many ways. It divides and pulverizes the soil, gives the roots a wider "pasturage," and also the benefits that followed the application of ashes; the minute particles of the ashes are so small as to be absorbed by the roots. Although this explanation of the benefits of tillage was erroneous, nevertheless Tull showed that tillage is necessary to the best agriculture and that it is not merely a means by which seeds can be put into the land, weeds killed, and the crop taken out.

Tillage also causes moisture by deepening the arable soil so that moisture is held, and also by checking evaporation from the surface by means of a thin blanket or mulch of granulated earth that is made by surface-working tools. Water is lost from the soil by underdrainage and by evaporation from the surface. The more finely the soil is granulated, within certain limits, the more water it will hold. Its capillary power is increased. As the water evaporates from the surface, the moisture is drawn up from the under surface so that there is a more or less constant flow into the atmosphere. If any foreign body, as a board or a blanket, is spread on the land, the evaporation is checked. A similar result may follow when the soil is covered with a layer of dry ashes or sand or sawdust. Very similar results are also secured when the surface soil and the under soil is thereby broken. This surface soil itself may be very dry, but it may serve as a blanket or mulch to the soil beneath. In some cases this preservation of moisture by frequent shallow tillage is probably the chief advantage of the tillage of the land in the growing season.

Land that is well tilled has different chemical relations from that which is neglected. Nitridation, decomposition, and other bacterial activities have ceased. The stores of plant-food are rendered available. The soil is made more productive.

The first requisite for the growing of the plant is to have the soil in such condition that the plant can thrive in it. It is only when the land is well tilled and prepared, or when its physical condition is nearly or quite perfect, that the addition of concentrated fertilizers may be expected to produce the best results. Fertilizing, therefore, is a secondary matter; tillage is primary. The ideal tillage is that which is practised by the gardener when he grows plants in pots. The soil is ordinarily sifted or riddled so that unnecessary parts are removed, and most of it is brought into such condition that the plants can utilize the crop. The gardener adds leaf-mold or sand or other material, until the soil is brought into the proper physical condition. He also provides drainage in the bottom of his pots or boxes. Often the gardener will produce as much from a handful of soil as a farmer will produce from an acre. L. P. B.
TILLANDSIA (Elias Tillands was professor of medicine at the University of Abo, Sweden; in 1673 he made a catalogue of plants of the vicinity of Abo). Bromeliaceae. Mostly epiphytes and all natives of America, allied to billbergias, orchids, guzmania, pineapple, and the like; ornamental greenhouse subjects.

Perennial herbs, mostly of upright growth (the common T. usneoides being a marked exception), the bases of the narrow entire lvs. often dilated and forming cups that hold water and in which utricularias and other water-plants sometimes grow: fls. usually borne in spikes or heads, singly beneath bracts, perfect, with 3 sepals and 3 petals which are twisted or rolled in the bud, 6 stamens, a superior ovary with filiform style: fr. a 3-valved caps containing hairy or plumose seeds. Vriesia is distinguished by having 1 or 2 scales or figules at the base of the petals on the inside, whereas the petals of Tillandsia are ellip.

Some of the cult. tillandsias belong to still other genera. This is the case with T. zeyr, which is properly Cryptanthus zonatus (Fig. 1120, Vol. II). This is an odd plant, producing crinkled leaves, which is whitish beneath and brown-barred above, and small clusters of white fls. See p. 902, where other kinds of Cryptanthus in the American trade are described. Many species are described in horticultural literature as having been intro. into cult. by suckers; also by seeds. For further cultural notes, consult Billbergia.

A. Plant-body slender and hanging: fls. solitary in lf.-axils.

B. Flower larger and nodding: fls. in terminal clusters, mostly in the Southern regions.

C. Stems short, usually papery: fls. solitary, in the axils of the bracts.

D. Stems erect or filiform recurved 2-ranked lvs.: fls. carried in the wind by means of the soft hairs, and find lodgment on trees, where the plants grow. A few species, however, grow on the ground.

E. Vegetative stems solitary, creeping: fls. usually carried by means of the soft hairs, and find lodgment on trees, where the plants grow. A few species, however, grow on the ground. In cultivation, most of the species are treated as pot-plants. The growing season is summer. In winter the plants should be kept nearly dormant, although not completely dry. They need a warm temperature and plenty of light while growing. Give a soil rich in peat. In some cases sphagnum may be added to advantage. Propagation is by suckers; also by seeds. For further cultural notes, consult Billbergia.

T. recurvata, Linn. SPM[ISH, FLORIDA, or LONG Moss. Figs. 3816, 3817. Whole plant hoary-gray, hanging from the trees, the sta. very slender and often several feet long: lvs. scattered, narrow-linear, 1-3 in. long: fls. solitary in the lf.-axis, small and not showy, the petals yellow and reflexed at the end. Trop. Amer. and in the U. S. from Texas to Fla. and E. Va.; extends southward to S. Brazil. B. M. 6309. Gn. 37, p. 221. Gt. 45, p. 267.

—This is one of the most characteristic plants of our southern regions. In moist regions it gives a most weird aspect to the forests. It is used as a packing material, and also, when specially prepared, for upholstery. It is rarely cult., although it is not uncommon in greenhouses, being hung on branches and beams; but it must be renewed frequently. The plant is named for its resemblance to the lichen Usnea.

T. usneoides, Linn. SPANISH, FLORIDA, or LONG Moss. Figs. 3816, 3817. Whole plant hoary-gray, hanging from the trees, the sta. very slender and often several feet long; lvs. scattered, narrow-linear, 1-3 in. long: fls. solitary in the lf.-axis, small and not showy, the petals yellow and reflexed at the end. Trop. Amer. and in the U. S. from Texas to Fla. and E. Va.; extends southward to S. Brazil. B. M. 6309. Gn. 37, p. 221. Gt. 45, p. 267.

—This is one of the most characteristic plants of our southern regions. In moist regions it gives a most weird aspect to the forests. It is used as a packing material, and also, when specially prepared, for upholstery. It is rarely cult., although it is not uncommon in greenhouses, being hung on branches and beams; but it must be renewed frequently. The plant is named for its resemblance to the lichen Usnea.

AA. Plant-body stiff and nearly or quite erect.

B. Stamens shorter than the petals.

c. Fls. few in the cluster.

E. Stamens much longer and erect: fls. solitary, in the axils of the bracts.

F. Stamens shorter than the petals: fls. solitary in the axils of the bracts.

G. Lvs. rosetulate, about 1 ft. long, dilated at the base, long recurving: spike large, the showy distichous bracts carmine: fls. small, much exerted beyond the bracts, the large wide-spreading segments, bluish purple. Ecuador, Peru. P. R. 16:610; 27:370 (as var. Repellana). G. C. I. 12:461. R. H. 1872:230; 1898: 206 (as var. tricolor). F. M. 1872:44. —A handsome and popular species. This interesting species has also been described as Phytarrhiza Lindeni, Morr.
TILLANDSIA

BB. Stamens longer than the petals.

c. St. thickened and bulb-like at the base.

bulbosa, Hook. Small scurvy plant a few inches high, the st. swollen at the base: lvs. 3-5 in. long, much dilated and clasping at the base and terete above: fls. few, in racemes, long and many, the upper one much exerted but not spreading petals purple. Var. picta, Hook., has the upper lvs. and bracts scarlet. W. Indies to Venezuela. B.M. 4388. F.S. 3: 221.

c. St. not prominently swollen.

D. Lvs. linear or almost filiform from the base or abruptly from a dilated base.

polystachya, Linn. (T. angustifolia, Swartz. T. parviflora, Baker). Lvs. rosetulate, lepidote or scurvy, curved, equaling or exceeding the st.: infl. compound, somewhat paniculate, the lateral fls. shorter than the central ones, the bracts distichous and pointed and little exceeding the calyx: fls. blue. S. Fla. to Brazil.

tenuifolia, Linn. (T. cupanii, Le Conte, not Cham. & Schlcht. T. Bruyantii, Ell. in part). Plant less than 6 in. tall, reddish, clustered: lvs. awl-shaped and erect, nearly terete, concave at the base, scurfy: fls. few in a simple or somewhat compound spike, the blue petals exceeding the bracts and recurving at the apex. Ga. to Brazil.

D. Lvs. gradually narrowed from a broad base.

utriculata, Linn. Plant 2-3 ft. high: lvs. glaucous and scurfy, becoming subulate and recurved at the summit but much dilated and imbricated at the base: forming pockets that hold water: infl. branched, the central ones, the bracts and recurving at the apex. St. thickened and bulb-like at the base. St. wt prominent, much dilated and bulb-like at the base. St. simple, very short (about 1 in.), very slender, recurved, about equaling the lvs., with 2 or 3 bracteoles, of which one is a compressed, shining a simple infl.: fl. erect; sepals glabrous; petals violet. S. Amer. Gt. 3: 138. R.H., Baker. V. 1006. H. 105. T. Zehnt., Hort., is properly Guzmania Zahnii, Mez. Tubular, branching from the base, glabrous throughout: lvs. 1 ft. long, about 1 in. broad, crimson stipules are often infl. paniculate, subtended by scarlet bracts: fls. yellow. Costa Ricas. B.M. 6050 (as Cariquatu Zahnii). In 1992, the flowering names are accounted for under Vriæsia: corticulata, fenestrata, glabra, hieroglyphica, perennis, Saundersii, tessellata, sobrina (in part).

L. H. B. GEORGE V. NASH.

TIMOTHY: Phleum pratense.

TINANTIA (named after Tinant, a Belgian botanist.) Commelinoideae. Erect herbs, either hardy or grown in the greenhouse: lvs. medium-sized or large: peduncle terminal, rarely with 1-3 extra in the upper axis: cyme terminal, with 1-3 branches filiform from nearly their base: fls. pedicellate: sepals distinct, green: petals distinct, obvate; stamens 6, all perfect; ovary sessile, 3-3-celled: caps. 3-celled, loculicidally dehiscent.—About 6 species, Trop. Amer. T. flava, Scheid., is a tradesplant-like herb: st. glabrous, 1 ft. high: lvs. ovate-lanceolate, plicate above, glabrous beneath: peduncle villous, 1-3-branched at apex, branches umbellate: fls. blue, with their pedicels conspicuously bracteolate at base. Known also as Tradescantia erecta. T. undata, T. longifolia, B.M. 1340. B.R. 1406. L.B.C. 13: 1200.—Sometimes seen in old gardens but not offered in the trade.

TINNÉA (named in honor of Mlle. Tinné). Lobáltea. Tall perennial herbs or subshrubs, pubescent or woolly, adapted to the warmhouse. Lvs. very entire: floral whorls usually laxly 2-fl., axillary or in a terminal raceme: fls. fuscescent or violet-purple, fragrant; calyx ovoid, 2-lipped; corolla-limb somewhat 2-1ipped; stamens 4, didynamous; ovary shortly 4-lobed: nutlets obovoid-ellipuate.—About 23 species, Afr. T. Sacleuxii, Sprunger. Dwarf shrub with the branches shortly and densely pubescent: lvs. short-petiolate, oblong or ovate, entire, ½-1 in. long: cymes axillary, 2-4-fl., calyx ovate-lanceolate, plicate above, glabrous beneath; peduncle villous, 1-3-branched at apex, branches umbellate: fls. blue, with their pedicels conspicuously bracteolate at base. Known also as Tradescantia erecta. T. undata, T. longifolia, B.M. 1340. B.R. 1406. L.B.C. 13: 1200.—Sometimes seen in old gardens but not offered in the trade.

TIPUANA (name apparently Latinized from a Brazilian name). Leguminosæ. Showy unarmed trees, used ornamentally in the extreme southern U. S. Lvs. unevenly pinnately compound, without stipels; lfts. several, alternate; stipules minute, caducous; fls. showy, yellow or pale purplish, in loosely branched terminal panicles; calyx tuberous, teeth short and broad; standard ovate or suborbicular, not appendaged; wings obliquely obovate or oblong; keel-petals obliquely oblong, obtuse, lightly connate; stamens all connate in a sheath which is split above: pod stipitate, indehiscent, 1-3-seeded, samara-like.—About 4 species, S. Amer. Here belongs the plant recently intro. to S. Calif. as Macherium Tipu, which is said to yield one of the rosewoods of S. Brazil.

speciosa, Benth. (Machærium Tipu, Benth.). Tender yellow-fl. tree: lts. 11-21, oblong, emarginate or entire, ¼ in. long; veins somewhat parallel: standard broadly orbicular; wings very broadly half-ovate, much larger than the keel: pod veiny. S. Amer.

F. TRACT HUBBARD.

TIPULARIA (Latin, Tipula, a genus of insects, alluding to the form of the flower). Showy unarmed trees, used ornamentally in the extreme southern U. S. Lvs. unevenly pinnately compound, without stipels; lfts. several, alternate; stipules minute, caducous; fls. showy, yellow or pale purplish, in loosely branched terminal panicles; calyx tuberous, teeth short and broad; standard ovate or suborbicular, not appendaged; wings obliquely obovate or oblong; keel-petals obliquely oblong, obtuse, lightly connate; stamens all connate in a sheath which is split above: pod stipitate, indehiscent, 1-3-seeded, samara-like.—About 4 species, S. Amer. Here belongs the plant recently intro. to S. Calif. as Macherium Tipu, which is said to yield one of the rosewoods of S. Brazil.

speciosa, Benth. (Machærium Tipu, Benth.). Tender yellow-fl. tree: lts. 11-21, oblong, emarginate or entire, ¼ in. long; veins somewhat parallel: standard broadly orbicular; wings very broadly half-ovate, much larger than the keel: pod veiny. S. Amer.

F. TRACT HUBBARD.
petals similar, spreading; labellum 3-lobed, produced into a long spur behind; column erect, wingless or narrowly winged.—Two species, one Himalayan.

TITONIA (of mythological derivation; Tithonos was the favorite of Aurora). Compositae. Robust half-hardy annuals sometimes shrubby at base; ifs. alternate, petioled, entire or 3-lobed; heads large, on a long thickened peduncle, heterogamous; ray-fls. neuter, disk-fls. perfect and fertile; involucre hemispherical or broadly campanulate; receptacle convex; corolla yellow, ray-fls. ligulate, disk-fls. tubular, 5-toothed; achenes somewhat pilose.—About 10 species, Mex., Cent. Amer., and W. Indies.

diversifolia, Gray (Mirabilis diversifolia, HemsL.). Large shrub with rather stout branches, glabrous or nearly so; ifs. petioled, membranaceous, glabrous or puberulent, ovate or almost orbicular, entire or 3-5-lobed, 9x6 in., rarely 6x4 in. wide; heads orange, up to 6 in. diam., terminal or lateral, usually in 3’s, on short thickened peduncles; achenes club-shaped. S. Mex. and Guatemala.

TOCÓCA (tooco is the native name of T. guianensis). Including Sphärogynae. Melastomaceae. Glabrous or hirsut-pilose shrubs, sometimes beardedit with setae at the axis, grown in the greenhouse for their foliage.

Leaves petioled, large, membranaceous, rarely coriaceous, entire or dentate, 5-nerved; ifs. rather large, arranged in terminal and sometimes also lateral panicles, white or rose; calyx glabrous, pilose or hirsute, tube campanulate, terete or ribbed, limb obtusely 5-lobed: petals 5-6, oblong or obovate; stamens 10-12; ovary 3-5-celled; berry fleshy; seed obovoid or pyramidal.—About 50 species, natives of Brazil, N. Venezuela, and Guiana.

Tooco requires a warm house temperature, with sharp and fairly moist places. Use leaf-mold mixed with fibrous loam, and provide ample drainage. It is best propagated from what are called split joints, or eyes with the leaf rolled up, and inserted in thumb-pots in fine sand with chopped moss; then insert pot in sand or cocoa fiber, with bottom heat of 75° to 80°. Cover with bell-glass or other inclosure to exclude air and to keep a fairly moist (but not wet) condition. In about two months the cuttings will have rooted. The wood for propagating should be well ripened. (H. A. Siebrecht.)

imperialis, Nichols. (Sphärogynae imperialis, Laut.). St. short, erect, or little branched, somewhat shrubby, oppositely, decussate, oval, with 5 longitudinal ribs running from base to apex and many parallel transverse veins connecting them. Peru. T.I. 24:284.—Native of Peru, and intro. to Eu. by Linden in 1871. It is said to be easily grown in a greenhouse.

platyphyllya, BentH. (Sphärogynae latifolia, Naud.). Short-stemmed plant with succulent somewhat tortuous st.: ifs. broadly ovate, minutely denticate-ciliate, 7-nerved: ifs. rosé or red; ovary 3-loculed. Colombia, Venezuela, Costa Rica.—Cogniaux puts this species in the same section characterized by having the ifs. destitute of vesicles and the calyx not winged. In this section it is unique by reason of its herbaceous branches with long bristles, especially at the nodes; the other species of the section have shrubby and glabrous branches. A very beautiful plant, but considered to be difficult to grow. Wilhelm Miller.

TODDÁLIA (Kaká Toddálii, Malabar name of T. acutalea). Rutáceae. Shrubs usually somewhat climbing or arborescent, unarmed or prickly, adapted to the warm and parched canyons of the desert S. Lvs. alternate, 3-lobate; ifs. sessile, lanceolate, leathery, entire or 3-lobed; petals 5-6, imbricate or valvate; male ifs., stamens 2, 4, 5, or 8, ovary rudimentary; female ifs. ovary ovoid, oblong or globose, 2-7-lobed: fr. pea-like, hard, coriaceous, globose, permanently syncarpous.—About 20 species (including Vepris), natives to the Old-World tropics and the Cape. In Toddalia proper the petals are valvate, and the stamens as many as the petals; in the subgenus Vepris the petals are imbricate and the stamens twice as many as the petals.

lanceolata, Lam. (Vepris lanceolata, A. Juss.). Small tree or large shrub, erect, without prickles, entirely glabrous: petals 1-2 in. long; ifs. oblong-lanceolate, 2-3 in. long, acute, entire, waved at the edge, ½-1 in. broad: panicles axillary and terminal, thyrsoid: petals a line long, imbricate; stamens 8, in the male ifs. exserted: fr. of a pea, globose, fleshy, gland dotted. Mauritius, Mozambique, Cape.—Intro. by Reasoner Bros., 1891.

TODÉA (H. J. Tode, a German botanist, 1733–1797). Osmodendraceae. Grape Fern. A group of ferns with fleshy sporangia, as in Osmunda, but having these borne on the backs of ordinary ifs. The last three species, although frequently united with Todéa, more properly form a distinct genus Leptopteris, differing widely in habit from the original Todéa; they form delicate foliage plants resembling the filmy ferns in habit. For cult., see Ferns.

A. Texture leathery: ifs. bipinnate.

bárbara, Moore (T. africana, Willd.). St. short, erect: ifs. in a crown, 3-4 ft. long, 9-12 in. wide; pinnae erect, spreading, sometimes 2 in. wide: sori closely placed, often covering the whole under surface at maturity. S. Afr. to New Zel. G. 37:265.—A very resistant and useful fern. It deserves wider cult.

AA. Texture thin: ifs. with linear divisions.

b. Ips. bipinnatifid.

hymenophylloides, Rich. & Less. (T. pellácia, Hook.). Lvs. 1-2 ft. long, 8-12 in. wide, lowest pinnae about as long as the others: rachis densely covered. New Zel.

supérba, Col. St. erect, woody: ifs. 2-4 ft. long, pinnae often crisped, the lower gradually reduced; rachis densely tomentose. New Zel.

bb. Lvs. bipinnate.

Fraseri, Hook & Grev. St. erect, woody, 18-24 in. high: ifs. 1-2 ft. long, lowest pinna nearly as large as the others; rachis narrowly winged, naked. Austral.

L. M. Underwood.

TOFIÉLDA (named after Tofield, a Yorkshire botanist). Liliaceae. Perennial herbs, mostly hardy; six or more from a short or repent rhizome: ifs. radical or clustered at the base of the st., short-linear, somewhat distichous; caluline ifs. few or none: frs. small, in a terminal spike, subseccisile or short-apedicellate; perianth persistent, segms. oblong or narrow; stamens 6; ovary sessile; caps. 3-lobed.—About 25 species, mostly north temperate and boreal regions but 1 or 2 in the Andes. T. racemosa, BSP. (T. pabens, Michx. Tridántia race­mosa, Small). Sts. slender, 1-2 ft. high, minute glandular; ifs. narrow-linear, 6-12 in. long; perianth rigid, whitish, 2 lines long. Pine barrens, N. J. to Fla. and Ala. B.M. 3859. Of no special horticultural value.
CXII. A good type of commercial tomato.—Brinton Best.
TOLMIA (named for Dr. Tolmie, surgeon of Hudson Bay Co.). Saxifragaceae. Herbaceous, glandular pubescent, hardy; rhizome scaly; stts. simple; calcareous lvs. alternate, radical petioled, cordate-incipient-lorate; stipules, membranaceous; racemes terminal, slender, simple; fls. rather seccund, nodding, green; calyx-tube elongate, funneliform-campanulate; 5-lobe; petals 5, capillary; stamens 3; ovary narrowly oblong, 1-celled; caps. exserted from the calyx, superior, 2-valved, 2-beaked.—One species. Borders and wild-garden.

MÉNISÉSI, T. & Gray (Leptáxia Méniési, Raf.). Perennial herb, 1-2 ft. high, with slender creeping root-stocks and some summer runners; lvs. round-cordate, more or less lobed and crenately toothed, slender-stalked, all alternate, those of the st. 2-4 in number; raceme 8-10 in. long; fls. and caps. nearly 1/2 in. long, greenish or tinged purple. Forests of Mendocino Co., Calif. to Puget Sound.—Prop. naturally by adventitious buds, produced at the apex of the petioles of the radical lvs. and rooting when these fall to the ground.

WILHELM MILLER.

TÔLPI (name unexplained). Compositae. Herbs, annual and perennial, allied to Crepis, with showy yellow heads, suitable for the flower-garden or for borders, but apparently not offered in this country; species about 15, in the Medit. region, and the Canaries and Azores. St. rarely somewhat woody; lvs. mostly radical or on lower part of st., entire, dentate or pinnatifid, the upper ones few and narrow. Heads homogamous; ligulate, the involucre campanulate with narrow bracts in several series; receptacle naked or pitted: achene subterete, 6-8-ribbed, the pappus of 8-10 very slender capillary; stamens 3; ovary narrowly oblong, 1-celled: blooms from midsummer till frost. B.M. 95.

TOLUÍFERA: Myroxylon. The following species now planted as a shade tree in S. Fla. was mentioned under Myroxylon. M. Pereirea, Klotzsch (Toluífera Pereirez, Basil.). Tree: lvs. uneven-pinnate; lfts. 6-9, from 2-3 in. long, 14-16 lines broad, oblong, glabrous, petiole 1-2 1/2 in. long, terete and sparingly puberulent: pod 2 1/2-3 in. long. Cent. Amer.

TOMATO. The plant Lycopersicum esculentum (which see, page 1931, Vol. IV), grown extensively for its edible fruit.

The tomato is probably grown more extensively in North America than elsewhere, and the varieties have reached a high degree of perfection. The American standard or ideal is a tomato that is nearly globular, solid and “smooth” (that is, not wrinkled). (Fig. 3818.)

The flat angled and wrinkled tomatoes (Fig. 3819) are now little grown in this country. These forms are little adapted to canning, in which use enormous quantities of tomatoes are employed, and they do not satisfy the popular desire. The old-time pear, cherry, and plum forms (Fig. 3820) are still grown for curiosity and also for the making of pickles and preserves, but their field culture is relatively not important. The currant tomato, grown for ornament and curiosity, is considered to be Lycopersicum pimpinellifolium. It sometimes hybridizes with the common species (Figs. 2234, 2235, Vol. IV).

The tomato requires a warm soil and climate, a sunny open position, and also a long season. The plants are usually started in hotbeds or glass houses, being transferred to the open as soon as settled weather comes. They are usually set from 4 to 5 feet apart each way and are allowed to grow as they will, finally covering the ground. For the same use, however, the plants are often trained, in order to forward their ripening and to secure larger and better-colored fruits. The best method is to train to a single stem supported by a stake or perpendicular wire or cord (Fig. 3821); or sometimes it is tied to the horizontal strands of a trellis. This single-stem training requires close attention, and if the time cannot be spared for it, the vines may be allowed to lie on an inclined trellis or rack. This rack training keeps the plants from the ground and thereby allows the individual fruits to develop perfectly and also checks the spread of the fruit-rot; but it usually does not give such perfect fruits as the single-stem training, since the number of fruits is limited in the latter. Sometimes a serious difficulty in tomato-growing is a rot of the fruit. This seems to cause most damage following close wet weather when the fruit is ripening. It is thought to be worst on plants that cover the ground thickly with foliage and do not allow it to become dry on the surface. Usually it does not seriously lessen the crop beyond a few pickings; and if the plants are brought into bearing early and are kept in thrifty condition for subsequent bearing, the percentage of total injury is greatly reduced. The tomato is tender to frost. The green fruit remaining when frost kills the plants may be ripened in tight drawers or cupboards, if it is nearly or quite full grown. The tomato is a short-lived perennial, but in cold climates it is grown from seeds as an annual. It may be propagated from cuttings.

L. H. B.

General culture of the tomato.

The tomato plant comes from regions in South America where the conditions of temperature and moisture in its growing season are very constantly favorable for its rapid growth and the ripening of a large yield of fruit. Although it cannot be classed as a tropical and hardly as a semi-tropical plant, it thrives best in a day temperature of 65° to 85° F., makes very slow growth in one below 40° F., and, unless hardend by gradual exposure, will be killed by a short exposure to a temperature of 32°. It is a rapid-growing, short-lived plant and under favorable conditions will mature its first fruit in ninety to one hundred and twenty days from the sowing of the seed and continue in bearing for fifty to ninety days, when it will generally die of exhaustion, though its life may be prolonged (with lessened vigor) either by cuttings or layering. It is emphatically a sun-loving plant and unobstructed sunlight is essential for its most vigorous growth and greatest fruitfulness. An attempt to grow tomatoes of superior or even good quality in an orchard or at a season when the sunlight is likely to be dimmed much of the time by clouds or mists is very likely to be disappointing.

The splendid color often seen in Italian-grown fruits is due to cloudless skies rather than to superior varieties or cultural methods. Under favorable conditions the plant is a vigorous and rapid grower and capable of maturing an enormous crop of fruit, but it requires for even a fair yield very constantly favorable conditions, and any check in its growth from cold or cloudy weather or too deep and harsh cultivation, even if the plant seems fully to recover, will surely materially lessen, the yield of fruit. Many cases have been seen in which cultures within a few miles of each other and on similar soil have matured crops differing greatly in quantity and quality as a result of such difference in cultural practice as to bring one crop into the fruiting-stage in better condition, or at a time when the weather was matured for the fruiting stage of fruit. The plant, however, is very tenacious of life and will often live and produce some fruit under most unfavorable conditions and many who have grown it for years do not know of the amount of fruit a healthy tomato plant is capable of producing. It is doubtful whether the average yield of all the cultures in the United States exceeds 6,000 pounds of marketable fruit to the acre. Yet every
season for the past fifty years many fields have been known where the salable crop was from 30,000 to 40,000 pounds to the acre, with exceptional still larger yields.

Exposure is often an important factor in determining the profit of a crop. Generally a gentle inclination to the southward, with protection of higher land or forest on the side from which cold and damp winds may be expected will give the largest yield of the most marketable fruit, but a sharp inclination to the south, particularly if it be steep or such as to form a hot pocket, rarely produces a maximum crop, although, because of the early ripening of the fruit, it may be a profitable one.

The largest yields recorded were generally grown on red clay loam. Large yields are often secured from soils of very different compositions, from “gumbo” prairie, marsh muck, stiff clay, to a light sand provided the conditions of drainage, fertility, and tilth are favorable, but a maximum crop can never and even a profitable one very seldom be grown on a cold soil, or one which is poorly drained, sodden, sour, or hard and solid from want of cultivation. A good crop of tomatoes very seldom follows one of potatoes or tomatoes.

Tomatoes are rank feeders and the use of fresh stable manures and those carrying a large proportion of nitrogen is likely to result in a rank growth. Tomatoes ripen a small crop of fruit of poor quality. The best yields and quality of fruit will usually be from fields rich from fertilizing in previous years. On unfertile fields where one is obliged to use commercial fertilizers, those comparatively rich in potash will generally prove most profitable. The largest yield and best fruit have generally been from rich clover sods, which were plowed as early as practicable in the spring, rolled, and made friable by repeated surface cultivation.

Although in all but the extreme northern part of the United States, in very high altitudes and in some parts of the Puget Sound country, tomatoes will generally ripen a full crop from seed sown in the open ground, from Washington northward plants so grown will rarely ripen their crop until past midsummer and much of it will miss the long days of sunshine, which are essential for the development of the best quality. On this account it is desirable, in most cases, to start the plants under glass, so as to give them fifty to sixty days’ growth by the time they can be set in the open ground without danger from killing frosts. It is very easy to grow plants to this age, but the character of the growth and the condition in which they go into the fields are most important factors in determining the quantity and quality of the fruit.

Starting the plants under glass is usually accomplished best by sowing the seed in boxes about 4 inches deep and of convenient size for handling, filled with soil made up of two-fifths well-rotted cow-manure, one-fifth old well-rotted cow-manure, and one-fifth coarse sharp-grained sand. Soils used in plant-boxes or beds should always be sterilized by spreading over steam-pipes perforated on the lower side sand by steam until a potato buried about 3 inches in the soil is cooked soft. The seed can be sown rather thickly and covered 1/4 to 1/2 inch deep. The boxes should be well watered and set in the shade until the plants show above the soil, when they should be set in full sunlight and kept at a constant temperature between 65° and 80°, and given water as needed. The plants should develop large seed-leaves and bud within ten to fifteen days, when they should be transplanted into the frames. The soil of the frames should be 3 to 6 inches deep and freshly made up and sterilized as recommended for the plant-boxes. The plants may be set twelve to twenty-four to the square foot, according to the time they are expected to remain before setting in the field. The beds should be closely watched and the sash opened as the air in them becomes warmed by the sun to a temperature above 60° and as promptly closed as it cools below 40°. The plants should be watered as necessary to prevent the plants wilting, but this should be done as far as practical in evening or early morning, rather than during bright sunshine. If necessary the beds may be protected by covering with plants, by covering the sash with sacks, old carpets, straw, or even a sprinkling of earth. An inexperienced person will be surprised to see how effective even a slight covering often is. In case frost does come in, it is best to keep the beds covered until they can warm up without direct sunshine, even if this takes a day or two. Cases have been known in which plants that seemed to be killed were saved by a veil of paper warming up. For a few days before the plants are to be set in field, they should be hardened off by scant watering and fuller exposure both to the sun and night air, and the day before they are to be set should be thoroughly sprayed with bordeaux mixture. The field, particularly if it has been a clover sod, should be prepared and cut two weeks killed by keeping it absolutely free of green vegetation for at least a week before the plants are to be set and the evening before scattering over the surface poisoned bait made by thoroughly mixing one pound of paris green or similar poison with fifty pounds of bran or middlings moistened with sweetened water. The evening after the plants are set, the poison should also be scattered along the rows. Next day the plants should be again sprayed with bordeaux.

Field culture should begin the day after the plants are set and be repeated every four or five days and as soon after every rain as it can be done without puddling the soil. At first the culture should be as close to the plants and as deep as possible, but it should be farther from the plants and shallower each time until it is a mere stirring of the surface in the center of the row, always taking care to disturb the vines as little as possible. The plants should frequently be looked over.
carefully for potato bugs, the most effective way of combating them being by hand-picking the beetles and eggs when they first appear.

When quality and quantity of fruit is second to early ripening, the seed may be sown earlier and the growth of the plants checked by crowding and a scarcity of water; so treated they generally will form a crown cluster of well-developed fruit by the time one dares risk them in the open. They are then set close in the row and rather deep, with the stem and root slanting to the south and will ripen the first cluster very early, although the remainder of the crop will be late and poor.

When quality rather than quantity of fruit is of first importance, staking and pruning is sometimes advantageous, especially if the soil is inclined to be wet. With many growers stakes 2 inches square and 5 to 6 feet long have given the best satisfaction. As soon as the tomato plant forms its first cluster of bloom it divides, and both branches are allowed to grow and then tied to the stakes while all other branches are cut off just beyond the first cluster of blossoms; during the early part of the season this will require daily attention. Staking has been found profitable and is very generally practised in the southern states.

Even when first discovered by Europeans, the plant or plants now commonly called tomatoes existed in many forms differing so materially in habit of plant and character of foliage and fruit that they were classed by botanists as distinct species, and the number of varieties offered has increased with frequent changes until American seedsmen have catalogued tomatoes under at least 513 distinct names, while many other more or less distinct forms are commonly grown abroad, particularly in Italy.

The following are some of the names used in seedsmen's catalogues, many of them standing for distinct forms of vine or fruit, while others are simply variations in stocks.

- **Currant or Grape.**—Bank-growing, but slender small-leaved vine, very productive of long currant-like stems of bright red fruits not over ½ inch in diameter, of little culinary value.
- **Red and Yellow.**—Strong-growing, very productive of cherry-shaped fruits, which are excellent for pickles and preserving.
- **Pear, both Red and Yellow.**—Strong-growing vine, small, long-necked, pear-shaped, two-celled fruits.
- **Plum, both Red and Yellow.**—Long oval-shaped, 2-celled fruits, which are excellent for preserving.
- **Turk's Turban.**—Long oval, bright red fruit, with a peculiar growth on the blossom end.
- **Potato or Broad-leaved (in a number of variations).**—Comparatively small vine, with broad entire leaves.
- **Dwarf Champion.**—Vine very short, compact, leaves thick, crumpled, nearly entire.
- **Peach, both Red and Yellow.**—Fruits covered with down similar to the currant or grape plant.
- **Diodem.**—Fruit bright red, distinctly striped with yellow.
- **White Apple.**—Round smooth whitefleshed fruit of delicate flavor and the best of all varieties for eating from the hand.
- **Golden Queen.**—Fruit bright yellow, often with a distinct red blush.

Each of the above is so distinct in habit of plant foliage or fruit that botanists might perhaps classify them as distinct species, while the following are some of the more distinct of the varietal forms listed by seedsmen under different names.

- **Eratoma.**—Comparatively small weak-growing vine, but maturing very early a large crop of smooth bright red fruit.
- **Bony Burt.**—Vigorous vine, ripening very early and evenly a large crop of uniformly round bright red fruit.
- **Markette.**—Large smooth bright red fruit, with red fine-flavored but not very solid flesh.
Growing of tomatoes in the South.

The growing of tomatoes on a commercial scale in the southern states began just prior to 1900 and has gradually increased until it is now one of the most important crops grown in that section. Especially is this true of Florida, Mississippi, and Texas.

The crop in Florida begins to move in December and continues at intervals during the winter months. The movement in Mississippi and Texas is more concentrated, beginning the latter part of May and closing the last of June. During the height of the tomato season, solid trainloads of tomatoes are shipped out of the two last-named states daily.

In growing the tomato for the northern markets, earliness is of prime importance. For this purpose, the soil of the south should be loose and porous, but not too rich. Especially should an excessive amount of organic matter be avoided. A good average soil, with 1 inch of leaf-mold added gives good results.

The seeds are sown about January 20. They are placed in rows 4 inches apart, ½ inch deep, and from three to four seeds to the inch. Under normal conditions, the seed should begin germinating in six to eight days. The temperature should not be allowed to go over 80°F, during the day, or below 65°F at night. The heat should be so regulated as to produce a slow, steady growth. Too much heat produces rapid, succulent growth, often causing the plants to become weak and spindling, which conclusions are easily affected by adverse weather and more subject to the attacks of diseases.

As soon as the young plants begin to grow, plenty of ventilation should be given and the soil frequently stirred. The soil should be kept moist, but not wet. By the last week in February, the plants begin to crowd in the row, at which time they should be moved to the coldframe.

The coldframe is usually located in the field where the crop is to be grown. The soil in the coldframe should be richer and should contain more organic matter than that in the hotbed. The rows are laid off about 3 to 4 inches apart, and the plants set 4 inches apart in the row. A board with wooden pegs set 4 inches apart may be used to advantage in opening the holes for the plants. It is advisable to set the plants deeper than they stood in the hotbed, and, as soon as transplanted, they should be given a good watering. Special pains should be taken to protect them from sudden changes in temperature. At first they should be carefully covered at night; and if the weather is very threatening, an extra cover, such as cotton bagging, Sudan grass mats, and the like, should be used. Whenever the weather is clear and bright, the top should be lifted during the warm part of the day.

During the latter part of March, when the nights are warm, the cover may be left off entirely, so as gradually to harden the plants. By the first of April, the tomatoes begin to crowd in the row, which is a good indication that they are ready for moving to the open field.

Tomatoes for the early market should be planted on well-drained elevated land, that has some form of protection for the first six weeks or two months of its growth. This necessarily means extra care and expense, which, in turn, means that the grower, in order to succeed, must exercise a higher degree of intelligence than is shown in the production of the average vegetable crop. It has been clearly demonstrated that it does not pay to grow tomatoes on a large scale, nor does it pay to grow them when most of the help has to be hired. The best results are obtained when a single family through its own labor and expense, which, in turn, means that the grower, in order to succeed, must exercise a higher degree of intelligence than is shown in the production of the average vegetable crop. The labor should be well broken with a turning plow, then disked, harrowed, and laid off in 4-foot rows. A furrow should be run down each row and fertilizer applied and mixed in with the soil. Just before taking the plants from the coldframe, the soil should be given a thorough wetting. Then one end of the coldframe should be knocked out and the soil should be removed to a depth of 2 inches, up to within a few inches of the first row of plants. A sharp spade or mason's trowel is then used and a 4-inch square is cut around each plant, after which the block of soil containing the tomato is carefully lifted and placed in a flat box or on a wide board, which is then
set in a wagon. The wagon should be made to straddle one row and the plants lifted out from the rear and placed from 2 to 3 feet apart in the three adjoining rows. Special pains should be taken when the plants are placed in the furrow to prevent the soil from breaking away from the roots, as they will wilt easily at this stage. Moist soil should be driven by hand and pressed around each plant. A sweep or small turning plow should then be run around each row so as to fill in the remainder of the furrow.

Tomatoes should receive frequent and thorough cultivation from the time they are set in the open field until the first fruits begin to ripen. A crust should never be allowed to form on the soil, nor should weeds be allowed to grow. A five-tooth cultivator is one of the best implements that can be used in cultivation.

When moved to the open field, the plants are often beginning to show their first cluster of blooms and are also beginning to force out shoots from the axils of the leaves. The plants should be gone over carefully every few days and suckers should be removed before they have grown longer than 1 inch. It is a serious mistake to neglect removing shoots and suckers, even for a few days.

When three or four fruit-clusters have set, the terminal bud is pinched out, and thereafter no new growth whatever should be allowed. This severe pruning undoubtedly reduces the amount of fruit to the acre, but it is a considerable aid in the development of quality and earliness.

The staking, like the pruning, should begin soon after the plants are set in the field. A 4-foot stake, 1 by 2 inches, should be driven down within a few inches of the plant, and coarse twine wrapped around the plant and tied to the stake. Two or three tyings should be made during the development of the plant. The staking holds the vines and fruit off the ground, prevents rott ing of the fruit in wet weather, and allows the sun and air to strike the fruit, thus inducing earliness, while, at the same time, reducing the danger from diseases.

Tomatoes in the southern states north of Florida begin to ripen about the middle of May. As soon as the ripening period arrives, the tomato patch should be gone over every day during the shipping-season. As soon as the fruit shows a deep creamy white color, with a faint blush of pink, it is ready for harvesting. At the first of the season, the fruit may be allowed to take on a deeper color than later on.

Tomatoes are gathered in one-half-bushel baskets, lined with coarse ducking, and carried to the packing-sheds, which are generally located in the field, and then packed in four-basket crates, averaging twenty pounds, or one-third bushel each. As a rule, there are two grades: fancy and choice. The fancy are packed with the stem end down and average about twelve to the basket. The choice are packed on the side and average about fifteen to the basket. The six-basket crate is now becoming popular in some sections.

The bulk of the crop is shipped in refrigerator cars, well iced. It is now becoming the custom, when distant markets are to be reached, to harvest the fruit as soon as it is mature, but while still quite green in color. Each tomato is wrapped with soft paper and packed in flats or six-basket carriers and shipped in refrigerator cars, with the ventilators open, but without ice. This is known as the "green-wrapped" pack. It requires 896 four-basket crates to fill a car. A fair average yield is 250 boxes to the acre, although a few growers sometimes produce as high as 600. A good average price for a season is 60 cents a crate.

A medium to large tomato, one that is smooth and does not crack easily, is the best for early shipping. The Acme has been the leading variety for many years, while the Earlana, Stone, and Beauty, are grown on a small scale in some sections.

3823. A prolific tomato, the result of training to a single stem.

There is no standard fertilizer for tomatoes. Tomato soils of Texas are relatively rich in potash; so, as a rule, it is not necessary to use more than 1 per cent of this ingredient. Most of the Texas growers use a fertilizer containing from 8 to 10 per cent of phosphoric acid, 2 per cent of nitrogen, and 1 per cent of potash. A fertilizer containing from 400 to 600 pounds of equal parts of acid phosphate and cottonseed meal to the acre gives very satisfactory results. In the states east of the Mississippi River, the amount of potash is considerably increased; the total amount of fertilizer used to the acre is also considerably greater. From 800 to 1,000 pounds of fertilizer to the acre, containing 6 per cent phosphoric acid, 7 per cent potash, and 3 per cent of nitrogen, seems to be satisfactory. Fifteen or twenty loads of manure to the acre, applied broadcast, two or three months in advance of planting the crop, will always give good results.

The damping-off fungi often attacks the young plants while they are in the hotbed. These fungi work on the stem of the plant, just where it enters the soil, causing it to shrivel and the top to fall over. Wet soil and a damp sultry atmosphere are conditions that favor the development of this disease. Frequent stirring of the soil and thorough ventilation will go a long way toward preventing the appearance of this trouble. A thin coating of tobacco dust or a mixture of three parts of lime to one of sulfur, spread over the soil after the seed is planted, will also help to hold the disease in check.

The blossom-end rot is a very destructive disease. It makes its appearance when the fruit first begins to ripen, thereby destroying the earliest and most profita-
Tomato-growing under glass.

The tomato ranks next to the cucumber and egg as a vegetable forcing crop. It is grown extensively under glass near all of the large cities of the North from the Mississippi River to the Atlantic coast. In some instances houses are devoted wholly to tomatoes, while in the larger number of cases other crops are grown in rotation with tomatoes. A very common practice is to use the same glass and the same fruit as before before the fruit is full grown, there is danger in using any poison as a spray.

E. J. Kyle.

Tomato-wilt sometimes causes considerable damage. This is a large green worm that enters the fruit near the stem-end. As soon as the fruit is infested, it is entirely worthless and should be removed and fed to hogs or destroyed. The boll-worm can be partially controlled by spraying with arsenate of lead; but, as it seldom makes its appearance before the fruit is full grown, there is danger in using any poison as a spray.

Tomato-wilt is a microscopic worm which attacks the roots of a tomato plant and causes small bead-like knots to form. Ground infested with this pest should be avoided and whenever there is danger of infestation, cowspeas should not be planted on the preceding tomatoes, as most varieties of peas encourage the development of the nematode.

The boll-worm sometimes causes considerable damage. This is a large green worm that enters the fruit near the stem-end. As soon as the fruit is infested, it is entirely worthless and should be removed and fed to hogs or destroyed. The boll-worm can be partially controlled by spraying with arsenate of lead; but, as it seldom makes its appearance before the fruit is full grown, there is danger in using any poison as a spray.

E. J. Kyle.

The nematode is a microscopic worm which attacks the roots of a tomato plant and causes small bead-like knots to form. Ground infested with this pest should be avoided and whenever there is danger of infestation, cowspeas should not be planted on the preceding tomatoes, as most varieties of peas encourage the development of the nematode.

In the starting of tomato plants for forcing, there should be uninterrupted growth from germination until the plants have attained full size in the beds. It is customary to sow the seed for the full crop soon after June 30, and for the spring crop from January 15 to February 1. If a very early spring crop is wanted, the seed should be sown January 1 or even earlier. The seedlings may be planted in beds or flats at the first transplanting and the second shift should be made to pots large enough to care for the plants without crowding. A third shift to 4- to 6-inch pots is often made, and with good management this should result in very fine plants.

Most of the large commercial growers employ solid beds. Raised benches are used in some sections, especially when carnations precede the tomatoes. Solid beds require no expense for construction and maintenance and it is less difficult to maintain uniform soil-moisture conditions. It is an advantage when bottom heat is desired and this should be considered if the crop is to be grown at midwinter. If lettuce is grown until the tomatoes are planted early in the spring, solid beds will be found entirely satisfactory. Large pots are used inside the houses, but they are not practicable on a large commercial scale.

Some persons have an idea that the tomato does well in poor soils. This is an erroneous impression, for high yields are obtained only in rich soils. It is true that the proportion of plant-food must be well balanced. An excess of nitrogen, with copious watering and high temperatures, causes a rank growth of plants and a low yield. But the soil must be well provided with the mineral elements and enough moisture must meet the needs of the plant. If lettuce is grown until March, and enough manure employed to obtain good crops, the soil should be in ideal condition for tomatoes. It must be borne in mind that the greenhouse soil is a kind of manufactured soil, and it is important to give special attention to the supply of fiber or organic matter. The productivity of greenhouse soils, whatever the crop may be, depends more on their physical properties than on their chemical composition. Stable manure, used in ample quantity for lettuce, will make the best preparation for tomatoes and no additional manure will be needed to applied to the tomatoes, except as a mulch. Special fertilizers have not been found necessary, and seldom are an advantage, when stable manure has been used in sufficient amount to keep the soil in proper physical condition. While sandy loams are preferable for growing tomatoes under glass, any of the common soils, clays included, will give good results when properly handled.

There is the greatest diversity of practice among growers concerning planting distances. Some prefer to plant close together in rows with liberal spacing between rows. For example, a highly successful gardener sets the plants 14 inches apart in rows 30 inches apart. Some plant 2 feet apart each way with alleys at convenient distances. In large commercial houses, liberal spacing between rows is a great advantage in training the plants, pollinating the flowers, and picking the fruit.

It is possible to do a little intercropping between the tomato plants. Lettuce and radishes are sometimes grown between the rows, by starting the crops immediately after the tomato plants have been set. The practice is only fairly satisfactory because the tomato plants shade the lettuce and radishes so that the latter crops are seldom very good.

While tomato plants may be trained to two or more stems, the almost universal practice under glass is to grow single stems. (Figs. 3822, 3823.) This is easily accomplished by removing with thumb and finger all lateral branches as fast as they appear. The stems may be supported in any convenient way. Small strings, are usually employed. A common practice is to use fairly heavy string or twine for the uprights which are tied to wires running lengthwise in the house.

Tomatoes under glass may be tilled, if it is preferred, but the better practice is to mulch the ground.
with 3 or 4 inches of fresh horse-manure which has been steamed in thin layers a few days before being applied. The mulch should be applied after most of the fruit has been set. If applied too soon, an excessive vine growth and sparse setting of fruit may result. A mulch of manure keeps the soil in a loose and friable condition; it conserves moisture more perfectly than the most thorough tillage; it furnishes plant-food every time water is applied; it prevents weed growth and saves labor in rendering tillage unnecessary.

The temperature of the house at night should not fall below 60°. From 10° to 15° higher during the day will provide excellent growing conditions. If there is bright sunshine and the ventilators are open, there need be no fear if the temperature should rise to 100°. Some fresh air should be admitted every day, but good judgment should be exercised in ventilating the houses. Excessive watering must be avoided. High temperatures, over-watering, and poor ventilation are responsible for many failures.

Some attention must be given to the pollination of the flowers. Various methods are followed. Some careful growers use a little camel's-hair brush on each flower that is likely to contain ripe pollen-grains, and the grains of pollen are thus carried from flower to flower just as bees and other insects might perform this work out-of-doors. Jarring the plants daily is usually sufficient to get a good set of the spring and early summer crops. Whatever the method employed, the work should be done, if possible, when there is bright sunshine and the atmosphere of the house is as dry as possible.

Greenhouse tomatoes have certain enemies which must be controlled if a satisfactory crop of fruit is desired. Steam sterilization of the soil previous to setting the plants is practicable in most large greenhouses. This is by far the most effective means of destroying the nematodes which cause an abnormal development of the roots and interfere with the nutrition of the plants. Steam sterilization also helps to prevent some of the diseases to which the tomato is subject. Blight, mold, and the cedema are among the most serious diseases. Frequent and thorough application of bordeaux mixture is valuable in controlling various diseases. The white-fly is the most destructive insect pest. It may be controlled by fumigating with hydrocyanic gas.

Some of the most successful growers are able to obtain yields of ten pounds to the plant for the spring crop. This, however, is considerably above the average when the entire country is taken into account. Six pounds to the plant, for the spring crop, and four pounds to the winter crop is considered satisfactory. An average of 10 cents a pound for the spring crop makes it a profitable undertaking, and 30 cents a pound is not too much for the winter crop.

The greenhouse tomato should be of the highest quality and special care should be exercised in marketing it. Small packages holding about five pounds are preferable. The tomatoes should be clean and wrapped in paper bearing the name of the grower. The grower should be able to guarantee every specimen which is packed in the number 1 grade.

R. L. Watts.

TOMMASINIA: Angelica. The following species, in the lists under Tommasinia, should be entered with Angelica in Vol. 1, p. 287. Angelica verticillaris, Linn. (Tommasinia verticillaris, Berton). Peucedanum verticillare, (Koch). Advertised in this country as a lawn plant. It is a hardy perennial, about 1 ft. tall, with many small yellow-green fls.: lvs. 3-parallel, the lfts. ovate, acute-serrate and the lateral ones often 2-lobed and the terminal one 3-lobed, the petiole much dilated at base. Piedmont region, S. Eu.

TORENIA (named for Olaf Toren, clergyman; traveled in China 1750-1752 and discovered T. asiatica). Scrophulariaceae. Glabrous, pubescent or hisrate annual or perennial herbs, mostly low, branching and somewhat decumbent, grown sometimes in the greenhouse for winter bloom, but mostly grown as garden annuals.

Leaves opposite, entire, crenate or serrate: racemes short, few-fl., terminal or false-axillary: calyx tubular, plicate or 3-5-winged, apex obliquely 3-5-toothed or 2-lobed; corolla-tube cylindrical above, 2-lipped; stamens 4, perfect, in pairs of unequal length: caps. oblong.—About 33 species, Trop. and E. extra-Trop. Asia and Trop. Afr.

Torenias are of easy cultivation and are very useful in the window-boxes and borders, or even for large masses. The flowers are not large but the plants are floriferous and keep in good leaf and flowers from spring to frost. T. Fournierii has the best habit for a bedding plant, but it may be bordered with P. flava. They are easily raised from seed, sown indoors or in the open, but may also be grown from cuttings.

In Florida T. Fournierii is an excellent substitute for the pansy, which is cultivated only with difficulty so far south. Young plants come up by the hundreds around the old plants from self-sown seed during the rainy season. The species can also be propagated with great ease by cuttings. The torenia shows its full beauty when planted in beds or borders or in masses in front of small evergreen shrubs. It flowers abundantly throughout the summer, and even late in fall isolated flowers may be found.

The best results are obtained by treating it as an annual. Any good and rich light soil seems to meet its requirements. It succeeds almost everywhere but prefers shade and moisture. It even grows luxuriantly in wet places along ditches and water-courses where forget-me-nots grow in the North. If such localities, however, are very shady, the flowers, though much larger, are neither produced so abundantly nor are they colored so brightly as in sunny situations. On the other hand, it is sometimes found in such dry positions, where only cacti and yuccas manage to live, that one can scarcely understand how it is able to succeed. In good soil the torenia attains a height of 8 to 10 inches, and when planted about 8 inches apart soon covers the ground entirely. There is already a great variety in colors, but the typical plant has beautiful light blue and royal purple flowers, with a bright yellow throat, in texture rivaling the most exquisite velvet. (H. Nehrling.)

a. Fls. mainly yellow.

flava, Buch.-Ham. (T. Ballioni, Godefr.). Usually decumbent and creeping: lvs. 1-2 in. long, ovate to oblong, coarsely crenate; petiole half as long as the blade or less; fls. axillary and solitary or scattered at the ends of the branches in pairs on an erect rachis; corolla-

AA. Fls. mainly blue or white.

- b. Lvs. cordate-lanceolate.

**Fournieria**, Lind. (T. eidentula, Hort., not Benth.).

Low, bushy, usually annual, becoming nearly 1 ft. high; st. 4-angled; lvs. petioled, cordate-lanceolate, 1-1 1/2 in. long, crenate-serrate; petiole 6 mm. long; corolla-tube narrow, yellow; corolla-limb 2-lipped, the posterior lip not cut, pale blue, the anterior 3-lobed; lobes round-obtuse, dark purplish blue, the anterior lobe marked with a yellow blotch. I.H. 23:249. R.H. 1876, p. 465.

B.M. 6747. G. 1:58. Var. alba, Hort. (var. White Wings), has pure white fls. A.F. 5:401. G.M. 36:57. Var. compacta, Hort., is a more compact form than the type and rather larger-flld. G.W. 10, p. 610. Var. grandiflora, Hort., has somewhat larger fls. and is more free-flowering. Var. speciosa, Hort., is a showy form offered in the trade, probably very similar to var. grandiflora.

BB. Lvs. ovate or deltoid-ovate.

**asiiatica**, Linn. Fig. 3824. Annual, erect or diffuse; st. quadrangular; lvs. ovate or ovate-lanceolate, long-accuminate, serrate, obtuse, not cordate at the base, rough to the touch; peduncles axillary, single-flld.; corolla large; tube dark purple; limb 4-lobed, of a delicate pale purple-blue, with a dark blotch on 3 of the lobes, without a yellow eye; stamens 4, the 2 longer with a subulate spur. India. B.M. 4240. Var. pulcherrima, Hort., has larger, dark violet-blue fls. with a spot on the upper lip. G.Z. 4:96.

**atropurpurea**, Ridley. Lvs. ovate or ovate-deltoid, 2 1/2-3 x 1 1/4-2 in., short-petioled, serrate: fls. usually solitary on peduncles at the ends of the branches; calyx narrow, wingless; corolla dark purple, 1-1 1/2 in. long, tube narrow at the base, much exserted, and curved above, limb about 1 in. across with 4 rounded lobes. Malay Penins. B.M. 8365.

**Torr. and Hem.**

**T. taxifolia**, Am. (T. edentula, Hort., not Benth.).

Large, free-flowering. Var. speciosa, Hort., is a showy form offered in the trade, probably very similar to var. grandiflora.

**TOWNSENDIA** (David Townsend, botanical associate of Wm. Darlington, of Pennsylvania). *Compositae*. Low many-stemmed herbs, nearly all of which are natives of the Rocky Mountains; sometimes planted.

Leaves linear or spatulate, entire: heads rather large, resembling those of *Aster*; rays in 1 series, from violet to rose-purple or white and blooming from early spring to summer. About 17 species. The annual or biennial species have larger heads than most of the perennials. Judging from the literature, the largest-fld. of the perennials are *T. condensata*, *T. Wilcoxiana*, and *T. Rothrockii*, 3 species which seem not to be in cult. as yet. The species mentioned below are presumably among the most desirable of the genus. They are offered by collectors of Colo. wild flowers. As a genus, Townsendia is distinguished mainly by its achene, which is commonly beset with bristly duplex hairs, having a forked or glochidiate-capitate apex. Townsendia is practically unknown to floriculture. For fuller account, see Gray's *Synoptical Flora of North America* and Coulter and Nelson's *Manual of Rocky Mountain Botany*.

**grandiflora**, Nutt. Biennial or perennial, 9-18 in. high; its spreading from the base, sometimes branching also above; upper lvs. often linear: bracts of involucre conspicuously attenuate-acute and sericeous-margined: heads large; rays ½-2½ in. long, bright blue or violet. Summer. Foothills W. Neb. to Colo. and New Mex.

**exscapa**, Porter. Nearly stemless perennial with sessile heads surrounded and surmounted by the linear lvs.: heads ½-1½ in. across; rays white or purplish-tinted; involucral bracts narrowly lanceolate, mostly acute, not pappus-bristles very setose. April, May. Dry hills, plains, or mountains, Sask. to Rockies, south to New Mex. and Ariz.—Known as "Easter daisy" in Colo.

*T. condensata*, Parry. Very handsome: lvs. spatulate-obovate, crowded around the large, broad, sessile heads: rays 100 or more, narrow. Wyo.—T. Rothrockii, Gray. Lvs. spatulate, radiate around the solitary head which is closely sessile at surface of ground, or at length with 1 or 2 additional heads from same crown. Colo.—*T. Wilcoxiana*, Wood. A small stemless herb; lvs. in rosettes, spatulate-lanceolate, on short scapes. June. Dry plains and hills, Okla. to Colo.

**TOXICODENDRON** (Greek, poison tree): *Hyrcanaceae*. Stout many-stemmed herbs, the typical species tall-climbing, grown in the greenhouse and a favorite out-of-doors in the South.

Leaves opposite, distantly feather-veined; cymes lax, terminal or pseudo-axillary; fls. white; calyx small, 5-parted, with 5-10 scales or glands inside at the base; corolla saucer-shaped, tube cylindrical, 5-lobed, lobes oblong, twisted to the left, overlapping towards the right; disk annulate, truncate or 5-lobed; ovary 2-carpelled; foliodes elongate, slender, terete.—About 10 species, E. Asia and Malay.

**TRACHELOSPERMUM** is a *most satisfactory greenhouse shrub* for a general collection. It requires no special treatment, except that the plants should be kept on the dry side during the winter. It requires several years to work up a good-sized specimen. Young plants should be given greenhouse treatment and encouraged to grow. Large well-established specimens thrive in a coolhouse. In summer the pots may be plunged outdoors in a partially shaded position. The species is propagated by cuttings of half-ripped wood taken with a heel in spring. The *star jasmine* is one of the many good old standard greenhouse plants that are too little seen nowadays. The specimens require considerable room, and the gardener is sometimes compelled to keep them in a cold pit until the chrysanthemum season is over, although this treatment is not to be advised. It is a tender evergreen shrubby climber from China, with fragrant white five-lobed flowers. It is a favorite in the South, where it is grown out-of-doors and known as the "confederate jasmine." In northern conservatories it is generally known under its synonym, Rhynchospermum. Handsome specimens may be grown in large tubs, making dense bushes 3 to 4 feet high and as much in diameter. (Robert Shore.)

**jasminoides**, Linn. (Rhynchospermum jasminoides, Lindl.). *STAR JASMINE*. Also called "Confederate," "Malayan" or "African" jasmine. Fig. 3826. Tender, evergreen, climbing shrub: lvs. short-stalked, ovate-lanceolate, acuminate, glabrous; pedicels much longer than lvs.; calyx-lobes reflexed; corolla-tube contracted

England, but young plants are more floriferous than old ones. Seed may be sown in March. The plant is easily prop. by cuttings. According to Gn. 47, p. 303, plants from cuttings are dwarfer than seedlings.
below the middle; several jagged scales at base of corolla; 5 large glands at base of ovary; 2 united, 3 free.

**TRACHYCARPUS** (Greek, rough or harsh and fruit). *Palmaeae*, tribe *Coriphaeae*. Indoor and outdoor palms, one of which is widely grown and very hardy.

Tall unarmed palms: lvs. suborbicular or reniform, folded, many-cut; segms. narrow; rachis none: spadices many between the lvs., stout, branched; spathes many, sheathing, coriaceous, tomentose, compressed; bracts minute: fls. small, polygamous; sepal 3, ovate; petals 3, broadly ovate, valvate; ovary 6; carpels 3: drupes 1–3, globose or oblong.—About 4 species, Himalayas, China, and Japan. Monographed by Beccari in Webbia 1:41–72 (1905).

Fortune's palm (*T. excelsa* or *T. Fortunei*) is grown both indoors and out in America wherever palms are grown, although it is not one of the most popular species with northern florists. It is grown throughout California and even as far north as Oregon. It is commonly known by the name of Chinese windmill palm in southern California. There are two types of *trachycarpus*, those which have the trunks covered with old leaf-sheaths—the Himalayan type—and those which have smooth polished trunks—the far-eastern species.

*excelsa*, H. Wendl. (*T. Fortunei*, H. Wendl. *Chamaerops excelsa*, Thumb. *C. Fortunei*, Hook. f.). Fortune's Palm. Fig. 3827. Trunk robust, clothed with old leaf-sheaths: lvs. nearly orbicular; segms. numerous, ensiform: fls. clustered 2–4 on a tubercle: fr. transversely globose-reniform, deeply umbilicate. Upper Burma, China, and Japan; will grow in the open in Ga., withstanding 10° F.—This description follows Beccari, who refers *T. Fortunei* to *t. excelsa*. Hooker in founding *T. Fortunei* (B.M. 5221) speaks of it as a more robust tree than *T. excelsa*. The latter (which is from Japan) is said to have smaller and stiffer lvs., less deeply divided (usually only about midway to stilt segms.), while *T. Fortunei* (China) has lvs. divided much below the middle (as in Fig. 3827), and the segms. more falcate at least in older lvs. This group needs further study botanically, and also horticulturally in this country.

**TRACHYMENE**

**TRACHYMENE** (Greek, rough and pod; the upper surface of the pod is tuberculate—roughened). *Lecynanthus*. Unarmed trees: lvs. with 2 lfts. which are coriaceous; stipules caducous: fls. white, panicked at the ends of the branches; calyx-tube disk-bearing, narrow-turbinate, segms. 4; petals 5, sometimes the 3 upper clawed and suborbicular, the 2 lower minutely scale-like, sometimes all subequal and clawed; stamens 10, free; ovary short-stipitate; pod ovoid-oblong, thick coriaceous, warty-rugose, indehiscent.—Three species, Trop. Afr., Mascarene IsIs., and Trop. Asia. *T. verrucosum*, Oliver (*T. Hornemannium*, Hayne). Tree wholly glabrous excepting the tawny or silky pubescent infn.: lfts. 1-paired, obliquely oblong or elliptical, acuminate or apiculate: panicles overtopping the lvs.: calyx-segms. obvate-elliptical or oblong: petals posterior and lateral subequal, anterior equal or rudimentary: pod 1–2-seeded, oblong or obovoid, 1½–2 in. long. Mozambique and Madagascar. G.W. 51, p. 633. *T. verrucosum* has the anterior petals nearly equal the rest; *T. Hornemannium* has them rudimentary.

**TRACHYMENE** (Greek, rough membrane, alluding to the fr.). *Umbelifera*. Hisrate or rarely glabrous annual or perennial herbs, used as garden annuals; lvs. ternately dissected or rarely undivided; stipules none: umbels simple: fls. white or blue: calyx-teeth minute or obsolete, rarely 1–2, subulate; petals entire, obtuse; disk flat: fr. laterally compressed, usually flat.—About 25 species, mostly Australian but a few from Bornoe, New Caledonia, and Celebes.

*Cardella*, R. Graham (*Didiscus cardella*, DC.). Fig. 3828. An erect annual about 2 ft. high, somewhat
TRACHYMENE

F. W. BARCLAY.

TRADESCÁNTIA (named for John Tradescant, gardener to Charles I; died about 1635). Commelinaeae. Spermatophyta. Perennial hardy herbs, varying greatly in habit from erect and bushy to trailing and rooting at the nodes, grown for their ornamental value both out-of-doors and in the greenhouse.

Stems simple or densely trancched: lvs. various; cymes simple, sometimes umbrellate or densely panicaete; fis. more or less pedicelled, few or numerous, rarely solitary, red, blue, or white; sepals distinct, concave, green or colored; petals distinct, obovate or orbicular; stamens 6, all usually perfect; ovary 3-celled with 2 superposed ovules: capsule loculecidally dehiscent.—About 90 species, all American, ranging from Manitoba to Argentina. The genus was monographed in 1881 by C. B. Clarke (DC. Monogr. Phaner. 5). The genus Zebrina, usually confounded with this by gardeners, differs among other things, in having a tubular perianth.

To horticulturists, tradescantias are known as hardy herbs, coolhouse plants, and greenhouse plants. T. virginiana is the best known of the hardy species, withstanding the climate of the northern states. The wandering Jew of greenhouses and hanging-baskets, usually known as T. tricolor, is partly T. fluminensis and partly Zebrina pendula. T. Regine is perhaps the best known greenhouse species at present, although various species may be expected in botanic gardens and the collections of amateurs. The glasshouse species are known warmhouse species at present, although various species may be expected in botanic gardens and the collections of amateurs. The glasshouse species are essentially foliage plants. Several species have hand-somely striped leaves. All tradescantias are free growers, propagating with ease from cuttings of the growing shoots.

5. naviculários, Ortg. Stoloniferous: st. creeping, geniculate-ascending, glabrous: lvs. sessile, ovate, acute, glabrous: fls. bright rose, in terminal umbels which are sessile; sepals spreading, keeled; petals broadly ovate. Peru. Gt. 26:901.

6. reflexas, Raf. Slender, glabrous or nearly so: lvs. narrow, linear-attenuate from a lanceolate base; umbels terminal; bracts soon deflexed; fls. blue; sepals ovate-lanceolate, glabrous or with a tuft of hairs. Wet places, Ohio to Mich., Minn., Iowa, Texas, and S. C.

8. occidentális, Smythe (T. virginíaca var. occidentális, Brit.). Slender, 1 ft. high: lvs. narrowly linear, involute, base often enlarged and scurfy: fls. blue or roseate; sepals glandular-pubescent. Iowa to Neb., Texas, and New Mex.

9. gencílida, Jacq. (T. hypopóthos, Koch & Boué). Procumbent, sts. geniculate, elongate, pilose: lvs. ovate-

10. elongáta, Meyer. Nearly glabrous, procumbent and rooting at the base, then suberect to the height of 1-2 ft.; lvs. lanceolate or oblong-lanceolate, acuminate, sessile, light glaucous-green above and striped with silver, reddish purple beneath: peduncles 1-5, terminal: fls. rose, purplish colored, the sepals green. Trop. Amer.

EE. Fls. rose or purplish.

FF. Staminodes unequal, 5 long and 3 short.

GG. Lvs. lanceolate to ovate-lanceolate.

12. Warscewicziana, Kunth & Bouché (Dickoria trudowskiana. Warscewicziana, Planch.). Fig. 3831. Dickoria-like, having a stout caudex or trunk, marked by scars and finally branching: lvs. green, atrophious, 1 ft. or less long, clustered at the top of the st., recurving, lanceolate-acuminate; fls. bluish-purple, numerous in small crowded clusters along the branches of a panicle-like cluster. Guatemala. B.M. 5185. R.H. 1860, p. 136.

HH. Plant without a stout caudex, more or less decumbent at base.

13. dracémoides, Greenm. Roots fascicled, tuberous: lvs. erect or nearly so, 8-20 in. high, simple or sparingly branched: lvs. lanceolate-attenuate to ovate-acuminate: 4-6 x 3/4-1 1/2 in., villous-pubescent, strongly ciliate: infl. an open, oblong racemose panicle; fls. rose; sepals oblong, apex rounded; petals obovate. Mex.

3831. Tradescantia Warscewicziana.
TRAGIA (from Hieronymus Bock [or Tragus], a German botanist, 1498–1554). Euphorbiaceae. Herbs, sometimes twining and often with stinging hairs, rarely cult.: lvs. alternate, toothed or lobed; fls. monocious, racemose, apostalous, inconspicuous; stamens simple, generally 3; styles united above the base, with the apex free; ovules 1 in each of the 3 cells.—About 50 species of tropical and temperate regions; related to Plukenetia and Dalechampia. T. cannabina, Linn., of Trop. Asia, is used for fiber to some extent. T. solandri, Linn., of T. Eu., is a native of the W. Indies, has stinging hairs. Probably not cult. Several species of Tragia are native in the U. S.

J. B. S. Nottage.

TRAGOPÔGON (Greek for goat’s beard). Compositae. Goat’s Beard. Erect biennial or perennial herbs with narrow grass-like leaves and heads of yellow or purple flowers, belonging to the ligulate section of the composite family (tribe Cichoriaceae).

Mostly weedy plants with a tap-root; florets perfect, with slender style-branches and sagittate anthers; pappus composed of bristles in a single series; involucre cylindric or nearly so, with approximately equal-length bracts in a single row.—Between 30 and 40 species, native to S. Eu., N. Afr., and Cent. and S. Asia. One of them is cult. for its edible tap-root (salsify) and another is now a frequent weed in this country. The fls. of these open only in the morning.

a. Fls. purple.

porrifolius, Linn. Salsify. Vegetable Oyster. Oyster Plant. Figs. 3532, 3832. Tall strict biennial, sometimes 4 ft. high when in bloom, glabrous: lvs. keeled, tapering from a broad often clasping base; fls. showy, closing at noon or before, the outer rays exceeded by the involucral scales; peduncle thickened and hollow beneath the heads. S. Eu.—Naturalized in many parts of the country, often becoming a persistent weed. See Salsify.

AA. Fls. yellow.

pratensis, Linn. Goat’s Beard. More or less branched, 3 ft. or less tall: lvs. as in the preceding: outer rays exceeding the involucral scales; rays yellow, showy, about 2½ in. wide: peduncle scarcely swollen. A weed, from Eu.

L. H. B.

TRAGOPRURUM LANCEOLATUM var. LATIFOLIUM: Atriplex Mueckelii. 

TRAILING ARBUTUS: Epigaea.

TRAINING: Pruning.

TRANSPIRATION is the term applied to the escape of water from leaves and other parts of the plant in the form of vapor.

There is no closed “circulation” of sap in plants comparable to the streaming of blood in animals. Water which generally contains various mineral soil constituents in solution enters the roots, and most of it passes upward through the stems directly to the leaves, where it is evaporated. In plants of a succulent character, the intake often exceeds the loss, and a large amount of surplus liquid may be accumulated in various organs, from whence it may pass to the leaves in times of drought.

The movement of water set up by transpiration carries water and the contained salts to the centers of food formation in the leaves, and the evaporation process facilitates exchange of gases with the air. Transpiration also tends to equalize temperatures. That an enormous amount of water is performed by the plant in transpiration may be seen when it is known that a single sunflower plant will evaporate a pint of water from its leaves in a single day, and about seventy times this much in the course of its development. A birch tree with 200,000 leaves will transpire from 700 to 1,000 pounds of water daily in the summer. A single oak tree will throw 120 or 130 tons of water into the air during the course of a season, and an acre of beet trees containing 400 to 600 specimens will transpire about 2,000,000 pounds in a single summer. It is estimated that 98 per cent of the energy derived from sunlight by leaves is expended in the work of transpiration.

To determine the exact amount of water transpired by a plant, a specimen not more than a yard in height, growing in a pot, may be used. Set the pot on a square of oilcloth, then bring the cloth up around the pot and tie closely to the stem of the plant. This will prevent evaporation except from the shoot. Now set the prepared plant on one pan of a scale, together with a small measuring-glss, and balance. Allow the plant to remain in the warm sunshine for eight hours. Then note the amount of water which must be poured into the glass to reach the original level and restore the balance: this will represent the amount of transpiration.

To demonstrate that water actually does come from the leaf, cut off a small leafy shoot of any convenient plant and thrust the base of the stem through a piece of cardboard into a tumbler of water: seal the opening around the stem with wax or gelatine: then cover the exposed part of the shoot with another tumbler and set in a warm light place. Moisture which could have come only from the leaves will soon gather on the glass. Some transpiration occurs over the entire surface of the plant, although only about one-thirtieth as much is given off by the stem as from the same amount of leaf-surface.

The structure of the leaves is such as to facilitate transpiration. The interior of the leaf is made up of a great number of loosely arranged cells which evacuate water into the air between them. The air in the leaf communicates with the atmosphere through openings called stomata, which are generally placed on the lower side of the leaf. Consequently the watery vapor diffuses out through the stomatal opening. Near the outer end of the stomatal chimneys are guard-cells which undergo alterations in form that change the size of the opening of the guard-cells and modify the rate of water loss. The position and shape of the guard-cells are affected by the age of the leaf, turgidity of the tissues, wind, and sunlight. The rate of transpiration may also be affected by cutinization or other alterations in the cell-walls through which evaporation into the stomatal chambers takes place, or by the presence of colloids retentive of water in the cells.

Species characteristic of arid regions generally have limited waterproofed surfaces with a comparatively small number of stomata. This modification is exemplified by the cacti, which transpire not more than one three-hundredth as much water as a broad-leaved plant of the same volume; and such succulents may lose as little as one forty-thousandth of their total weight by transpiration in a day.
TRANPLANTING is a general term to designate the removal of living plants whereby they may become established in new quarters.

Transplanting may be performed when the plant is in a dormant condition, as in winter, or when it is still actively growing. Small herbaceous plants are usually the only ones that are transplanted when in a growing condition, and this only when the plants are living under special garden conditions where they may have the best of attention as to watering and shading. Considered from the standpoint of the plant, transplanting is always a violent operation, for it destroys a considerable part of the root-system, loosens the plant's attachment to the soil, and arrests for the time being a large part of its progressive vital activities. To overcome these dangers, the earth into which the plant is set should be well prepared and moist, so that the plant may quickly reestablish itself; part of the top usually should be removed to lessen transpiration, and with succulent and growing plants some shade should be provided for a time. The deeper and finer the soil, the greater the quantity of moisture it holds, the more successful the transplanting operation will be, other things being equal. The operation is also more successful in humid regions, as in the Atlantic states, than it is in dry regions, as on the plains and westward. In the more arid parts of the country transplanting is performed as little as possible, whereas in the eastern part great quantities of annual and other garden plants are transferred from seedbeds to the open ground.

The successful transplanting of any plant depends in part on the condition of the plant itself. The younger the plant, as a rule, the better it withstands the operation. Herbaceous or growing plants that are relatively short and stocky and compact, transplant better than those that are long, "leggy," and weak. The stocky and compact plants are better able to withstand the vicissitudes of inclement weather when they are transferred from a protected place to the open air, and they probably also have more recuperative power to make new roots and to attach themselves to the earth. Many plants may be "hardened off" or gradually acclimated to sun and air before they are transplanted. The more frequently a given plant is transplanted the more readily it endures the removal. The root-system becomes close and compact and there is relatively less injury to the roots at each subsequent removal, providing a long interval does not take place between the operations.

The success of transplanting also depends to some extent on the weather at the time the removal is performed. If cool, cloudy, and damp weather follows the transplanting, the plants are much more likely to live. Plants usually establish themselves more quickly on freshly turned soil, because it contains a relatively large amount of moisture. To bring the earth into contact with the roots, it should be firmed closely about the plants. This packing of the soil tends to bring the subterranean moisture upward where it may supply the roots; it also tends to increase evaporation from the surface of the soil and thereby to waste the water, although much of the moisture is utilized by the plant as it passes upward. To prevent the escape of moisture from the surface of the soil, it is customary to cover the ground with a mulch, from 1 to 3 inches in depth, of litter, sawdust, leaves, or coarse manure. When practicable the water may be saved by keeping the surface well tilled, thereby providing a mulch of earth. See Tillage.

In dry weather it may be advisable to water newly set plants, particularly if they are green and growing fast, as tomatoes, cabbages, and other annuals. The water may be applied in a hole or depression about the plant or at one side of it, rather than on the surface; and the following morning the loose fresh earth should be drawn over the hole in order to provide a surface mulch and to prevent the soil from packing. Of course, this particular pains cannot be taken in large field operations.

All kinds of plants can be transplanted, but some of them remove with great difficulty. In these cases the skill which is born of experience with these particular plants must be invoked for success. The difficulties are of various kinds. In some cases the difficulty may be a tap-root system, as in the case of the black walnut and the hickories. In these instances the plant may be severed a year or two before it is to be removed, and the crown or top of the plant may be cut back so as to sever the tap-root some distance below the ground by means of a spade or other sharp instrument that is thrust underneath the plant. In other cases the difficulty is the inability of the plant to make new feeding roots quickly, and one of the situations in which this occurs is the transplanting of large trees. Such plants often may be treated like the tap-rooted plants; that is, the long cord-like roots may be severed at some distance from the crown a year or two before the plants are to be removed. In other cases the inability to be transplanted is probably due to the excessive rate of transpiration from the foliage. Such plants are particularly valuable in large areas where great quantities of plants are to be set, and also in hard and dry land where it is difficult to make the proper openings with the hand and also to supply the plant with sufficient water.

For most small plants that are to be reset in small quantity, the dibber is a most useful implement to expedite the operation. See Potting. Special transplanting-boxes are on the market, to be used instead of the small flats and pots, for purposes of economy. These boxes are usually made of thin basket stuff and are thrown away when the plants are taken from them for transplanting. See transplanting-boxes.

Plants grown in pots or small shallow boxes transplant more readily than those raised in the open soil. Particularly is this true of pot-grown plants, for the bevel or slope of the pot allows the ball of earth to be "knocked out" readily. See Potting. Special transplanting-boxes are on the market, to be used instead of the small flats and pots, for purposes of economy. These boxes are usually made of thin basket stuff and are thrown away when the plants are taken from them for transplanting. See transplanting-boxes. (Fig. 3833.) The seeds are sown directly in these boxes.

In the case of large trees and shrubs, success often may be attained by transplanting in the winter, when a ball of frozen earth may be removed. It is usually better to give the transplanting of large trees into the hands of an expert than to attempt to perform it with
unskilled help and inefficient appliances. Only a certain proportion of the efforts in transplanting very large trees are really successful. The trees may live for several years and yet never fully recover or make satisfactory subjects. The surest and best results are usually secured only when the trees are nursery-grown and have been transplanted two or three times within a few years of their final removal. There are some species that remove from the wild with relative ease when they are of large size, among which are elms, maples, pine oak, basswood; but the large number of species do not readily re-erupt from the operation. See Arboriculture, Vol. I, page 302.

It is sometimes said that a plant cannot recover from the transplanting operation, that the severing of the roots inflicts injuries that are not outgrown, and that a new type of root growth is never established. These fears appear to be groundless. In many cases the plant does not regain itself, but these instances are probably due to lack of skill in the operation rather than to any inherent difficulty in the transplanting process itself. But even if the transplanting process were found to be theoretically injurious, nevertheless it must be employed in the practice of modern horticulture.

L. H. B.

TRANSPORTATION of horticultural products. Commercially, fruits and vegetables are grown primarily for profit. Whether the business of fruit- or vegetable-growing results in profit or in actual loss to the grower depends on a great many factors. Among the more important are quality and quantity of produce, distance from markets, cost of transportation, the condition in which the produce reaches the markets, and the supply and demand. In present-day fruit-growing, especially when the localities of production are often thousands of miles distant from the larger markets, there is no factor of greater importance than rapid and efficient transportation. The fruit-grower is, or should be, aware of the necessity of safe and rapid transportation, together with the delivery of perishable produce at the markets in sound attractive condition. Soundness and freedom from decay or deterioration are fundamental to profitable marketing, therefore to successful fruit-growing. All the labor and moneys invested in production are wasted if the produce cannot be transported and delivered in good condition.

Transportation is the link that connects the producer with his market, his zone of distribution being determined largely by the cost of transportation and absolutely by the distance over which the produce can be shipped in sound marketable condition. This distance will necessarily vary with the variety of fruit, the localities in which grown, cultural methods, care exercised in handling and preparing it for shipment, the promptness with which it is cooled, and the temperatures maintained in transit. The factors above mentioned are the more fundamental ones governing the condition of horticultural produce in transportation. It is clear, therefore, that successful transportation depends not only on conditions in transit but on the prehandling of the produce prior to shipment. The responsibility for the condition of these products when delivered at the market is a common one as between producers, shippers, and carriers. The very best refrigeration that is practicable cannot be expected to deliver perishable products in sound merchandising condition that have been badly handled prior to loading or shipment. Nor can such produce properly handled be delivered in good marketable condition without adequate refrigeration in transit during warm weather or sufficient protection against freezing in the cold weather.

The railways of the United States annually pay out millions of dollars in claims on account of breakage, decay and deterioration, freezing, and other damage in transit of perishable produce. This does not begin to cover losses sustained by the shippers in claims that are not paid, or deterioration for which no claims are made, and the injurious effect on the price received for the produce actually sound. The economic losses to consumers, carriers, shippers, producers, especially consumers and producers, who finally shoulder the greater part of the burden, are enormous. This great wastage of the nation's food-supply is an important factor in the high cost of living and is very generally one of the main reasons for losses instead of profits to the growers or producers. The most important fact in this connection is that most of these losses are unnecessary and preventable. As the decay and consequent losses occur in transit, it is of the utmost importance that growers, shippers, and carriers have a clear and accurate knowledge of the fundamental factors governing condition of fruits and vegetables in transportation.

Few commodities are more subject to decay and deterioration in transit than are fruit and vegetable crops. In considering the transportation of these products and their behavior in transit, it is absolutely essential that the fact be kept in mind that fruit and vegetables are living organisms with a definite span of life beginning in the orchard or field and ending normally in actual death-decay. It must be remembered, therefore, that, in preparing these products for shipment, in transportation, and through all stages to the ultimate consumer, one is dealing with real organisms, the life-span of which will be lengthened or shortened by methods of handling and conditions in transportation. A correct interpretation of the reasons for the losses from decay and deteriorations occurs in transit is, therefore, necessary if growers, shippers, and carriers have a clear and accurate knowledge of types of troubles that destroy the market value of fruits and vegetables. The prevention of these losses must be based on a clear understanding as regards the relation of the development of these troubles to methods of growing, packing, shipping, and to temperature conditions in transit. The types of troubles that may destroy or lessen the value of those products are of two kinds, decay and skin-blemishes. In ordinary transportation the former is by far the most important, while in storage skin-blemishes may be very important factors. Decay may result either from attacks by fungous or bacterial organisms, or through physiological breakdown which may be termed natural death decay. The organisms causing decay in transportation may be conveniently be divided into two groups, those which are parasitic, or which may cause decay of sound uninjured fruits; and those which are saprophytic or which have not the power to attack the sound unbroken skin of fruits or vegetables. Saprophytic organisms are responsible for by far the largest proportion of losses due to fungous decay in transportation and can be controlled only through careful and correct handling methods in the harvesting and preparation of the fruit for shipment.

Physiological breakdown or death-decay hinges largely on proper handling methods and temperatures...
In transportation. It is plain, therefore, that the fundamental factors influencing, to the greatest extent, the behavior of fruits and vegetables in transportation can be divided under the following heads: (1) Cultural; (2) Maturity at time of picking; (3) Care exercised in all handling operations; (4) Promptness of cooling; Precooling; (5) Temperatures in transportation.

Cultural history of the crop.

In so far as cultural practices determine the crop's freedom from disease when harvested and its inherent keeping quality, are cultural operations responsible for condition of these crops in transportation. Of especial importance are the methods of orchard or field sanitation. Field or orchard diseases attacking growing fruits or vegetables very often cause serious decay in transit. Peaches from orchards or sections affected with brown-rot (Sclerotinia) or Monilia usually show serious development of brown-rot after shipment. In certain humid sections of the Pacific coast, for example, the prevalence of brown-rot makes long-distance shipping of cherries and fresh prunes a hazardous venture. Certain vegetable crops, such as lettuce, celery, and tomatoes, when transported long distances, sometimes develop serious decay in transit through diseases that attack the growing crops in the fields. Such decay can usually be controlled and delayed by disease control methods applied in the fields or orchards when the produce enters the transportation chain. Some of the more common diseases affecting crops in field or orchards, can be controlled only through proper orchard- or field-sanitation practices. While the rapidity of the development of such decay in transportation can be controlled, to some extent by rapid, prompt cooling, the handling and maintenance of very low temperatures, the only real preventive lies in the control of these diseases in fields or orchards.

Maturity at time of harvesting.

The picking-maturity of peaches, muskmelons, and other quick-ripening fruits is governed largely by the distance from market and general experience as regards the carrying quality of such fruits at different stages of maturity under ordinary refrigeration. When they are to be shipped for considerable distances, the usual practice is to pick and pack them while still so green, hard, and immature as to be unfit for immediate consumption. Sometimes they are harvested in such a green stage that they do not properly ripen in transit, and while not entirely worthless from a marketing standpoint, their poor eating quality necessarily results in very low prices. Fruits from certain sections have undeniably gained a reputation for poor quality because of the custom of consumers never having tasted any properly matured fruit. There is no questioning the fact that if the quick-ripening fruits entering into long-distance transportation could be harvested at much nearer full maturity, that is, hard, ripe, and transported to the consumer in sound condition, both producer and consumer would benefit greatly, the former in increased returns, the latter in securing a more wholesome and palatable fruit.

The reason for the present condition is largely found in the notion that such fruits must be picked while still very green and hard to carry in sound condition to the market. To some extent this idea is well founded. Greater care, however, in all handling operations, with prompt cooling will enable growers and shippers successfully to handle the quick-ripening fruits at more advanced stages of maturity. When precooling facilities are available, it has been demonstrated that it is not only possible but practicable to harvest such fruits as peaches and pineapples at advanced stages of maturity as will give the consumer a product possessing its maximum fine quality and wholesomeness. When such facilities are not available, much can be accomplished toward the same end through proper and careful handling, prompt loading, and slowing of the load in the car in such a way as to facilitate circulation and consequent quick cooling or refrigeration. The practicability of successfully transporting more nearly tree- or plant-ripened fruits possessing their maximum fine quality of the variety when delivered to the consumer, will depend both on the grower and the carrier. The grower must exercise, first of all, the greatest care in handling and get his fruit under refrigeration quickly. The carriers must have the facilities in which the product can not only be cooled faster but transported at lower temperatures than is ordinarily obtained in the average equipment. What has been said above, relative to the desirability of harvesting certain fruits at much advanced stages of maturity, does not, of course, apply to such fruits as pears, lemons, and fruits or vegetables which should be picked green in order that they may possess their maximum fine quality when finally ripened or cured.

Cultural history of the citrous fruit crop.

In the harvesting and preparing of the citrous fruit crop for shipment determines, to the greatest degree, its shipping or keeping quality. Extensive investigations conducted on a commercial scale by the Bureau of Plant Industry, United States Department of Agriculture, for a number of years, covering a wide range of fruits and vegetables, have clearly and conclusively demonstrated that decay occurring in transit after arrival at the market is due very largely to rough methods of handling. The fungous organisms causing decay gain entrance through mechanical abrasions of the skin made in picking, hauling, packing, or other handling operations. Every break or tear in the skin offers lodgment for fungous spores, which, given proper moisture and temperature conditions, germinate and produce decay. Both high temperatures and moisture atmosphere favor rapid development and growth of these fungous organisms. If handling and storage conditions are usually fairly high during the harvesting season, as is frequently the humidity. During periods of muggy or rainy weather, the conditions are ideal for the germination and development of fungous spores, and almost every injury is certain to result in decay. The fundamental consideration, therefore, in all handling operations is the preservation of the skin in a sound and unbroken condition.

The handling operations involved in the harvesting and preparation of the citrous fruit crop for shipment may serve as a very good example. In the harvesting of citrus fruits the mechanical abrasions may result from cuts made by the choppers used in severing the fruits from the tree, from contact with thorns on the trees, from dropping the fruits into the picking-sack or field-box, rough handling in loading, and jarring in hauling over rough roads or on springless wagons. Any injury or breakage of the skin makes the fruit susceptible to decay. Even slight injury or breakage of the surface cells of the skin offers lodgment for fungous spores which, given proper moisture and temperature conditions, germinate and produce decay. Both high temperatures and moisture atmosphere favor rapid development and growth of these fungous organisms. If handling and storage conditions are frequently high during the harvesting season, as is frequently the humidity. During periods of muggy or rainy weather, the conditions are ideal for the germination and development of fungous spores, and almost every injury is certain to result in decay. The fundamental consideration, therefore, in all handling operations is the preservation of the skin in a sound and unbroken condition. In a short article it is obviously impossible to go into details as to how injuries are made in handling from field to car. The handling operations involved in the harvesting and preparation of the citrous fruit crop for shipment may serve as a very good example. In the harvesting of citrus fruits the mechanical abrasions may result from cuts made by the choppers used in severing the fruits from the tree, from contact with thorns on the trees, from dropping the fruits into the picking-sack or field-box, rough handling in loading, and jarring in hauling over rough roads or on springless wagons. The fundamental consideration, therefore, in all handling operations is the preservation of the skin in a sound and unbroken condition.
even more careful handling to avoid bruising and to preserve the skin of the fruit in an unbroken condition during all the operations of picking, hauling, and packing. Peaches are very commonly injured through the pickers exerting too great pressure with the thumb or other fingers when removing the fruit from the tree, thereby handling in loading, and bruising in the various operations of grading and packing. Sizers or graders have been used to a considerable extent in the handling of peaches, most of the graders now in use afford too many opportunities for injury to be universally recommended in the handling of such crops. In red raspberries, for example, the most serious decay results from too great pressure on the berry when removing it from the core. The use of three fingers instead of two minimizes the pressure and danger of injury. The inclusion of over-ripe berries in cups or crates intended for long-distance shipment is also a very prolific source of decay. The marketing or distributing zone of such fruits and berries can be extended by several thousand miles by the exercise of a little more care in picking and grading. In grapes the most serious injuries result from the loosening of the berry from the pedicel, and it requires the most careful handling, both in picking and packing, to avoid this type of injury which is chiefly responsible for the frequent excessive decay occurring in transportation.

Careful handling involves the exercise of thoughtfulness in the manipulation of the fruit from tree to car in order to preserve the skin of the fruit in an unbroken sound condition. It necessitates the most careful supervision of labor. It means simple and the minimum amount of machinery for washing, drying, sizing or grading, and constant attention to keep it clean and in perfect order. The whole handling problem is an economic one related to systems of both hiring and supervising labor. In citrous states cooperative associations have found it necessary to take over the field handling as well as the packing-house handling to insure uniformity of careful work. Where each grower does his own picking, the bad handling of one nullifies, to a large extent, the good work of the other, especially if the fruit from the different growers is pooled and shipped in the same car. The advantage of this method of cooperative handling depends largely on having the right kind of manager and foreman, men who not only know what careful handling is and means, but who can secure such work from every man in the organization having anything to do with the physical handling of the fruit. The system of paying labor is largely responsible for carelessness in handling and decay in transit. Too much emphasis cannot be laid on quality as the tendency is at present decidedly in the direction of attaching too much importance to quantity. Quantity at the expense of quality is poor economy in the handling of any perishable fruit crop.

There is considerable question and argument as regards the best picking-receptacles, particularly as to whether picking-sacks or -bags are preferable to pails or baskets or other similar containers. For citrus fruits, and other hard thick-skinned deciduous fruits, canvas picking-bags are usually preferable. Peaches and other thin-skinned deciduous fruits are injured by the rubbing of one fruit against another, and must be picked in receptacles with rigid sides. In such receptacles the fruit will not be subjected to more or less rubbing against one another as they would be in a picking-bag where every fruit necessarily moves somewhat with the movement of the picker.

Quickness and promptness of cooling.

Next to care exercised in the physical handling of the fruit, temperature is the most important factor in determining the life-span of the fruit. The question of temperature in the handling of fruits for transportation is related primarily to the promptness and rapidity with which the produce is cooled and maintained at low temperatures in transit. Most of the fruits and vegetables are harvested during periods of high temperatures. The physiological and chemical changes that constitute ripening proceed very rapidly at high temperatures and but very slowly at temperatures slightly above freezing. High temperatures shorten the life-span of the fruit, both through rapid ripening and the rapid development and growth of producing organisms. Low temperatures retard the ripening processes as well as the germination and growth of fungi causing decay. It is, therefore, of the greatest importance that the produce be cooled as promptly and as quickly as possible after removal from the tree or field. Delay of a few hours of the more quick-ripening fruits after harvesting in the field or packing-house during the heat of the day may mean the shortening of the normal life-span of such fruits by days. Prompt cooling is essential, whether this is accomplished by precooling before shipment or slower cooling in a refrigerator car. Advantage also may be taken of cool night temperatures by allowing the fruit to remain uncapped out in the open over night and packed later in the cool of the morning. More cooling can usually be accomplished this way over night than in a whole day in a refrigerator car, especially if the fruit is wrapped and tightly packed.

Precooling.

The prompt quick cooling of produce prior to shipment has been termed “precooling.” It is usually accomplished by mechanical means in warehouse plants before loading in cars, or in car-precooling plants after loading. In the latter case the precooling is accomplished by forcing large volumes of cold air through the load in the cars. Most of the smaller warehouse plants have been built and successfully operated using ice and salt for refrigeration. As to which system is the best is still more or less of an open question and depends largely on local conditions. Warehouse plants have the advantage of the rapid cooling of the produce can be commenced immediately after packing without any delay. The cooling is usually more uniform and very often the plants are used as warehouses to hold fruits and vegetables in good condition for considerable periods when, on account of market conditions, or for any other reason, it is desirable to do so. Mechanically cooled warehouse-precooling
plants are expensive to build and operate, and where the harvesting-season is short, the benefits from precooling must be very marked to justify the expense. The salt and ice plants were designed to meet this objection and have proved very practicable where ice can be obtained at a reasonable rate and where the daily output does not exceed a few cars. The principal objections to car-precooling plants are the delay between loading and precooling and the more or less unequal cooling of the different packages in the car. The delay incidental to finishing the loading of a car, and the switching to a precooling plant is sometimes considerable and, in some instances, the total delay may approximate, to some extent, the slow cooling under regular refrigeration. In a number of instances, where car-precooling plants are in operation, in order to minimize delays, there is too much of a tendency to cut down the actual period of precooling, which results in partial precooling only. Some of the reasons why precooling has not been more generally used may be found in the rather heavy initial investment necessary to build a plant, and the delay in shipment necessitated by holding over for precooling. Especially is this true with deciduous fruits where, in many sections, the shipping-port and where each shipper is desirous of getting his fruit or produce to the market as quickly as possible.

Precooling has been utilized more in connection with the handling and shipment of citrus fruits from California and elsewhere. It has apparently been found to be profitable in the citrus industry largely because of the long orange shipping-season, and for the reason that it is utilized also to reduce the cost of transportation. Precooled fruit from the growers’ warehouses is shipped without any icing, especially in the upper tiers, in transportation. The delay incidental to finishing the loading of the fruit in the various positions in the car. Very often the upper tiers are 15° to 20° higher in temperature than the bottom tiers and have ripened to such an extent as to make it necessary or desirable to sell them separately from the remainder of the fruit. This can be done by leaving straight uninterrupted aisles between rows from one end to the other. Cleats between each layer from bottom to top will also facilitate quicker cooling. Racks so constructed as to provide a space of 4 inches between rack and floor for free circulation of cold air from each bunker toward the middle of the car, beneath the load will greatly facilitate quick cooling of every package in the load. In loading fruit into preiced cars, it is very commonly the practice to leave both doors open during the entire period of loading. Much of the refrigeration is lost in this way which could easily be conserved if more care was exercised to open the doors only when absolutely necessary.

In so far as methods of loading and stowing are concerned, the responsibility for the safety of the load and, to some extent, its quick cooling rests on the shipper. The other factors, however, in actual transportation that have to do primarily with quick cooling and the maintenance of low temperatures in transit and freedom from breakage, to overcome any delays, must share responsibility. When properly prehandled produce has been stowed and loaded correctly, both as regards liability to shifting in ordinary freight handling and as to facilitating air circulation and quick cooling, a shipper has largely fulfilled his responsibility so far as products in transportation is concerned. Following this, the responsibility for the safe transportation of properly loaded product rests almost entirely on Temperatures in transit.

The necessity for the maintenance of low temperatures in transit has already been emphasized. The question is often asked: How low ought the temperatures in a refrigerator car to be for best results? The only answer to this problem is: As low as possible, consistent with safety from freezing. The same principle applies as in storage. The lower the temperature above actual freezing, the more effectively are ripening and the development and growth of decay-producing organisms checked. While fruit may continue to grow very slowly at temperatures of 40° F. or below, few germinate at this temperature. If, however, germination has already taken place, the best that can be expected of refrigeration is to check their development and development of decay-producing organisms.

The good effects of quick and prompt cooling have been nullified to a considerable extent by the rapid deterioration and simply transfers the troubles in transit. from the first receiver at the market to the retailer or consumer. Precooling must be thorough and as uniform as possible. The refrigerator car used for the shipment of precooled produce should be sufficiently insulated to maintain reasonably low and uniform temperatures in transit.
the transportation company, both as relates to freedom from breakage and efficient refrigeration. The carrier half of the bunker in the earlier and cut. In switching is mainly responsible for the condition of a properly stowed load as regards shifting, breakage, and the like. The efficiency of the refrigerator car is primarily responsible for the quickness of cooling and the maintenance of uniformly low temperatures in transit as well as liability to freezing damage in cold weather. The efficiency of a refrigerator car depends not only on the quantity, quality, and condition of insulation but on the size of the car, the kind of ice-bunker, and facilities for efficiently free circulation and quick refrigeration of all packages in the car.

Salt, as a means of securing lower temperatures in refrigerator cars, is in use extensively in the transportation of meats and similar products requiring temperatures below freezing. It has been used only very sparingly with fruits. Recent tests with somewhat modified equipment indicate that salt can be used to good advantage in securing quick cooling and in maintaining proper low temperatures in transit.

The methods of icing and charging for refrigeration in transit vary considerably in different sections of the country. From Pacific coast points to the East, the carriers, under certain blanket rates, assume all responsibility for refrigeration in transit from point of shipment to destination. In the deciduous fruit sections all cars, unless precooled, go out under standard refrigeration, that is, pre-icing before loading and full re-icing enroute at all regular re-icing stations to destination. The refrigeration rate is uniform on all cars to any one point. Under the standard refrigeration rate for citrus fruits, the cars are usually not iced until after loading unless otherwise requested by the shipper who pays a somewhat higher rate for pre-iced cars. With citrus fruits from California, various other rates are in effect permitting one pre-icing and a re-icing before final shipment, or precooling, and one icing with no re-icing in transit. When the growers do their own precooling and initial icing in transit, a charge is made only for the use of the car and freight on the ice hauled in the bunkers. In the shipment of fruits from Florida there is not only the standard refrigeration rate which calls for full re-icing at the regular icing stations. The shipper, however, also another rate for half-icing, which means the refilling of the bunkers at the various icing stations to one-half of their capacity, the racks on the floors of the bunkers being raised so as to hold the ice in the upper half. In the eastern states, the so-called blanket refrigeration rate at various points is not used to any considerable extent in the shipment of fruits and vegetables. The refrigeration charge to the shipper is usually based on the amount of ice consumed in transit as shown by the carriers' records at icing stations. The shipper pays for the ice actually used and the icing is done according to the instructions furnished by him on the bill of lading. If the shipper orders full refrigeration in transit, the cars are re-iced at the regular icing stations. He may, however, have the option of giving other instructions if he so desires, namely, either the number of hours enroute or the icing stations at which he wishes the cars to be re-iced. Under the standard refrigeration rates, applying in points on the Pacific coast territory, the responsibility for refrigeration in transit rests entirely with the carriers. In eastern territory the responsibility is divided between the shipper and the carrier.

Freezing in transit. The transportation of fruits and vegetables in sound condition in transportation is related not only to efficiency of refrigeration but protection against freezing. During protracted periods of cold weather, such as sometimes occur in the northern and eastern states in the winter, the protection of fruits and vegetables in transit is a real problem. While a number of factors enter into the question of freezing protection in transit, the principal one is insulation. Aside from condition and quantity of insulation, shippers and carriers have both attempted to minimize the danger from freezing by heavy tight loading and lining the inside with heavy paper, sometimes using several thicknesses, by putting in floor-racks and by placing stoves in the bunkers or in the middle of the car.

Both tight and heavy loading are desirable when there is danger from freezing. The tight load tends to hold the heat more effectively and the heavier the load the more heat there is to draw on. Lining with heavy building-paper, or other paper of similar character, gives added protection. Certain roads have found floor-racks of special value in minimizing the danger from freezing. Results both experimentally and commercially fully justify their use to minimize frost damage as well as an aid to more effective refrigeration. The use of stoves or heaters is hardly to be commended, as frequently the injuries from overheating certain parts of the car result in deterioration as regards quality, condition, and appearance that exceed what the freezing damage would have been. In the transportation of potatoes during the colder months from northern producing districts such as Montana, freight cars are uniformly re-iced from pre-icing stations. Ordinary freight cars with specially constructed bins so as to provide an air-space between floor and sides of car and the load are used very largely also. A stove is placed in the middle of the car and a messenger accompanies three, four, or more cars to keep the fires going properly. The heat from heaters either outside or inside the cars is depended on more than the insulation to maintain temperatures above freezing.

H. J. Ramsey.

TRAPA (abbreviated from calcitrapa, which is the same as caltrops, an instrument of war used to impede the progress of mounted warriors; it had four spine-like projections, like the fruit of the water caltrops); Trapaceae or Hydrocharitaceae; by some retained in Onagraceae. Floating plants adapted to the aquarium. Flowers small, axillary, solitary, short-peduncled; calyx 4-parted, the segments persistent, sometimes spinescent; petals and stamens 4; ovary 2-loculed; ovules I-seeded.-Three species, native to the warmer parts of the eastern hemisphere. TRAPA natans is one of the daintiest aquatics in cultivation. It is perfectly hardy and very desirable for aquaria, pools, ponds, or sub-culture. Its beautifully mottled or variegated foliage is very attractive. The flowers are white, small, and inconspicuous. The fruits are very large in comparison with the flowers and leaves, but they are hidden beneath the foliage until they ripen, when they drop off. They are good to eat raw, like chestnuts, and are sweeter and more palatable before the shell becomes hard. The nut is not likely to become of commercial importance in America. The seeds drop from the plant and remain in the pond all winter. Seeds must be kept in water or moist to retain their vitality. (William Tricker.)

Trapa natans, Linn. Water Chestnut. Water Caltrops. Jesuit's Nut. Petiole of floating lvs. 2-4 in. long, nearly glabrous; blade rhombic-orbicular, dentate in upper half, slightly villous along the nerves beneath: fr. 4-spined, but the 2 lateral ones shorter. Eu., Orient. Gen. 24, p. 557. G.C. II. 10:213. B.R. 259.—It has two kinds of lvs. The submerged ones are root-like, long, slender, and feathery. The floating lvs. form a loose rosette. The 4-spined angles are swollen and spongy near the apex. The fr. is an inch or two across and has 4 spinescent angles. It is roasted and eaten in some parts of Eu. like the common chestnut. It is sparingly
TRAPA

naturalized in this country. Var. verbanensis, Lessati (T. verbanensis, De Not.), of Lake Maggiore in Italy, has deltoid lvs. and compressed 3-angled fr. with 2 short horns.

bispinosa, Roxbg. SINGHARA-NUT. Petiole of floating lvs. 4-6 in. long, woolly; blade 2 x 8 in., slightly crenate or serrate, more or less hairy on both sides, with 2 of the spines sometimes absent. India, Ceylon.—Said to yield very large and sweet nuts which are sold under the name of Singhara-nut; much used by natives.

T. bicoria, Less. Lin. f., the Ling of China, is by some referred to T. natans: the fr. has 2 strong opposite long decurved horns like those of a bull's head.

WILLIAM MILLER.

TRAUTVETTERIA (E. R. von Trautvetter, a Russian botanist). Ranunculaceae. Tall erect perennial herbs grown somewhat for their broad leaves and small white flowers borne in clusters.

Leaves broad, palmately lobed: fls. white, small, corymbosum-paniculate; sepals 3-5, caducous; petals none; carpels many, forming 1-seeded achenes.—Two species. N. Amer. and E. Asia. Very hardy, thriving in ordinary or rich soil. Easily propagated by division of roots either in late fall or early spring. There is not likely to be much difficulty associated with this operation. Offered by dealers in native plants.

grandid, Nutt. (T. palmata var. occidentalis, Gray). Actea grandis, Dietr.). Much like the above species: lvs. membranaceous, more deeply lobed, often to the base, thin, sparsely hairy beneath along the ribs; reticulations less distinct: styles longer and somewhat curled. Wash., Idaho, Brit. Col.

The genus Trautvetteria is variously interpreted. Many authors regard it as monotypic, the Japanese form (T. pinnatifida, Roth & Zucc.) being included in one cosmopolitan species (T. carolinensis). E. L. Greene, on the other hand, described 6 new American species at one time in 1912: T. coerulea, from Ga.; T. Americana, from Ore.; T. platypetala, Mo.; T. rostrata, Calif.; T. saniculifolia, Idaho; and T. media from New Mex. K. J. DAVIS.

TRAVELER'S TREE: Rastenola.

TREE OF HEAVEN: Ailanthus.

TREES: Arboriculture.

TREFOIL: Clover, Trifolium; sometimes applied to Lotus, Medicago (tick trefoil), and other Leguminosae.

TREMA (Greek, trema, hole, alluding to the pitted stome). Ulmaceå.

A group of about 30 species of evergreen trees or shrubs in the tropical and subtropical regions of the Old and New Worlds: lvs. alternate, short-petioled, serrate, 3- or 5-nerved or pinnervened, stipulate: fls. small, in nearly sessile clusters, monocious or dioecious, apetalous, 5- or rarely 4-merous; sepals of staminates fls. valvate below, imbricate above; stamens 4-5; ovary 1-celled, superior style with 2 linear arilli from beneath, 3-nerved at the base, crescent-serrate, pubescent on both sides, more densely beneath, 3-nerved at the base, 2-4 in. long: fls. in small axillary clusters: fr. globose, black, ½ in. long, crowned by the remnants of the styles. S. Afr. Wood, Natar Fl. 4:380.—It is said in Calif. that in deep soil it makes a much-branched bushy tree with foliage similar to mulberries, and remarkable for the bright orange color of the old lvs. before dropping down.

orientalis, Blume (Celtis orientalis, Linn.). Small tree; branches pubescent: lvs. rigid, ovate-oblong to ovate-lanceolate, acuminate, cordate at the base, crescent-serrate, searhird above, clothed with silky, appressed pubescence beneath, 3-6 in. long: fr. ovoid, ½ in. long, black. S. Asia. Wight, Icon. 1971.—A plant offered under this name seen by the writer proved to be a true Celtis, not a TremÀ.

ALFRED REHDER.

TREMÁNDRÀ (Greek, hole of earth; the anthers burst open through a hole). Tremandraceae. More or less stellate-tomentose shrubs, sometimes grown in the greenhouse. Lvs. opposite, ovate, dentate: fls. in 5's; petals not inclosing the stamens, which are rather large for the family and borne in panicle umbels; sepals 5-12, valvate, somewhat thick; stamens 8-12, valvate, somewhat thick; stamens 8-12; ovary 8-12-loculed: fr. large; orange.—About 9 species. Should be grown in a warm moist house, as the plants naturally grow in damp jungles.

palmtÀ, Vis. (Gastonia palmata, Roxbg.). A small tree frequently 20 ft. in cult., with the ends of the branches sparingly prickly and the young parts tomentose: lvs. crowded at the ends of the branches, 1½ ft. across, palmately 5-9 lobed to below the middle; petals 1-1½ in. long: panicle 12-bracteate, peduncled, erect; umbels 6 in. through, long-sleeked; fls. 1 in. across, yellowish white, showy. Himalayas. B.M. 7008.

T. SundalCa. Annam. G.C. III. 53:296.—T. sundalià, Regel, is apparently a form of T. palmata; T. sundalCa, Miq., is a distinct species from Java and Sumatra, with leaf becoming recurved. See Gillettina.

TREVÉSIA (after the family Treves di Bonfigli of Padua, patrons of botany). Araliaceae. Showy and rather striking small trees or shrubs from Trop. Asia and the islands in that region: lvs. either palmately cut or simple, or digitately or pinnate compound; fls. rather large for the family and borne in panicled umbels; petals 8-12, valvate, somewhat thick; stamens 8-12; ovary 8-12-loculed: fr. large; orange.—About 9 species. Should be grown in a warm moist house, as the plants naturally grow in damp jungles.

TREVÉSIA (after the family Treves di Bonfigli of Padua, patrons of botany). Araliaceae. Showy and rather striking small trees or shrubs from Trop. Asia and the islands in that region: lvs. either palmately cut or simple, or digitately or pinnate compound; fls. rather large for the family and borne in panicled umbels; petals 8-12, valvate, somewhat thick; stamens 8-12; ovary 8-12-loculed: fr. large; orange.—About 9 species. Should be grown in a warm moist house, as the plants naturally grow in damp jungles.

TREVIRÁNA: A section of Achimenes.

TREVIÓRIA (named for Sir Trevor Lawrence). Orchidaceae: Epiphytic orchid grown in the greenhouse. Pseudobulbs elongated-pyramidal, not compressed, 1-1½ in. lvs. large, rather leathery, folded, contracted to the petiole: scapes arising from the base of the pseudobulbs, simple, bearing a lax few-fl. raceme: fls. large, fleshy, pedicelled; sepal rather thick, spreading, lateral ones oblique, very large; petals fleshy, twisted, conspicuously narrower than the sepals; labellum fleshy, concave, erect, not movably jointed with the base of the column, lateral lobes erect, axe-shaped, lady surrounding the column, middle lobe hastate; column rather long, terete, clavate or abruptly truncate at apex; rostellum 2-toothed, membranaceous; pollinia 2: caps. fusiform.—About 3 species. Trop. Amer.

CHORIAS, Lehni. Lady cespitosa: pseudobulbs long-pyramidal: fl. oblong-lanceolate, acuminate, long-
petiolated: spike pendulous, few-fl., commonly 3 fls. fleshy, greenish; dorsal sepal, oblong-lanceolate, acuminate, revolute, lateral ovate, obliquely acuminate; petals ligulate, oblong-lanceolate, plicate; spike pendulous, few-fl., rachis stout: fls. up to 2½ in. across, green; sepal broad-ovate, subacute, concave, fleshy; petals much narrower than the sepal, oblong-lanceolate, spreading-recurred, plicate, lip fleshy, lateral lobes car-shaped, erect, midlobe 5-grooved, stipitate, swollen, 2-cuspidate. Colombia. B.M. 7805 (as T. Chloris).

TRÆWIA (from C. J. Trew, a German physician, 1695–1769). Also spelled Tréwia. Euphorbiaceae. Small tropical softwood trees rarely cult. in greenhouses, being little known to gardeners and apparently not in the American trade: branching from the base: lvs. opposite, entire, 3–5-nerved; fls. dioecious, in lateral racemes or the pistillate singly, apetalous; stamens simple, 5 or more; styles free above the base. About 5 species: mostly in Trop. Asia. Related to Mallotus. T. nudiflora, Linn., with broadly ovate, acute or acuminate, cordate to subcuneate lvs., has been in cult. in Eu. from S. Asia. It is prop. by cuttings in sand.

Trianea: Lianolium.

TRIBRÔMA: Theobroma, p. 3331.

TRICÁLÝSIA (Greek, triple calyx; true of some species). Including Kraussia. Rubiaceae. Erect or climbing shrubs, used as ornamentals in extreme South. Branches opposite, terete or obtusely quadrangular. Lvs. opposite, short-petioled; stipules short, broad, apiculate and intra-petiolate: fls. rather small, subsessile, calyx pyramidal, the tube cohering one-third its length, anthers 10, hairy; capsules small, leathery, 5–6 lines diam. Trop. Amer. and intro. into S. Flia. T. undulatifolia, Hort., is offered in the foreign trade.

TRICHINÜM (Greek, hairy, alluding either to the plant in general or to the fl.-heads). Amaranthaceae. Herbs, subshrubs or rarely shrubs, glabrous or pubescent, adapted to greenhouse cult.: lvs. alternate, narrow, rarely obovate or spatulate, entire: fls. in dense spikes or globose or obovate heads, white, straw-colored or rose, hermaphrodite; perianth narrow or elongate, 5-parted, segms. equal, linear, rigid, usually plumose; stamens 5; ovary sessile or stipitate, glabrous or lanuginous, ovule 1: fr. an indehiscent uricle.—About 60 species, natives of South America.

exaltátum, Benth. (Pilóta exaltáta, Nees). A tender perennial, 2–3 ft. high, erect, usually branching above: lvs. 2½ in. long, oblong-lanceolate, rather thick, contracted into a long petiole; upper lvs. smaller: spikes erect, long-peduncled, at first ovoid-campanulate, becoming longer: perianth 5-lobed, tomentose, with dull red tips. B.R. 25:28 (as T. alopecuurifolium).—Intro. in this country as a greenhouse subject.

TRICHÔLÒS (Greek, for three, and Chloëis, a genus of grasses, referring to the 3 awns which differentiate the two genera). Gramineae. Perennial grasses that resemble Chloris but differ in having 3-awned lemmas. Species 5, Mex. and S. A. Amer.

mendoncina, Kurz. (T. Blanchardiana, Hack.). Spikes several, erect, slender, approximate at top of the culms, feathery with the delicate awns. Argentine.—An ornamental grass, readily grown from seed.

A. S. HITCHCOCK.

TRICOCÂLÔN (Greek, hair and stem; said to allude to the bristles that tip each tubercle on the st.). Aeclepiadaceae. Perennial herbs, suitable probably for the greenhouse. Sts. low, thick, fleshy, many-angled, angles tuberculate; tubercles aculeate: fls. in dense spikes, ovary 5-cleft, lobes broadly ovate; corolla disk-shaped, deeply 5-cleft, lobes broadly ovate; disk double, short-stipitate, outer deeply 5-cleft, inner 5 lobulate.—About 15 species. Trop. and S. Afr. T. pictum, N. E. Br. St. subglobose or cylindrical, oblong, very obtuse, 2–3 by about 2 in., irregularly tessellate-tuberulous, glabrous; fls. flescised, erect, fasicled 2–4-fl.; sepal broad-ovate; corolla not less than ¾ in. diam., white marked with purple spots and numerous short lines, lobes broad deltoid-ovate, acute. S. Afr. B.M. 8579. T. Pilatusii, N. E. Br. Plant 5–9 in. high, branching at base: sts. ¾–2¾ in. diam., cylindrical, with many tuberculate angles, glaucous-green, glabrous, tubercles ending in stiff bristles; fls. in small clusters, between the angles, toward the top of the sts.; sepal ovate, very acuminate; corolla bright creamy yellow, glabrous and smooth outside, densely papillate on the inner face of lobes. S. Afr. Var. major, N. E. Br. Plant and fls. larger than the type. S. Afr.

F. TRACY HUBBARD.

TRICOCRÊNÜM (Greek, hair and spur; alluding to the long slender spur). Orchidaceae. A small group allied to Rodriguezia (Burlingtonia); the plants grow in dense matted tufts.

Pseudobulbs very small, each bearing a broad fleshy
ICHOCENTRUM

H.: infl. a few-fl. raceme on which usually only 1 fl. opens at a time; sepals and petals free, spreading; labellum larger, spurred, with 2 lateral lobes and a 2-parted middle lobe; column short; pollinia 2, on a wedge-shaped stipe.—About 20 species. Epiphytes of dwarf stature, growing best on blocks; free-flowering; they suffer from too much water at the root; give them a warmhouse temperature. Prop. by division.

**Albo-purpureum**, Reichb. f. Lvs. oblong-lanceolate, 3 in. long, tufted: fls. on short peduncles, 2 in. across; sepals and petals obovate-lanceolate, inside maroon-brown, with greenish tips, outside greenish; labellum subquadrate, white, with a large purple spot on each of the lateral lobes. Brazil. B.M. 5688. A.F. 6:609. J.H. III. 51:382.

TRICHOSPORUM (Greek, hair and tongue, referring to the fine hairs on the labellum). Orchidaceae. Epiphytic herbs, occasionally grown in the warmhouse. Sts. leafy, elongated, not pseudobulbous: lvs. distichous, apex into 4 short lobes. Panama.

**Epiphytic herbs, occasionally grown in the warmhouse.**

**TRICHOSPORUM (Greek, hair and tongue, referring to the fine hairs on the labellum).** Orchidaceae. Epiphytic herbs, occasionally grown in the warmhouse. Sts. leafy, elongated, not pseudobulbous: lvs. distichous, apex into 4 short lobes. Panama.

**HEINRICH HASSELBRING.**

**TRICHOGLOSSIS** (Greek, hair and tongue, referring to the fine hairs on the labellum). Orchidaceae. Epiphytic herbs, occasionally grown in the warmhouse. Sts. leafy, elongated, not pseudobulbous: lvs. distichously arranged along the st., narrow: peduncles lateral, very short, 1- to few-fl.; fls. small or medium; sepals spreading, lateral very broad at the base, dorsal oblong; petals like the dorsal sepal; lip adnate with the column-foot, forming a long horizontal spur-like chin, spreading above, lateral lobes erect, short, midlobe rather broad, spreading; column short, wingless; pollinia 2, globose.—About 30 species, Malaya and the Philippines. T. Solenophora, Kunze. Sts. elongated: lvs. fleshy, somewhat lanceolate, up to 5 in. long, about 1 in. wide: racemes 1-fl.; sepals obovate-oblong, 4-5 lines long, bright green, each with 5 transverse brown-purple bands; petals much smaller, similar in color, but with only 3 bands; lip 1½ in. long, white, soon becoming yellowish with 2 blood-red spots on the disc, filiform-crenulate. T. Dawsonidna, Swartz. Lvs. 12-18 in. long, oblong-lanceolate; fls. 2 in. diam., yellow-green barred with brown; sepals oblong-lanceolate; petals shorter; lip subessiculate, side lobes oblong, midlobe ovate, acute, with a short falcate wing on each side of the tip. Burma.

**FRANCIS TRACY HUBBARD.**

**TRICHOLÉPIS** (Greek, hair and scale, the involucral scales are narrow with long hair-like tips). Compositae. Annual or perennial herbs, which are branched and unarumed: lvs. alternate, entire, toothed or the lower pinnatifid; heads terminal, solitary, homogamous; involucre ovoid or broader; bracts many-rowed, very narrow, unusually with long recurved hair-points: fls. all hemaphrodite, similar and fertile, yellow, red, or purple; tube slender; limb 5-cleft: achenes glabrous, oblong or obovoid, ribbed.—About 7 species, India.

**Furcata, DC.** Glabrous or puberulous herb, 1½-6 ft. high, branched from the base; lvs. 2-6 x ½-2½ in., elliptic-lanceolate, acute or acuminate, denticulate, short-petioled; head rather large, yellow; involucral bracts needle-like. Himalaya. Grown for ornament.

**TRICHOMANES** (Greek, soft hair). Hymenophyllaceae. A group of filmy ferns distinguished by its tubular cup-like indusium and filiform elongate receptacle. (Fig. 3837.) Very delicate in texture and capable of being grown successfully only under shaded glass. Over 100 species are known. Various species may be found in the collections of fanciers, but the following appear to be the only ones regularly in the American trade. For culture, see Ferns.

**Radicans, Swartz.** Lvs. 2-8 in. long, 1½ in. wide, bipyramidal, pinna ovate, obtuse; indusia terminal, on short lobes. Tropical America, extending into the southern states as far as Ky.

**Prieurii, Kunze (T. anceps, Hook.).** Lvs. 12-18 in. long, 6-12 in. wide, tri-quadrinpinnatifid; pinnae ovate-lanceolate; sori 2-12 to a pinnule, small, in sinuses; indusia with a much dilated lip. Trop. Amer.

**L. M. UNDERWOOD.**

**TRICHONÉMA: Romanes.**

**TRICHOPHILIA** (Greek, hair and cap; the anther is concealed under a cap surmounted by three tufts of hair). Orchidaceae. Handsome orchids, usually grown in pots, although epiphytal. Pseudobulbs crowded on the short rhizome, flattened and often elongate, 1-lvd., surrounded with dry scales at the base; lvs. large, solitary, erect, fleshy, keeled; fls. abundantly produced on short, nodding or decumbent scapes; sepals and petals narrow, spreading, often twisted; labellum large, forming the most conspicuous part of the fl., united with the column below, lateral lobes convolute, middle lobe spreading; anther bent over; pollinia on a triangular caudicle; cincinnus fimbrately winged.—About 20 species, ranging from Mex. to S. Amer. The fls. keep fresh a long time, both on the plant and when cut. They need an intermediate or greenhouse temperature. If grown too warm, they suffer. Prop. by division.
TRICHOPILIA

nobilis, Reichb. f. (Pilama nobilis, Reichb. f. T. candida, Lindl.). Pseudobulbs large: lvs. broadly oblong-acute: fls. white; sepals and petals linear-oblong, acute, 2 in. long; labellum twisted, greenish white, with a yellow spot in the throat. Vernacula. I. H. 19:94 (as T. fragrans var. nobilis). F.M. 1872:21 (as T. fragrans)—This has larger stouter pseudobulbs and shorter broader lvs. than T. fragrans. The labellum is larger and the petals shorter compared with the size of the fl. Var. alta, Hort., has fls. pure white.

tortilis, Lindl. Pseudobulbs oblong, compressed, somewhat curved, 2-4 in. long: lvs. solitary, oblong, acute, 6 in. long: fls. solitary, on decumbent stalks shorter than the lvs.; sepals and petals linear-lanceolate, 2½ in. long; spirally twisted, brownish green, sometimes with a yellow blotch at base of lip. Colombia. HEINRICH HASSELBRING.

suavis, Lindl. Fig. 3838. Pseudobulbs thin, compressed, 2 in. long: lvs. broadly oblong, 8 in. long; scape pendent, about 3-fl.: fls. on long, curved stalks, large; sepals and petals lanceolate-acute, wavy, 2 in. long; labellum large, twisted, brownish green; labellum forming a tube around the column, upper portion expanded, 4-lobed, white with crimson spots, becoming entirely crimson within. Fls. profusely in summer and sometimes again in winter. Mex. B.M. 5739. B.R. 1883. H.C. 3:101. B. 3:122. C.O. 5. Var. alta, Hort., is advertised.

TRICHOSANTHES (Greek, hair and flower, alluding to the fringed edge of the petals). Cucurbitaceae. Snake Cucumber. Climbing herbs, annual or perennial, sometimes shrubby at base, roots sometimes tuberous, grown both in the greenhouse and outdoors as tender annuals.

Leaves entire or 3-5-lobed, base cordate; tendrils simple or 2-3-crenate: fls. rather large or small, white, monocious; male fls. racemose, calyx-tube oblong or cylindrical, dilated above, 5-lobed, corolla rotate, 5- parted; stamens 3, ovary rudimentary; female fls. calyx and corolla as in male, stamens rudimentary or none; ovary oblong or globose: fr. usually large, fleshy, globose, oblong, ovoid-fusiform, or conical.—About 50 species, Trop. Asia, N. Austral, and Polynesia. Monographed in DC. Monogr. Phan. 3:351. The fr. is often ornamental and highly colored; in T. Anguina it has been noted over 6 ft. in length. The plants flower in July from seed sown in March. They may be treated as tender annuals.

A. Frutes or small or none on the racemes of male fls.

b. Fr. ovod.

cucumeroides, Maxim. Root fleshy, tuberous; st. slender, 12-15 ft.: lvs. ovate in outline, 4-6 in. long, more or less palmately 3-5-lobed, margin crenulate; peduncle bearing the male fls. 1-4 in. long and 3-15 fls.
TRICHOSANTHES

petals about ½ in. long, oblong, acute, longly fringed: fr. oblong, shortly rostrate, nearly 3 in. long, vermilion-colored. Japan.—Offered by importers of Japanese plants.

Anguina, Linn. (T. colombiana, Jacq.). SERPENT or SNAKE Gourd. Fig. 3839. St. slender, tall-growing: lvs. nearly circular in outline, 5-7 in. across, 3-7-lobed; lobes round; margin undulate or wavy: peduncle bearing the male fls. 4-10 in. long, 8-15-fld.: body of petals oblong, less than ½ in. long, fringed ½ in. long: fr. slender, contorted, often exceeding 3 ft. in length... B. R. 1859: p. 655.

AA. Bracts large on the male raceme.

b. Calyx-segments entire.

cc. Lvs. lobed.

Kirlibwii, Maxim. (B. vitifolius, Naud.). Perennial root tuber-like: st. annual, high-climbing, 20-30 ft.: lvs. nearly circular in outline, 3-8 in. across, deeply 5-7-lobed, the lobes oblong, acute, coarsely serrate: racemes bearing the male fls. 4-8 in. long, 3-8, rarely only 1-fld.: petals triangular-wedge-shaped, deeply cut and the segments, much cut and longly fimbriate, ovate, somewhat acute; base shortly attenuate, yellowish orange, about 4 in. long, 2½ in. in length. Mongolia.

cc. Lvs. not lobed.

cordata, Roxb. (T. palmata, Wall.). Root tuberous: st. robust, high-climbing: lvs. wide, ovate-cordate, acute or shortly acuminate, 5-8 in. long, rarely somewhat angled or obscurely lobed; margin slightly dentate: peduncle bearing male fls. 5-8 in. long, 4-8-fld.: calyx-segments finely acute: fr. globose, red, orange-streaked, not acute at the apex. India.

bb. Calyx-segments toothed.

bracteata, Voigt (T. palmata, Roxb.). St. stout, climbing to 30 ft.: lvs. broadly ovate, scabrous above, usually deeply 3-7-lobed; lobes acute; margin dentate: peduncle of male fls. 4-8 in. long, 5-10-fld.: fr. globose, red with orange stripes about 2 in. long. India.

F. W. BARCLAY. F. TRACY HUBBARD.†

TRICHOSMA (Greek, three and ridge, referring to the 3-lobeled labelium). Orchidaceae. A genus of 1 species resembling Cypea. Sepals and petals similar, erect spreading, the lateral pair forming a distinct mentum with the projecting foot of the column; labelium 3-lobeled, the lateral lobes erect, convolute over the column, middle lobe with longitudinal ridges: sts. slender, 2-lvd.: inflo. racemose. T. albo-marginata of the trade is unidentified.

sulivis, Lindl. (Éria coronaria, Reichb. f.). Lvs. lanceolate, undulate, 3-nerved: fls. few in a terminal raceme, white, yellowish or purplish, fragrant; sepals ovate-lanceolate; petals oblong; labelium ovate-oblong, streaked with purple; disk yellow, middle lobe with several crenate ridges. Himalaya. B. R. 28: 21.

HEINRICH HASSELBRING.

TRICHOSPORUM (Greek, hair and seed; seeds with 1 or more long hairs at the ends). Syn., Echynanththus, Geissorhiza. Subshrubs or shrubs, often climbing over trees, glabrous or rather villous, grown in the greenhouse. Lvs. opposite, fleshy or leathery: fls. showy, scarlet, greenish or yellow and green mixed, fuscaded in the axils or at the ends of the branches; rarely solitary; calyx truncate, 5-cleft or 5-parted; corolla-tube elongated, ventricose or broadened above; limb somewhat 2-lipped, usually strongly oblique; perfect stamens 4; disc annular, usually thick, cup-shaped; ovary superior, oblong or linear: caps. long-linear, 2-valved—About 55 species, India, Malaya, and E. Trop. Asia.

These beautiful free-flowering plants are propagated by cutting the branches that have been made during the season of growth into lengths of about 2 inches, having two leaves attached and another joint to insert in the sand. They root in about a month in a close frame when the temperature top and bottom is maintained around 70°. Being epiphytal under natural conditions, these plants like a loose open material to grow in, and equal parts of osmunda fiber and sphagnum moss to which plenty of broken charcoal has been added are the best potting material. Shallow pans are best to grow them in, and provision should be made for the water to pass freely through them. The plants should not be allowed to flower the first season, the aim being to secure a good foundation for a future plant, and this is done by pinching the shoots three or four times during the season, growing them in a night temperature of 65°. If properly tended they may be kept cooler and given enough water to prevent shriveling. The plants should not be stopped the second season, but allowed to run to flower; but after they have finished flowering they may be pruned back to within 6 inches of the base of the plant. Trichosporums should be grown hung from the roof of the house, near the glass, and when the sun gets strong they should have a light shade. When well rooted in the pan they are growing they will be subject to insect pests. (George F. Stewart.)

A. Calyx deeply 5-parted, the lobes acute.

grandiflorum, D. Don (Echynanththus grandiflorus Sprong.). St. creeping, mostly herbaceous, 4-5 ft.: lvs. lanceolate, acuminate, 4-5 in. long, repand-serrate, fleshy: fls. aggregated; calyx fleshy and short; corolla arches-tubular, 2-3 in. long, downy, orange-scarlet. E. India. B. M. 3843. P. M. 5: 241.—Will succeed in an intermediate house.

AA. Calyx tubular, entire or shortly 5-toothed.

Lobbianaum, Kunze (Echynanthus Lobbiana, Hook.). The commonest species in cult. in this country: differs from T. pulchrurn in narrower and nearly entire lvs., corolla downy and projecting only twice or less than the length of the purple downy.
TRICHOSPORUM  

caely. Java. B.M. 4260, 4261.—A very attractive plant when well grown.  

Wall. lvs. lanceolate: calyx tubular, short-toothed, gla-  

brous; corolla about 2 in. long, orange-red, pubescent. E. Indies. B. Dicheanum, Kunze (Erycbanthus javanicus, Hook.). Allied to T. pulchrum; differs in having a pubescent calyx and corolla, 1-fld.; fls. small and whitish, in corymbs, in clusters, axillary, solitary; calyx 1½ in. long, lobes narrowly lanceolate, acuminate; corolla cylindrical, funnel-shaped, scarlet with dark purple nerves and spots. SUMMER. T. marmoratum, Kunze (Erycbanthus marmoratus, F. Moore).  

Lem.), may be expected to appear in choice warmhouse collections.  

When well grown,  

TRICHOSTÉMA (Greek, hair and stamen, referring to the filaments). Lobélia. Blue Cups. Hardy or half-hardy herbs, adapted to the wild-garden or rockery.  

Leaves entire; floral lvs. similar: floral whorls axillary, densely or laxly many-fld.; calyx campanulate, 10-nerved, 5-toothed; corolla-tube slender, usually exserted, without a ring inside; limb subequally 5-cleft, lobes oblong or broadly declinate; stamens 4, didymo-  

mous; ovary deovly 4-lobed; nectaries obovoid, reticu-  

lately roseo. —About 10 species, N. Amer.  

dichóstéma, Linn. BASTARD PENNYROYAL. Low, viscid annual: lvs. oblong or lanceolate-oblong, obtuse, short-petioled; corolla blue or pink, sometimes white. Sandy fields, Mass. to Rv., Fla., and Texas.  

Janâtum, Benth. A perennial shrubby plant with rosemary-like lvs. and cymes of fls. in a naked terminal thyrse, 1-nerved, sessile, margins revolute; calyx and corolla covered with dense violet or purple wool; corolla ¼in. long. S. Calif.—A very handsome shrub, known as “ramero.”  

Pérpusi, Brandeg. Perennial, somewhat woody, much branched, 1-½ ft. high; lvs. short-petioled, ovate, ½-¾ in. long, dark green; floral whors axil- 

The petals are divided into 3 pointed lobes. Syn., Tricytis. Elascocarpos. Trees grown in the greenhouse, hardy in the extreme South where they are used as ornamentals.  

Leaves alternate or opposite, serrate: peduncles axillary, solitary, 1-fld.; fls. rather large; calyx cam-  

panulate, truncate, obliquely 5-toothed, deciduous; petals 5, 3-dentate or -lobed; stamens numerous; ovary 3-5-lobed, ovoids many in a cell: caps. leathery, usually angled, loculicidally 3-5-valved.—Two species, Chile.  

The accepted name is now Crinodendron.  

C. Patágua, Molina (C. Hoekeriannum, Gay. Tricytis dependens, Hook., not Ruiz & Pav. T. hexap­  

F. TRACY HUBBARD.  

TRICÝRTIS (Greek, three connexities, referring to the nectar-bearing stamens at the base of the three outer perianth-segments). Liliaceae. TOAD-LILIES. Half-hardy perennials, pretty garden plants; also used for pot culture.  

Rhzinus short-creeping; st. erect, simple below the infl., leafy; infl. terminal, or laxly dichotomous in the upper axis: fls. few, rather large, somewhat longpedicelled; perianth usually beau- 

tifully spotted inside, campanulate, segments distinct from the base, lanceolate, acute; stamens 6; ovary ob-  

long, 3-cornered, 3-lobed: caps. narrowly oblong. T. bicónsulá, L.  

a. Base of lvs. not clasping the st.  

b. Plant not stolon- 

férus.  

F. TRACY HUBBARD.  

TRICYRTIS (Greek, three connexities, referring to the nectar-bearing segments of the three outer perianth-segments). Liliaceae. TOAD-LILIES. Half-hardy perennials, pretty garden plants; also used for pot culture.  

Rhzinus short-creeping; st. erect, simple below the infl., leafy; infl. terminal, or laxly dichotomous in the upper axis: fls. few, rather large, somewhat long-pedicelled; perianth usually beautifully spotted inside, campanulate, segments distinct from the base, lanceolate, acute; stamens 6; ovary oblong, 3-cornered, 3-lobed; caps. narrowly oblong. T. bicónsulá, L.  

a. Base of lvs. not clasping the st.  

b. Plant not stolon- 

férus.  

F. TRACY HUBBARD.  

3377  

TRICYRTIS  

3841. Tricytis hirta. (×5)  

formosa,  

Baker. Sts. flexuous, about 1 ft. high: lvs. few, sessile, oblong-campanulate, acute, base cuneate, lower 4–5 in. long, ¾–1 in. broad, both surfaces green: fls. few, in a lax corymbs. yellow-purple, scarcely spotted, about ¾in. long: style as long as the stigmas. Formosa.
BB. Plant stoloniferous.

stolonifera, Matsum. Herbaceous, 2 ft. high, with a stoloniferous base: st. reddish purple below, greenish above, at first hairy, later glabrous; fls. elliptic-lanceolate, acuminate, narrowed to a sheathing base, 8-15 in., glabrous above, with dark blotches and sunken nerves; fls. purple, indistinctly blotched; perianth yellow at base, segms. elliptic, acute, 1 in. long, 2-laterally saccate at base. Fornosa. B.M. 8560.

AA. Base of lvs. clasping the st.

b. St. pilose, with spreading hairs.

hirta, Hook. (T. japonica, Miq.). Fig. 3841. St. 1-3 ft. high, everywhere clad with soft whitish spreading hairs; fls. 6-15, racemose or suberacemose, whitish, the outer segms. covered with rather large purple spots. Widespread in the woods of Japan. B.M. 5555. Gn. 30. p. 431; 49:290. V. 12:2294. Var. nigra, Hort. (T. nigra, Hort.), has black instead of purple spots. Gn. 49:290. A form with variegated lvs. was once offered in this country.

BB. St. not prominently hairy, puberulent or very slightly pilose.

c. Fls. yellow, unspotted.

flava, Maxim. St. dwarf: lvs. oblanceolate: fls. racemose, yellow, not spotted. Seen by Maximowicz in the gardens of Yedo only.

cc. Fls. spotted, not yellow.

d. Spots rather large.

pilosa, Wall. St. 2-4 ft. high, very slightly pilose: lvs. oblong: fls. numerous, loosely corymbose, whitish, with large purple spots; style half as long as the stigmas. Himalayas, 5,000-6,000 ft. B.M. 4955 (perianth-segms. narrowly oblong). F.S. 12:1219.

dd. Spots minute.

e. Style as long as the stigmas.

latifolia, Maxim. St. glabrous, flexuous, 2-3 ft. high: lvs. broadly oblong or the uppermost ovate: fls. few in a terminal corymb, whitish, with minute purple spots; style as long as the stigmas. Japan.

ee. Style half as long as the stigmas.

macropoda, Miquel. St. 2-3 ft. high, puberulous above: lvs. oblanceolate: fls. in a loose corymb, whitish purple, with minute purple spots; style half as long as the stigmas. Blooms in June and July, according to J. B. Keller. Japan, China. B.M. 6644 (perianth-segms. broadly ovate, decidedly yellow, spotted red and veined red near tips). In F. S. 18:1820 is figured a plant with sessile lvs. striated with white, and no fls., which he refers to T. macropoda. This was sent out by Van Houette as T. hirta, but it is a glabrous plant and probably lost to cult. Var. striata, Hort., is offered in the trade as a form with variegated green-and-white lvs.

T. grandiflora, Hort., should be compared with T. hirta, var. nigra. It is a name scarcely known to botany. It is said to have fringed flowers (basal and staminal). (In Oct. and Nov. there is no fragrant fl.). Dutch growers say that T. grandiflora has white fls. motted with black.

WILHELM MILLER.

TREDAX (an old Greek name used by Dioscorides, meaning summer eating, alluding to a plant that was a summer vegetable). Compositae. Hardy perennial herbs, possessing little beauty. Plants branched, hirsute or glabrous: lvs. opposite, incised-dentate or pinnately cut, segms. few and narrow; heads medium-sized, long-peduncled, heterogamous: ray-fls., yellow, male disk-fls. greenish, fertile; involucres ovoid, campanulate or rather hemispherical; bracts few-rowed, slightly unequal: achenes turbinate. About 27 species, Trop. Amer.; one species also occurs in India and Mauritius. Two species have been cult. occasionally. T. coronopifolia, Hemsl. About 1 ft. high; lvs. variously pinnatifid or trifid, lobes linear: fls. yellow, rays 5-lobed. Mex. T. triobata, Hemsl. (Gallinago tri­obata, Cav.). About 1 ft. high: lvs. 3-lobed or pinnately incised: fls. yellow; rays 5-toothed. Mex.

TRIENTALIS (Latin for the third of a foot; referring to the height of the plant). Primulaceae. STARFLOWER. CHICKWEED-WINTERGREEN. Very glabrous small perennials sometimes grown in wild borders. Rhizomes slender, creeping: st. solitary, slender, erect: lvs. usually the same number as the petals, somewhat whorled, obovate-elliptical or lanceolate, very entire; peduncles 1-3-fl., filiform, without bracts: fls. white; calyx 5-9-parted, segms. linear-lanceolate, persistent; corolla rotate, 5-9-parted; tube very short, segms. elliptic-lanceolate, very entire; stamens 5-9; ovary free, globose; caps. globose, 5-valved, many-seeded. Two species, one in Eu., the other in N. Amer.

AA. Lvs. acuminate at both ends.

americanus, Pursh. St. naked below, 3-8 in. high, 5-10-fl. at the summit: lvs. lanceolate: divisions of the white corolla finely acuminate. Damp woods, La. to Va.

ee. Lvs. obtuse (acute in var. latifolia).

europaeus, Linn. St. either naked or with a few scattered lvs. below the cluster of obovate or lanceolate oblong, obtuse or abruptly somewhat pointed lvs.: divisions of the white or pink corolla abruptly acuminate or mucronate. Alaska, Eu., and Asia. Var. arctica, Ledeb. Dwarf: lvs. in long decreasing divisions, white. Var. latifolia, Torr. St. naked below the cluster of 4-7 oblong-obovate, or oval, mostly acute lvs.: corolla white to rose-red. Woods, W. Calif. to Vancouver's Isl. By Pax & Knuth in Engler's Das Pflanzenreich, hft. 22, this plant is kept separate as T. lati­folia, Hook., making 3 species in the genus.

F. W. BARCLAY.

TRIFOLIUM (name refers to the three leaflets). Leguminosae. CLOVER. Low annual and perennial herbs, useful for cover-crops, soil-enrichment, and also in lawn-seed mixtures.

Leaves digitately 3-, rarely 5-7-foliate; stipules adnate to the base of the petiole; fls. usually purplish, red or white, rarely yellow, in spikes, heads, or umbels, or rarely solitary; calyx-teeth or lobes about equal or the lower longer, the 2 upper sometimes more or less connate; petals usually withering rather than falling off, more or less adnate to the base of the stamen-tube; stamens 9 and 1; ovary small, ripening into a few-seeded, mostly indehiscent pod. Between 200 and 300 species, most abundant in the N. Temp. zone.

The clovers are very important agricultural plants, but they have little distinctly horticultural value except as cover-crops and green-manures. See Clover, page 505, Vol. II. For the role of clovers as nitrogen-fixers, see Legumes, page 1834, Vol. IV. The species described
are offered mostly as forage plants. Many clovers are perennial, although they are of relatively short life, so that frequent resowing is necessary if plants are to be kept in robust condition. Some of the species are annual, and these tend to become weeds. All are propagated readily by means of seeds; but as the seeds are small and oily, they may not germinate well in dry hot soil. Some annual white-flowered species are offered in some parts, particularly in the East, where they have been introduced from Europe: T. agrarium, Linn., yellow or hop clover, with oblong-obovate sessile leaflets; T. procumbens, Linn., low hop-clover, more spreading, leaflets obovate and the terminal one stalked; T. dubium, Schth., with leaflets truncate or emarginate at apex and the terminal one stalked. A silky-pubescent white-flowered annual species from Europe, T. arvense Linn., is the rabbit-foot clover of fields and waste places. T. odoratum of seedsmen is evidently Melilotus. Allied genera are Lespedeza, Medicago, and Melilotus.

a. Fls. in a long spike.

incarnatum, Linn. Crimson or Scarlet Clover. Fig. 1633, Vol. II. Annual, erect, 1-3 ft. high, soft-hairy: lvs. long-stalked, the lfts. broadly obovate and denticulate and sessile or nearly so by a cuneate base, the stipules large and thin and veiny and somewhat toothed: heads becoming 2-3 in. long, very dense; lfts. sessile, bright crimson and showy, the calyx sharp-toothed and hairy. S. Eu. B.M. 328.—An escape in some places. Now much used as a cover-crop in orchards. See Cover-Crops. It is very showy when in bloom. If seeds are sown at midsummer or later, the plants may be expected to survive the winter and bloom early in spring.

rubens, Linn. Perennial, 20 in. or less tall, in clumps, the st. erect: lvs. short-stalked, the lfts. oblong-lanceolate and strongly denticulate, the stipules long-linear-lvd. marsh plants of little value to the cultivator, although 1 species is listed abroad for planting in bogs or wet places. Perennial, erect: lvs. rush-like, more or less diffuse or trailing glabrous plant: lfts. obovate and serrulate, and green-manuring.

filiforme, Linn. Yellow Suckling Clover. Annual, of diffuse growth: lvs. obtuse or obcordate, somewhat denticulate, the terminal one stalked, the stipules broadly ovate, lancilanceolate and somewhat denticulate, the lfts. oblong-lanceolate and subacute to retuse, ciliate and entire, the stipules small and loose: fis. white, fragrant. Eu. and thought to be native in the northern part of the U.S. and in Canada, but naturalized everywhere.—Much used in lawns, and in some places prised for pasture. There are forms with red and purplish foliage. This is considered by most authorities to be the shamrock of Ireland. A form of it is offered as T. minus, "the genuine Irish shamrock." See Shamrock. Var. atropurpureum, Hort., is a dwarf form: lvs. bronze, edged with bright green. Var. pentaphyllum, Hort., is a creeping rock-plant: lvs. have a bronze luster. Var. purpureum, Hort., has fine bronzy purple foliage. The species assumes many forms.

b. Corolla yellow.

c. Individual fls. pedicelled.

hybridum, Linn. Alsike or Swedish Clover. Ascending or nearly erect, 1-3 ft. high, branching, glabrous: lvs. long-stalked, the lfts. obovate and serrulate, stipules ovate-lanceolate and thin; heads small and loose, nearly globular, long-stalked: fis. rose-colored or sometimes white on the top of the head. Eu. B.M. 3702.—A good forage plant; also naturalized. Thrives best on moist lands. Very hairy. Perennial.

c. Fls. in globular or ovate heads.

Corolla white or ochroleucous (yellowish white).

alexandrinum, Linn. Egyptian Clover. Berseem. Annual, with appressed hairs, the st. tall, erect or ascending and branching: lvs. numerous, the lfts. oblong or lanceolate and somewhat dentilicate, the stipules lanceolate-subulate and partly free from the petiole: head stalked or sessile, ovate, becoming oblong-conic in fr.: fls. ochroleucous. Egypt. Syria.

pannonicum, Jacq. Hungarian Clover. Perennial, very hairy, the st. usually simple, 2 ft.: lfts. lance-oblong and subacute to retuse, ciliate and entire, the stipules narrow and longer than the short petioles: heads ovate-oblong, stalked: fls. pale yellowish white or creamy yellow. Eu., Asia.—Handsome plant for the border; also recommended for forage.

repens, Linn. White Clover. Fig. 3842. Low creeping glabrous perennial: lvs. long-stalked, the lfts. obtuse and obscurely toothed, the stipules small and scale-like: heads long-peduncled from the ground, small and loose: fls. white, fragrant. Eu. and thought to be native in the northern part of the U.S. and in Canada, but naturalized everywhere.—Much used in lawns, and in some places prised for pasture. There are

3843. Day and night positions of red clover leaf; unfolding young leaf at the right.

stipules ovate-lanceolate and thin; heads small and loose, nearly globular, long-stalked: fis. rose-colored or sometimes white on the top of the head. Eu. B.M. 3702.—A good forage plant; also naturalized. Thrives best on moist lands. Very hairy. Perennial.

c. Individual fls. sessile.

d. Plant perennial.

pratense, Linn. (T. pratense perennis, Hort.). Common Red Clover. Pea-Grass. Fig. 3843. Ascending and somewhat hairy, 1-½ ft.: lvs. long-stalked, the lfts. oval or obovate and sometimes notched at the end and the blade marked with a large spot, the stipules broad but with a bristle point: heads globular, ovate, sessile: fls. red-purple. Eu., but everywhere intro., and much grown for pasture hay and green-manuring.

dd. Plant annual.

resupinatum, Linn. (T. suaveolens, Willd.). Annual, diffuse or trailing glabrous plant: lfs. obovate and serrulate and as long as the petiole, the stipules lanceolate-acuminate: heads globose, with rudimentary involucres; fls. purple. Greece, Egypt to Persia.—Grown for ornament.

I. H. B.

TRIGLOCHIN (Greek, referring to the 3-pointed fruit of some of the species). Alismaceae; or by Buchenau in Engler’s Das Pflanzenreich, hft. 16 (IV. 14), 1903, placed in the Scheuchzeridce. Thirteen species of linear-lvd. marsh plants of little value to the cultivator, although 1 species is listed for planting in bogs or wet places. Perennial, erect: lfs. rush-like, more or less fleshy, sheathing at base: fls. small, spicate-raceme, on a long jointless naked scape, greenish; perianth of 3-6 parts; stamens 3-6; ovaries 3-6, united. T. maritima, Linn., the species mentioned, is widely distributed in the northern hemisphere along seashores and also in interiors: scape to 2½ ft. tall: lvs. thick: fr. ovoid or prismatic, pedicelled, in a long open racemose spike. The plant has a grass-like appearance and inconspicuous bloom.
TRIGONELLA (Latin, a little triangle; probably referring to the shape of the fls.). Leguminosae. Annual or perennial herbs, usually strong-smelling; Ivs. pinnately 3-foliate; lfts. with the veins often running out into teeth; stipules adnate to the petiole: fls. yellow, blue, or white, solitary, capitulate, somewhat umbellate or shortly and densely racemose, sessile or pedunculated at the axils; calyx tubular; petals free from the stamens, standard obovate or oblong; wings oblong, keel shorter than the wings, obuse; stamens 9 and 1; ovary sessile or short-stipitate, many-ovuled; pod sometimes thick and long-angled, sometimes linear, compressed or terete.—About 58 species, 1 from Australia, the others from Eu., Asia, and extra-Trop. Af.

Fænæm-Græcum, Linn. Fenugreek, which see. White-flèd. annual, 1-2 ft. high, blooming in June and Aug. Distinguished from other species in its section by the erect unbranched st. and obovate lfts., which are obscurely dentate; stipules lanceolate-falcate, entire: calyx pilose: pods falcate, twice as long as the beak. Eu., Orient.

F. TRACY HUBBARD.†

TRIGONIUM (Greek, three and small angle, alluding to the triangular form of several parts of the plant). Orchidaceæ. Epiphytic herbs, grown in the warmhouse.

Stems very short, soon thickened into fleshy 1-2-lvd. pseudobulbs: lvs. leathery, not folded, linear or oblong; scape from below the pseudobulb or from a simple rhizome, many-sheathed, 1-fld.: fls. rather large, short-pedicelled, between spathe-like bracts; sepals about equal, connivent or coherent into a 2-angled tube at base; petals much smaller than sepals; lip erect, lateral lobes clasping the column, midlobe spreading, fleshy or callous at base; column without wings or lateral lobes clasping the column, midlobe spreading at base; petals much smaller than sepals; lip erect, oblong: scape from below the pseudobulb or from a pseudobulb, oval, compressed, 2-lvd., compressed: fls. - heads about 1 in. long. Aug., Sept.

spatulatum, Lind. & Reichh. f. Pseudobulb ovate, 2-edged: l. broadly ligulate, 8 in. long: fl. terminal; dorsal sepal ovate from a ligulate base, acute, lateral sepals oblong-lanceolate, acute, all yellowish purple; petals lanceolate, with a fleshy disk below the apex; lip narrow, angulately 3-lobed, midlobe transversely semi-ovate, rather acute. Colombia.

subspèns, Rolfe. Rhizome subreptent, stout: pseudobulbs rather distant, oblong, somewhat compressed, obscurely 3-ribbed, about 1 in. long, 1-lfd.: l. ligulate, rather obtuse, 6-7 by about 1 in., rather leathery: scape 6-7 in., his with numerous lanceolate sheaths; dorsal sepal rhomboid-oblong-lanceolate, about 1 in. long, lateral suboblique, broad-elliptic, all greenish yellow; petals whitish with 3 brown lines, narrowly illiptic-oblong; lip greenish yellow, with brown radiating veins on the side lobes, 3-lobed, short, midlobe oblong. Habitat unknown.

The following species are sometimes found in coll.: T. acuminatum, H. & B. (Trigona). Pseudobulb ovate, acute, sulcate: l. linear; fl. dull straw-yellow, reflexed: petioles very short, all yellowish green; lfts. recurved at apex; petals ovate-lanceolate. British Guiana.—T. Eryngium, Batei. Very similar to the above, ovate, compressed, 2-lvd.; lfts. oval, often 1½ in. long, linear-spatulate, acute, 6-7 in.; bl. compressed, densely pilose at the base; petals yellow with brown veins; sepals ovate-lanceolate, apex acuminate, about 1 in. long, violet; lip with a fleshy yellow front lobe and narrow purplish side ones.—T. odoratissima, Cass. (Liatrîs odoratissima, Michx.). VANILLA PLANT. Also called Carolina vanilla, dog's-tongue, etc. Rather stout, glabrous, perennial herb 2-3 ft. high, corymbose branched above: lvs. entire or sometimes dentate, oblong, 4-10 x 1-1½ in., oblong, ovate or oval, sometimes spatulate: fls. corymbose-paniculate: fls.-heads about 1 in. long. Aug., Sept. B.B. 3:319.—The other species (T. paniculata, Cass.) has a similar range and is distinguished by its viscid-pubescent st. and thyrsoide-paniculate fls.

TRILLIUM (Latin, trîplum, triple: leaves and floral parts in threes). Lilàceæ. Wake-Robin. BIRTHROOT. WHITE WOOD LILY. GROUND LILY. Interesting and handsome perennial herbs, hardy and very useful for spring-flowering in the wild border or rockery or even in the garden border.

Rhizome short, thick, ascending or horizontal; stts. simple, erect, sheathed at base: lvs. 3, whorled at the top of the stalk: flowers 3, 6-7 in., the petals usually larger, spreading, 3-nerved; fls. 1, between the lvs., sessile or pedicellate, erect, cernuous or reflexed, violet, lurid, white or greenish; perianth persistent, segments distinct, spreading, 3 external thinner herbaceous, green or rarely colored, 3 inner petals like usually larger, spreading, sometimes recurved; stamens 6; ovary with a broad base, sessile, ovoid or subglobose, 3-celled: berry globose or ovoid, usually 3-ribbed, indehiscent.

—About 30 species, N. Amer. and extra-Trop. Asia from the Himalayas to Japan.

Trilliums are amongst the characteristic flowers of American woods. The best-known species is T. grandi-florum, which ranges from Canada to the mountains of North Carolina and extends westward beyond the Great Lakes. All trilliums delight in moist rich soil. They thrive in woods mold. The root is a deep-seated mostly perpendicular rhizome (Fig. 3844). It is customary to transplant trilliums from the woods when in bloom. This is because the plants can be found readily at that time and because the desire to grow them is strongest when the plants are in flower. It is better to transplant in midsummer, or later, however, when the growth is completed, although the plants are difficult to find after the tops have died. The bloom is made largely from the energy stored in the tuber the previous season. After flowering, the plant stores energy for the succeeding year. By midsummer this work is accomplished and the tops die; then the plants are at rest and they are in proper condition to be moved. However, good results are sometimes secured by moving them in spring. These remarks will apply to most early spring-blooming small herbs. Give trilliums a rich deep rather moist soil in partial shade. Plant deep. A colony will last for years. Trilliums force well. See Forcing. Plants may be propagated by seeds sown as soon as ripe. Blooming plants may be expected in two or three years. Trilliums are among the choicest of all
early spring plants, and they should be more common in gardens. They can be made to thrive well in borders about city yards. They may also be colonized in grass where the lawn-mower is not used. Best results are usually attained, however, when they are planted alone in masses.

INDEX.

3845. Trillium sessile var. californicum. (X about 1/4)

3846. Trillium grandiflorum. (X X3)

2. nivale, Ridd. A dwarf species, 5 in. or less high, early: lvs. narrow and obtuse, 1-2 in. long: fls. white, on a short erect or inclined pedicel, the petaloids about 1 in. long, narrow and nearly or quite obtuse. Low woods, Pa. and Ky. to Minn. and Iowa. B.M. 6449.

3. undulatum, Wild. (T. erythrocrophum, Michx. T. pictum, Pursh.) Of medium to large size, 1 ft. or more high: lvs. large, ovate and acute or acuminate, short-stalked: fls. rather large, white, on a short but slender erect or inclined pedicel, the petals ob lanceolate and wavy, about 1 in. long and usually purplish at the base. Woods, Nova Scotia to Mo. and Ga. B.M. 3002. L. B.C. 13:1232.

4. sessile, Linn. Strong-growing, 1 ft. or less high: lvs. broadly ovate or rhomboidal, acute, more or less spotted: fls. sessile in the whorl of lvs., small, purple or greenish, the petals narrow and acute. Woods, Pa. to Minn., Ark., and Fla. B.M. 40. L.B.C. 9:875. F.S. 22:2311.—Variable. Var. giganteum, H. & A. (var. angustipetalum, Torr.). Similar to var. californicum, but the lvs. somewhat petiolate and the petals narrower. Calif. and Ore. Apparently not in the trade. The forms of T. sessile appear to be the only trilliums native to Calif. except T. ovatum. Var. californicum, Wats. (var. giganteum, Torr.). Fig. 3845. Much stouter, the lvs. often 6 in. long and spotted, and the petals sometimes 4 in. long: fls. purple, rose-color, or white, the petals rhomboidal-ovate or narrower. Calif. and Ore. G.F. 3:321 (adapted in Fig. 3845). Var. Nuttallii, Wats. (T. viridescens, Nutt.). Lvs. pubescent beneath, as also the upper part of the st.: petals linear-lanceolate, purplish green with brown base. Ark. Var. rubrum, Hort. A form of var. californicum, with lfs. deep red-purple. Var. Wrhayi, Wats. (T. discolor, Wray). Petals spatulate-obtuse, 1 in. long, greenish. Ga. B.M. 3097.

5. lanceolatum, Boykin (T. recurvatum var. lanceolatum, Wats.). Plant often more than 1 ft. tall: lvs. lanceolate, sessile: fls. dull or brown-purple, an inch or
TRILLIUM

more long, narrow-lanceolate or linear, the sepals ascending or somewhat reflexed, the filaments usually exceeding 3° in. in length. Ga. and Ala.—Little known in cult.

6. recurvatum. Beck. Strong-growing, usually 1 ft. or more high: lvs. ovate or ovate-oblong, tapering to both ends, on short but slender petioles: fls. brown-purple or dull purple, about 1 in. or more long, the petals narrow and erect, the sepals narrow and reflexed. Woods. Ga. to Minn., Mass. and Me. B.M. 3250. Not known to be in the trade.

7. petiolatum, Pursh. St. scarcely arising above the ground: lvs. ovate-elliptic to reniform, with stalks as long as the blade or even longer (blade 3-5 in. long): fls. purple, the petals 1-2 in. long and narrow-ob lanceolate, the sepals erect. Idaho, Ore. and Wash.—Little known in cult.

8. grandiflorum, Salisb. Figs. 1588 (Vol. III), 3846. Stout, 1 ft. or more high: lvs. broad-ovate or rhombic-ovate, narrowly to broadly roundish-rhomboidal, abruptly acuminate, 3-8 in. long: fls. dark purple, recurved or deflexed; sepals lanceolate to ovate-lanceolate, acute; petals about the same length. ovate or broadly ovate, acute or obtuse. N. C., Tenn., and Ga., in the mountains.—Allied to T. erectum.

12. pusillum, Michx. Small, usually not 1 ft. high: lvs. lanceolate or oblong, oblong-flattened, less than 1 in. long, on a short erect pedicel, petals lanceolate and exceeding obtuse petals. Pine lands, N. C., S. C.

13. cernuum, Linn. Plant 1 ft. or more high: lvs. very broadly rhombic-ovate, nearly or quite sessile: fls. white, the petals 1 in. or less long, ovate-lanceolate, wide-spreading or reflexed, undulate, equaling or exceeding the sepals. Newfoundland to Ga. and Mo. B.M. 954. Mn. 10:49.

14. stylonum, Nutt. (T. seeroutum, Ell., and T. Crises, Ell.). Slender, 12-14 in. high: lvs. ovate-lanceolate, narrow at each end, short-stalked: fls. rose-color, the petals oblong, obtuse or acute, curved, undulate, sometimes 2 in. long. N. C. to Fls.

T. Cernuum, Wall. A species of Temp. Himalaya, little known and described by Hooker as follows: "Lvs. shortly petiolate, ovate or ovate-cordate, acute: sepals subequal, narrowly linear."—T. obsoletum, Pursh. Founded on a Canadian plant, which has been referred to T. erectum. Maximowicz keeps it distinct, however, extending its range to Kamchatka and Japan. It is the T. erectum var. japonicum, Gray. According to Wall., "is distinguished by a somewhat produced connective (between the anther-cells) and very short stigmas."

9. ovatum, Pursh. Much like T. grandiflorum, but the petals narrow-lanceolate or narrow-ovate, the sepals 1-2 in. long, narrow, or less rhombic. Calif. to B.'r. Col.—The Pacific coast representative of T. grandiflorum.

9. ovatum, Pursh. Much like T. grandiflorum, but the petals narrow-lanceolate or narrow-ovate, the sepals 1-2 in. long, narrow, or less rhombic. Calif. to B.'r. Col.—The Pacific coast representative of T. grandiflorum.

TRIPETALÉIA

(Tripetalum, name shortened by Linnæus from Triostospernum, which is from Greek for three bony seeds). Caprifoliaceae. Feverwort. Horse Gentian. Coarse hardy perennial herbs, glabrous or glandular-pilose: st. rather simple, terete: lvs. opposite, sessile, rather fiddle-shaped or obovate, entire: fls. usually solitary, axillary, solitary or clustered, dirty white, yellow, or purple; calyx-tube ovate, limb 5-lobed, persistent; corolla tubular-campanulate, base of tube gibbous, limb oblique, lobes unequal; stamens 5; disk small, swollen; anthers 5-celled: berry fleshy, ellipsoid, 3-5-celled. About 8 species. N. Am., Himalayas, and China.

perfoliátum, Linn. St. 2-4 ft. high, stout: lvs. ovate, shortly acuminate, narrowed below into connate-perfoliate or simply connate base: corolla dull brown-purple. Rich soil. New England and Canada to Ill. and Ala. B.B. 3:234.—Sometimes offered by collectors. It is a weedy plant of very easy cult. P. W. BARCLAY.

TRIPÉTEA

(Greek, three and petals). Ericaceæ. Two species of Japanese shrubs with deciduous alternate, short-petioled entire lvs. and white or pinkish fls. in terminal racemes or panicles: sepals and petals 3; stamens 5, shorter than the petals, the anthers opening with a longitudinal slit; ovary 3-celled, superior, short-stalked; style slender, curved: caps. septicidal, many-seeded. Closely allied to Elliotia, but easily distinguished by its 3-merous fls. T. paniculata has proved well hardy at the Arnold Arboretum, and probably also by cuttings. T. paniculata, Sieb. & Zucc. Shrub, to 6 ft.: lvs. short-petioled, rhombic or rhombic-ovate, acute, cuneate at the base, glabrous except a few hairs on the midrib beneath, 1-2½ in. long: fls. in panicles 2-4 in. long, white, tinged pink, 1½ in. long, style exserted; bracts subulate. Aug.-Sept.

3382
TRIPETALEIA

Japan. T. bracteata, Maxim., has smaller obovate obtuse lvs. and pink fls. in racemes, with elliptic or obovate bracts. Japan.

ALFRED REHDER.

TRIPHASIA (from the Greek for tripælia). Ratibidae, tribe Cistaceae. Small ornamental shrubs or trees distantly related to the orange, sometimes used as hedge-plants.

Plants with spreading branches; spines double, axillary; lvs. alternate, sessile, trifoliolate; fls. cupulate, 3-merous, white, stamens 6, free; fr. an ovate berry filled with a sweet, sticky pulp and containing usually a solitary seed. —Only 1 species is known.

trifolia, P. Wilson (Lamomia trifolia, Burm. T. americana, Lour. T. trifoliata, D.C.). LIME-BERRY. Fig. 3818. A shrub or small tree, sometimes attaining a height of 15 ft.: lvs. trifoliolate, dark green; lfts. ovate, retuse, entire-margined, lateral ones smaller than the central one; spines in pairs, straight, very sharp, shorter than the lvs.: lfts. white, fragrant, axillary, solitary; petals thick; stamens free, filaments subulate, shorter than the corolla; style thick, longer than the stamens; fr. ovate, small, dull red, \( \frac{1}{2} \) in. diam., having a thick skin, 1-celled, generally with only a single large seed, imbedded in the mucilaginous spicy pulp. Burmann, Fl. Ind., tab. 35. Jacq. Icon. pl. rar. v. 3, pl. 463. L.B.C. 1:18. Riss. & Poit. Hist. nat. ou. 2 ed., pl. 108. —Of unknown nativity but widely cult. and naturalized in tropical and subtropical regions, being grown as an ornamental plant. Prop. by seed. The frs., which are filled with a highly aromatic juicy pulp, are sometimes used in tropical countries for making marmalade. The shrub is attractive, flowering and fruiting freely and is used for lawn planting and hedges, but it is injured by severe frosts. This species is able to grow in soil too salty to support the common citrus frs. and is being tested as a stock for use on such soil.

WALTER T. SWINGLE.

TRIPHORA (Greek, bearing three flowers). Orchidaceae. Terrestrial plants with leafy sts. and fleshy tubers. Fls. axillary, solitary or several; sepals free, equaling the petals; lip erect, not crested, spurless, 3-lobed; column elongated, clavate; pollinia granular-powdery, tailless. —Species about 10, American. By some authors retained in Pogonia.

trianthophora, Rydb. (T. pendlula, Nutt. Pogonia pendula, Lindl.). Sts. sometimes tufted, 2-12 in. tall; lvs. nearly orbicular to ovate, 2-8 in. long, clasping: fls. single, or 2-7, drooping, pale purple; sepals and petals obtuse, elliptic; lip about as long as petals, narrowed into a short claw. E. N. Amer. B.R. 908.

GEORGE V. NASH.

TRIPLARIS (Latin, from tripælia, the parts of the fructification are in 3's). Syn., Velasquézia. Polygonaceae. Trees grown out-of-doors in the extreme S., in the warmhouse in the N. Lvs. alternate, short-petioled, column elongated, clavate; pollinia granular-powdery, tailless. —Species about 10, American. B.R. 908.

TRIPLETREE (Latin, from tripælia, the parts of the fructification are in 3's). Syn., Velasquézia. Polygonaceae. Trees grown out-of-doors in the extreme S., in the warmhouse in the N. Lvs. alternate, short-petioled, column elongated, clavate; pollinia granular-powdery, tailless. —Species about 10, American. B.R. 908.

TRIPLETTREE (Latin, from tripælia, the parts of the fructification are in 3's). Syn., Velasquézia. Polygonaceae. Trees grown out-of-doors in the extreme S., in the warmhouse in the N. Lvs. alternate, short-petioled, column elongated, clavate; pollinia granular-powdery, tailless. —Species about 10, American. B.R. 908.

TRIPSIACUM (Greek, to rub or thrash, probably alluding to the ease with which the fertile spike can be broken up). Gramineae. Perennial grasses with stout culms and monocious infl., in spikes terminating the culm and branches: fls. monocious, in the same spike, the stamineate above; spikes terminal and axillary; stamineate spikelets 2-fld., in pairs at each joint; pistillate single, 1-fl., imbedded in each joint of the rachis, so that the smooth cartilaginous axis and the outer glume form a nearly cylindrical mass; at maturity the pistillate spikes separate into the joints. —Species about 6, of the warmer parts of N. Amer., one extending north to Cent. U.S. and in many places furnishing considerable native fodder.

dactylolides, Linn. (T. violaceum and T. Dactylis of the trade). GAMA-GRASS. SESAME-GRASS. Culms in bunches, 4-7 ft.; spike 2-3 at summit and often single from the upper axes. Moist soil, Conn., Ill., Kans., and southward. Dept. Agric., Div. Agrost., 20:13. —A wild fodder-grass, sometimes cult. for forage and also in gardens as a curiosity. Raised from seed, or more certainly from cuttings of the rootstocks.

For an illustrated account of Tripsacum-Euchlaena and Tripsacum-Zea crosses, see article by Collins and Kempton, Journal of Heredity, March, 1916.

A. S. HITCHCOCK.

TRIPTERYGIUM (Greek, three and wing, in reference to the 3-winged fr.). Celastraceae. Three shrubs from E. Asia with deciduous alternate rather large lvs. and small white fls. in terminal panicles; fls. polygamous; calyx 5-lobed; petals 5; stamens 5, inserted at the margin of a cupular disk; ovary superior, 3-angled, incompletely 3-celled, with short style; fr. a 3-winged, 1-seeded nutlet. The following species has proved hardy at the Arnold Arboretum and is a handsome shrub conspicuous chiefly on account of its large bright green foliage contrasting well with the reddish brown sts. terminated in July and Aug. by conspicuous panicles of small whitish, fragrant fls. It apparently grows well in my soil. Prop. is by seeds and probably by cuttings.

T. Regelii, Sprague & Takeda (T. Wulfordii, Regel, not Hook. f.). Glabrous shrub, to 2 ft., with angled warty reddish brown branches: lvs. petioloed, broadly elliptic, acuminate, broadly cuneate at the base, serrat, 3-6 in. long.: fls. greenish white, \( \frac{1}{2} \) in. across, in terminal panicles leafy at the base, and to 8 in. long; fr. little over \( \frac{1}{2} \) in. long, with 3 broad wings. July, Aug. Manchuria, Korea, Japan. Gt. 18:612. Not yet in the American trade.

ALFRED REHDER.
TRISETUM (Latin, three and brevisset: the florets are 3-awned). *Gramineae.* Tufted hardy perennials of no real horticultural interest. Inf. terminal spike-like or loose panicles: spikelets 2 (rarely 3–5)–fl.; rhachilla prolonged beyond the upper palea; glumes unequal, keeled; lemma membranaceous, keeled, 2-toothed at apex, bearing a slender dorsal sana; palea narrow, 2-toothed. About 90 species, widely distributed throughout the temperate regions of the world. *T. flavescenta,* Beauv. (Arvensis flavescenta, Lam.). Calyx 1½–2⅔ in. high, erect, simple, glabrous: sheaths shorter than the internodes; ligule ½ in. long; blades 1½–5 in. long, 1–3 lines wide: panicle open; branches somewhat flexuous: spikelets 3–4–fl.; glumes smooth or scabrous; awn long, bent, and twisted. Exu., Asia, and intro. into Amer. B.B. (ed. 2) 1:217. Not in common cult., but occasionally used in agriculture.  
F. Tracy Hubbard.

TRISTAGMA (Greek, three drops, alluding to the 3 nectar-glands of the ovary). Including *Stephanolirion,* *Lilirha.* Herbs with subglobose tunicate corms, used for fall-blooming. Lvs. radical, few, narrowly linear: scape simple, leafless: fls. in a terminal umbel, not loose: spikelets 3–4–fl.; glumes smooth or scabrous; awn long, bent, and twisted. Eu., Asia, and intro. into Amer. B.R. 1861, a French botanist). Lvs. 6–9 in. long, about 2 lines wide: scape slender, about 1 ft. long: fls. 1 in. long, 2–5 in. umbel, the segms. linear and greenish; crown none. —Now treated by Baker as *Brodiaea.* Baker. Likely to be offered by Dutch bulb-growers.  
T. narceaeoides, Bent. & Hook., does not appear to be in the American trade. It is 1 ft. or more high, with short narrow-linear lvs., and white fls. bearing a bright orange narrow-lance-like crown of 3–5 broad unequal more or less connate scales.  
F. Tracy Hubbard.†

TRISTRAMA, R. Br. (Lophostemon arborascens, Schott). BRISBANE BOX. Fig. 3549. An unbranched tree attaining 150 ft.; young shoots and calyx hoary-pubescent; lvs. 3–6 in. long, ovate-lanceolate, glabrous, usually crowded at the ends of the branches and apparently verticillate; fls. mostly on the branches well below the lvs.; petals about 1½ in. long, white and spotted, fringed. Queensland. B.R. 1839 (as *T. macrophylla*). —A handsome evergreen shade tree, valuable for avenues in hot dry regions, as it withstands great drought; it also produces timber valued for strength and durability. Much grown in New S. Wales as a boulevard tree. Hardy in Cent. Calif., withstanding an exceptional temperature of 26° F. at Berkeley.

Joseph Buett Davy.

TRISTELLATEIA (Latin, three and star: each flower has 3 winged frs., which have the appearance of stars). *Malpighiaceae.* Scandent shrubs, probably adapted only to the warmhouse. Lvs. opposite or verticillate in 4's, entire, petioles usually 2-glandular at the top, base with 2 very short atipules; racemes terminal or lateral, sometimes paniculate; fls. yellow; calyx 5-parted; petals clawed, keeled outside, sagittate-ovate; stamens 10, all perfect; ovary 3-lobed: samara 3, mature at the latter part of October. About 20 species, Madagascar, Indian Archipelago, and Austral. *T. australis,* A. Rich. Strong climbing shrub with pendent shoots; lvs. ovate or ovate-oblong, 2–x1–2½ in., glabrous; racemes 2–6 in. long; fls. opposite, short-peduncled, yellow; petals 5, obtuse or ovate-oblong, 5–6 lines long; filaments finally deep red. Malaya and Australasia. B.M. 3334.

TRITELIA: *Brodiea.* The following species, listed under *Tritelea,* is to be combined with the treatment of *Brodiea* in Vol. I, p. 576.  

"is probably a form of this species rather than the *T. violacea,* Kunth, a Chilean species."  
L. H. B.

TRITHRINAX (apparently triple Thrinax, alluding to leaf-division). *Palmaceae,* tribe *Carypeae.* South American fan palms, some of which are known to be cultivated in the open in the United States. The genus is distinguished from allied genera chiefly by the following characters: fls. hemaphrodite; petals inbicate; filaments connate into a tube; carpels distinct; styles long, distinct, terminal in fr.—Five species. *T. brasiliensis* is a little-known palm. It seems to have been confused in the trade with *Thrinax Choco,* which is referred to this work as *Acanthorhiza Choco.* The fls. of the former are bifid; of the latter apparently not. André says the first species described below is unique by reason of its sheaths at the base of the lvs. These, he says, "are composed of fibers which are at first parallel and longitudinal, then obliquely intersected and finally plaited at right angles like the mats of pandanus in which the coffee of the Antilles and Bourbon is exported. At the summit these narrow strips unite and form a series of very long, robust, recurved spines which are evidently designed to protect the fls. and frs. against climbing animals." Not in common cult. in Amer., although 3 of the 5 known species are planted.

brasiliensis, Mart. Trunk slender, 6–12 ft. high, 2–3 in. thick: lvs. palmate-flabelliform, glabrous and often

bracteolata, Mart. Plant as above, 6–12 ft. high: lvs. palmate-flabelliform, glabrous and often

brasiliensis, Mart. Plant as above, 6–12 ft. high: lvs. palmate-flabelliform, glabrous and often

campêstris, Drude & Gris. Fig. 3850. Differs from T. brasiliensis in the segms. being shallowly bifid and

white-tomentose above but nearly glabrous beneath, and with stouter spadix branches: plant more rigid. Argentina.— Said to be a striking palm.

acanthócoma, Drude. Dwarf, stout, with many strong reflexed spines, the caudex with netted sheaths: lvs. large, fan-like, cut nearly to base into about 40 narrow bifid segms.: spadix branched. Brazil. Gt. 27:301.

TRITICUM (old Latin name for wheat). Gramineae. The genus as now limited comprises 2 sections, Eglitops, with 12 species of S. Eu. and Asia, one of which is thought by some to be the original of the cult. wheats; and Triticum proper, which includes wheats and speltcs. As far north as N. Y. and Mass., however, they are usually best wintered in damp (not wet) earth indoors. The best-known kinds are T. vulgare (Linn. (T. sativum, Lam. T. vulgare, Vill.). (For account of a wild species of Syria, the probable ancestor of wheat, see Aaronsohn, Bull. Soc. Bot. France, 56:227). T. Richardsonii, Trin. Under the name Cryptopyrum Richardsonii, Schrad., this species has sometimes been catalogued by seedsmen as an ornamental plant. It is a perennial with a slender nodding spike of awned spikelets. The species property belongs in Agropyron (A. Richardsonii, Schrad.) and resembles the wild A. caninum, Linn., with which some authors unite it. It is native from Que. across the continent. A. S. Hitchcock.

TRITOMA: Kniphofia.

TRITONIA (name explained as follows by Ker-Gawler, its author: "Name derived from Triton, in the signification of a vane or weathercock; in allusion to the variable direction in the stamens of the different species"). Including Montbretia. Iridacae. BLAINVILLE. Sth. Afr. Showy-flowered corn-bearing herbs used both as greenhouse and summer-blooming subjects.

Corms or bulbs small, covered with fibrose sheaths or tunics: sts. simple or slightly branched: lvs. few, narrow-linear or broader and sword-shaped, usually falcate: spathes disposed along the rachis or the few branches, short, membranaceous, often 3-toothed: fls. 1 to 2 in a spathe, sessile; perianth-tube slender, limb concave or broadly campanulate, lobes obovate or oblong, nearly equal; ovary 3-celled: caps. membranaceous, ovoid or oblong.—About 50 species, S. Afr. Allied to Crocosmia, Acidanthemum, Sparaxis, and Cladiolus. Few of them are in general cult., although many of the species have been intro. at one time or another. Those of the Montbretia class are showy hardy summer-flowering bulbs, to be handled like gladioli; or they may be left in the ground permanently if given protection of mulch in cold climates. As far north as N. Y. and Mass., however, they are usually best wintered in damp (not wet) earth indoors. The best-known kinds are T. crocosmiflora and T. Potzii. Most of the Latin names in catalogues belong to these, as sulphurea, tigridea, pyramidalis, grandiflora, elegans, floribunda. To gardeners, tritonias are usually known as montbretias. Garden tritonias grow 1 ft. or more tall, producing several to many showy fls. of a yellow, orange, or red color, and bearing several stiffer linear or sword-shaped lvs.

a. Three lower perianth-segms. bearing hatchet-shaped processes.

bracteata, Worsley. True lvs. about 3, appearing after flowering, about 1 ft. high and 3 in. broad; the early lvs. are really bracts: scape about 1 ft. high, flexuous, much branched; fls. 50-60, tawny red, scentless, opening singly or in 2's, subtended by the large foliaceous bract, irregular in shape, about 1 in. across; outer segms. about 3 in. broad, inner segms. about 3 in. broad and recurved. S. Afr.

aa. Three lower perianth-segms. without hatchet-shaped processes.

b. Fls. hooded.

Clusiána, Worsley. Allied to T. secuira, from which it differs in having lvs. twice as long and wide, no obtuse or other indentation on the outer perianth-values: plant about 1 ft. high; fls. orange (?), hooded, all facing one way. S. Afr.—This species with hooded fls. seems to form a link between Tritonia and Antholyza.

bb. Fls. not hooded.

c. Perianth-segms. obovate.

crocáta, Ker-Gawler. Slender, simple or branched from near the base, bearing few fls. in loose 1-sided racemes: fls. about 2 in. across, tawny yellow or orange-red, the stamens one-third the length of the perianth-limb. Cape Colony. B.M. 184 (as Ixia crocata). Gt. 54: 82. Var. miniatá, Baker (T. miniatá, Ker-Gawler), has light red fls. B.M. 609. There are color varieties, as purpurínea, Hort., cocca-

3850. Tritonax campêstris.

3851. Tritonia Pottsii. (x4)
TRITONIA

**TRITONIA** (Greek, wheel and to allude) is a genus of flowering plants in the family Iridaceae, comprising about 100 species, widely dispersed over the world.

Some of the following plants occur in the trade under *Montbretia* (or *Tritonia*).

- **Crocosmia** (Montbretia) is a genus of flowering plants in the family Iridaceae, comprising about 30 species, native to South Africa and Madagascar. The name *Crocosmia* derived from the Greek words κρυος (kryos) meaning frost and σμια (smia) meaning dew, referring to the frost-resistant nature of the plant. Crocosmia are deciduous perennial plants with sword-shaped leaves and bright orange-red flowers in summer. They are commonly grown as garden plants and are known for their vibrant colors and easy care.

- **Tritonia** crocosmiflora** is a species of flowering plant in the genus *Tritonia*. It is native to South Africa and is typically grown as an ornamental plant due to its attractive flowers and ease of care. The species is known for its showy orange-red flowers with blood-red throats, which bloom in summer. Tritonia plants are popular in gardens and are often chosen for their ability to grow in a variety of conditions. **Tritonia crocosmiflora** .

- **Crocosmia aurantium** is a species of flowering plant in the genus *Crocosmia*. It is native to South Africa and is typically grown as an ornamental plant for its vibrant orange-red flowers with blood-red throats, which bloom in summer. Crocosmia aurantium is a popular choice for gardens and is known for its showy and long-lasting flowers, which make it a favorite among gardeners. **Crocosmia aurantium**.
TROLLIUS

TROLLIUS [old German, trol, something round; trolblume, in allusion to the shape of the flowers). Ranunculaceae. Globe-flower. A group of neat hardy herbaceous perennials of a dozen or more species, mostly found in moist or marshy places of the North Temperate zone; useful in garden borders. Roots fibrous, thickened; Ivs. palmately divided or lobed; fls. large, solitary, white, yellow, golden yellow, or purplish, those in cult. usually yellow or orange-yellow; petals 5 to many, small, ungulate, with a nectariferous pit at the base of the blade; sepals 5–15, large, usually constituting the showy part of the fl.; stamens many; carpels 5 to many, sessile, many-ovuled; follicles in a head.—Very like Ranunculus in general appearance, but distinguished at once by bearing follicles rather than achenes. For monograph, see Huth, in Helos ix. (Berlin), 1892; and for the Eastern Asian species, Finet & Gagnepain, Contrib. Fl. As. Or. 1: 136–139; also in Bull. Soc. Bot. France 51:393–396 (1904).

Trolliuses are grown for the beauty of their globular flowers and show of dark green leaves. They are suited to wet sunken gardens, wild borders, and edges of water-gardens, although in a good garden soil not lacking in moisture they do well. They may be increased either by seeds or by dividing the old plants; but the young plants grow slowly at first, and will not flower before the second season from seed. The usual globe-flower of the horticulturist is T. europaeus, with incurring sepals so that the flower has a ball-like appearance; in most of the species the sepals spread nearly or quite horizontally. They bloom in spring and early summer.

puwuha, 8, 9, 10.
sinensis, 10.
patulus, 8.
laxus, 8, 11.
yuzanensis, 8, 10.

a. Number of sepals exceeding 10 (15–20).
b. Sepals incurved, forming a globe-shaped fl.

1. europaeus, Linn. (T. globosus, Lam.). Flg. 3853. Sts. erect, 15 in. or more high, often branching; lower Ivs. petioled, others sessile; Lvs. only 5-parted, lobed, cleft, and toothed, those of the root- Ivs. on short petioles: fls. of a lemon-yellow color, solitary or in 2’s, 1–2 in. across, globe-like in form; sepals 10–15, ovate; petals spatulate, often longer than the stamens; fr. much as in T. laxus. Wet upland meadows of N. Eu. May–July. G. N. 40:102; 71, p. 310. G. 19:609. G. W. 15, p. 129. J. H. Ill. 51:594; 54:555.—Different forms are offered or sometimes listed. Var. Loddigesii, Hort., has deep yellow fls.

Var. napelliformis, Huth (T. napelliformis, Roep.). St. many-fld. and Ivs. deeply divided.

bb. Sepals spreading, making an open fl.

b. Petals longer than the stamens.

2. asiaticus, Linn. Plant much like T. europaeus, often taller, the smaller bronze-green lvs. more finely lobed and cleft; fls. a rich orange-color with sepals spreading. May. Siberia. B. M. 235.—The blossoms of this are well suited for cut-fl. purposes. The plants thrive best and produce richest colors if partially exposed to the sun. T. giganteus, found in garden lists, is a very tall form of this species.

cc. Petals shorter than the stamens or not exceeding them.

3. dechangaricus, Regel. Much like T. europaeus, but fls. open or spreading, golden yellow within and reddish outside; sepals about 15, rounded and mucronate; style subulate and straight. Turkestan.—Mentioned in foreign lists.

4. alticus, C. A. Mey. (T. caucasicus var. alticus Fin. & Gagn.). Plant 1–2 ft., with foliage much like that of T. europaeus: fls. large (2 in. across), yellow or pale orange, with 15–20 broad and obtuse sepals (perhaps sometimes as few as 10); petals 5–15, narrowly linear and obtuse. Altai region, Siberia. Gt. 6:66.—Little known in the trade.

aa. Number of sepals 5–10, spreading.

b. Petals one-third or one-half longer than the stamens.

5. Ledebouri, Reichb. f. Plant about 2 ft., with Ivs. divided to the base and the divisions lobed and toothed; fls. yellow, with 5 spreading veined ovate sepals; petals 10–12, narrowly linear, not prominent but surpassing the stamens. Siberia.—Listed, but apparently little known horticulturally.

6. chinesis, Bunge (T. sinensis, Hort.). Long regarded as a form of T. asiaticus, but now separated; stout striate glabrous herb: radical Ivs. obsolete; lower st-Ivs. reniform and the upper orbicular-reniform, sometimes 7 in. across, palmately 5-parted, the segms. broad-oblanceolate: sepals 12 or 13, the outer ones broad-ovate and obtuse, the inner ones rather longer and narrower; petals 20, linear, over 1 in. long, exceeding the glabrous stamens. N. China. B. M. 8095.—

3853. Trollius europaeus (X 10).

In English gardens this species is said to thrive well and to seed freely when grown in the bog-garden or beside water.

7. japonicus, Miq. St. low (4–8 in. high), shape-like and 1-fld., the Ivs. being radical and involucrate: fl yellow, with 5 or 6 sepals which are 1 in. or less long. Japan.—Sometimes combined with J. chinensis; apparently closely allied to T. laxus. Franchet & Savatier, in Flora of Japan, maintain the species as distinct.

8. patulus, Salisb. Low, 1 ft. or less high; radical Ivs. palmately dissected, the segms. incised-dentate: fl golden yellow; sepals usually 5, sometimes 6 or 7, ovate and spreading; petals and stamens nearly equal, the former 1–3; style erect and about equaling the ovary. Caucasus to Persia.—Finet & Gagnepain define this species very broadly, to include others. They make var.
TROLLIUS

TROLLIUS (from Greek word for trophé; the leaves are shield-shaped and the flowers helmet-shaped). Tropæolum.

Narrow form of gardens (but not of botanists). Climbing or rarely diffuse soft-growing herbs, grown in the garden for their showy flowers. Roots fleshy, sometimes tuberous; lvs. alternate, peltate or pinnately angled, lobed or dissected; stipules none or rarely minute, bright-like or dissected; peduncles axillary, 1-flowered; fls. irregular, usually orange or yellow, rarely purple or blue, but the garden forms now show a great range of color; sepals 5, connate at their base, posterior produced into a long slender spur;

petals 5 or fewer by abortion, usually narrowed into distinct claws, two upper smaller or dissimilar and inserted in the mouth of the spur; stamens 8, free, unequal, with declined usually curving filaments; ovary 3-lobed, ripening into 3 indehiscent carpels (these constitute the “seed” of commerce).—About 45 species, S. Amer., chiefly from the cooler parts of Peru and Chile. Monographed in 1902 by Buchenau in Engler’s Pflanzenreich Hft. 10 (IV. 131).

The common species, T. minus and T. majus, are also grown for their young pods and seeds, which are made into pickles. The perry-tasting leaves are sometimes used like cress, in salads. Probably most species are perennial. Tropæolum thrive in any warm sunny fairly moist place. The tops are tender to frost. For early effects, seeds may be started indoors in pots or boxes. The common climbing species are T. majus and T. peltatum, both of which are very useful for window-boxes, balconies, for covering banks and walls, and for growing amongst shrubbery. The common dwarf species, T. minus, is earlier and usually more floriferous, and is very useful for the front row in the border. On rich soils, nasturtiums produce very heavy foliage that overtops the bloom. T. peregrinum, the canary-bird flower, is grown either indoors or in the open. Probably most species are perennial. Many of them are tuberous and withstand some frost at the root; but the half-hardy species are little known in this country.

A. Species annual or perennial but not tuber-bearing.
B. Petals 5, entire or rarely emarginate or crenate at the apex.
C. Inferior petals not ciliate at the base.
D. Plants perennial, low, prostrate, glabrous.

I. polyphyllum, Cav. Perennial, half-hardy: st. succulent, prostrate or climbing: lvs. peltate, orbicular, cut beyond the center into 7-9 narrow divisions; fls. much like T. majus in shape, but smaller; spur slender but rather short, the calyx tri-lobed. petals obvolute-cuneate, unguiculate, yellow, wavy or emarginate, the 2 upper ones streaked with red. Chile. B.M. 4042. P.M. 10:175. F.S. 20:2066. G.C. II. 20:241. Gn. 46, p. 156. G.M. 88:367. St. naturally prostrate.—T. Leichtlinii, Hort. Garden hybrid between T. polyphyllum and T. leptophyllum (see suppl. list), raised by Max Leichtlin, of Baden-Baden. More closely approaching the former, but with larger lvs., more

TROLLIUS

genuina, Fin. & Gagn. to include T. laxus, Salisb., T. pumilus, Don, and T. pumilus var. yunnanensis, Franch; also var. Lédebouri, Fin. & Gagn. (T. Lédebouri, Reichb. f.), differing from the type in having the sepals longer than the stamens.

9. caucasicus, Stev. (T. pbulus var. caucasicus, Huth). Radical lvs. palatomately dissected, the segms. incised-dentate; sepals 5-8, elliptic, spreading; petals 10, usually equaling the stamens; style about equaling the ovary. Caucasus, Armenia, etc.—Perhaps a form of T. pbulus, as considered by Huth. Under the name T. caucasicus, the plant offered abroad is described as a hardy perennial, with large orange fls. in July and June; 2-3 ft. In horticultural literature the fls. are usually described as globular, which raises a question as to the identity of the cult. plant.

10. pumilus, Don. St. 1 ft. or less high, from a horizontal rootstock, the base bearing old lvs., with few lvs. on the st. and those above the middle: lvs. small, 1-2 in. diam., orbicular, thickish, 5-parted, the segms. broadly obvolute and 3-lobed; lfs. 1 in. across, solitary, yellow or sepals 5 or 6, rounded, atched at the end; petals 10-12, about equaling the stamens, cuneate-oblong; foliaces many. Alpine Himalaya.

Var. yunnanensis, Franch. St. to 2 ft. high and sometimes 3-flowered: lvs. narrowly dentate, the teeth short and rigidly mucronate; cauline lvs. 1 or 2; sepals 6-9, broadly ovate or suborbicular; petals long-clawed, shorter than the stamens. W. China.—Described as horticulturally not unlike Caltha palustris, but superior, with dark green lvs. and bright golden yellow salverform fls. in May.

11. laxus, Salisb. (T. americanus, Mullh.) Sts. slender, weak, ½-2 ft. long, somewhat ascending: radical and lower st-lvs. long- or short-petioled; all the lvs. 5-7-parted; lfs. cuneate and much cleft and toothed: fls. usually solitary, 1-2 in. across; sepals 6-7, entire or toothed at the end, more spreading than the other species; petals many, much shorter than the stamens: follicles ¼ in. long, straight beak one-fourth as long; head of fruit ½ in. across. Bogs and damp places, Mich., to New England and Del. and westward. May-July, or Aug. B.M. 1889 and L.B.C. 96 (both as T. americanus).

Var. alibiflorus, Gray (T. alibiflorus, Rydbg.). Much like the type but usually lower, more slender: lfs. usually 5: fls. pale or white; petals nearly equaling the stamens. Mountain tops, Colo., northward and westward.

12. acialis, Lindl. Plant only 3-4 in. high: lvs. as in the above, or only 5-parted: fls. lemon-yellow, spreading, on sts. hardly reaching from the ground; sepals 9, nearly lanceolate, acute, sometimes toothed; petals spatulate, shorter than the stamens. N. India. B.R. 20:32.

T. aurantiacus, Hort., described as lemon-yellow: probably a form of T. europaeus.—T. Excelsior, Hort., and T. Atheras, Hort., with deep orange fls., are probably T. europaeus forms.

K. C. DAVIS.

L. H. B.†

TROPÆOLUM

(TROPÆOLUM (from Greek word for trophy; the leaves are shield-shaped and the flowers helmet-shaped). Tropæolum. A narrow form of gardens (but not of botanists). Climbing or rarely diffuse soft-growing herbs, grown in the garden for their showy flowers.

Roots fleshy, sometimes tuberous; lvs. alternate, peltate or pinnately angled, lobed or dissected; stipules none or rarely minute, bright-like or dissected; peduncles axillary, 1-flowered; fls. irregular, usually orange or yellow, rarely purple or blue, but the garden forms now show a great range of color; sepals 5, connate at their base, posterior produced into a long slender spur;
nearly orbicular, undulate and with points on the margin; fls. large, long-squarred, orange-red, the upper petals large, rotundate, broad and entire, the 3 lower ones small and clawed and coarsely toothed and also fringed on the claws. Colombia, B.M. 11:271. G.M. 9:16. Var. minutum, Hubb. (T. Lobbianum var. minutum, Hort.), is said by some to be a hybrid with bright vermilion fls. Var. Regina, Hubb. (T. Lobbianum var. Regina, Hort.), is a form with bright salmon-red or salmon-orange fls. There is a horticultural strain of more compact growth, known as T. Lobbianum compactum; this strain occurs in numerous colors. Horticultural color-forms listed under the name T. Lobbianum are atropurpureum, dark purple; aureum, clear golden yellow; fulgens, dark scarlet; Chatszidum, yellow, washed with red.

dd. Plant glabrous.

e. Lvs. orbicular-reniform; nerves terminating in mucros; petals mucronate.

4. minus, Linn. Fig. 3855. Dwarf annual, not climbing, smaller in all its parts than T. majus: lvs. orbicular-reniform, apiculate at the ends of the veins: petals narrow and apiculate at the apex, the lower intensely maculate. Peru. B.M. 96.—Very likely blended with T. majus by hybridization, in garden forms. T. pinnatum, Andr., is either a monstrosity of this species or more probably a hybrid between T. minus and T. peregrinum, having the lvs. somewhat poliuate,
brous: lvs. peltate near the margin, cordate-orbicular, divided to about the middle into 5 lobes, which are mostly apiculate: fls. canary-yellow, odd and very irregular; spur green, hooked: 2 upper petals erect and large, obovate-clawed, much fringed; 3 lower petals small and narrow. Ciliate. Supposed to be native of Peru and Ecuador. B.M. 1351. B.R. 718. G.W. 10, p. 497.—An excellent quick-growing vine, although the fls. can scarcely be called showy.

AA. Species tuber-bearing.

b. Tuber large, obconical or pear-shaped.

7. tuberum, Ruiz & Pav. Root producing a pyriform tuber 2-3 in. long: st. climbing, glabrous: lvs. peltate near the base, cordate-orbicular, 5-lobed nearly or quite to the middle: fls. rather small, the calyx and long spur red, the petals yellow, small and nearly erect and little exceeding the calyx. Cerru and Bolivia. B.M. 3714. F.S. 5:452. P.M. 5:49. R.H. 1853-341 (tubers). J.H. III. 30: 355. H.U. 1, p. 4.—Plant stands some frost. In Peru, the tubers are eaten, and the plant is sometimes cult. in Eu. for the tubers. It appears in the American catalogue of European dealers. The tubers are usually boiled, or said to be eaten in a partially dried condition.

BB. Tuber longer, moniliform in many members: lvs. in 5 parts, usually divided to the base: petals scarlet.

8. pentaphyllum, Lam. Slender climber, the glabrous colored sts. arising from a tuberous root: lvs. divided to the base into 5 oblong or obovate segms. or lfts.: fls. small (about 1 1/2 in. long), the large red spur being the conspicuous part, the lobes green, and the 2 small petals red. Argentina. B.M. 3190. B.H. 22:73.—A half-hardy species, showy because of the great number of bright small fls.

BBB. Tuber small, spathoid or somewhat flattened, rarely elongated: lvs. smaller or small, divided to the base.

c. Throat of the spur venetosose-turbinate, aperture narrow; spur cone-like, its tip cylindrical-subulate; petals lemon-yellow.

9. tricolor, Sweet, emended by Lindl. (Sweet spelled the specific name tricolor), but, as Lindley pointed out, this is orthographically incorrect) (T. coeruleum, Miers). Fig. 3857. Perennial from a fleshy or tuberous root: lvs. peltate, orbicular, divided into 6 oblong villous lfts.: fls. about 1 in. long, somewhat cornusopia-shaped, the calyx being the conspicuous part; main part of the calyx vermiculatum, the short lobes purplish, the small petals yellow. Chile. B.M. 3189. B.R. 1935. F.S. 4:369. P.M. 2:123. Gt. 62, p. 273. G.W. 6, p. 277.—Very choice half-hardy climbing, prostrate plant and probably the best known in this country of the tuberous-rooted kinds. Usually grown indoors. Its growth is very delicate. Var. grandiflorum, Hort. (T. Jardtii, Paxt. T. Jardtii, Buchen.), differs only in having larger lvs. F.S. 5:29.

CC. Throat of spur open; spur short or very short, conical; throat of corolla narrow, almost closed when old; petals white.

ccc. Throat of spur conical, aperture broad; throat of corolla broad, open; petals yellow.

TRÁXIMON (Greek, edible, which does not apply).

Compositae. Mostly perennial nearly stenless herbs, belonging to the Cichoriacere, with clusters of sessile radical lvs. and simple scapes bearing a head of yellow or purple fls. in summer, on a naked or bracted stalk: involucre campanulate, the bracts in several rows: rays blunt and 5-toothed at the apex.—Species 30, in N. Amer., except possibly 2 species which are S. American. The plants are little known to horticulturists. The name Tróximon is now given up for Agoseris (Greek, goat eulacrora).

Agóseris cuspidáta, Dietr. (Tróximon cuspidátum, Pursh. Nethoçádis cuspidáta, Greene). Root thick: lvs. entire, linear-lanceolate, thickish, 4-10 in. long, the margins conspicuously white-woolly and crisped: scape about 1 ft. high: fls. yellow, about 1-1 1/2 in. wide: achene not beaked. Prairie of Ill. and Wis. to N. D.—Cult. easy in any good border. Not unattractive. It has rather large dandelion-like heads of fls. in late summer. May be offered by collectors. N. TAYLOR.

TSÜGA (its Japanese name). Pinàcece. HEMLOCK. Ornamental trees, grown chiefly for their graceful habit and handsome evergreen foliage. Resinous trees with slender horizontal branches: lvs. usually 2-ranked, short-petioled, linear, flat or angular, falling away in drying: staminate aments axillary, subglobose: ovulate ament terminal, the scales about as long as the bracts, each with 2 ovules at the base; cones small, ovate, or oblong with thin flexible persistent scales, much longer than the bracts; seeds winged.—Nine or 10 species in N. Amer., E. Asia, and the Himalayas. The genus is closely allied to Abies and Picea and differs little in the structure of the fls.; the cones are very similar to those of the larch, but the lvs., which are much like those of Abies in their outward appearance, though smaller, are very different in their internal structure from all allied genera, having a soli-
The hemlock spruces are evergreen trees of pyramidal habit, with spreading irregularly whorled much rami­
fied branches clothed with small linear usually two­ranked leaves and small cones which are usually freely produced. The cones are only about 1 inch long except in some species, which has cones two or three times as large. *T. canadensis* is quite hardy North and the Japanese species and *T. caroliniana* have proved hardy as far north as Ontario. *T. Mertensiana* is almost as hardy. *T. heterophylla* is tender. There are probably no more beautiful hardy conifers than the hemlocks, and they must be ranked among the most ornamental and useful trees for park planting. They do not have the stiff formal appearance of many of the conifers, but are graceful and stately at the same time. *T. heterophylla* is the most vigorous species and is more graceful than the Canadian hemlock, but tenderer. *T. Mertensiana* is noticeable for its light bluish green foliage and the more narrow pyramidal habit. *T. Sieboldii* is a very handsome species with dark green glossy foliage, but of slow growth and in cultivation usually remains shrubby. *T. canadensis* bears pruning well and is well suited for tall hedges (see Gn. 2:289. Gn. M. 2:15; 4:19). The other species will probably bear pruning equally well. The hemlocks are not very particular as to the soil, provided it contains a sufficient amount of constant moisture. *Tsugas* are not difficult to transplant. Propagation is by seeds sown in spring and by grafting on *T. canadensis*. The varieties and the Japanese species are also raised from cuttings. See also *Arboriculture, Abies, and Picea* for cultivation.

- Margin of lvs. entire; apex of lvs. usually emarginate, sometimes obtuse.
- Margin of lvs. finely denticulate, at least toward the apex; apex of lvs. obtuse or acutish.
- Cones peduncled; scales almost orbicular, glabrous.
- Cones sessile; scales oval, slightly puberulous outside.

**1. Sieboldii, Carr. (T. Araragi, Koehne). Fig. 3858.**

Tree, attaining 100 ft., with spreading slender branches: branchlets pale yellowish brown, somewhat glossy, gla­brous, with reddish fl. cushions: lvs. linear, usually broadest at the apex, emarginate, grooved and glossy dark green above, with 2 whitish lines beneath, ½–3/4 in. long; cone ovate, 1–1½ in. long, the peduncle exceeding the bud-scales; bracts bifid. Japan. G.F. 10:492 (adapted in Fig. 3858). F.E. 32:1501. S.I.F. 2:4.

**2. diversifolia, Mast. (Abies diversifolia, Maxim. T. Sieboldii nana, Carr.). Fig. 3859.**

Tree, very similar to the preceding, but smaller and chiefly distinguished by the reddish brown pubescent branches: lvs. linear, emarginate or obtuse, shorter and narrower, broadest at the middle or toward the base: cone smaller, ½–3/4 in. long; peduncle not exceeding the bud-scales; bracts truncate, crenulate, not or slightly bifid. Japan. G.F. 6:495; 10:493 (adapted in Fig. 3859). S.I.F. 2:4.

**3. caroliniana, Engelm. Carolina Hemlock. Tree, attaining 70 ft., of more compact habit and with darker green foliage than the following: young branchlets light reddish brown, finely pubescent or almost gla­brous: lvs. linear, obtuse or acutish. There are probably more beautiful hardy conifers than the hemlocks, and they must be ranked among the most ornamental and useful trees for park planting. They do not have the stiff formal appearance of many of the conifers, but are graceful and stately at the same time. *T. heterophylla* is the most vigorous species and is more graceful than the Canadian hemlock, but tenderer. *T. Mertensiana* is notice­able for its light bluish green foliage and the more narrow pyramidal habit. *T. Sieboldii* is a very handsome species with dark green glossy foliage, but of slow growth and in cultivation usually remains shrubby. *T. canadensis* bears pruning well and is well suited for tall hedges (see Gn. 2:289. Gn. M. 2:15; 4:19). The other species will probably bear pruning equally well. The hemlocks are not very particular as to the soil, provided it contains a sufficient amount of constant moisture. *Tsugas* are not difficult to transplant. Propagation is by seeds sown in spring and by grafting on *T. canadensis*. The varieties and the Japanese species are also raised from cuttings. See also *Arboriculture, Abies, and Picea* for cultivation.

**3859. Tsuga diversifolia. (×15)**

most commonly used in the E. for framing and clap­
boarding of buildings. It is not used for finishing
lumber. A number of garden forms have been raised;
the following are the most important: Var. álbo-spica,
Nichols. Tips of the young branchlets creamy white.
Var. compácta, Sénéc. (var. compácta rósea, Beisen.)
Dwarf conical pyramid with numerous short branchlets
clothed with small lvs. Var. globós, Beisen. (var.
globúlis erécta, Kunkler). Dense, globose, much-
branchled form with numerous upright branches nod-
ding at the ends. Var. grácilis, Gord. (var. microphylla,
Hort.). Slow-growing form with slender sparingly ramified branches, spreading
and more or less drooping at the ends: lvs. very small, about 2¾ in. long.
Var. náná, Carr. Dwarf and depressed
form with spreading branches and short
branchlets. Var. parviflóra, Veitch.
Lvs. very small, % in. long or shorter: branchlets stout,
closely set and numerous. Var. péndula, Parsons (var.
Sérpenús péndula, Hort., var. Sargentúna, Kent.).
Flat-topped form with spreading branches and drooping
branchlets. Var. pendula, H. (var. pendula, Schneid.)
Sargentii pendula, Sarg., not Carr.
Flat-topped form with numerous upright branches nod­
ing at the base. Recently intro. and probably as hardy as
T. yunnanensis). Has proved hardy at the Arnold Arboretum
and thrives well.—T. dumosa, Sarg. (T. braziiensis, Carr.). Tree,
3–20 ft.: lvs. gradually tapering from the base, aculate, acutish,
with broad silvery white lines beneath, %–1¾ in. long: cone 1 in.

The form of the chalice or perianth-cup, the substance of the flower, the shape of the segments, and the color, are marked features in the tulips of the different classes and seasons. The usually cultivated tulips have very broad flower-segments, obtuse or abruptly narrowed and short-pointed, as in Fig. 3862. In the wild, however, are many forms with long-narrowed segments, as shown in Fig. 3863 (adapted from Gardener's Chronicle), and these may be seen sometimes in the gardens of amateurs; they are very interesting and often showy. It appears that in earlier times the sharp-pointed flower-parts were desired. Other tulip forms are represented in Figs. 3864 and 3865, as well as in the succeeding pictures accompanying this article.

The colors of tulips cover a wide range except that there are no real blues. There are clear whites, yellows and orange, crimsons and reds, violets and purples, and many vari-colored types. The tulips known as "breeders" are self-colored kinds; that is, the flowers are of solid colors, usually in dull and neutral shades of red and yellow with tints of bronze, buff, and brown. The reason for the name is this: When tulips are grown from seeds, the flowers at first are usually self-colored; the same bulbs when grown for a few years tend "to break" into mixed colors, particularly into feathered markings; the self-colored stage is a breeding-stage for other kinds. When the bulbs are multiplied asexually (as explained farther on), they reproduce the stage in which they then are; if propagated in the "breeder" stage, they give self-colored flowers; if in the "broken" stage, they give partly colored flowers. These stages are longer or shorter in different lots of seedlings, and are not definite epochs. The "broken" tulips are of many kinds. Those with white ground or under-color and blue or purple markings are "hybloeënem" or "hybloeems," and those with yellow ground-color and red to brown over-color are "bizarres." The terms "hybloeem" and "bizarre" are also sometimes applied to selfs, or breeders, when the colors are prevailingly blue or purple in the one case or prevalingly yellow in the other. Selected strains of breeder tulips, with very large bloom, long stems, and "art colors" are now popular. The so-called "rectified" tulips are broken breeders with solid colors in stripes, plumes, and patches; they are hybloeem and bizarres. It is said that the "breaking" is facilitated by certain soils.

There are many classes of tulips. We might distinguish three roughly: (1) The early single tulips of the Duc Van Thoï kind, of small stature, excellent for first bloom and for early bedding, being out of the way for other bedding plants; they lack the size of bloom and the "substance" of later kinds. There are also later-flowering single tulips of the early class. (2) Later-flowering or "tulipa" tulips, comprising the main-season kinds that have been preserved by cultivators in the old countries since the collapse of the tulipomania of Holland. (3) The Darwins are stately plants, mostly selfs or "breeders," closing the tulip season, with very rich and deep colors in crimsons, reds and purples; there are
some whites but no yellows. This Darwin race is relatively recent, having been given its present name (in compliment to Charles Darwin) little more than twenty-five years ago. Broken rectified Darwins in several color combinations are known as Rembrandt tulips.

There are many other classes or subclasses, and races of intermediate season, that need not be mentioned here.

Vari-colored garden tulips are classified by F. D. Horner (England) into six main sections or classes, and the self-colored or "breeder" strains into three classes, as follows: (1) Flamed Bizarres. These have a yellow ground flamed with red, very dark, almost black, and chestnut-brown. (2) Feathered Bizarres. These have similar colors, but the yellow grounds are marked or penciled on the margin, whereas the flamed flowers have a heavy 'beam' of color in the center of the petals. (3) Flamed Bybloemens. These have a white ground marked with lilac, purple, and very deep black-purple color. (4) Feathered Bybloemens. Similar in color, but with feathered instead of flamed petals. (5) Flamed Roses. These are flamed with rose and scarlet colors on the pure white ground. (6) Feathered Roses. These have a white ground, and are flamed with rose and scarlet colors. There are three more classes of what are termed 'breeder' Bizarres. Yellow selfs. Bybloemens. Lilac and light to deepest purple selfs. Roses. Rose and scarlet selfs. They are termed 'breeder' because in the course of a few years these self-colored flowers become flamed or feathered, and pass out of the breeder state."

The common garden tulips, in their many forms, are probably all developments of the Gesneriana group, comprising T. Gesneriana, T. suaveolens, and the like. Many of the forms sometimes catalogued as "botanical tulips" are also very ornamental and are always interesting in a collection. A number of species may be had in the trade. They should be better known.

Tulip history (Stubenrauch).

The tulip has an unusual and interesting history, on which we may pause briefly. The origin of the garden tulip seems to be lost beyond recovery. It is often said that it is derived from Tulipa Gesneriana, but this does not explain it. It merely means that in 1753 Linnaeus grouped all the garden tulips he knew under the name of Tulipa Gesneriana. But the tulip of that day had been cultivated for two centuries by Europeans, and previously for an indefinite period by the Turks, from whom, of course, we have no exact records. (Fig. 3866.) One might study wild tulips in their native places and compare them with descriptions without being certain of the original form which the Turks brought from the wild, simply because of the lack of records at the beginning. It is necessary to have some scientific name for the garden tulips. The one most one dare say is that the garden tulip are chiefly referable to T. Gesneriana and T. suaveolens, with the distinct understanding that these names do not represent an original wild stock. Tulipa suaveolens requires explanation. This name, which dates from 1757, stands for a kind of tulip discovered wild in southern Europe long before that date. There is no proof that it was native; the probability is that it had escaped from gardens and run wild. In 1799, it was distinguished from the other tulips then known by the fragrance of the flowers; the earliness of bloom, slightly greater size and pubescent scape. From the early records it appears that there were fragrant early-blooming flowers among the first tulips received from Turkey. This is one of the main reasons for thinking that T. suaveolens is not native to southern Europe. At all events, it is clear that T. suaveolens has played an important part in the evolution of the garden tulip, the Due van Thal class being credited to this source. The distinctions between T. suaveolens and T. Gesneriana given in the sequel are those of Baker, but they do not hold at the present day. It is impossible to refer any given variety with satisfaction to either type. Some writers have said that the leaves of T. suaveolens are shorter and broader than those of T. Gesneriana. This character also fails. All grades of pubescence are present. Some pubescent plants have long leaves and odorless flowers. Others have short glabrous leaves and fragrant flowers.

For practical purposes it may be said that most of the common garden tulips, at least the late-flowering ones, are T. Gesneriana, while many of the early-flowering kinds, e.g., the Due van Thal class, are supposed to be derived from T. suaveolens. It is impossible to press much nearer the truth, as the prototypes of the old garden favorites cannot be known completely and precisely.

The first tulip seeds planted by Europeans were sent, or brought to Vienna in 1564 by Busbequius, the
TULIPA

The narrow-petaled varieties are practically unknown. After the introduction of seed to Vienna the tulip became rapidly disseminated over Europe, both by home-grown seed and by new importations from Turkey. In 1556 Gesner first saw the flower at Augsburg, and it is mainly on his descriptions and pictures that the species T. gesneriana was founded. One of the earliest enthusiasts was the herbalist Clusius, who propagated tulips on a rather large scale. A picture from him is shown in Fig. 3866. He did not introduce the tulip into Holland, but the appearance of his specimens in 1591 did much to stimulate the interest in the flower in that country. The best of Clusius' plants were taken from him, as the admirers of the tulip were unwilling to pay the high prices he demanded. After this, the propagation of the tulip proceeded rapidly in Holland and the flower soon became a great favorite. The production of new varieties became a craze throughout the Netherlands, culminating in the celebrated "tulipomania" which began in 1634. The excitement continued for four years, the price of bulbs often being above that of the precious metals. Thirteen thousand florins were paid for a single bulb of Semper Augustus; but the dealings were often in the nature of pure speculation, no bulbs changing hands. Governmental interference was necessary in order to end the ruinous speculation. After the craze subsided, the production of varieties continued upon a normal basis, and has persisted throughout the centuries in Holland, making that country the center of the bulb-growing industry of the world down to the present day.

The introduction of the tulip into England is credited to Clusius, about the year 1577. Tulips reigned supreme in English gardens until the beginning of the eighteenth century, when they were neglected by the rich for the many new plants from America. For a time the tulip was considered more or less of a poor man's flower, although it has at no time been without many staunch admirers among the upper classes.

With the Turks the narrow acuminate flower-segments were in favor, while western taste preferred the rounded forms (Fig. 3868). The Turks seem to have been satisfied with a preponderance of the reds and yellows, for in the first sowings of Turkish seeds the larger part of the resulting blooms were of those colors. It thus came about that flowers so colored were considered common and undesirable in the European gardens and all effort was directed to the production of the rarer white-grounded forms with finely and distinctly marked stripes, those with a sharp bright red being the favorites. Indisputable evidence of this is seen in the old Holland "still-life" paintings of that time, where one finds none but the rarer forms represented (Solms-Laubach). All the early tulips of direct Turkish origin had acute more or less narrow and reflexed segments. In the Dutch fields the center of the bulb-growing industry of the world down to the present time, for the narrow-petaled varieties are practically unknown among our common garden forms, so much so that the extreme typical one has been referred to a separate species (T. acuminata, Fig. 3872). In the Dutch fields they are now known as "thieves," and are destroyed as soon as they make their appearance. The quest for unusual colors appears to have been one feature of the tulip furore. Dumas' "Black Tulip" is interesting in this connection.

Parrot tulips were known toward the end of the seventeenth century. They were often considered...
the original form from which this strain might have been developed. Many of the garden varieties of today exhibit more or less laciniation, so that it is probable that "Parrot" strains might be developed from them by simple selection.

Double tulips seem to have made their appearance at an early date. In "Hortus Eystettensis" (1613), there are four forms figured, one of which, at least, seems to have been almost wholly made up of bracts, as it is shown entirely green and is described as being "wholly herbaceous and green." The other three there figured are: one red, one yellow, and the other white with maroon borders. Solms-Laubach places the advent of double tulips at a much later date, 1665, and gives as the first authentic record the account of "'Tulipa lutea centifolia, le monstre jaune double." Flowers with as many as 200 petals are mentioned. A double form of "T. serotina" was known in 1701, and at the beginning of the nineteenth century a double form of T. gallica was described.

Cultivation of the tulip.

"The tulip is one of the easiest plants to grow, but, like other plants, it profits by extra care. In any ordinary soil it gives excellent satisfaction, if good bulbs are secured in the first place.

For outdoor cultivation for spring bloom the bulbs should be set in September to December in the latitude of New York. They should be planted before hard freezing weather comes. The soil should be a sandy loam, well worked to a depth of at least 12 inches for best results, and enriched with leaf-mold and well-rotted cow-manure. Fresh manure of any kind should never be used near bulbs of any sort. On heavier soils tulips can be successfully raised if extra care is given to insure perfect drainage. Drainage is important under all conditions. The bulbs will never prove satisfactory in low wet situations, and if there is danger from standing water it is best to raise the beds several inches above the surrounding ground. The production of large perfect flowers depends on a large supply of fibrous roots. Size of bulbs is not so important: a large bulb cannot offset a deficiency of roots.

Plant the bulbs 4 to 6 inches deep (to the bottom of the bulbs) and 4 to 9 inches apart, depending on the class or size of the plants, the closer distances being for the early single kinds and the wider distances for the later and larger kinds. Care should be exercised to place all the bulbs at the same depth, as otherwise they will not all bloom at the same time. When the ground begins to freeze, cover the beds with leaves, dry forest litter, or other light material. After danger of heavy frosts is past in spring the beds should be uncovered, and if the work of preparation and planting has been well done the tulips will require little or no further care. In England many of the beds of choice and delicate varieties of tulips are protected when in flower from heavy rains and hot sun by means of light cloth screens, and are thus kept in good condition for some time.

Tulips may remain in the ground several years if the tops are not cut off and if the maturing leaves are not smothered by other plants. In practice, however, the best results are usually not secured in this country after the bulbs have been in the ground two or three years. The Darwin class seems to lack in constitution, and the plants should be renewed every two years or so.

In old-fashioned gardens, tulips often remain year after year; but when the beds are needed for other flowers in succession, the bulbs are lifted as soon as the flowers are past and reset elsewhere until the plants mature and the tops die down naturally. Then the bulbs are taken up, sorted and dried, and stored in a cool dark place until planting-time; or they may be planted at once in the permanent quarters if the area is ready to receive them. Even in borders and among shrubbery, it is well to take up the bulbs every two or three years and sort out the small ones, replanting the remainder; or, if they are weak, to discard all of them for new ones. For the best bedding work, it is advisable to use strong freshly imported stock each year.

To make design-beds, choose bulbs of very uniform size. Dig out the bed, removing all the earth a little deeper than the bulbs are to be planted, then make a thin layer of soft earth on which the bulbs may rest; this should be stroked level and be at a uniform depth. Then place the bulbs in the design and fill in around them carefully by hand; then place the earth back in the bed.

For pot culture (winter and spring bloom), a mixture of fine garden loam, two parts to one of well-rotted manure (cow-manure composted for two years is best), mixed with enough clean sand to make the mass easily friable, is most suitable. If no loam is obtainable and a heavier garden soil must be used, one part of the latter will be sufficient, in which case the addition of an equal proportion of leaf-mold will be advantageous. From three to five bulbs, according to size, to a 6-inch pot are effective. Deep pans are often used with good effect; a 6-inch pan may hold five or six early singles, and an 8-inch pan as many as ten (Figs. 3867, 3868). Fill the pots lightly and press the bulbs into the soil, thus bringing the base in close contact with the soil-particles. Cover the bulbs to the tip and press the soil firmly all around. Water once freely and cover the pots entirely with soil, leaves, or litter, so that they will be out of reach of frost, or place them in a dark cold (not freezing) cellar or room until the bulbs have become well rooted, which under ordinary conditions will re-
The tulip can be grown to perfection in the Pacific Northwest, but the cost of production, on account of the high wage-rate, may be a controlling problem. As the situation looks now, the American can produce fully as good a bulb, and one that will mature earlier than the Holland-grown; but whether these can be sold in the eastern market in competition with the Dutch is a question yet to be determined. It is probable that the bulbs can be grown as far south as San Francisco. South of San Francisco, the single early tulips bloom very close to the ground; on the other hand, the Darwins seem to do very well in the Santa Cruz and Ventura regions. At the government bulb-farm at Bellingham, Washington, good tulip bulbs with normal increase have been produced under adverse conditions.

Put a little charcoal crown.

Propagation is effected in various ways. Tulips may be increased by offsets, but these are not constant as new bulbs produced within the outer tunics by means of cutting the old bulbs. Fig. 3869 shows a section of a bulb with new inner bulb and outer offset in place. The new bulb is completely inclosed in a sac which afterward becomes the outer dry membranous tunic. The pubescence, if any, may be found on the inside of this sac, even in the earliest stages of growth.

The new bulb is attached to the base of the flower-stem, immediately above the root-crown from which the former proceeds directly upward. Each new bulb-tunic (including the outer sac) is provided with a growing tip, which often extends above ground into a leaf, each one coming up within the other. Fig. 3869 shows the separated leafy bulb-scales, and indicates the homology of tunics and leaves. Sports among the offsets are at present mainly depended on for the production of new varieties. These have been found susceptible to the breaking off process, though perhaps slower to respond than the seedlings. Seed production is now practiced only in exceptional cases. The production of hybridized varieties by crossing the old forms with some of the newly introduced species is likely to come into favor.

Tulips are “Holland bulbs,” that is to say, the bulbs are grown mostly in Holland and are extensively shipped to this country. Considerable interest has been aroused in the growing of commercial bulbs in this country, particularly in the Puget Sound region. The tulip can be grown to perfection in the Pacific Northwest, but the cost of production, on account of the high wage-rate, may be a controlling problem. includes species that are nearly all of small stature and possess comparatively small fls. It is a charming plant, growing about 9 in. high. The fls. have yellow segms. edged with white. When fully open in sunny weather a group produces a brilliant effect, and it is one of those small bulbous plants that are most appropriate for the rock-garden planted between other low-growing plants. The bulbs may be left undisturbed in the ground; a group planted amongst Alchemilla mollis in the rock-garden at Kew flowered quite as freely the second year as the first."—W. I. in G.C. III. 52:206 (with fig.). Baker describes it st. 1-fl., and not more than 3 or 4 in. long; lvs. 2-3 glaucous, lanceolate; perianth above 1 in. long, funnel-shaped, bright yellow inside, the outer segms. ob lanceolate and green-tinged on outside. E. Turkestan.

Subgenus II. Tulipa proper, without distinct style.

A1. Outer bulb-tunic quite or nearly glabrous

b. Perianth yellow, flushed with green outside. ........................ 2. fragrans

BB. Perianth crimson tinged with yellow outside. ........................ 3. Hageri

BBB. Perianth vermilion. ....................... 4. præstans

2. fragrans, Munby. Height 6-12 in.; proper lvs. 3, crowded at middle of st., linear or lorate; fls. yellow, greenish outside; perianth funnelform-campanulate, 1½ in. long, in a cluster; segms. oblong-lanceolate, acute; filaments bearded at base; ovary slightly narrowed at collar; stigmas small. Algeria. Gn. 45:456.—Allied to T. syriaca, differing in position of the lvs. and segms. uniformly wide.

3. Hageri, Heldr. Height 6-8 in.; lvs. 4-5, lorate acute, not undulate; fls. chiefly red, about 2 in. across; perianth broad-campanulate, 1½ in., inodorous; segms. acute, red, with a large green or purple-black basal blotch margined with yellow; stamens purple-black; filaments linear, bearded at base; ovary narrowed at collar; stigmas small. Hills of Parnes range in Attica. B.M. 6242. F. 1877:169. Var. nitens, Hort. Wallace. Said to be much finer than the type; fls. 3 in. across, bright orange-red, the outer segms. flushed with gray and bronze, black at base. Asia Minor. Gn. 63, p. 372.

4. præstans, Hoog (T. suaveolens var. sulphurea, Regel). Bulb about 1 in. diam., rounded, with leathery skin which is almost glabrous inside: scape to 18 in., white-hairy, 1- to several-fl.: fls. light scarlet-vermilion, the segms. all uniform in shape, pointed: lvs. hairy, rather wavy. B.M. 7320. B.C. III. 33:325. Gn. W. 24:317.—Once confused with T. suaveolens, but now considered to be clearly distinct, and that species is identified with the Duc van Tol form.

A2. Outer bulb-tunic always hairy at base inside and usually furnished with a few scattering hairs above but sometimes without them.

b. St. and lvs. pubescent. ....................... 5. suaveolens

BB. St. and lvs. glabrous. ...................... 6. straunigula

c. Leafy only at base of st. ........................ 7. australis

d. Lvs. lanceolato-f. yellow. .................. 8. primulina

dd. Lvs. lorate-lanceolate. ..................... 9. viridiflora

CC. Leafy to middle of st. or above.

d. Perianth uniformly dark scarlet with a bright yellow basal blotch. 10. fulgens

dd. Perianth uniformly with a blackish-twin basal blotch, bordered with bright yellow. ....................... 11. macrospela

DDD. Perianth variable, but rarely with a dark-twin basal blotch. 12. Gesneriana

13. nitida

5. suaveolens, Roth. Duc van Tho. Tulips. Height 3-6 in.; lvs. 3-4, mostly at base of st., lowest lorate-lanceolate and broad; perianth campanulate, 1½-2½ in. long, edges ciliate, bright red or variegated; segms. all acute; filaments glabrous; anthers yellow; ovary prismatic; stigmas very large. S. Russia and S. Eu., but possibly only a naturalized form of old intro. Turkish garden varieties. F.S. 12:1223. B.M. 839. Var. paulinae, Hort. St. with 2 fls., bright scarlet, rather pointed in form, with black mark at base of each segm.

6. straunigula, Rehoul. Said by Baker to be very near T. suaveolens, but much taller and the segms. furnished at base with a large black blotch; typically red-fl., but with yellow varieties. Italy. B.R. 1900 (as T. acrocarpa). Var. masculata, Hort., has soft yellowish fls. blackish at base.

7. australis, Link. Height 12-18 in.; st. slender; lvs. 2-3, crowded at lower portion of scape, channelled; bud nodding; perianth 1½ in. across, funnel-form-campanulate, yellow, outside ridged; segms. obovate-oblong, acute at apex, slightly puberulent; anthers yellow; filaments flattened, bearded at base; ovary narrowed at collar. Savoy, France, Spain, Portugal, and Algeria. Gn. 45:456.

8. primulina, Baker. Bulb ovoid, 1 in. diam., the outer coats brown and thinly armed-hairy inside: st. glabrous, 1-fl., less than 1 ft. long; lvs. 3-6 near base of st., linear and channelled, glabrous: fl. very fragrant, pale primrose-yellow somewhat red-tinged on outside. Algeria. B.M. 6736. Closely allied to T. australis.

9. viridiflora, Hort. Outer bulb-tunic glabrous except around root-crown, where there is a dense fringe: st. glabrous; lvs. 3-4, glaucous, edges slightly ciliated near base; fl. large, soft green, edged with yellow or white. Gn. 32:514.—Garden form. Bears some resemblance to a Parrot tulip. Var. præcox, Hort., is larger, pale green.

10. fulgens, Hort. Garden form with beautiful scarlet fls.: height 5-15 in.; lvs. 3, lanceolate or ovate, very wavy: perianth-segms. all obovate-ovate, acute; anthers yellow; pollen yellow; filaments white, flattened, glabrous; ovary prismatic; stigmas small, not wavy.

11. macrospela, Baker. A supposed hybrid of unknown origin. T. Gesneriana probably being one of its parents. Height 10-18 in.; lvs. 3-4, long and narrow, lowest long-lanceolate, flat, pendent: peduncle wiry; perianth campanulate, slightly funnelform, emitting a heavy sweetish unpleasant odor, bright crimson to cerise or cherry-red, with a distinct nearly black cuneate basal blotch broadly margined with yellow or yellowish white at top; segms. obtuse or outer sometimes acute, outer reflexed, inner erect; filaments dilated, white at base, black, violet or striated above, glabrous; ovary prismatic; creamy white; stigmas same color, large, slightly undulated.

12. Gesneriana, Linn. COMMON GARDEN OR LATE TULIPS. Figs. 3862, 3884, 3885, and others. Height 6-24 in.: st. erect: lvs. 3-4 or more, lower lorate-lanceolate or obovate-lanceolate, often undulated, glaucous, pubescent variable; peduncle variable; fls. 1-2½ in. long, inodorous, bright red or varicolored, when bright red with only an obscure basal
TULIPA 3399

TULIPA

emarginate; anthers yellow; filaments black, glabrous; deep scarlet with a broad-cuneate dark violet-blue ovary narrowed at collar; stigmas yellow, twice as long as fl.-stalk, not undulated, outer acute; segments yellowish white; stomata black; ovary with a small cusp in the center; filaments glabrous, flattened; ovary prismatic; stigmas large and usually crisp. Origin uncertain. Intro. from the Turkish gardens in 1554. Long since hybridized and cult. out of all semblance to any wild forms. Supposed original from (Baker) in B.M. 6430 (as T. Schreinta). Darwin tulips (Fig. 3871) are a strain of long-stemmed late self-colored tulips.

Var. Dracótina, Baker.  PARRÓS TULIP. Fig. 3870. Similar in habit; perianth usually yellow and red striped and spilted; segms. deeply cleft and incisately dentate. F.S. 21:2221 (as T. turcica).

Var. spatulata, Hort. (T. spatulata, Bertol.). This differs from the type in its larger fls. of a brilliant red color with a large purplish black blotch at the base of each of the segms. Italy.—Probably the largest of the wild tulips.

Var. Stranovayáïína, Hort. Very large brilliant scarlet fls., with a handsome dark basal blotch. One of the naturalized tulips found without disposition to vary in fields near Florence, Italy. F. 1881: 65.

Var. álbo-oculá, Krelnge. Deep campanulate fl., with a slight sweetish mawkish odor, bright red, with a distinct white basal blotch; inner segms. obtuse, outer acute; filaments white.

13. níta, Hoog. Bulb ovoid and small, with long neck, the brown coats glabrous inside except a few short hairs at base and top; scape slender and very short (2–5 in. high), glabrous: lvs. 3, linear-lanceolate, falcate and channeled: fl. bell-shaped, 1 1/2 in. long, bright crimson with a large dark basal blotch margined short (2–3 in. high), glabrous: lvs. 3, linear-lanceolate, falcate and channeled: fl. bell-shaped, 1 1/2 in. long, bright crimson with a large dark basal blotch. Intro. to cult. 1890. B.M. 7440. G.M. 39: 390.—Allied to T. Greigii and T. pulchella.

18. cariná, Hort. Krelage. Lvs. 3, not crowded, as long as fl.-stalks, slightly undulate, lightly ciliate on edge near base: perianth open-campanulate, 3 in. long, dark scarlet, tinged with green just above and blending into a bright yellow basal blotch; segms. acute, cuspidate; stomata yellow; ovary prismatic; stigmas white, not undulated. Habitat unknown. Vars. rubra and violacea, Hort., are offered.

19. vitellina, Hort. Lvs. 4, not crowded, as long as fl.-stalk, not undulated, thinly ciliate on edges; peduncle slightly tinged with red near fl.: perianth campanulate, 2 in. long, sulfur-yellow, no basal blotch; inner segms. rounded, outer acute; filaments yellowish white; stomata not undulated.—Said to be "hybrids between T. eugeniae and T. Greigii." It is one of the "Cottage Garden" tulips, a class of old-fashioned tulips which have been preserved from oblivion in the gardens of the poor. Recently they have been restored to popular favor. Well worth attention.

20. vólifó, Linn. Height 9–15 in.: lvs. usually 3, at base of scape, channeled, linear-lorate: peduncle sometimes 2-fl. in cult.: bud nodding; perianth funnelliform-campanulate, 1 1/2–2 in. long, yellow, segms. all acute, inner narrow; ovary bladder-form (narrowed at collar); stigmas smaller than ovary-diam., yellow. Said to be native in England and widely so in Eu.—In cult. as T. florentina and T. florentina var. odorata.

21. Ostrowskiana, Regel. Outer tunics of the bulb blackish, strigoïds-pilos at their apex inside: st. 3-ld., glabrous, 1-fl., 8–10 in. high, including the peduncle: lvs. glaucescent, glabrous, immarginate, the lower narrowly lanceolate, strongly undulate, the upper linear-lanceolate to sublinear, shorter than the st.: peduncle glabrous: sepals more or less spreading, elliptic, pers...
ceptibly narrowed into a short cup, purplish brick-red, base marked with a blackish spot, glabrous; filaments glabrous. Turkestan. Gt. 33:1144. B.M. 6710 (as T. Kupferbourniana).

22. Kolpauskiana, Regel. Tunics of the bulb fuscous, stigmos-pilose toward the apex inside: sts. 3-lvd., 1-fld.: lvs. erect-spreading or spreading, undulate, obscurely cartilaginous margined, margin smooth or scabrous, lower lvs. narrowly lanceolate or linear-lanceolate, upper rather linear (sublinear); peduncle glabrous; perianth erect; sepal spreading, elliptic-lanceolate to lanceolate, all acute or rarely rather obtuse, yellow, outer ones very often becoming reddish or greenish dorsally or entirely purple in a variety, apex and base glabrous; stamens glabrous. Turkestan. B.M. 6635 and G.C. III. 27:309 (both as T. Borsczewski).—Nearly allied to T. Generiana, Linn., which differs in the 3-4-lvd. st., the broader immarginate lvs. and in the campanulate-continvously often obtuse segms. of the perianth.

23. Sprénegri, Baker. Late-flowering: height 10–18 in.; lvs. 4, close together, long, linear-lanceolate, stiff: peduncle wiry, tinged with deep red under fl.; perianth open-campanulate (star-shaped), 2 in. long, bright scarlet with a somewhat dull brown basal blotch, all around with dull orange-yellow, all blending into one another; segms. all oblong-ovate and cuspidate; filaments reddish brown; ovary reddish; stigmas equal to narrow collar. Hab. (?) Intro. by Damman & Co., Naples, 1894. Gn. 50:438. Gt. 44:1611. G.M. 49:665. Said to be the latest tulip.

A4. Outer bulb-tunic with scaring appressed hairs all over inside.

B. St. pubescent (T. maculata finely so and sometimes glabrous; T. Tubergeniana not considered).
C. Perianth usually bright red with a yellow basal blotch.
D. Perianth orange-scarlet, vermilion, or red, with a dark brown, purplish, or bluish black basal blotch.
E. St. glabrous, or essentially so (see No. 77).

24. elegans

Cc. Lower lvs. linear.
Dd. Lvs. very much undulated, entirely so.
Ee. Perianth-segms. all round or oblong at top, not ending in point.
Ff. Inner and outer segms. acute or at least short-pointed.

25. maculata

26. Micheliana

27. ingens [iana

28. Maximowiczii, Regel. Lvs. erect: peduncle glabrous; perianth crimson, with a black basal blotch; segms. obtuse, ending in a short sharp point; anthers light purple; filaments linear, not bearded. B. Bokhara, 1889. Closely allied to T. lino-folia, from which it differs in having outer bulb-tunic hairy at apex (not wooly), erect lvs. and sharp-pointed perianth-segms.

29. E. Bokhara, 1889. Closely allied to T. lino-folia, from which it differs in having outer bulb-tunic hairy at apex (not wooly), erect lvs. and sharp-pointed perianth-segms.

30. Kesselringii, Regel. Lvs. 4–5, crowded at base of st., lorate-lanceolate, or linear-channeled; peduncle sometimes obscurely puberulent; perianth campanulate, 1½–2 in. long, bright yellow, flushed with red and green inside; inner segms. subobtuse, outer acute; stamens bright yellow; filaments glabrous; stigmas not equal to ovary-diam. Turkestan. B.M. 6754.

31. st., lorate-lanceolate, or linear-channeled; peduncle sometimes obscurely puberulent; perianth campanulate, 1½–2 in. long, bright yellow, flushed with red and green inside; inner segms. subobtuse, outer acute; stamens bright yellow; filaments glabrous; stigmas not equal to ovary-diam. Turkestan. B.M. 6754.

32. Korolkowii, Regel. Height 6–9 in.: lvs. 2–3, falcate, margin crisped: perianth campanulate, red, with a distinct black basal blotch; inner segms. oblong, outer obovate; filaments lanceolate; stigma small.

33. Kaufmanniana, Regel. Height 12–18 in.: lvs. 3–4, lorate-lanceolate: perianth fine scarlet, campanulate, 2½ in.; segms. obovate, cuspidate, very wide beyond middle; anthers purple; filaments glabrous; stigmas small.—A well-marked garden race, with the habit of T. generiana, from which it differs by its small stigma, pubescent peduncle, and bright red fl.-segms., with a broad black basal blotch.—Baker.
TULIPA

34. **Hoogiana**, Fedtsch. Outer bulb-scales covered on inside with reddish hairs: st., including bloom, 6-18 in. in. long, smooth: lvs. 4-6, lanceolate-tapering, smooth, with a narrow membranous white short-ciliate margin, the lowest 8-10 in. long and 1½-3 in. broad: fl. scarlet, with a large black blotch bordered with orange on each segm. within the cup and a corresponding yellow mark on the outside; segms. broad, somewhat abruptly acuminate at apex; filaments linear-lanceolate, blackish violet; anthers black. Cent. Asiatic desert (Bokhara), “a brilliant scarlet, at the base clear yellow.”—T. *Kaufmanniana* is a handsome and valuable species blooming exceptionally early. Sometimes called “water-lily tulip” from the resemblance of the partially opened fls. to those of nymphaea.

35. **saxatilis**, Sieber. Distinct: bulb ovoid, medium size: height 12 in. or more: st. usually maroon, the lowest 1 in. down and bearing 2 fls.: lvs. usually 3, sometimes lowest 12 in. long, lanceolate or linear and glabrous; perianth oblong-cuneiform, 2½-3 in. long, 3 in. across, light yellowish white; segms. narrow not undulated: perianth brilliant red, white streaked with red, with a bluish violet, dark basal blotch; filaments colored like the blotch in perianth. Var. *albiflora*, Hort., white-fls., mentioned. G.W. 12, p. 378.

36. *arména*, Boiss. Lvs. 5, crowded at base of st., falcate, glaucous and glabrous, slightly undulated, long-ciliate on edge all around, longer than fl.-stalk: peduncle glabrous, finely dotted: perianth open-campanulate, slightly sweet-scented, 2 in. long, dark scarlet with black basal blotch margined all around with yellow; inner segms. rounded, outer acute; anthers purple; filaments flattened, black, not bearded.—This name is referred by Baker without hesitation to *T. gesneriana*, but the plants in the trade as *T. arména* differ as indicated above.

37. **Billietiéna**, Jord. & Fourn. Lvs. 3-4, undulate, not ciliate on edge: perianth open-campanulate, 2 in. long, 3½ in. across, inodorous, bright yellow, flushed with scarlet-pink, especially outside, with obscure basal blotch striated with blue-black lines; anthers dark gray or blackish; filaments yellow, with dark striations; ovary narrowed at collar; stigmas light yellow, very large and crisped. Savoy, Italy. B.M. 7253. G.M. 38:311.—One of the late tulips.

38. **Didítrí, Jord. Height** 12-18 in.: lvs. 3-4, undulate, acuminate: perianth campanulate, 2-2½ in. long, 4½ in. across, bright crimson, with purple basal blotch margined with yellow or yellowish white; outer segms. reflexed; stamens same color as basal blotch; ovary narrowed at collar; stigmas larger than collar-diam., white, Savoy, Italy, and Alps. B.M. 6639. G.W. 21:1067. Var. *Mauríiana*, Baker. Lvs. narrower, slightly undulate: perianth brilliant red, with white yellow blotch. Var. planifólia, Baker. St. slender: lvs. narrow, not undulated: perianth deep red, faintly marked with yellowish red or blackish blotch. Var. *alba*, Krelage. Peduncle stiff, motived with perianth light lemon-yellow, or white tinged green outside, basal blotch limited to a few dark striations; filaments same color as fl. Var. *utíescens*, Krelage. Lvs. 3, slightly falcate; perianth light yellowish white streaked with red, with a bluish violet, dark basal blotch; filaments colored like the blotch in perianth. Var. *albiflora*, Hort., white-fls., is mentioned. G.W. 12, p. 378.

39. **acuminata**, Vahl. Fig. 3872. Height 12-18 in.: lvs. 4, lowest lanceolate, all undulated at margins: peduncle shining: perianth very open, light yellow splashed with red lines; segms. sometimes 3½ in. long, less than ½ in. wide, with edges rolled in; stases yellow; filaments flange, glabrous; ovary prismatic; stigmas very large, yellow, not undulated. Turkey(?). “This, the well-known Turkish tulip, is a most distinct type, its origin and the nature of which is not clearly known. It has the bulb, leaf, and glabrous peduncle of *T. gesneriana*, and the flower is similarly variable in color.”—Baker.

41. *Borszczówi*, Regel (later spelled *Borzseövi*). Pronounced *Borzseövi*). Bulb ovate, fuscos, outer tunics pubescent within: plant glaucous, very glabrous: st. 12-15 in. high, white prunose, lower third covered with lacerate scarious sheaths, 1-ft.: lvs. bluish green, ovate-lanceolate, gradually attenuate from the broader base to the apex, decreasing in size, four in number, the lower up to 6 in. long, more or less undulate: petals cuneate-ovate, sparse rounded to the noticeably abrupt cusp, red with an obovate black blotch at base; stamens glabrous. Steppes of Kara-Kue on the Aral Sea. Gt. 33:1175.
42 Dámmannii, Regel. Height 6 in.: lvs. 4, placed whorl-like at middle of st., linear-lanceolate, recurved, obscurely bristly, ciliate on margin, otherwise glabrous; peduncle glabrous; perianth funnelform, spreading; stamens, purplish red or reddish with an oblong-lanceolate black blotch without yellow border; segms. narrowly oblanceolate filiform, glabrous; stigmas broader than ovary-diam. Mt. Lebanon, 1889. Gt. 38:1300.—Allied to T. linifolia and T. Mazamoezoviczii.

A6. Outer bulb-tunic woolly at apex inside.

b. Filaments bearded at base. 43. Lownei

b. Filaments not bearded.

c. Perianth crimson or scarlet, with a distinct basal blotch. 44. linifolia

c. Perianth yellow, without basal blotch. 47. Batalinii

44. Lownei, Baker. Height 2–4 in.; st. glabrous, sometimes 2-headed; lvs. 6 or 7, lanceolate, acuminate, glaucous; peduncle slender, glabrous; bud slightly nodding; perianth funnelform, small, white with a bright yellow basal blotch, tinged outside with light purple or purplish pink, inner segms. wider; stamina yellow; ovary narrowed at collar; stigmas very small. Mountains of Syria and Palestine, 1874.

45. Wilsoniana, Hoog (T. Watsoniana, André). Differers from T. linifolia in bearing a mass of protruding woolly hairs from the bulb rather than short and bristly hairs, in having fewer and somewhat broader lvs., fls. more distinctly reddish and more upright-graced on the outer stages of development, in the ovate inner segms., and in the longer ovary and broader filaments. Mountains of Trans-Caspia, south-west of Aschanbad. G.C. III. 29:327.—Named for G. F. Wilson of Weybridge, England. The fls. are “of a particularly deep and full vermilion-scarlet” outer segms. oblong, with small cusp; inner segms. ovate, more or less reflexed; scape short, 2–4 in. high.

46. montana, Lindl. Bulb large and ovoid, with dense pubescence; height 4–8 in.; lower lvs. oblong-lanceolate, acuminate, undulated, very glaucous; peduncle glabrous; perianth campanulate, 1½–2 in. long, 2 in. across, deep crimson, paler outside; segms. ovate or oblong, flat, acute, the inner often ovate obtuse; filaments purplish; ovary prismatic; stigmas small. Mountains of Persia. B.R. 1106. Var. Julia, Koch. Dwarf, from Caucasus. Not more than 3–4 in. tall; fls. bright red, 1 in. or less long; all 6 segms. obovate and obtuse.

47. Batalinii, Regel. Bulb globose, with thin tunic; height 3 in.; st. glabrous; lvs. 5, crowded into a sort of whorl just below middle of st., linear-lanceolate, glabrous, slightly undulated; perianth campanulate, slightly funnelform, pale yellow; segms. slightly unequal, oblong-ovate or obtuse or short-acute, sometimes deeply incised on the edge near the top; filaments linear, terete, yellow; ovary elliptic-oblong, compressed, trigonous; stigmas coroniform. E. Bokhara, 1889. Gt. 38:1307. B.M. 7991. G.C. III. 19:759; 49:382.—One of the early tulipes.

A7. Outer bulb-tunic everywhere woolly inside.

b. Filaments bearded at base.

c. The filaments flattened. 48. biflora

cc. The filaments cylindrical. 49. Clusiana

48. biflora, Pall. Height 3–6 in.; st. glabrous or slightly pubescent, usually 2– or 3-fl., rarely 4-, 5- or 6-fl.; lvs. often 2, sometimes 3, linear, long; perianth funnel-form, campanulate, 1 in. long, 2 in. across, pale yellow or white inside, tinged green or red or even purplish outside; segms. acute; filaments flattened, ciliate at base; ovary narrowed at collar; stigmas small. Mountains of Cent. Siberia and the Caucasus. B.R. 535. B.M. 6518. Var. turkestánica, Hort. More robust than the type and larger in all its parts; fls. often 4 or 5 on the scape. G.C. III. 47:85.

49. Clusiana, Vent. Described by Baker as “one of the most widely spread and clearly marked of all the tulips, and one that shows the least tendency to outgrow the bulb.” Bulb generally 1-fl.: height 12½ in.; st. slender, glabrous; lvs. 4–5, very narrow and folded double, linear-acuminate, pendent; peduncle slender, tinged with brown directly under fl.; perianth small, when open 2 in. across, funnelform-campanulate, very fragrant, delicate white (sometimes described as lemon-yellow), with a purplish black base and black stamens, outline flushed with red; segms. acute; claw linear or on edge; stamina yellow; filaments cylindrical, densely bearded at base; ovary pyramidal; stigmas small, tinged with red. Portugal, through Medit. region to Greece and Persia. B.M. 1390. Gt. 77, p. 171. Gn.W. 22:329.

50. stellata, Hook. Close ally of T. Clusiana, with similar lvs. and habit, according to Baker, but the segms. more obtuse and the fl. always without the distinct purple eye, the fl. very wide open in sunlight. Himalaya. B.M. 2762.—Bright yellow variations are mentioned.

51. Biebersteiniana, Schlutt. f. Height 6 in.; st. slender, glabrous; lvs. 2–4, crowded together, long, channelled, glabrous, slightly ciliated on edge; bud slightly nodding; perianth funnelform, 2½–3 in. long, bright yellow tinged with scarlet-pink on edges and sometimes green outside; at base a brownish yellow discoloration; inner segms. obtuse, outer acute; anthers yellow; pollen yellow; filaments yellow; ovary prismatic; stigmas yellow, undulated. Asa Minor.

52. Occlus-solis, St. Amans. Tall, 12–18 in.; st. slender, glabrous; lvs. 3–4, lorate-lanceolate, acute, glabrous; perianth funnel-form, campanulate, 2½–3 in. long, 4½ in. across, scentless, erect; segms. bright red, with a large long black yellow-bordered blotch, very acute, the inner ones often less so; anthers yellow; filaments purple; ovary prismatic. South of France, Italy, and Switzerland. B.R. 380 (as T. Gesneriana). Var. Lortétii, Baker. A slight variety, the basal spot oblongate and black. Marseilles. Var. lycica, Baker. St. 6–8 in. long; lvs. crowded; perianth-segms. all acute, inner oblongate-oblong; apex sub deltoid; blotch black; anthers and filaments dark purple. Lycia, Asia Minor. Var. alépica, Baker. A form with fls. considerably smaller, with a small, very narrow black basal blotch. Asia Minor, Syria, and Palestine.

53. praecox, Tenore. Height, 12–18 in.; st. slender, glabrous; lvs. 3–5, lorate-lanceolate, acute, undulated at margin; perianth beautiful scarlet, campanulate, 2–3 in. long, 3 in. across, erect, scentless; basal blotch oblong or oblongate and purplish black, margined with yellow; segms. widely imbricated, outer slightly longer, acute, puberulent at apex; inner shorter, obtusely cuspidate; anthers yellow; filaments long, dark purple, glabrous; ovary prismatic; stigma pubescent, reddish. Italy and S France; also Algeria.
CXIV. Tulip varieties of the Tulipa Gesneriana type.
TULIPA

Greece, Syria, Palestine, and Persia. Very closely allied to last, and figured as such in B.R. 294, 1145, 1146; differs, according to Baker, "by its more robust habit of growth, earlier flowering, and ovate more imbricated perianth-segments, with a less clearly marked basal blotch."—One of the oldest known species.

T. siss., Hook, is "often confused with vittellina in gardens, though its flowers are yellow, very robust, taken, at least a fortnight later in blooming. Vittellina is almost white and rarely seen."—T. Ferruginea, Hort. Fl., varies very large, intense glowing crimson with a darker blotch at the base of the segments: lvs. very broad, many-versed: of robust habits and stiff growth. B. C.C. 111, 112.—T. gallica, Linn. Turuncs alvery hirsute within: st. glabrous: lvs. linear-lanceolate, acuminate: fls. yellow; outer segments ciliate to oblanceolae; inner segments, spatulate, rounded. Asia Minor.—T. botanica, Regel: Dwarf: fls. large, goblet-shaped, rich vermilion, with a large black spot at the base of each of the segments. Bokhara.—T. Lichinei, Regel: Bulb-tunics glabrous inside: height 9-16 in.: st. glabrous: lower lvs. lanceolate-linear: 3-4: erect: perianth between campanulate and funnelform: outer segments narrow and acute, the outer bright purple with broad white margin, the inner much shorter and obtuse at apex and yellowish white. Kashmir. Gu. 60: 174.

ARNOlD V. STUBBENRAUcH.

L.H.B.

TUMBOA (native name). Gnetaceae. Appealing strictly the rules of priority; T. Baines, Hook. 1, becomes the name of the strange plant long known as Welwitschia mirabilis; in this work, the description is given under the latter name.

TUNISIAN: Alcives Forli.

TUNICA (Latin, a tunic or coat, from the imbricated involucre). Caryophyllaceae. Annual or perennial hardy herbs, usually elements but stilt with the habit of Gyrostilphi but botanically more nearly allied to Dianthus; sometimes grown in flower-gardens.

Leaves narrow: fls. as in Dianthus, but smaller, gathered in cymose panicles or heads; calyx tubinatile or elongate-tubular, obtuse; stamens 10; petals 5-7; ovary 2-3-celled; berry globose, almost sessile; fruit 2-3 in. long: fls. subsessile, crowded; perianth campanulate, tube long: lvs. subulate, crowded; perianth campanulate, tube 3-4 in. long: fls. yellow, erect; spikes drooping, lax, about 2-3 in. long: perianth campanulate, dark purple, about 3-in. across: ovary globose. Mountains of N. India. B.M. 660. On the same plants in culture it is supposed that this species is known botanically; it is described as having elegant narrow lvs. and erect, 3-spicate in bloom, the upper half clothed with fuzzy white, dark-like spreading flat stigma. Singapore.

F. TRACY HUBBARD.

TURNA (named after William Turner, died 1568). Turnieracea. Glabrous, pubescent or tomentose herbs, shrubs, or subshrubs, suitable for warmhouse cult. Lvs. sparse, entire, serrate or somewhat pinnatifid; stipules small or none. fls. axillary, solitary, rarely racemose or fascicled. calyx tubinatile, funnelform or campanulate, 6-lobed, sessile-campanulate, 5-7-cleft: petals 5-7; ovary nearly sessile, free, oblong: stigma broadly peltate, on a white columnar, exerted style. B.M. 7828. Macrocyclista Baker (Maccrocleista. Kuntze). Ritshome. P. Broad: calyx tubinatile, 6-lobed, reddish: stigma broadly peltate, on a fleshy white columnar, exerted style. B.M. 7829. Var. Fosteriana, Hort. is a wiry-stemmed Annual or perennial hardy herb, usually elements but stilt with the habit of Gyrostilphi but botanically more nearly allied to Dianthus; sometimes grown in flower-gardens.

Leaves narrow: fls. as in Dianthus, but smaller, gathered in cymose panicles or heads; calyx tubinatile or elongate-tubular, obtuse; stamens 10; petals 5-7; ovary 2-3-celled; berry globose, almost sessile: fls. subsessile, crowded; perianth campanulate, tube long: lvs. subulate, crowded; perianth campanulate, tube 3-4 in. long: fls. yellow, erect; spikes drooping, lax, about 2-3 in. long: perianth campanulate, dark purple, about 3-in. across: ovary globose. Mountains of N. India. B.M. 660. Singapore.

F. TRACY HUBBARD.

TURNÉRÁ. (native name) Glabrous, pubescent or tomentose herbs, shrubs, or subshrubs, suitable for warmhouse cult. Lvs. sparse, entire, serrate or somewhat pinnatifid; stipules small or none. fls. axillary, solitary, rarely racemose or fascicled. calyx tubinatile, funnelform or campanulate, 6-lobed, sessile-campanulate, 5-7-cleft: petals 5-7; ovary nearly sessile, free, oblong: stigma broadly peltate, on a white columnar, exerted style. B.M. 7828. Macrocyclista Baker (Maccrocleista. Kuntze). Ritshome. P. Broad: calyx tubinatile, 6-lobed, reddish: stigma broadly peltate, on a fleshy white columnar, exerted style. B.M. 7829. Var. Fosteriana, Hort.

T. Macro-
The greatest difficulties are the root-maggot, which is the larva of a small fly, and the flea-beetle. The maggot may be killed by injecting bisulfide of carbon into the soil about the roots before the grubs have burrowed deeply into the tissues. In general field operations, however, this treatment is impracticable and one must rely on growing the crop in fields which are not infested with the maggot; that is, rotation is the chief recourse. The flea-beetle may be kept in check by spraying the plants with bordeaux mixture, or perhaps better by sprinkling them with paris green diluted with land-plaster (one part by bulk of paris green to fifty of plaster).

The turnips and rutabagas have firmer and richer flesh than the turnips. They are usually more prized for consumption in winter, and turnips are usually more popular in the spring and early fall markets. Rutabagas are also more prized for stock-feeding. They yield heavily, are rich and succulent and keep well in any ordinary cellar. Rutabagas started in the middle of June in the northern states will reach their full growth by October. They are usually not harvested until heavy frosts have come. The roots of rutabagas and turnips sometimes persist through the winter, even though they have been solidly frozen, and send up flower-stalks in the spring; but, unlike salad, the roots should not be left in the ground to freeze if they are to be used.

L. H. B.

**TURNIP, INDIAN:** *Arista mus trophyllus.*

**TURPÉA** (named for Turpin, French fl-painter, died 1840 in Paris), *Staphyleaceae.* A genus of about 10 shrubs or trees in Trop. and Subtrop. Asia, the Malay Archipelago, W. Indies, and Mex., with opposite odd-pinnate or simple lvs. and small fls. in large terminal or axillary panicles: calyx 5-parted, persistent; petals 5, broadly spatulate to orbicular; stamens 5; ovary superior, 3-celled, with a large lobed disk at the base; styles 3, distinct or united; fr. 3-celled, fleshy or leathery, with few or many seeds in each cell. Occasionally planted for their handsome foliage in S. Calif. Prop. is by seeds or by cuttings of mature wood under glass with bottom heat.

**TURPÉIA** (named for Giorgio della Torre or Turra, botanist of Padua, Italy). A genus of about 73 species, Trop. and S. Afr., Trop. Asia, and Austral.

**TURRÉA** (named for Cirolia della Torre or Turra, 1667–1698, botanist of Padua, Italy). *Medicine.* Trees or shrubs, sometimes grown in the greenhouse in the North; in the South used as outdoor ornamentals.

Leaves alternate, petiolate, entire or obtusely lobed; peduncles axillary, few-fl., and many-bracted; fls. elongated, white; calyx 4–5-toothed or parted; petals 4–5, elongated, free, twisted; staminal tube 8–10-toothed, anthers 8–10; disk annular; ovary oblong, 5–10-celled; ovules 2, supereous in each cell: caps. 5–many-celled, loculically 5–many-valved.

Fls. solitary or in pairs, axillary.

**heterophylla,** Smith, not Sond. Lvs. more or less obovate-cuneate, 3-lobed above, varying to subentire: fls. ±5–6 in. long. Upper Guiana. B.R. 30.4 (as **T.**
TYPHA (ancient name). Typhox. Cat-tail. Reed Mace. Hardy perennial marsh- or swamp-growing herbs, useful in the water-garden or along brooks or the margins of ponds.

Plants forming colonies, slender or stout, often tall, smooth; rhizome strong and之意ting; st. erect, simple or few and shorter; peduncles erect, terete, strait and not divided; spadix, male and female similar, superposed; fls. monocious, densely clustered in the cylindrical spadix; perianth consisting of slender hairs: fr. minute, subsees.—About 17 species, temperate and tropical regions. Monographed by Graebner in Eger's Pflanzenreich, hft. 2 (IV. 8) in 1900.

A. Female fls. without bracts.
B. Plant robust, more than 3 ft. high: lvs. flat.
c. Pedicels columnar, 1.5-3 mm. long.

latifolia, Linn. Fig. 3875. Plant stout, 4-8 ft. high: lvs. usually broad, linear, ¼-1 in. broad, exceeding the flowering culm: male and female spikes contiguous, rarely remote. N. Amer., Eu., Asia. R.B. 20, p. 199. Y. 2:197. J.H. III. 05:325. Var. eliator, Graebn. (El. eliator, Bör.), has narrow lvs. and shorter contiguous or slightly remote spikes. Eu.

dc. Pedicels short or elongate-cord, 1-1.5 mm. long.

Shuttleworthi, Koch & Sond. Plant stout, 3-4½ ft. high: lvs. linear, 2-6 lines broad, longer than the flowering culm: spikes cylindrical, contiguous, pistillate spikes thick and longer than the staminate. Eu.

bb. Plant slender, rarely over 3 ft. high: lvs. semi-cylindrical or rather flat.

Laxmannii, Lepech. (T. stenophylla, Fisch. & Mey.). Plant slender, 2½-4½ ft. high: lvs. very narrow, rarely even 3 lines broad, semi-cylindrical, grooved inside, convex outside; pistillate spike ovate-oblong or shortly cylindrical, brown, remote from the elongate staminate spike. S. E. Eu. to China.

aa. Female fls. in the axis of bracts.

b. Plant stout, 3-12 ft. high: axis of male spike hairy.

gustafii, Linn. Plant stout, 3-9 ft. high: lvs. narrow, 1-5 or 6 lines broad: spikes about equally long, remote, rarely contiguous; pedicels shortly conoid. N. Amer., Eu. and Asia; also in Trop. Amer.

bb. Plant slender, 1½-3 ft. high: axis of male spike destitute of hairs.

minima, Funk. Plant slender, 1-2½ ft. high: lvs. of the sterile shoots very narrow, linear, less than 1 line broad, of the flowering st. basally inflated sheaths rarely bearing very short involute blades: spikes remote or contiguous, female spike broadly ovate or shortly cylindrical, rusty brown. Eu., Caucasus, and Asia.

F. TRACY HUBBARD.
nate, 6 in. long; spadix with the female fls. below, the male above, the two separated by a sterile portion and the top of the spadix also sterile. China. The type does not seem to be in cult.; the form cult., var. Giraldii, Baroni, has larger and broader lvs., the spathe is purplish outside and is somewhat the color of a ripe olive, the tube and blade are more equal in length than the type; spadix is darker, being purplish black; pollen white. Mountains of N. China. G.C. III. 32:151. Probably adapted to outdoor planting for ornament.

F. TRACY HUBBARD.

TYPHONODORUM (Greek, stormy wind and gift). Aráceae. Robust herb, with a stout caudex 4-10 ft. high: lvs. thick, petioled, triangular-ovate or hastate, acuminaté: spathes with oblong tubes attenuate at both ends, blade 3 times longer than the tube, oblong-lanceolate, caudate-acuminate; spadix crect, strict, cylindrical; male infl. elongated, female short and cylindrical; fls. monocious in an elongated somewhat appendiculate spadix; perianth none; stamens 4-8 in the male fls.; ovary ovoid or subglobose and 1-celled in the female: berry large, compressed, orbicular. One species, Madagascar, Mauritius, and Trop. Afr. T. Lindleyanum, Schott (T. madagascariense, Engler). St. stout, 3-10 ft. high, 4-12 in. thick: lvs. deeply cordate or sagittate, 1½-3½ ft. long, 7 in. to 2 ft. across; petiole terete, 2-4 ft. long; spathe 1½-2 ft. long, tube 3-5 in. long, oblong, green, blade 13-19 in. long, 3-5 in. across, lanceolate, convolute below, yellow: seeds 1½-2 in. across, flattened-orbicular, edible. B.M. 8307.—A striking plant with the habit of Zantedeschia, growing in deep water. See Engler in Das Pflanzenreich, hft. 64 (IV. 23 De), 1915.
UDO, a spring blanched vegetable introduced in 1903 by Lathrop and Fairchild from Japan; it is *Aralia cori­data*, and for botanical description see page 344, Vol. I.

The plant is a sturdy hardy perennial, and the strong young shoots are blanched as they grow; these shoots are used as a cooked vegetable or as a salad. It is a plant of ancient and widespread cultivation in Japan, where there are distinct strains or varieties of it. The cultivation of udo in this country is in its amateur stage for the most part, although it has been grown by the acre in the Sacramento Valley. The following account is chosen from Bulletin No. 84 of the United States Department of Agriculture, 1914, written by David Fairchild.

"There is no doubt that the udo is worthy of adding to our list of spring vegetables, for it is easily grown, its shoots are readily blanched, and it requires little care. A patch of it can be forced every spring for at least six years, and probably much longer. When properly prepared its blanched shoots are delicious; they have their own characteristic flavor, can be prepared for the table in a great variety of ways, and are keenly appreciated by people of discriminating taste. Space for space, udo will yield about the same amount of food for the table as asparagus and will be ready for use at about the same time in the spring. Possibly more labor is required to blanch the shoots of the udo than those of asparagus, but the udo is probably somewhat easier to take care of and yields sooner."

Udo is readily grown from seeds placed in a greenhouse or coldframe, sown ½ inch deep in March or April. When 3 to 4 inches high, the plants are set in the open ground, standing 3½ to 4 feet apart each way; often they will be 6 feet high by autumn. When it is desired to propagate a particular strain, cuttings may be made of the green shoots taken when about ½ inch in diameter and cut 5 inches or more long, the lower end being severed just below a joint.

The stout young shoots are blanched as they emerge from the ground. In mild climates, earth may be mounded over them, but a large drain-tile placed over the mound provides a better method for the home garden.

This method "has at least one disadvantage, however, in that the shoots have a tendency to leaf out and produce a number of unopened leafstalks which take away from the robust growth of the shoots. A method which obviates this defect in using tiles is to put around each hill a deep box or small half cask from which the bottom has been removed and fill it with light sand or such a light material as sifted coal-ashes. Shoots which come up through such a medium are almost free from the elongated leafstalks which are developed when the shoots are produced in the dark air-chambers under the tiles. Care must be taken in any method of mounding up or filling in dirt or ashes over the crowns that the shoots do not break through into the sunlight, for as soon as they do this they become green and take on a rank objectionable flavor. Properly grown udo shoots produced from three-year-old plants should be from 12 to 18 inches long and 1 inch to 1½ inches in diameter at their bases.

"After the removal of the crop of udo shoots in the spring, the crowns of the plants should be completely uncovered and the plants allowed to grow normally throughout the summer, but they should not be permitted to flower unless seed is required, the flower-clusters being pinched or cut back as they form."

For use, the shoots are first boiled in salt-water for ten minutes or so and the water changed to remove the turpentine flavor. An hour's stay in iced-water will remove the resin from the shoots, provided they are cut into thin slices or shavings; the slices may then be used in salads without cooking. It is used also in soups, and on toast.

**UHDEA.** A name proposed by Kunth in 1847 for a Mexican composite, still sometimes listed as *U. bipinnatifida*, Kunth. It is properly *Montanoa bipinnatifida*, Koch, the name Montanoa dating from 1825. See page 2064, Vol. IV.

**ULEX** (ancient Latin name of this or a similar plant). *Leguminosae. FURZE. GORSE. WHIN.* Ornamental woody plants grown for their handsome yellow flowers and evergreen appearance.

Spiny shrubs: Ivs. mostly scale-like, only vigorous shoots near the ground bearing fully developed lvs.: fls. papilionaceous, axillary at the end of the branchlets; calyx 2-lobed, divided nearly to the base; standard ovate, wings and keel obtuse; stamens alternately longer and shorter; pods small, ovoid, few-seeded; seeds strophiolate.—About 20 species in W. and S. Eu. and in N. Afr. Closely allied to Cyrisus and chiefly distinguished by the deeply 2-lobed calyx. The fls. yield a yellow dye. Sometimes cult. as a winter fodder plant in Eu., the green sprigs of one year's growth being eaten.

The furzes are much-branched shrubs with dark green spiny branches, usually almost leafless, and with
showy yellow papilionaceous flowers which are axillary and often crowded at the ends of the branches. They are not hardy North, but under protection they survive the winters in New England. They are valuable as sand-binders for covering dry sandy banks and are also well suited for seaside planting. On account of their dark green branches they have the appearance of evergreen plants and they are very showy when covered with their yellow flowers. They are also sometimes used for low hedges. They prefer sandy or gravelly porous soil and a sunny position; in rich garden soil they grow more rampant, but do not bloom so well. They should be sown where they are to stand, as they do not bear transplanting well, or if this is not feasible, they should be sown singly in small pots and the plants then planted out in their permanent places. Propagation is by seeds sown in spring after the danger from frost has passed; by greenwood cuttings under glass; or by cuttings of nearly mature wood in early summer in a coldframe under glass, forming roots the following spring. Varieties and rarer kinds are sometimes grafted in spring in the greenhouse on U. europaea.

**U. europaea** Linn. FURZE. GORSE. WHIN. Fig. 3876. Much-branched very spiny rigid shrub, 2-4 ft. high; branchlets striped, villous when young; lvs. scale-like or narrow-lanceolate, pubescent: fls. axillary, 1-3, crowded at the end of the branches and forming racemes; corolla bright yellow, about \( \frac{3}{4} \) in. long, fragrant; calyx yellow, hairy; pod oblong, over \( \frac{1}{2} \) in. long, villous, dark brown. April, June and often again in Sept., Oct.; in Calif. almost the whole year. W. and S. Eu; naturalized in waste places in the Middle Atlantic states and also on Vancouver IsI. S.E.B. 3:323. R.F.G. 22:2068. G.W. 17, p. 285.—There is a variety with double fls., var. plenus, Schneid. (var. flore-pleno, Loud.). Gn. 63, p. 441. G.M. 52:393. Another variety is var. strictus, Webb, of upright, pyramidal habit and less spiny, but as it does not bloom freely, it is of little value.

**W. americanus** Forst. Dwarf shrub of dense habit, similar to the preceding species, but smaller in every part, less rigid and with slenderer spines: fls. about \( \frac{1}{2} \) in. long, with the wings straight and shorter than the keel; calyx slightly downy, not hairy: pod \( \frac{1}{2} \) in. long, nearly incised in the calyx. Autumn. W. Eu, England to Spain. S.I.F. 3:322. R.F.G. 22:2068, 3.

**ULLUCUS** (native name). Chenopodiaceae; Volkens in Engler's Pflanzenfamilien places this in Bauelaceae. Fleshy perennial herbs, decumbent and climbing, grown in Peru and Chile for the tubers: rhizomes produced near the base of the plant underground, and much eaten in S. Amer. Sometimes the plant is cultivated in northern countries, but only as a curiosity. It is prop. by the tubers, as are potatoes.

**ULLMÄRIA**: Piliferaudula.

**ULMUS** (ancient Latin name of the elm). Ulmaceae. ELM. Ornamental trees chiefly grown for their handsome foliage and often planted as shade and street trees.

Deciduous, rarely half-evergreen; winter buds conspicuous, with imbricate scales; lvs. short-petioled, usually unequal at the base, with caduceous stipules: fls. perfect or rarely polygamous, apetalous, in axillary clusters or racemes; calyx campanulate, 4-9-lobed, with an equal number of stamens; ovary superior, with a 2-lobed style, usually 1-loculed and with 1 ovule: fr. a slightly compressed dry nutlet, with a broad rarely narrow membranous wing all around (Fig. 3877).—About 18 species of Ulmus are known, distributed through the colder and temperate regions of the northern hemisphere, in N. Amer. south to S. Mex., but none west of the Rocky Mts., and in Asia south to the Himalayas. The wood is heavy, hard, and tough and often difficult to split. It is especially useful in the manufacture of wagon-wheels, agricultural implements, and for boat-building. The inner mucilaginous bark of the branches of U. fulva is used medicinally and that of some Chinese species is made into meal and used for food. The tough inner bark of some species furnishes a kind of bass which is sometimes woven into a coarse cloth, especially that of U. japonica in Japan.

The elms are mostly tall trees, rarely shrubby, with alternate usually 2-ranked, medium-sized or sometimes rather small leaves and with inconspicuous generally greenish brown flowers appearing mostly before the leaves. Most of the cultivated species are hardy North, but U. crassifolia and U. alata are tender; U. parvifolia and U. serotina are of doubtful hardiness, although they have persisted near Boston. The elms are mostly tall and long-lived and are very valuable for park planting and for avenue trees, especially U. americana, which is the favorite tree for street planting and a shade tree for dwelling houses in the northeastern states. It is the most characteristic tree of this region and of characteristic beauty. Its habit is at once majestic and graceful, and the wide-spreading head, borne upon a considerable height on a straight and shapely trunk, affords ample shade and shelter. Besides the American elm several other species are used as avenue trees, as Ulmus fulva, U. racemosa, and the European U. campestris, U. hollandica, and U. foliacea. Of U. hollandica, the vars. belgica, superba, Klemmer are among the best for street planting; of U. foliacea, the vars. stricta, Wheatley, and Dampieri. In the southern states U. serotina, U. crassifolia, and U. alata are sometimes used as avenue trees. There are several varieties of striking and peculiar habit, as U. glabra var. fastigiata and U. foliacea var. monumentalis, with narrow columnar head; U. glabra var. pendula, with horizontal limbs forming widespread tiers; U. glabra var. Camperdowni with long pendulous branches. U. foliacea var. umbrosafera, with a dense, globose and rather small head, may be used as an avenue tree for formal gardens. Several species and varieties are interesting in winter on account of their branches being furnished with broad coryck wings. The foliage of most species turns pale yellow in fall, but that of the European species remains green much longer.

Unfortunately many insects and fungi prey upon the elm, especially on the American elm. One of the most
destructive is the elm leaf-beetle, which destroys the foliage. The canker-worm is also serious; to keep it from doing damage, band the trunks a few feet above, the ground with cloths covered with a sticky substance, which prevents the ascent of the wingless female. The trees should be sprayed. A borer, Saperda tridentata, sometimes does considerable damage to the wood. The elms grow best in rich and rather moist soil, and the American elm especially requires such a soil to attain its full beauty, but some species, as *U. racemosa* and *U. alata*, do well in drier situations. Elm trees are not difficult to transplant, and rather large trees may be moved successfully if the work is done carefully. They bear pruning well, but generally do not need much attention of this kind. Propagation is by seeds ripening usually in May or June and sown at once. Most of the seeds will germinate after a few days, but some remain dormant until the following spring. In spring, also by layers, which are usually put down in autumn and are fit to be removed in one year. A moist and rather light soil is best for this method. Trees raised from layers are said to bear seed less early and less profusely and are therefore especially recommended for street trees, as the foliage of trees that fruit under glass, the cuttings growing most readily from forced plants. *U. campestris*, *U. foliacea*, and some of their varieties are also propagated by suckers. In nurseries most of the varieties are propagated by grafting, either by budding in summer or by whip- or splice-grafting in spring outdoors or on potted stock in the nurseries most of the varieties are propagated by grafting under glass, the cuttings growing most readily.

**KEY TO THE SPECIES**

A. Blooming in spring, before the lvs.: calyx not divided below the middle.

B. Fls. on slender pedicels, drooping: fr. ciliate.

C. Fr. glabrous except the ciliolate margin: branches do not cory: margins of lvs. ciliolate.

D. Lvs. widest above the middle, densely pubescent beneath: buds elongated, pointed, pubescent.

Tall and wide-spreading tree, attaining to 120 ft., usually with high light gray trunk, limbs gradually outward-curving with pendulous branches; branchlets pubescent when young, glabrous in fall; buds acute, glabrous: lvs. ovate-oblong, unequal at the base, acuminate, doubly serrate, pubescent when young, at length glabrous and rough above, pubescent or almost glabrous beneath, 5–6 in. long; fls. in many-flid. clusters; stamens 7–8, exserted: fr. oval or elliptic, viscid, usually with 2 opposite very broad wings; branchlets almost glabrous: buds acute, glabrous: lvs. ovate-oblong to oblong-lanceolate, often falcate, acute or acuminate, doubly serrate, subcoriaceous, glabrous above, pubescent beneath, 1.4–2 in. long; fls. in short, few-flid. racemes; stamens usually 5: fr. elliptic-ovate, with narrow wing and with 2 incurved horns at the apex, villous, ± glab. Va. to Fla., west to Ill. and Texas. S. 7:718.—Tripod tree, sometimes used as an avenue tree in the southern states; not hardy N.

5. fülya, Michx. (U. rūbra, Michx. U. ellipitica, Hort., not Koch. U. Heyderi, Spae. U. sitûbra, Hort.). Slippery Elm. Red Elm. Figs. 3877, 3880. Tree, attaining 70 ft., with spreading branches, forming usually a broad, open, flat-topped head: branchlets pubescent and scabrous with minute tubercles: lvs. obovate to oblong, very unequal at base, long-acuminate, doubly serrate, of firm texture, very rough above, pubescent beneath, 4–7 in. long; fls. in dense clusters; stamens 5–9: fr. orbicular-oval, little notched at the apex, ± glab. Que. to Fla., west to Dakotas and Texas. S. 7:314. Em. 2: 334.—The reddish brown pubescence of the bud-scales is very conspicuous in spring, when the buds are unfolding.

horizontal branches, stunted branches, and small lvs., forming a hemispherical bush. Forms of *U. glabra* are frequently planted in the East.

7. *laciniosa*, Meyr. (*U. montana var. laciniosa*, Trautv. *U. major var. heterophylla*, Maxim.). Tree, usually not exceeding 30 ft., but occasionally taller: branches sparingly hairy or glabrous, finally pale yellowish brown or grayish brown, older branches brownish, smooth, or more or less intermediate between the parents, in some specimens the mature branchlets glabrous or slightly pubescent white and by the presence of 3-lobbled lvs. even on the fruiting branchlets of mature trees, while in the variety of *U. glabra* the mature branchlets are reddish brown and quite hairy while young and the 3-lobbled lvs. appear chiefly on vigorous shoots.

Pyramid tree: lvs. thicker and firmer; more cuspidate; in a more open notch at the apex; seed touching the base of the notch. England, W. and S. Eu. H3;has been at the apex, seed touching the base of the notch. Eng­

Pyramid tree: lvs. thicker and firmer; more cuspidate; in a more open notch at the apex, seed touching the base of the notch. England, W. and S. Eu. H3;has been at the apex, seed touching the base of the notch. England, W. and S. Eu. H3;has been

3879. A feathered elm.—*Ulmus americana.*

8. *japonica*, Sarg. (*U. campesiris var. japonica*, Rehd.). Tree, to 100 ft., with a broad head and often more or less pendulous branchlets: young branchlets densely pubescent and rough with minute tubercles, pale yellowish brown, sometimes developing corky ridges: lvs. obovate or elliptic, acuminate, oblque at the base, scabrous and hairy above, pubescent beneath with slight axillary tufts of hairs, 3-5 in. long; pairs of veins 12-16; petiole % in. long, densely pubescent: fls. nearly sessile, tetramerous: fr. obovate-oblong, about % in. long, gradually narrowed toward the base, with an open notch at the apex; seed touching the notch. Japan, Manchuria, Amurland. G.F.6:327. S.T.S. 2:101.—Intro. into the Arnold Arboretum in 1895; it has proved perfectly hardy there, grows rapidly, and promises to become a valuable ornamental tree.

10. *holfandica*, Mill. (*U. Dippeliana, Schneid. U. glabra × U. foliacea*). Under this name are united here a number of elms which are apparently hybrids between the Scotch elm and the smooth-leaved elm. They are more or less intermediate between the parents, in some forms resembling the first, in others the second parent. As the type of this collective group the following variety may stand, as it is probably not different from Miller’s *U. hollandicca*. Var. *major*, Rehd. (*U. major*, Smith. *U. sebra var. major*, Smirke. *U. campéstris var. major*, Plant.). DUTCH ELM. Tree, to 100 ft. or more, with a short trunk and wide-spreading branches, suckering: bark of trunk deeply fissured: young branchlets glabrous or with few hairs: buds ovoid, minutely pubescent: lvs. broadly oval, acuminate, very unequal at the base, dark green, lustrous and nearly smooth above, sparingly and minutely pubescent and glandular beneath, with conspicuous axillary tufts, 3-5 in. long; pairs of veins 12-14; petiole % in. long, densely pubescent: fls. nearly sessile, tetramerous: fr. obovate-oblong, about % in. long, gradually narrowed toward the base, with an open notch at the apex; seed touching the notch. R.F.G.12:665. Var. *végeta*, Rehd. (*U. végeta*, Lindl. *U. glabra var. végeta*, Loud. *U. Huntingdonii*, Hort.). HUNTINGDON ELM. Tall tree with rough bark and forked st.; suckering: young branchlets stout, glabrous or sparingly hairy: lvs. oval, acuminate, very unequal at the base, smooth and glabrous above, glabrous below except small axillary

3880. Fruit of slippery elm.—*Ulmus fulva.* (× 2).
pendulous branchlets; suckering: bark gray, deeply fissured: young branchlets glabrous or nearly so: buds minutely pubescent: lvs. oval or obovate, acuminate, very unequal at the base, lustrous and smooth above, with white axillary tufts beneath and glandular, sparingly and minutely pubescent at first, doubly serrate, not ciliate, 2-3½ in. long; pairs of veins about 12; petiole ½-1½ in. long: fls. 4-5-merous: fr. obovate, cuneate at the base, broad and rounded at the apex; the seed nearly touching the closed notch at the apex. 

3881. Camperdown elm.—Ulms glabra var. Camperdownii. 

3882. Ulms glabra var. Camperdownii. (×3) 

13. parívólia, Jacq. (U. chinênsis, Pers.,) CHINESE ELM. Half-evergreen small tree or shrub, with spreading pubescent branches: lvs. ovate to oblong or oblong, very short-petiolate, nearly equal at base, obtuse or obtusish, subcoriaceous, simply serrate, glossy and glossy above, pubescent beneath when young, usually glabrous at length, 3½-4 in. long: fls. short-pedicelled, in clusters; stamens 4-6, much exerted: fr. oval to elliptic, notched at the apex, smooth above, about ½ in. long. July-Sept. N. China, Japan. S.I.F. 1:37. R.H. 1909, pp. 398, 399. —Has proved hardy near Boston. The recently described U. sibélica, Davieau, and U. Sibériquina, Davieau, are probably only forms of this species; they are said to differ in their deciduous lvs. and the former, besides the persistent deeply fissured bark, excelling in the other two species and the larger fr. exceeding ½ in. (B.S.D. 1914: 24, 25); the latter differs in the crenate-dentate lvs. with 8-10 pairs of veins and in the contracted fr. (B.S.D. 1914: 24; also S.I.F. 1:37 represents this form).

14. crassífolia, Nutt. CEDAR ELM. Tree, attaining 80 ft., with spreading limbs and slender, often pendulous branches, often furnished when older with 2 opposite corky wings: lvs. short-petiolate, ovate to ovate-oblong, usually very unequal at the base, obtuse or acute, doubly and obtusely, sometimes almost simply serrate, subcoriaceous, somewhat rough and lustrous above, pubescent beneath, 1-2 in. long: fls. in 3-5-fld. very short racemes; stamens 5-8, little exerted: fr. oval-elliptic, pubescent, notched, ½ in. long. Aug. Miss. to Ark. and Texas. S.S. 7:315. —Tender N.

15. serícola, Sarg. Tree, with short spreading and pendulous branches, often furnished with irregular corky wings: lvs. oblong to obovate, unequal at the base, acuminate, doubly serrate, glabrous and lustrous above, pubescent on the veins beneath, 2-3 in. long: fls. in 3-5-fld. pendulous racemes, each 5-6-parted to the base: fr. elliptic, deeply notched, densely ciliate, ½ in. long. Sept. Tenn. to Ga.; sometimes planted in simple pendunculate umbels, which in the bud are surrounded by an involucre of 6 caducous bracts; perianth-tube very short; limb with 6 segments; stamens 9, filaments with an orange-colored gland at base, anthers opening by uplifted valves: drupe subglobose or ovoid with a hard endocarp.—One species, Calif. Prop. by seeds.

3853. California laurel.—

UMBELLULARIA (from Latin umbella, a sunshade; referring to form of inflorescence). Lauraceae. California Laurel. Tall umbrageous tree, glabrous, used as a shade tree in California and similar regions. Leaves alternate, evergreen, petiolated, slightly coriaceous: fls. small, greenish,
places, particularly along streams in the Coast Range foothills and mountains, and attaining its greatest size in the cool fog-moistened alluvial valleys of the coast of N. Calif. and S. Ore.; it is but rarely seen in the drier interior valleys of the state. It often crowns the highest points of the coast-range hills, up to about 2,500 ft. altitude and far from the nearest spring or other visible sign of moisture, but in such cases the rock strata are nearly vertical and easily penetrated by the long roots which are able thus to reach hidden supplies of water. In such places it usually forms dense clumps or thickets of shrubs or small trees which are frequently shorn by the cutting ocean winds as though by a gardener's shears, suggesting its adaptability for clipped-hedge and windbreak work. It is used in boat-building, for jaws, bits, cleats, cross-trees, and the like. The branches are occasionally used for poles for chicken-roosts, as the strong odor pervading wood and bark as well as lvs., is said to keep away lice. The lvs. are used for flavoring soups and bland-manges but are too strong to give as agreeable flavor as those of Laurus nobilis or Prunus Laurocerasus. The tree is sometimes cult. for ornament in S. European parks and gardens. Sargent describes it as 'one of the statelest and most beautiful inhabitants of the North American forests, and no evergreen tree of temperate regions surpasses it in the beauty of its dark dense crown of lustrous foliage and in the massiveness of habit which make it one of the most striking features of the California landscape and fit it to stand in any park or garden.'

JOSEPH BURTT DAVY. F. TRACY HUBBARD.

UMBILICUS: Cotyledon.

UNGANÁDIA (named for Baron Ungnad, who in 1576 introduced the common horse-chestnut to western Europe by sending seeds to Clusius at Vienna). Sapiencia. MEXICAN BUCKEYE. Small tree or shrub which has been grown abroad in the coolhouse, but is hardy in the S. U. S., where it is used as an ornamental. Lvs. alternate, without stipules, odd-pinnate; ifs. 3-7 pairs, serrate, terminal long-petioled; ifs. polygamous, irregular, aggregated in lateral fascicle or corymbose; calyx subequal, campanulate, 4-5-parted, lobes imbricate; petals 4-5, subequal, clawed, apex connate-cristate; disk 1-sided, oblique, tongue-shaped; stamens 7-10, unequal in length; ovary stipitate, ovoid, 3-celled: caps. 3-lobed, loculicidally 3-valved, leathery, cells 1-seeded; seed emetic.—One species, Texas. The seed, or "bean," has a sweet taste, but is considered emetic and poisonous. The fr. does not have a prickly husk like the horse-chestnut.

F. TRACY HUBBARD.†

UNOINA (an ancient Latin name of some unknown plant, derived from unio, unity). Gramineae. Perennials with loose usually showy panicles: spikelets broad and very flat, several-fl'd., some of the lower lemmas empty; glumes and lemmas keeled, nerve'd, pointed, but awnless.——Species 5, all American. Cult. for the ornamental panicles, which are suitable for dry bouquets.

LATIFÓLIA, Michx. SPIKE-GRASS. Fig. 3884. Culms 2-4 ft.: lvs. broad and flat, often 1 in. wide: spikelets large and thin, at maturity drooping on slender pedicels, forming a very graceful and ornamental panicle. Pa. to Kan., and southward.—Often grown in Hardy borders. One of the best of our hardy native perennial grasses.

PANICULÁTA, Linn. SEA OATS. Fig. 3885. Culm taller, 4-8 ft.: lvs. narrow and convolute: spikelets broader, upright on short pedicels, forming an elongated drooping panicle. Sand-hills along the seashore of the southern states; can be grown as far north as S. Ont. Dept. Agr., Div. Agr., 7:271. U. Palmieri, Vasey, a dicesorous perennial with extensive root-stocks, growing in sand-flats along rivers of N. Mex., is harvested by the Cocopa indians who use the grain for food. G. F. 2:463.

A. S. HITCHCOCK.

UNÓNA (imitation of Anona). Annonaceae. A genus based by the younger Linnaeus on an American plant belonging to the previously established genus Xylopia, and afterward incorrectly applied to the Old World genus Desmos, of which it becomes a synonym. U. discolor, Vahl, cult. in tropical gardens for its sweet-scented ifs., is identical with the
URCEOCHARIS (from the genera Ureolina and Eucharis). A hybrid between *Ureolina pendula* and *Eucharis grandiflora*, or in gardener’s language *Ureolina aurea* and *Eucharis amazonica*. A flower of the hybrid and of each of its parents is shown in Fig. 3886. It is a tender winter-blooming bulbous plant with broad lvs. a foot long and half as wide, and large white bell-shaped 6-lobe’d fls. a dozen or so in an umbel, and each 2 in. across. The hybrid gets its white color from Eucharis, the fls. of Ureolina being yellow. The shape of its fl. is so singular a mixture of the two as to be very different in appearance from either. The hybrid lacks the beautiful staminal cup of Eucharis, and has a distinctly bell-shaped perianth. The showy part of Ureolina is the urn-shaped portion of the fl., the spreading tips being very short. The perianth of Eucharis is funnel-shaped, the spreading portion being large and showy. The perianth-tube and ovary of the flower of the hybrid and of each of its parents is shown in Fig. 3886.

3886. At the left, Eucharis grandiflora; middle, Ureolina pendula; at the right, the hybrid *Urceocharis Cibranii*. (All half size.)

---

URARIA (Greek oura, tail, referring to bracts). *Leguminosae*. Subshrubby perennials, adapted to the warmhouse; 1 species has been tried in S. Fls. Lvs. pinnately 3- or 5-7-foliate or the lower rarely all 1-foliate; lfts. usually large, stipellate; stipules free, acuminate: fls. purplish or yellowish, arranged in terminal hirsute racemes which are sometimes close and elongated, sometimes dense and spike-like; calyx-lobes subulate acuminate, 2 upper teeth short, 3 lower usually elongated; standard broad; wings adhering to the obuse keel; stamens diadelphous; ovary sessile or stipitate, few-ovuled: pod of 2–6 small, turgid, 1-seeded indelphous. Joes. About 17 species, Trop. Asia, Afr., and Austral.

**crinita**, Desv. Erect little-branched subshrubby perennial, 3–6 ft. high, distinguished from other species by having its upper lvs. composed of 2–7 oblong lfts., and pedicels clothed with long bristles; lfts. 4–6 x 1/2–2 in.: racemes dense, 1 ft. long, 1–11/2 in. thick; standard ovate, violet-purple within, pale blue outside; wings pinkish. Bengal to Assam, eastward through Burma to China, south to Malacca and the Malay Isls. to Java.

**URBOURIA** (named for Dr. Manuel Urumba). *Crassulaceae*. Perennial succulent herbs, caulescent or aculescent: lvs. closely imbricated, thick and rigid; inf. rather few-fl., cymose: calyx small, 5-lobed, lobes ovate to lanceolate, equal or unequal, much shorter than the corolla which is somewhat cone-shaped, lobes united at base into a tube; corolla 10, 5-parted, 10-carpelled. Mexico. Three or 4 species, Mex. See also *Cotyledon*, Vol. II, p. 868. *U. obscura*, Rose. Caulescent: st. about 4 in. high; lvs. ovate, about 3 x 2 in., thick but flattened, somewhat rounded at base; fls.-sts. thickish, with maroon lvs.: inf. 1-fl. or in a 2-branched raceme; fls. about 10; calyx-teeth lanceolate; corolla about 1/2 in. long, bright rose yellow below, lobes slightly spreading, yellow. Habitat unknown. *U. Pürpurei*, Rose. Aculescent: lvs. forming a very compact rosette, broadly ovate, acuminate, 11/2 in. long and nearly as broad at the base, gla-

---

F. TRACY HUBBARD.
URCEOLINA (Latin, small pitcher, alluding to the pitcher- or urn-shaped flowers). Amoryllidaceae. Bulbous herbs, used both in the greenhouse and for summer and autumn blooming out-of-doors.

Species: lvs. flat or petiolate, long or narrow, contracted to the petiole: fls. in an umbel, numerous, rather long-pedicelled; involucral bracts 2, scarios; perianth erect, finally recurved or pendulous, tube contracted above the ovary, then suddenly dilated, lobes subequal, spreading; ovary 3-celled: caps. ovoid-globose or subpyramidal, 3-angled or nearly 3-lobed.—About 3 species, S. Amer.

The species of urceolina are attractive plants and easily grown, flowering every year, but for some reason they are rather scarce. The bulbs are about 3 inches across and during the growing season have one or two leaves. The plants flower in December. After flowering the bulbs may be removed from the greenhouse to the intermediate house and placed in a spot where they will be kept dry. Just before growth begins in the spring, the bulbs should be taken out of the pots and the exhausted soil removed. The bulbs may then be replaced, one bulb in a 3-inch pot, using clean pots, plenty of drainage material and a rich light porous soil. Place the top of the bulb level with the soil. Remove the pots to the stove, and as soon as growth begins water freely. In the fall when the leaves turn yellow, water sparingly and finally withhold water altogether. The flowering season should begin in April or May by watering the plants freely. The plants flower in December. After flowering the bulbs may be removed from the warmhouse to the outdoors.

URDANA (from Uren, the Malabar name). Malvaceae. Herbs or shrubs of little horticultural interest: plants more or less covered with rigid stellate hairs: lvs. elongated or lobed: fls. clustered: calyx 5-cleft; petals 5, often tomentose at the back, free above, connate below; staminal tube truncate or minutely toothed, anthers nearly sessile: ovary 5-celled, cells 1-ovuled: ripe carpels covered with hooked bristles or smooth, indehiscent.—About 8 or 9 species, natives of the tropics and subtropics. U. lobata, Linn. Herbaceous, more or less hairy: lvs. rounded, angled, not divided beyond the middle, cordate, 5-7-lobed, lobes acute or obtuse, about 1-2 x 2-3 in.: fls. pink: carpels densely pubescent, spiny. Species of both hemispheres. Very variable. U. stelliptica, Linn. Shrubby with a few elongated, fulvous-pilose branches: lvs. distant, rather short-petioled, cuneately ovate-lanceolate, base somewhat cordate, stellate, hairy, commonly circinate-dentate: fls. rather large, 1-2 in., across, white, in axillary clusters; calyx-segms. lanceolate, acute; petals spatulate. Brazil. J.F. 3:281.

URERA (derivation not obvious, possibly from uro, to burn, alluding to the stinging hairs). Urticaceae. Trees or shrubs, rarely subshrubs, with stinging hairs usually scattered, one of which has been rarely cult. as an ornamental greenhouse shrub. Lvs. alternate, entire, dentate or lobed, feather-venined or 3-5-nerved; stipules free or more or less connate in one: panicles dichotomous, cymose or irregularly racemose, unisexual: fls. dioecious or rarely monoeccious; perianth of male fls. 4-6-parted, segms. ovate, stamens 4-5, ovary rudimentary; perianth-lobes or segms of female fls. 4, subequal or outer smaller, ovary straight or oblique: achene straight or oblique, compressed or ventricose.—About 40 species, Spec. Amer., Afr., also Mascarene Isls. and Pacific islands.

URSELIA, Gaud. (Urtica caracasana, Jacq.). Tree or shrub: lvs. broadly ovate, acuminate, basal sinus wide and open, crenate-dentate: fls. dioecious, in regularly dichotomous cymes; male cymes 4-6 times dichotomous, stinging or not, rose-colored; female fls. many times dichotomous, the fls. solitary or in 3's. Spec. Amer.

URGINEA (from the name of an Arabian tribe in Algeria). Lilidceae. Bulbous herbs used both in the greenhouse and out-of-doors.

Leaves radical, sometimes very narrowly linear, sometimes broadly strap-shaped or almost oblong: scape simple, leafless: lvs. in a terminal raceme, usually numerous, rather small or medium-sized, whitish, or rarely pale yellowish or rose, color more intense in the center of the segms.; bracts small, scarios; perianth finally deciduous, segms. 6, distinct, campanulate-connnivent or spreading after anthesis; stamens 6; ovary sessile, 3-celled, usually 3-cornerted: caps. 3-cornerted, grooved, or intruded between the angles, septicidally dehiscent.—About 75 species, Spec., Eu., Medit. region, India and Trop. and S. Afr. The sea-onion is closely related to the genus Scilla, but seems to be much closer to Ornithogalum, especially in habit, infl. and color of fls. The seeds of Urginea are numerous in each locule (in the sea-onion 10-12), strongly compressed and winged; in Ornithogalum and Scilla they are not compressed or winged and in Scilla they are solitary or few in each locule.

The sea-onion, known to apothecaries by the name of squill, and to gardens as Urginea maritima, is a bulbous plant native to the Mediterranean region. It has the same style of beauty as Ornithogalum pyramidalis but unfortunately it is only half-hardy. As an ornamental plant it is little known in America. The name seems not to appear in American catalogues, but the Dutch bulb-growers offer the bulbs in different sizes. A plant erroneously called sea-onion is Ornithogalum caudatum. This is considerably different in appearance and is a native of both hemispheres. Very rare the sea-onion blooms, but the plant is generally considered an autumn bloomer, and it is clear that the leaves appear after the flowers. In England the plant is said to have flowered as early as July and August. Baker writes that the leaves appear in winter. Some English cultivators say the leaves appear as early as October and November; others say not until spring.
URGINEA

The plant grows near the seashore and inland, in dry sandy places from the Canaries to Syria. It is also found in South Africa, which is unusual, as the North and South African species of any genus are not usually identical.

The bulbs of Urginea are collected in large quantities in the Mediterranean region for the drug trade. They sometimes attain a maximum weight of fifteen pounds. The bulbs, when eaten, contain about 22 per cent of sugar and are used in Sicily in the manufacture of whiskey.

Squills have emetic and cathartic properties. Sirup of squills has emetic and cathartic properties. Sirup of squills has been deprived of its outer scales and cut into thin slices, the central portions being rejected.

UROSTIGMA: Ficus. The following species now in cult. abroad was not included under Ficus in Vol. III, p. 1229. Ficus subtripinervia, Mart. (Urostigma; subtripinervia, Mart.). Large tree; lvs. chartaceous, ovate or lanceolate-elliptic or oblong, 1-2 x \( \frac{3}{2} \) in. 

URSINA (John Ursinus, of Regensburg, 1608-1666; author of "Arboretum Biblicum"). Composite: Here belongs the hardy annual known to the trade as Sphenogyne speciosa.

Annuals, perennials, or subshrubs; lvs. alternate, serrate, pinnatifid or usually pinnatisect; rays the same color on both sides or purplish brown beneath; involucre hemispherical or broadly campanulate; achenes often ribbed. -A genus of about 60 species, all native to S. Afr. One species, U. annua, is also found in Abyssinia. In Ficus Calyptris, vol. 3 (1864-65), Sphenogyne and Ursinia are treated as separate genera, the distinctions being as follows: the achenes are cylindrical in Sphenogyne, but obovate or pear-shaped in Ursinia, distinctly tapering to the base: the pappus is uniseriate in the former, biseriate in the latter, the inner series consisting of 5 slender white bristles. In the course of time these distinctions have been dropped and Sphenogyne included in Ursinia.

pulchra, N. E. Br. (Sphenogyne speciosa, Knowles & Weste.). Fig. 3887. Annual. 1-2 ft. high, with lvs. pinnately dissected into linear lobes and yellow or orange fl.-heads 2 in. across: rays about 22, 3-5-toothed; fls. yellow, with 2 pairs of sepals and a single erect ovary; lvs. simple, opposite, strongly nerved, dentate or crenate or incised. Several species of nettle are native in N. Amer. and a few are intro. weeds. The plants have very little ornamental value.

URVICEA (classical name, alluding to the burning hairs). Urticaceae. Nettle. About 30 annual and perennial erect simple or branching slender herbs, widely distributed, little if at all planted because of the stinging hairs and stts. and lvs.: fls. small, greenish and inconspicuous, racemose, spicate or clustered in the axils, monocious or dioecious, sometimes hemiphrö-dite; sterile fls. with 4 sepals and 4 stamens; fertile fls. with 2 pairs of sepals and a single erect ovary: lvs. simple, opposite, strongly nerved, dentate or crenate or incised. Several species of nettle are native in N. Amer. and a few are intro. weeds. The plants have very little ornamental value.

URVILLA (bears the name of Capt. Dumont D'Urville, French botanist and naval officer). Sapindaceae.

About a dozen species of climbing shrubs of Trop. Amer. Lvs. alternate, ternate, the lfts. entire or coarsely dentate and more or less pellucid-dotted: fls. whitish, on jointed pedicels, in axillary racemes, the peduncles ending in a pair of tendrils; sepals 5, the 2 outer ones smaller; petals 4; diak of 4 glands; stamens 8: fr. a 3-winged samara. Probably no species is in cult., the U. ferruginea, Lindl., of lists being Serjania cuspidata.

URTICÁRIA (Latin, a little bag or skin, referring to the bladders). Lentibulariaceae. Bladderwort. As known to gardeners, the bladderworts are of two rather distinct groups,—the aquatic mostly native kinds sometimes used in pools and aquaria, and the tropical terrestrial kinds sometimes grown in warm-houses with orchids and other special plants. The whole group is of little importance horticulturally.

As commonly understood, Utricularia is a genus of some 200 aquatic and terrestrial kinds of cosmopolitan distribution. Recently, however, the genus has been split into several genera, and the name Utricularia retained for certain aquatic species; with this taxonomic innovation, however, we are not concerned in this brief account. Under the older and prevailing definition,
Utricularia comprises plants with numerous slender wiry scapes bearing one or many fls.: calyx large, 2-parted or 3-lobed; corolla with a spur which is usually long and curved under the fl.; posterior lip erect, entire, emarginate or 2-fid; anterior lip often large, broad, and showy; spreading or reflexed, entire, crenate or 3-lobed, or the middle lobe various: lvs. of the aquatic species much dissected, sometimes disappearing at flowering-time, very delicate: plant floating or rooting in the mud, the lvs., branches, and sometimes the roots bearing minute bladders; lvs. of terrestrial species linear or spatulate and rosetulate at base of plant. The bladders trap small aquatic animals. These bladders have a valve-like door through which the animals enter when looking for food or when trying to escape from other creatures; they are most numerous and effective in the species which float in stagnant water. They are fewer in the marsh-inhabiting species. The terrestrial kinds often have minute deformed and useless bladders; these kinds are common in the tropics and are characterized by erect foliage of the ordinary type. These often form little tubers by which they may be propagated. The native aquatic species propagate themselves by seeds and also by winter buds. (A winter bud of another aquatic plant is figured under Elodea, p. 1110.) Some of the utricularias are epiphytic in a way. Those who are familiar with bromeliaceous plants know how who are familiar with bromeliaceous plants know how the water gathers in the axils of the lvs. These bromeliads are themselves often epiphytic, perching on high trees in moisture-laden tropical jungles. In the miniature ponds supplied by the If.-axils of Vriesia and other bromeliads live certain utricularias with fully developed and effective bladders. Occasionally they send out a long “feeler” or runner-like shoot which finds another bromeliad and propagates another bladerwort.

The aquatic utricularias are sometimes cultivated in aquaria, but their flowers are not showy, nor are those of any of the hardy kinds. A number of them are native in lakes and ponds in the United States and Canada. The showy species are the terrestrial and epiphytic kinds of the tropics. These, for complexity of floral structure, beauty of color and lasting qualities, vie with certain orchids. In fact, they are usually grown by orchid-lovers in orchid-houses. Perhaps the most desirable of the genus are U. montana, U. Endresii, and U. longifolia, each of which represents a different color. Well-grown baskets of these plants have numerous scapes a foot or so high bearing five to twenty flowers, each 1½ to 2 inches across. In general, such plants are grown in greenhouses. U. Endresii requiring a stove temperature, while some of the others may thrive in an intermediate house. As a class they are grown in baskets, near the light, using a compost of fibrous peat and sand. The plants are kept constantly wet during the growing season and until the flowers are gone. During the winter they are rested, being kept in a cooler place and given just enough water to keep the tubers from shriveling.

INDEX.

americanus, 1.  janthina, 5.  montana, 3.
bifida, 4.  longifolia, 9.  pinguicula, 2.
Endresii, 8.  punctata, 9.  reniformis, 6.
Forgotania, 9.  macrorhiza, 1.  vulgaris, 1.
Humboldtii, 7.  major, 8.

AA. Habit aquatic.

1. vulgaris, Linn. Hardy aquatic: sts. a few inches to 3 ft. long, with crowded 2-3 pinnately divided floating lvs. ½-1 in. long, provided with numerous bladders and yellow fls. ½ in. long or more, borne in few-fld. racemes: scapes 6-8 in. high: corolla closed, with reflexed sides and a conical blunt spur. Eurasia, in ponds and channels. Gn. 28, p. 403.—Sometimes listed among aquatic plants. What is considered by some to be the same species occurs far northward in N. Amer.; represented in the U. S. by var. americana, Gray, with a more slender and rather acute spur. Some authors consider the American plant to be distinct, and it then takes the name U. macrorhiza, LeConte, distinguished from the Eurasian material by longer sts., shape and direction of spur and reduced or rudimentary stolons. Sometimes collected for aquaria.

BB. Foliage ribbon-like.

2. prehensilis, E. Mey. An aquatic plant with fls. shoots twining above the water: lvs. (often disappeared at flowering-time) linear-lanceolate to lingulate, obtuse, sometimes nearly 1 in. long, narrowed into a slender petiole: bladders numerous on the lvs. and rhizoids, with the mouth near the stalk, nearly or quite globose, almost ¼ in. in diam.: fls. yellow, 1-6; upper lip of corolla broadly oblong-spatulate; palate erect, crested; spur straight and acute, descending, ¼ in. or more long. Trop. Afr. G.C. III. 48: 447.—A rapid grower and profuse bloomer in cult. Annual.

AA. Habit terrestrial or epiphytic: foliage entire, erect.

BB. Color of fls. yellow, with an orange palate.

4. bifida, Linn. Terrestrial species from Trop. Asia, with minute bladders and small fls. resembling a diminutive linaria: lvs. densely matted, erect, thread-like, 1-2 in. long: fls. yellow, with an orange palate, ½ in. long, 5-8 in a raceme: pedicels drooping fr.: scape about 6 in. or less high. India, Malay, China, Japan, Philippines. B. M. 6899.
UTRICULARIA

...with the seeds usually numerous and fleshy berries somewhat like those of Artabotrys or stamens, and developing into a cluster of pedicelled cluster of carpels projecting from the center of the mass terminating in a crest: gynecium formed of a parallel pollen-sacks on the back, very much as in Desmos), often connate at the base; stamens rows imbricate, or overlapping in the bud (not edge-to-edge as in Deemoo), often connate at the base; stamens numerous, short, cuneate or nearly truncate, with stellate-pubescent hairs, and with

posed of Old World tropical plants, more or less clothed with stolons and rhizoids. The species thrives under conditions suitable for nepenthes.

UTRICULARIA (Latin, ura, palate, referring to the hanging flowers). Lilitoea. BELLWORTH. "Wild Uvas" in some parts. Graceful woodland hardy perennial herb, useful in the wild border or in heavy shade; not showy, and little planted.

Uvularia (Latin, from ura, gape, on account of the grape-like clusters of the fruit). Arumudacea. A group very closely allied to the American Asimina, but composed of Old World tropical plants, more or less clothed with stellate-pubescent hairs, and with a climbing or scrambling habit.

Flowers either solitary or in few-flowered clusters, either terminal or if-opposed; sepals 3, often combined into a cup-shaped calyx; petals 6, in 2 rows, one or both rows imbricate, or overlapping in the bud (not edge-to-edge as in Deemoo), often connate at the base; stamens numerous, short, cuneate or nearly truncate, with parallel pollen-sacks on the back, very much as in Asimina, but with the connective either truncate or terminating in a crest-like crest; gynostemium formed of a cluster of ovaries projecting from the center of the mass of stamens, and developing into a cluster of pedicelled fleshy berries somewhat like those of Artabotrys or Canarium, but with the seeds usually numerous and arranged in 2 vertical rows, as in Asimina, or sometimes apparently 1-seriate. Few of this genus are in cult. For the principal Philippine species, see E. D. Merrill, in Philippine Journ. Science, Section Botany, 10:223-30 (1915). The following species is the only one occurring about Manila.

**Uvularia** (U. purpurea, Blanco), SUSONG CALABAO. CABALAO'S TEATS. Fig. 3889. A scandent shrub, often 16-20 ft. in length, the younger parts and lower surfaces of the lvs. rather densely and softly pubescent with radiating starlike clusters of short rusty hairs; lvs. oblong-ovate to oblong-lanceolate, 3-6 in. long, apex acuminate, base rounded or cordate, the petioles very short: fls. extra-axillary or If-opposed, solitary or 2 or 3 together in depauperate cymes: frs. a cluster of 18-28 pedicelled oblong velvety berries, red when mature; seeds many, in 2 rows, surrounded by whitish, aromatic, acridulous fleshy pulp.—According to P. J. Wester the fr. of this species together with that of an allied species having an orange-yellow, velvety skin and yellowish, granular, somewhat sweetish flesh is offered for sale in the markets of Manila. See The Philippine Agricultural Review 6:321, pl. 7, figs. a and b (1915) for further information.

W. E. SAFFORD.
UVULARIA

a. Lvs. pubescent beneath.

*grandiflora*, Smith. Sts. 1-1½ ft. high, with 1 or 2 lvs. below the fork: lvs. oblong, oval or ovate, somewhat acuminate: fls. pale yellow, 1-1½ in. long; segms. usually smooth on both sides: stamens exceeding the styles: caps. obtusely 3-angled, truncate. May, June. Rich woods, Que. to Minn. south to Ga., Tenn., and Iowa. B.B. 1:409.

AA. Lvs. not pubescent beneath.

*perfoliata*, Linn. Fig. 3890. Sts. more slender than in *U. grandiflora*, with 1-3 lvs. below the fork: lvs. oval-oblong or ovate: fls. pale yellow, about 1 in. long; segms. glandular papillose within; stamens shorter than the styles: caps. obtusely 3-angled, truncate. May, June. Rich woods, U. S.

*U. sessilifolia*, Linn.—Oakesia sessilifolia.

F. W. BARCLAY.
VACCINUM (ancient Latin name of the blueberry). Ericaceae. Blueberries, Bilberries, Deerberries, and Cranberries. Erect or creeping shrubs, often with green speckled twigs, well known in this country as the source of excellent wild berries; sometimes planted for ornament.

Leaves alternate, evergreen or deciduous, coriaceous or herbaceous; fls. solitary, axillary or terminal or in racemes; sepals 4–5 or obsolete; corolla gamopetalous, urceolate, cylindrical, campanulate, or rotate, 4–5-toothed or -parted, white or pink; stamens 8–10; anthers dehiscing by pores at the tips of long slender terminal tubes, epigynous; carpels 4–5; ovary inferior, 4–5-celled, or 8–10-celled by intrusion of the midrib of each carpel; fr. a many-seeded berry capped by the persistent calyx.—The genus consists of about 130 species of wide geographic distribution, extending from the Arctic Circle to the higher mountains of the tropics. They are most common in North America and the Himalayas. The genus is almost without representation in the southern hemisphere.

The well-known confusion in the popular names applied to Vaccinium is stated by Munson as follows: 'The terms 'bilberry' and 'whortleberry' usually mentioned as 'common names' by American writers are seldom or never heard among the common people in this country; while 'huckleberry' is reserved for species of Gaylussacia, 'blueberry' is usually applied to Vaccinium. 'Huckleberry,' 'bearberry,' and 'cranberries' are often persisting much longer than the bright-hued leaves of a large number of other plants. Of the ornamental species none is more strikingly beautiful late in autumn than the common high-bush blueberry, V. corymbosum. When well grown it is a stout, thick, spreading bush 8 to 10 feet high. The plant is beautiful when in flower; the fruit is attractive and of the best quality, and the bright scarlet and crimson effects in late autumn, rivaling the sumach in brilliancy, are unsurpassed. As an ornamental plant the species deserves a place in every garden. V. pensylvanicum also brightens waste places for a short time, but drops its foliage too early to be worthy of planting as an undershrub. The name is true of V. canadensis, which in many respects is similar. V. stamineum, though early deciduous, is attractive when in bloom and throughout the summer by reason of its graceful habit. It is particularly adapted for sterile sandy or gravelly situations, and it is one of the very few ornamental shrubs specially suited for densely shaded situations. It has the peculiarity of never forming a true flower-bud, the blossom being open from the first. V. arborescens forms an irregular shrub too diffuse and straggling to be of value except when planted in masses at the South. V. arborescens is as beautiful in its autumn coloring as is V. corymbosum and, like that species, retains its foliage late in the season; V. bilobum and V. uliginosum, with their shining box-like foliage, can be used very effectively as edging for the shrubbery border. (W. M. Munson.)

For the most part, Vacciniums are plants of peaty or sandy acid soil, and will not thrive in soils of a richer nature. Many species are very sensitive to the presence of lime, and they require special attention as to soil. See Blueberry.
VACCINIUM

1. arboresum, Marsh. FARBEBERRY. SPARKLEBEERRY. Spreading shrub or small tree, 6-25 ft. high, with glabrous or somewhat pubescent branchlets; lvs. 1-2 in. long, evergreen in the S., somewhat coriaceous, smooth and shining above, paler and sometimes pubescent beneath, obovate to ovate, acute or obtus, entire or obscurely dentilicate; fls. profuse, axillary, and leafy-racemose, pendulous, articulated with the slender pedicel; corolla open-campanulate, 5-lobed, white; stamens included; berry small, globose, black, rather astringent, inedible. Sandy soil along river banks, Fla. and Texas to N. C. and Ill. l.B.C. 19:1885, B.M. 1607 (as V. diffusum). B.B. 2:580.—"It forms an irregular shrub too diffuse and sprawling to be of use except in masses, for which purpose it is useful at the South."

2. stamineum, Linn. DEERBERRY. Squaw HUCKLEBERRY. Fig. 380. A divergently branched shrub, 2-5 ft. high, with pubescent twigs, not white-speckled; lvs. 1-4 in. long, oval to obovate-oblong or elliptical, entire, palle, glaucescent and pubescent beneath; fls. very numerous in large leafy-bracted racemes, showy, pointed with the slender spreading or pendulous pedicles; calyx glabrous; corolla pure white, rarely purple-tinged, open-campanulate, 5-angled, anthers and leafy-racemes, deciduous, of rather firm texture; fls. white or rose-color, in fascicles or very short racemes, developed with or a little before the lvs. from large and separate scaly buds, short-pedicelled: scaly bractlets as well as bracts mostly caduceous or deciduous.

3. melanocarpum, Mohr. SOUTHERN GOOSEBERRY. Similar to the last but more white-pubescent; calyx white-tomentose: berries twice as large, shining black, with a juicy purple pulp, sweetish and slightly tart. Southern states.

Section II. CYANOCoccus. Corolla from cylindraceous to campanulate-oblong or ovoid, 5-toothed; filaments hairy; anthers included, awned; ovary and berry completely or incompletely 10-celled by a spurious partition or projection from the back of each carpel; berry blue or black with a bloom, juicy, sweet, and edible, many-seeded; fls. white or rose-color, in fascicles or very short racemes, developed with or a little before the lvs. from large and separate scaly buds, short-pedicelled: scaly bractlets as well as bracts mostly caduceous or deciduous.

A. Berries thick, evergreen; bracts reddish, firm, tardily deciduous.
B. Septals obtuse; teeth of lvs. glandular; berries black.
C. Berries very pubescent at least beneath.
E. Plant tall.
D. Berries glabrous or nearly so except sometimes the midrib.
F. The lvs. elliptic, acute, green.
nearly cylindrical, ⅓-½ in. long, white or pink; bracts small, deciduous, berry black, almost or quite destitute of bloom. Swamps, S. Va. to Fla. and La. B.M. 3522. B.R. 302 (as V. fuscatum).—The distinction between this species and V. corymbosum is very slight. It is probable that, possibly excepting var. tenellum, this is only a southern form of V. corymbosum and should be reduced to varietal rank.

Var. tenellum, Gray (V. tenellum, Ait.). A low form, mostly less than 2 ft. high, with smaller lvs. and nearly white fls. in short close clusters. S. Va. to Ark., Fla., and Ala.

7. corymbosum, Linn. High-Bush Blueberry. Swamp Blueberry. Fig. 3892. A tall handsome bushy shrub, 4-12 ft. high, with yellowish green warty branchlets; lvs. large, ⅔-3 in. long, ovate-oblong to elliptical, acutish, glabrous, half grown at flowering time; corolla long-cylindraceous, ⅓-⅔ in. long, white, berries blue-black of excellent flavor. Moist woods or bogs, N. E. N. Amer. Em. 2:456. Amer. Agric. 1886:364.—Exceedingly variable, and many natural hybrids occur between this and other species, rendering the taxonomy very difficult. V. corymbosum is one of the most valuable species both for fr. and as an ornamental shrub. It thrives in peaty acid soil.

Var. amänum, Gray (V. amänum, Ait.?). A form with lvs. bristly ciliate or serrulate, bright green on both sides, shining above. „Mainly in the Middle Atlantic states.“ B.R. 400. B.M. 3433 (as V. corymbosum). Probable of hybrid origin.

Var. pallidum, Gray (V. pallidum, Ait. V. albiflorum, Hook. V. Constablæri, Gray). A pale and glaucous or glaucous form with or without some pubescence; plant generally low, 2-4 ft. high; lvs. ciliate-serrulate. Common in mountainous regions southward. B.M. 3428.—Probably a distinct species.

Var. fuscatum, Gray (V. fuscatum, Ait.). A tall form with the nature entire lvs. fuscos-pubescent beneath; fls. virgate, somewhat scapate on the naked flowering trusses. In and about swamps, Ga. and Fla. to La. and Ark.

8. atrocoecum, Heller (V. corymbosum var. atrocoecum, Gray). Downy Swamp Blueberry. A tall branching shrub similar to the last species; lvs. elliptic-oblong, acute, entire, dark green above, densely pubescent beneath, unexpanded at flowering-time; fls. in dense racemes; corolla shorter, greener, and often redder than in the last; berries said to be always black without bloom, smaller than in the last, of good flavor. Moist woods and bogs of E. N. Amer.—Apparently distinct from V. corymbosum, but seeming to hybridize with it.

9. canadense, Kalm. Canada Blueberry. Low erect shrubs, 1-2 ft. high, much branched: the branches very downy: lvs. entire, dark green, ⅔-1½ in. long, oblong-lanceolate or elliptical, acute. Ait. A form with mucr bloom. Low woods and bogs, New England, mountains of Pa., northwest and northwestern. B.M. 3446.—“This species, commonly known as ‘velvet-leaf’ or ‘sour-top’ because of the character of its foliage and the somewhat acid fr., usually grows in rather boggy localities. The fr. is more acid than the other low forms and matures from 1-3 weeks later. It is not so popular in the market as the sweeter kinds, but it is very prolific and its lateness in ripening is in its favor.”

10. pennsylvanicum, Lam. Low Blueberry. Fig. 3893. A dwarf shrub, 6-15 in. high; branchlets glabrous or hairy northward: lvs. membranous, oblong-lanceolate or elliptical, acute, distinctly serrulate with prickly pointed teeth, shining and green on both sides but often hairy on the midrib beneath: fls. on short pedicels; corolla short-cylindraceous, greenish white; berries large, bluish black with a bloom, sweet, the earliest to ripen in the North. E. N. Amer. B.M. 3434. Em. 2:456. Rep. Me. Exp. Sta. 1898:171. Var. angustibladium, Gray. A dwarf form with more decidedly lancesolate lvs. Newfoundland, mountains of New England and northward. Var. nigrum, Wood (V. nigrum, Brit.). Foliage very glaucous: berries black, without bloom. Usually found in colonies in the same situations as the typical form and occasionally the two are found intermingled. Rep. Me. Exp. Sta. 1898:171. The fls. are said to appear earlier than those of V. pennsylvanicum.—„This species is extremely variable in size and shape of fr. and fls., but, with the exception of the varieties noted, the variations do not appear sufficiently constant to warrant making separations. In general the plant is of low, semi-prostrate habit, is extremely prolific, and thrives well on dry sandy hills. It furnishes the bulk of the blueberries found in the eastern markets. When mown down or

burned, the new sweet shoots produce, the following year, a long spike-like race of bloom and fruit, which may be stripped off by the handfuls. Because of its character and early ripening habit, it is known on the blueberry plains as ‘Early Sweet’ or ‘Low Sweet.’ “

11. vaclians, Kalm. Low Blueberry. Erect, glabrous, widely branched, ½-3 ft. high: lvs. 1-2 in. long, ovate or oval, scarcely acute, entire or sparingly serrulate, pale or dull glaucous on both sides: fls. in
Rather dense clusters generally on the leafless summits of twigs; calyx reddish; corolla short-cylindrical, greenish white, often tinged with red; berries large, with much flavor, ripening late with V. canadense. Dry sandy or rocky places, N. E. N. Amer. Em. 1: 454.—"One of the most common species of the northern and central states, particularly west of the Alleghanies. One of the two commonest upland dwarf blueberries."

12. hirsutum, Buckl. Hairy Blueberry. Bear Blueberry. Fig. 3894. Low shrub, 1-2 ft. high. Ats. green, grooved, obscurely 4-angled; branches hirsute with spreading white hairs; lvs. oblong-lanceolate to ovate, acute or cuspidate, ½-1⅔ in. long, entire, deep green above, paler beneath, pubescent or hirsute on both faces, very short-petioled: racemes few-fl.; ovary, calyx, and corolla densely hirsute; sepals acute; corolla large, ovoid, campanulate, pale or reddish; berries purplish black, glanular-hirsute. Shaded mountain slopes, N. C. to Tenn. and Ga. G. F. 2: 205 (adapted in Fig. 3894).—"This species, discovered about 1840, was lost sight of for half a century until rediscovered by Sargent, and transferred to the Arnold Arboretum. It is readily distinguished by the hairy lvs. and fr. The fr. is described as fully as large as that of Gaylussacia baccata, shining black, and of an agreeable flavor. Under cult., it is not so densely hairy as in the wild state. It gives promise of being valuable under cult. as one of the latest of its kind to ripen. At the Arnold Arboretum the period of greatest fruitage is in the middle of Aug., berries remaining into Sept."

Section III. Euvaccinium. Corolla from ovate to globular and more or less urceolate, 4-5-toothed, rose-color or nearly white; filaments glabrous; anthers 2-awned on the back; ovary and berry 4-5-celled, with no false partitions: lvs. deciduous: fls. on drooping pedicels, solitary or 2-4 together, developing with or soon after the lvs.

A. Fls. 2-4 in a fascicle, from separate scaly buds, 4-merous............. 13. uliginosum
AA. Fls. solitary, axillary, usually 5-merous.

b. Branchlets not angled............. 14. cespitosum
BB. Branchlets angled.

c. Shrubs low (1½ ft. or less)........... 15. Myrtillus
c. Shrubs tall (3-6 ft.).

d. Lvs. serrate: berries blackish, without bloom............. 16. membranaceum
e. Lvs. entire or nearly so; corum

13. uliginosum, Linn. Bog Bilberry. A low spreading much-branched shrub, ¾-1½ ft. high; lvs. thickish, obovate or oval, obtuse or retuse, ½-1 in. long, entire, nearly sessile, pale and glaucous on both sides, slightly pubescent beneath: lvs. 2-4 together or sometimes solitary; calyx 4-parted, rarely 5-parted; corolla urn-shaped, 2-5-lobed, pink: berries bluish black with a bloom. Arctic and alpine N. Amer., Eu., and Asin. B.B. 2: 576.—"The plant is useful for the shurbbery border in cold wet acid situations and its fr., though of poor quality, is used for food by the natives of the Northwest."

14. cespitosum, Michx. Dwarf Bilberry. A dwarf tufted shrub, 3-12 in. high, nearly glabrous throughout: branches rounded: lvs. ½-1⅔ in. long, obovate, cuneate-lanceolate or cuneate-spatulate, narrowed at base, obtuse or acute, serrulate, smooth and shining: fls. solitary, on short axillary peduncles, nodding; corolla urceolate, small, rarely 4-5-toothed, pink or red: berries large, blue with bloom, sweet. Gravelly or rocky woods and shores, Maine, Vt., Wis., Col., Calif., and northward; also on alpine summits of New England and N. Y. B. M. 3429.—May be used in rock-gardens.
Section IV. 

VACCINIUM. Corolla from ovate to globular, and more or less urceolate, 4-5-toothed, rose-color or nearly white; filaments hairy; anthers awnless on the outer faces; ovary and berry 4-8-celled, with no false partitions: lvs. coriaceous and persistent; ils, in short racemes or clusters from separate buds, bracteate and 2-bracteolate. 

A. Corolla 5-lobed; stamens 10.  
B. Branchlets pubescent: plant erect.  
D. Branched glabrous: plant procumbent.  
E. Corolla 4-toothed; stamens 8.  
F. Corolla 3-toothed.  
G. Corolla 5-toothed.  
H. Corolla 6-toothed.  
I. Corolla 7-toothed.  
J. Corolla 8-toothed.  
K. Corolla 9-toothed.  
L. Corolla 10-toothed.  
M. Corolla 11-toothed.  
N. Corolla 12-toothed.  
O. Corolla 13-toothed.  
P. Corolla 14-toothed.  
Q. Corolla 15-toothed.  
R. Corolla 16-toothed.  
S. Corolla 17-toothed.  
T. Corolla 18-toothed.  
U. Corolla 19-toothed.  
V. Corolla 20-toothed.  
W. Corolla 21-toothed.  
X. Corolla 22-toothed.  
Y. Corolla 23-toothed.  
Z. Corolla 24-toothed.  

22. erythrocárpus, Michx. (Oxycoccus erhythrocárpus, Pers.). An erect, divergently branching shrub, 1-4 ft. high: lvs. 1\(\frac{1}{2}-3\) in. long, oblong-lanceolate to ovate, acuminate, finely bristly serrulate, thin, green both sides, paler beneath; petals solitary, axillary, shorter than the lvs., recurved, bracteate: corolla flesh-color, \(\frac{1}{2}\) in. long, 4-cleft, the lobes narrow, acute, revolute: berries globose, \(\frac{1}{2}\) in. diam., bright red turning darker, acid, scarcely edible. Higher Alleghanies, Va. to Ga. B.M. 7413.  

23. Oxycoccus, Linn. (Oxycoccus oxyccoccus, MeM.). SMALL CRANBERRY. CRANBERRY of the Old World. Slender creeping plants with short filiform sts., 4-10 in. long: lvs. ovate, acute, \(\frac{1}{2}\) in. long, with strongly revolute margins, coriaceous, evergreen, dark green and glossy above, white-glaucous beneath, glabrous; pedicels 1-4, terminal: filaments one-half length of anthers: berry red, \(\frac{1}{2}\)-\(\frac{3}{4}\) in. diam. Splashing swamps in sub-arctic and alpine regions of Old and New Worlds. — "Though smaller, its fr. is by many considered superior to that of the next."  

24. macrocarpón, Ait. (Oxycoccus macrocarpus, Pers.). LARGER AMERICAN CRANBERRY. Sts. slender, creeping, elongated, 1-4 ft. long, somewhat coarser and stouter than in the last, the fl. branches ascending: lvs. oblong or oval, obtuse or retuse, \(\frac{1}{2}-\frac{3}{4}\) in. long, in texture and coloration similar to the last, margin less revolute: pedicels several, axillary and lateral: fls. larger; filaments shorter than in the last; berry red, larger, \(\frac{1}{2}-1\) in. long. N. N. Amer. B.M. 2586. Emm. 2-456. See Cranberry.  

Section VI (Position of this species doubtful)  

Anthers mucilaginous: branches red.  

25. erythrinum, Hook. An erect, glabrous, evergreen shrub, with bright red twigs: lvs. ovate, obtuse, coriaceous, entire: lvs. in long, 1-sided, terminal racemes; corolla globose-campanulate, small (\(\frac{1}{2}\) in. long), rose-red, rarely whitish; berries black. Sandy moist pine lands, N. C. to Ga. B.M. 1152. — "Useful for the shrubbery border South."  

21. Vitis-idaea, Linn. (Vitis-idaea Vitis-idaea, Brit.). MOUNTAIN CRANBERRY. COWBERRY. PAINTBRIDGE BERRY in the N. FOXBERRY. Fig. 3806. Plants low, 6-10 in. long, creeping, glabrous: lvs. coriaceous, evergreen, obvate or oval, \(\frac{1}{2}-\frac{3}{4}\) in. long, obtuse, dark green and shining above, with blackish bristly points beneath: fls. in short subterminal racemes; corolla bell-shaped, white or rose-colored, 4-cleft: berries dark red, acid. Arctic region, to the coast and mountains of New England, Minn., and Brit. Col. L.B.C. 7:816 (as var. major); 11:1023 (as var. minor). — "The frs., which are rather larger than the others, are in allusion to that of the next,"  

VAGARIA (derivation obscure), Amaranthàceae. Large tunicate bulbous herb, useful for autumn-flowering: lvs. strap-shaped, appearing rather late: fls. in many umbels, short-pedicelled, white; perianth narrowly funnel-shaped, tube slender, lobes narrow, spreading; stamens affixed to the throat, slightly shorter than the perianth: ovary ovoid-globose, 3-celled: caps. membranaceous, somewhat valvately dehiscent. —One species, Syria.  

parviflora, Herb. Bulb globose, about \(\frac{1}{2}\) in. through: fls. white. Offered by European bulb-growers for outdoor planting.  

F. Tracy Hubbard.  

VALERIANA (Latin radix, to be strong, in allusion to medicinal uses), Valerianacea. VALERIAN. Gla­brous or rarely pubescent or villous perennial herbs, subshrubs, or shrubs, which are erect or scendent, most of them hardy and showy garden plants.  

Roots strong-smelling: lvs. especially the radical ones, entire or dentate, or the cauleine or all pinnatifid or once-, twice-, or thrice-pinnatisect: cymes sometimes dense, few-fl. and terminal, or clustered in dense or interrupted spikes, sometimes laxly corymbosely or variously panicled: fls. small, white or rose; calyx-lobes
before anthesis not conspicuous, after flowering divided into 5-15 plumose-ciliate sets; corolla-tube
attenuate at base, limb 5-cleft; stamens 3, rarely by
abortion 1 or 2; fr. a compressed achen with the rear
face 1-nerved, the front face 3-nerved.—About 265
species, mostly in the temperate and colder regions of
the northern hemisphere but a few in the tropics and
in the extra-tropical regions of the southern hemisphere.
The valerians in the American trade are hardy per-
essials of easiest culture. Only V. officinalis is well
known. This is one of the characteristic plants of old
gardens, being prized for the spicy fragrance of its
numerous flowers in spring. It spreads rapidly from
suckers arising from the roots, soon forming large
colonies. The common species are from seeds.

\[ \text{INDEX.} \]

- V. alba, 11.
- V. rubra, 7.
- V. officinalis, 12.

A. Rootstock perpendicular, branching below.

1. edulis, Nutt. Perennial, 2-4 ft. high, glabrous or
nearly so; rootstock perpendicular, fusiform, branching
below; lvs. thickish, not serrate, slightly pubescent;
radical oblanceolate to spatulate, entire or some spa-
ringly laciniate-pinnatifid, tapering into a margined color,
the sterile fls. larger. Moist soil. Eu. petiole; cauline
rarely none, commonly 1-3 pairs, ses-

b. St-lvs. not compound or lobed, but sometimes dentate.

4. montana, Linn. Perennial, glabrous or nearly so,
about 1 ft. high: rhizome slender, many-branched: lvs.
entire or dentate; those of the sterile young shoots and
the lowest ovate-rotundate or ovate, suborbicular, rather
long-petioled; cauleine lvs. triangular-oblong, acute or
acuminate; uppermost linear-lanceolate: corymp termi-
nal, compound or simple: fls. bright rose, dioecious. Eu.

b. St-lvs. (at least the lower ones) pinnate or
pinnately lobed.

c. Fls. dioecious or polygamous.

5. alpstris, Stev. (V. alpina, Adams). Perennial,
glabrous, about 6 in. high: rhizome horizontal, short,
slightly branched: radical and lower lvs. ovate-oblong,
repand-dentate; intermediate lvs. acuminate, subsessile,
equaly 2-3-paired or often undivided; uppermost linear,
small; corymp terminal, clustered and head-like:
fls. pink; ovary glabrous. Caucasus region.

6. dioica, Linn. Marsh Valerian. Perennial,
rather glabrous, about 1-2 ft. high: rhizome slender,
stoloniferous, long-creeping: lower lvs. and those of the
sterile shoots ovate-suborbicular, elliptic or spatulate,
entire, rather long-petioled; cauleine lower lyrato-pi-
uate-parted; upper pinnatisect with linear segms. in
3-5 pairs: corymp terminal: fls. dioecious, pale rose-
metal, the sterile fls. larger. Moist soil. Eu.

cc. Fls. hermaphroditic.

d. Radical lvs. (at least some of them) pinnatisect or
pinnate.

7. officinalis, Linn. COMMON VALERIAN. GARDEN
Heliotrope. Cay’s VALERIAN. St. GEORGE’S HERB.
Fig. 3896. Perennial, glabrous or more or less pubescent
below, 2-5 ft. high: rhizome truncate, sometimes
stoloniferous: sts. erect, simple below, somewhat
branching above, sulcate: lvs. all-pinnatisect; segms.
7-10-paired, usually dentate-serrate, those of the lower
lvs. ovate-oblong, of the upper lvs. lanceolate, acumi-
rate: corymp broadly paniculate, long-branched: fls.
numerous, white, pinkish or lavender, very fragrant.
Eu., N. Asia. G.W. 12, p. 472.-Varible. The medi-
valian valerian is obtained mostly from the roots of this
species. Var. alba, Hort., is a white-fld. form. Var.
rubra, Hort., is a red-fld. form.

8. excelsa, Poir. (V. sarable, Mikan). Perennial,
with long runners ending in rosettes: st. channelled,
glabrous; lvs. pinnate; lfts. 3-5-paired, usually serrate
dentate, rarely entire, terminal lfts. largest:
inf. rather crowded: fls. reddish or white, rather larger
than V. officinalis. Eu. Gn. 67, p. 3.

9. sitchensis, Bong. Perennial, 1 ft. or less high:
rootstock ascending, thick: radical lvs. ovate or oblong,
simple or somewhat lobed; cauline lvs. short-petioled,
3-5-foliate, divisions or lfts. orbicular to oblong-ovate
or in the upper ones ovate-lanceolate: fls. white, very
fragrant, in contracted cymes; corolla funnel-form,
about 3 in. long. Rocky Mts. to Alaska. G.F. 9: 515.—
A very early bloomer.

d0. Radical lvs. entire or merely dentate.

10. arizonicza, Gray. Perennial, glabrous, 6 in. high:
rhizome creeping, rather thick: sts. erect: lvs. succulent,
basal ovate, entire or nearly so, 1 in. long, intermediate
few, long-petioled, 2-4 lobed; cauleine sub-sessile, 3-5-
paired: cyme glomerate-congested: fls. whitish or
pinkish; corolla 3 in. long, turnicular broad, becoming

11. Phu, Linn. Perennial, glabrous or pilose, not so
tall as V. officinalis: rhizome inclined, simple, fusiform:
st. stout, tall, simple or slightly and shortly branched:
radical lvs. ovate-oblong, long-petioled, entire or at base.
VALERIANA

3-cut, segms. decate, terminal larger and ovate-cor- date, lateral 2 (rarely 4 or 5) obliquely elliptic: cyme large, corymbose: fls. pale rose: fr. glabrous, linear- oblong. Pyrenees.

V. alba, Maxiz., is Centranthus ruber var. alba—V. coccaea, Hort., is offered (Centranthus?)—V. cocvina alba, Hort., is offered in the trade.—V. Cornucopia, Linn., is Fella Cornucupia.—V. macrocorpus, Linn., is Centranthus macrocorpus.—V. ribea, Hort., is offered in the trade.—V. rubra, Linn., is Centranthus ruber.

3897. Valeriana olitoria.—Corn salad.

VALLISNERIA (diminutive of Valeriana). Valer­rianacea. Annual dichotomously branched herbs, chiefly spring plants, sometimes planted in wild-garden or rock-garden; one is a salad plant. Leaves, lower, in a radical rosette, entire; cauline, entire, dentate or rarely incise-pinnatifid; cymes sometimes corymbose paniclately fastigate, sometimes densely globose at the ends of the branches: fls. whitish, pale blush, or rose; corolla-tube short or rarely elongate, limb 5-serrated, spreading; stamens 3: fr. 3-celled, 2 of which are empty.—About 35 species, Eu., Aftr., W. Asia, and N. Amer., mostly in the Medit. region. Corn salad is both a salad plant and a pot-herb, chiefly for the proper time the stam. their stalks and rise to the bottom of the water. At the proper time the pseudo-fls. break away from their stalks and rise to the surface of the water. As they float about, some of the pollen is conveyed to the pistillate fls., and in this haphazard way the blossoms are fertilized and seed is produced.

VALLISNERIA (Antonio Vallisneri, 1661-1730, Italian naturalist). Hydrocharitaceae. Two species of aquatic plants, including the well-known eel-grass or tape-grass. This plant is found in fresh water around the world. It is a submerged plant with linear lvs. 1½-6 ft. long, depending on the depth of the water. The flowers terminate in a tuft at the bottom of the water, and the plant spreads by runners sent out from these tufts. Eel-grass is usually found in quiet waters. It has no horticultural rank, except as an aquarium plant. Like many other aquarium plants, it has special interest for students of botany. The pistillate fls. are borne on very long spiral threads and come to the surface, as shown in Fig. 3898. The stamine fls. are borne on very short stalks near the bottom of the water. At the proper time the stamine fls. “break away” from their stalks and rise to the surface of the water. As they float about, some of the pollen is conveyed to the pistillate fls., and in this haphazard way the blossoms are fertilized and seed is produced...
Both kinds of fls. are very small, and they are borne on separate plants. Eel-grass is readily collectable or can be procured from dealers in aquarium supplies or from collectors of native plants. The plant is sometimes called "wild celery," because it is said to impart a celery-like flavor to wild ducks that feed on it.

spiralis, Linn. EEL-GRASS, TAPPE-GRASS. Fig. 3808. Hardy submerged aquatic plant: lvs. thin, linear, 5-nerved, sometimes serrate near the apex: fls. white, Aug.-Sept. N. S. to Fla. and westward; Eurasia; Austral. R.B. 20, p. 194. V. 4:157.

WM. THICKER
WILHELM MILLER

VALLOTA (named for Pierre Vallot, French botanist). Amaryllidaceae. Scarborough Lily. Greenhouse tunicate bulb: scape robust, hollow: fls. large, in many umbels, sessile or shortly pedicelled; perianth funnel-shaped, straight, erect, tube short, throat large, lobes oblong-ovate; stamens affixed at the base of the lobes and shorter than them; ovary 3-celled: caps. oblong-ovate, dehiscent from the base.—One species, S. Afr. It has been proposed that Vallota be considered a subgenus of Cyrtanthus. The latter is a group of about 20 species of plants with fls. of various colors and naked at the throat. Cyrtanthus proper and the subgenus Monella have beautiful pendulous fls. in umbels, but the plants are not so easy to grow as Vallota. It has been suggested that they be crossed with the more robust Vallota in the hope of combining their varied colors and pendulous grace with the strong constitution of the Vallota. Such a process would be similar to the one by which the noble race of Hippeastrum hybrids has been given to the world. Vallota is undeniably related to Cyrtanthus through the subgenus Gastronema, which has erect fls. and differs chiefly in the stamens. Of this subgenus C. sanguiineus is in the trade (p. 945).

The Scarborough lily is generally rated as a greenhouse bulb, but it can be grown by the amateur who has no glass, provided the plant can be kept over winter in a well-lighted cellar. Many persons have had no success with vallota. Such failures are generally due to the plants being kept too dry during winter. Although Baker says the leaves die down at the Cape in autumn, the plant acts like an evergreen in cultivation. Unlike most bulbous plants, the vallotas should never be dug off but kept moderately moist about the roots throughout the year. The vallota is also strongly opposed to interference with its roots. It is possible to preserve a flowering specimen in most luxuriant health for three or four years without repotting, simply by applying liquid manure to the roots occasionally during the summer. The culture of vallota is not difficult when its peculiarities are understood. Several years are needed to work up a good plant to the specimen size. A vallota bulb is about twice as large as a hyacinth. For the first potting use a light soil, with a little sand at the base of the bulb, and place the bulb a distance below the surface equal to its own diameter. Use as small a pot as possible at every stage; shift only when the soil is well filled with roots and be careful to break no roots when shifting to a larger pot. The final potting is an important operation, as the plant is not to be disturbed again for three or four years. Drainage should be ample and perfect. It is the potting soil that the plant in its greatest care in handling the roots. Allow the bulbs to project a little beyond the surface. Some gardeners prefer to repot vallota in June or July when root-action has started, but before the flower-stems have pushed up. V. purpurea likes full sunshine at all times of the year. The plant will stand a few degrees of frost in winter. Beware of over-potting; it is better to have the bulbs crowd one another out of the pot. Amateurs sometimes raise vallotas in the window-garden, one bulb in a 6-inch pot with one or two flower-stalks, but a large specimen is well worth years of care. The Scarborough lily has been cultivated by rich and poor for over three centuries, and its popular name is supposed to have been derived in the same way as the Guernsey lily.—A Dutch bark having been wrecked off the coast of England, some bulbs washed ashore and became established as garden plants. Vallota is considerably grown for the London market, and it is said that some growers succeed in blooming their plants twice the same year, in winter and summer. At the Cape, the species is said to be native to peat-hogs, which fact would account for the special winter treatment which it needs. In California the plant blooms at various times of the year. (Michael Barker.)

purpurea, Herb. SCARBOROUGH LILY. Fig. 3899. Bulb large: lvs. appearing with the fls., strap-shaped, 1½-2 ft. long, drooping down in autumn: peduncle hollow, slightly 2-edged, 2-3 ft. long: fls. scented. G. Z. 18: 348; 3: 479; 9: 333; 10: 77; 37: 89. Gn. 30, p. 245; 42, p. 253; 53, p. 44; p. 71, p. 544. G. Z. 15: 32. J. H. III. 15: 453. R. H. 1870: 31; 1871: 33. G. A. B. grandiflora). A. F. 9: 211. Gn. 2: 361. A. G. 14: 81. —The typical form has the scapes about 1½ ft. high and blood-red fls. 2½ in. across. Var. alba, Hort., is a white-fl. form. G. C. III. 36: 150. Var. major, Hort., is 3 ft. high and has fls. over 3 in. across. B. M. 1430 (as Amaryllis purpurea). Var. minor, Hort., is smaller than the typical in all parts. B. M. 552 (as Amaryllis purpurea var. minor). Var. eximia, Buli., has fls. 4 in. across, with white, feather-like blottches on the base of the perianth-segs. Var. magna, Hort., is probably the best and most robust form: fls. 5 in. across, with a white eye. Colors said to be brighter and more uniform than in any other kind. Gn. 30: 244. G. C. III. 3: 240. —V. purpurea is a S. African representative of the American genus Hippeastrum, popularly known as "amaryllis." It has individual fls. being 3-4 in. or more across. V. purpurea has a large red funnel-shaped 6-lobed fls., blooming in Sept. and later. A pair of well-grown specimens in large pots or tubs make a showy ornament for the porch. Plants have been grown with over 50 fls.trusses, each truss bearing an umbel of 4-9 fls., the individual fls. being 3-4 in. or more across. V. purpurea is a monotypic genus and is distinguished from Hippeastrum by the seeds being winged at the base. The tube of the fl. is longer than in the typical Hippeastrums and at the base of each perianth-seg., is a cushion-shaped callus somewhat different from the minute scales or distinct neck that is often found at the
VALLOTA 3429

VALLOTA VANDA 3429

VANDA (native name in India). Orchidaceae. One of the most attractive groups of East Indian orchids, nearly all species having large handsome flowers. Dwarf and short-stemmed or tall and branched, sometimes climbing to a considerable height; erect species forming compact plants, with sts. and branches well clothed with 2 opposite rows of Ivs.; species like V. teres with the leafy stem often branched, with lvs. flat or cuneate and keeled or terete, sometimes fleshy and deeply channelled; apical pointed, lobed or toothed; fls. in racemes from the axis of the lvs.; sepal and petals similar, spreading, narrowed at the base almost to a claw; labellum firmly united to the column, spurred, lateral lobes small, erect, middle lobe spreading; pollinia on a common stipe.—About 25 species, natives of India and the Malay Isls., with outlying species in China and New Guinea.

Notwithstanding the various conditions surrounding the different species of vanda in their natural habitats, the plants may nearly all be cultivated successfully under the same general treatment. When a general collection is grown, a house of east and west aspect will be found best suited to the wants of vandas. The plants require plenty of light and do not need any shade from November until the middle of February. A house of east and west aspect will require less shading during late fall and early spring than one of southern exposure, and there will be fewer ill effects from direct solar heat at all times. From February until November shading will be necessary, but it should never be too heavy or black-spot is likely to appear. The winter temperature should range from 60° to 65° F. by night and 70° to 75° by day, with a gradual increase of 10° during the summer months. A few degrees more with solar heat and ventilation will do no harm. The atmosphere must be kept moist by damping the benches and paths freely once or twice a day, and ventilation should be given whenever possible, in greater or less degree according to outside conditions. Especially during wet cheerless weather is ventilation important, even if fire heat has to be applied to retain the desired temperature. Vandas may be grown well in either pots or baskets, but the latter are preferable, as they admit air more freely to the roots, whereby they are not so liable to decay from overwatering during severe weather. The best potting or basketing material consists of chopped sphagnum moss freely interspersed with pieces of charcoal. This material should be pressed in rather firmly about the roots, leaving a convex surface when finished. A plentiful supply of water is essential at all seasons with copious syringing over the foliage in bright weather. The compost should never be allowed to remain dry for a long time. V. tricolor and similar species grow very well among foliage plants in the warm-house, where their large aerial roots, which are freely emitted from the sides of the stems, may ramble among the foliage and thereby retain moisture a long time after syringing. A few species, such as V. Amesiaca, V. currela, and V. Kimballiana, with one or two other alpine species, require about the same treatment as other species of the genus. Stock is increased by removing a foot or more of the leading growth with a sharp knife, allowing several roots to remain attached to each growth and being kept in the usual manner. These new pieces should be frequently syringed overhead until they become established or they are likely to shrivel. The old stems will nearly always send out several new growths. The principal insect enemies of vandas are several species of scale, which breed fast in a dry atmosphere. They can be kept in check by syringing with strong tobacco-water and by sponging the plants with a 20 per cent solution of alcohol. (Robt. M. Grey.)

VANDA (after Capt. George Vancouver, commander of the Discovery in the voyage to the north-west coast in 1791-1795). Berberidaceae. Low hardy perennial herbs, grown in the garden border.

Bhzome cespitae: lvs. pinnate, 2-3-ternately compound: scape leafless, racemose or somewhat paniculate at the summit: sepals 6, in 2 rows, obovate, petal-like, reflexed; petals 6, ligulate; stamens 6: fr. a follicle, dehiscet by a dorsal suture.—Three species, natives of the Pacific coast of N. Amer. The lvs. are somewhat like maidenhair or rue, and the fls. are rather small and white or yellow. Vancouverias demand a rich soil in rather shady positions. They are not showy plants, but have foliage of an elegant and refined type.

WILHELM MILLER.

F. TRACY HUBBARD.

3. spathulata, Spreng. St. 2 ft. high: Ivs. 2-4 in. long, waved and var. Schroederiana, Hort! Fis. white, 2 in. across; sepals and petals 27: 1136. n. . : 7. . .: . .. . . : .

20. Sanderiana

2. parvifiora, Lindl. St. 4-6 in. high: Ivs. strap-shaped, 4-8 in. long, unequally obtuse 2-lobed: racemes erect, many-fld.: fis. small, yellow; sepals and petals obovate-spatulate; labellum shorter than the sepals, middle lobe cuneate-obovate, with 2 thickened ridges. Lata

10. tricolor

18. Hookeriana

12. limbata

4. lamellata, Lindl. Lvs. channelled, leathery, obliquely and acutely bifid at the apex: fis. pale yellow, stained with red; sepals and petals obovate, obtuse, undulate, the lower sepal larger and somewhat incurved; middle lobe of the labellum obcuneate, retuse, auriculate, having a pair of red elevated plates and 2 red tubercles just below the apex. Aug.-Nov. Philippines.

Var. Sanderiana, Hort. Tips and margins of sepals tinged with magenta-pink, the petals flushed with same color; lip deep magenta. G.C. III. 45: 415. Var. Wiegels, Hort. Fis. smaller than type; sepals and petals pure white; lip rose-pink.

VANDA

10. tricolor, Lindl. St. branched, tall, erect and leafy: lvs. strap-shaped, 10-12 in. long, channeled; raceme drooping, longer than the lvs.; fls. 2-3 in. across; sepals obovate, attenuated at the base, yellow with numerous brownish crimson spots; petals similar to the sepals in form and color but narrower; labellum about as long as the sepals, lateral lobes small, rounded; middle lobe pandurate, truncate, mucronate, pale lilac. June, July. Java. B.M. 6173.

13. Pariihi, Reichb. f. St. very short: lvs. few, 8-10 in. long, 2-3 in. wide, obvolutely 2-lobed; raceme drooping, 6-8-fld., on a short peduncle: fls. 2 in. across, fleshy, greenish yellow, freely spotted with reddish brown; sepals broadly ovate-oblong; petals orbicular; labellum half as long as the sepals, white striped with orange at the base; lateral lobes rounded, middle lobes labelliform. Summer. Moulmein, India. C.O. 11. Var. Mariottiana, Reichb. f. Sepals pale mauve with numerous darker blotches outside, petals mauve; both sepals and petals are mauve inside; labellum white at base, with yellow spots and mauve lines. C.O. 11a.

12.imbata, Blume. St. about 3 ft. high: lvs. linear, keeled, 6-8 in. long, unequally bilab at the apex; racemes 10-12-fld., 6-8 in. long, on peduncles of equal length; fls. 2 in. across; sepals and petals spatulate, bright cinnamon-
VANDA

6-10 in. long, bearing a drooping raceme 8-10 in. long: fls. 2-3 in. across; petals and dorsal sepal oblong-obovate, spotted, lateral sepals smaller, rhomboid obovate, colored like the dorsal sepal; lateral lobes of the labellum forming a cup-like spot, middle lobe broader, ovate, white tinged with rose; petals a little larger, deep rose; side lobes of the labellum broad, incurved, yellow spotted with crimson, middle lobe exceeding the sepals, fan-shaped, reniform, purple or rose-colored. Spring. Himalaya. B.M., 5845.

17. teres, Lindl. Fig. 3903. St. long, climbing; fls. terete, 6-8 in. long; peduncle 6-12 in. long, bearing a 3-6-fld. raceme: fls. 4 in. across; sepals nearly orbicular, yellow, veined and tessellated with brownish crimson; petals smaller, yellowish, with brownish crimson, purple outside; labellum crim­son, richly colored. July-Sept. Philippines. B.R. 34:332; 17:69; 31:384. F.S. 18:1921.-By some authorities retained in Vandopsis. They have been united with Vanda or with Stauropsis. They are distinguished from allied genera by the labellum, which is firmly united with the column, not spurred, concave at the base, with the terminal lobe compressed laterally. In appearance these plants resemble robust vandas, with which they are usually classed for horticultural purposes. Treatment the same as for Vanda.}

VANDOPSIS (like Vanda). Orchidaceae. Includes two or three species of orchids which have been united with the genera which are characterized by the labellum, which is united with the column, not spurred, concave at the base, with the terminal lobe compressed laterally. In appearance these plants resemble robust vandas, with which they are usually classed for horticultural purposes. Treatment the same as for Vanda.
pyremes 5–3 in number or putamen 5–3-celled.—About 70 species, tropical and subtropical regions of the world, Austral. excepted. Considered a section of Epimedium by Prantl, in Engler & Prantl, Pflanzenreich III. 2.

The voa vanga of Madagascar is a tropical fruit that has been recommended by the American Pomological Society as worthy of cultivation in southern Florida. The fruit is imperfectly described in horticultural writings. It is said to be a delicious berry ½ inch thick, but in Mauritius it becomes 1½ inches thick. It is a globose drupe, shaped something like an apple and contains five large "stones" or bony pyremes. The plant is a shrub 10 to 15 feet high. The species is widely spread in the tropics of the Old World. It was introduced to American horticulture by A. J. Bidwell, of Orlando, Florida. In 1887, the late H. E. Van Doman reported that the shrub grew exceedingly well, sprouting readily from the roots when frozen down. It grows readily from imported seeds.

madagascariensis, J. F. Gmel. Glabrous shrub, 10–15 ft. high; lvs. very large, oblong, obtuse or acute, membranous, short-petioled; fls. in copious, peduncled, axillary dichotomous cymes; corolla funnel-shaped, ½in. long, with 5 spreading deltoid teeth. Madagascar.

infausta, Burch. Shrub, 4–10 ft. high, twenny-tomentose, unarmed, sometimes a small tree: lvs. ovate, oval, or suborbicular, horizontal, usually rounded or obtuse at base, greenish above, rather paler beneath; fls. greenish, 5-merous, ½in. long; calyx lobes ovate or oval; corolla-tube cylindrical, glabrous, lobes ovate; ovary 5-3-celled; fr. globose, smooth, glabrous. Trop. Afr. B.M. 3014 (as V. selagitana).—Fr. said by some to be edible. Intro. into S. Calif. F. TRACY HUBBARD.

VANHOÜTTEA (named for Louis Van Houtte, a Belgian nurseryman). Syn., Houettea. Gesneriaceae. Low branching approach-hairy shrubs, probably adapted only to warmhouse culture: lvs. opposite, fleshy, crowded at the ends of the branches, lower surface more or less canescent-felted: fls. solitary, axillary, long-peduncled, red or speckled; calyx-tube adnate to the ovary, 5-ribbed, lobes elongated, acute; corolla-tube elongated-cylindrical, lobes 5, rounded, spreading disk broad with 5 glands, the 2 posterior usually grown together; ovary almost entirely inferior: caps. with a twisted beak. About 5 species, Brazil. V. calcarata, Lam. (Houettea pardina, Decne. Gesneria pardina, Hook.). St. about 1½ ft. high, erect, rather stout, terete, brown, branched: lvs. rather stoutly petioled, elliptical, acute, rather thick and fleshy, strongly serrated, downy above and more so beneath: peduncle axillary, solitary, 1-fld., shorter than the lvs.; calyx-tube turbinate, adherent with the lower part of the ovary, segms. large, acute, spreading; corolls 1½ in., or more long, ochre-red, yellow within, spotted with deep red, especially the limb and tube inside; ovary semi-inferior, hairy, with 5 yellow glands. Brazil. B.M. 4448. H.U. 6, p. 289. Cult. probably as for achimenes and similar plants. F. TRACY HUBBARD.

VANILLA (Spanish, little sheath or pod). Orchidaceae. VANILLA. Climbing orchids whose branched stems ascend to a height of many feet, ornamental but known mostly as the source of vanilla used for flavoring and which is produced from the seed-pods. Nodes bearing lvs. or scales and aerial roots in alternate arrangement; fls. in axillary racemes or spikes, without an involucre at the top of the ovary; sepals and petals similar, spreading; labellum united with the column, the limb enveloping the upper portion of the latter; column not winged.—About 20 species in the tropics. The genus was monographed in 1887 by R. A. Rolfe in Journ. Linn. Soc., vol. 32.

The most important species is V. planifolia, the vanilla of commerce. It is a native of Mexico, but is now widely cultivated in the West Indies, Java, Bourbon, Mauritius, and other islands of the tropics, its chief requirement being a hot damp climate. The plants are propagated by cuttings varying in length from 2 to about 12 ft, the longer ones being the more satisfactory. These are either planted in the ground or merely tied to a tree so that they are not in direct connection with the earth. They soon send out aerial roots, by which connection with the soil is established. They are usually trained on trees so that the stems are supported by the forked branches, but posts and trellises are also used as supports. In most places where vanilla-culture is practised, pollinating insects are lacking and the flowers must be pollinated by hand. Plants bear their first fruit about three years after setting. They then continue to fruit for thirty or forty years, bearing up to fifty pods annually. The vanilla pods are picked before they are ripe, and dried. The
VARIEGATION. This term is usually applied to a class of variations, especially in leaf-coloration, in which the leaves become striped, banded, spotted, or otherwise variegated by yellow, white, red, or various other colors in connection with the normal green of other portions of the leaves. In the case of yellow and white variegation, the term albiflora is sometimes used, especially when the plants are largely marked with white or yellow, as in Abutilon sellowianum, Pelargonium zonale, and variegated forms of Eunymus japonica, Hydrangea hortensis, Hedera helix, Polyscia hirsuta var. Victoria, and others.

Among the dracaenas, caladiums, and codieums, besides the white variegation, there are developed beautiful reds, pinks, yellows, and so on. As a rule, the term variegation is not used in cases of color variation in which only the surface of the leaf is involved, as in many of the begonias, sansevierias (S. thyrsiflora and S. zeylanica), Allocaasia cuprea, Cissus discolor, and others. In many such plants the markings are due in part to hairs, scales, or air in the cuticle or epidermal cells, as in sansevierias and begonias.

In some begonias, many varieties of calathea (as C. ornata var. alboflora), the epidermal cells develop decided color variation, though the plants do not usually involve the mesophyll or inner cells of the leaf. In some genera, however, especially calathea, all gradations are found between purely epidermal variegation and changes involving the deeper layers of the leaf. In Codiaeum variegatum, C. Veitchii, and C. Makoyana, the same is true of many other genera. Different kinds of variegation are shown in Figs. 3906, 3907.

True variegations may be distinguished from ordinary colorations, chlorosis, and the like, by the fact that the colored areas are usually quite sharply defined. They do not gradually blend into each other, but have definite boundaries. Cells in the variegated areas are found, as a rule, to contain the same chlorophyll bodies (chromatophores) as the ordinary green cells of the plant. However, in the variegated parts, the green color is not developed, and the chromatophores are often smaller or are somewhat swollen and vacuolated. In other cases, as in Codiaeums, modified chlorophyll is developed in the variegated parts. In practically all cases, however, when the chromatophores are not destroyed, they retain the power to convert sugar into starch and they thus store up starch in their tissues from the sugar manufactured by the healthy cells of the leaf.

White or albino variegation is of course due to a lack of any coloring in the chromatophores, and sometimes to the entire absence of these bodies. The cells seem to have lost completely the power of making chlorophyll. These albicant variegations are to be looked upon as the more extreme forms of variegation, and usually arise through a feeble or atrophied condition of the plant. Seedlings raised from parents both of which are variegated in this way are usually very weak. High feeding and favorable conditions of growth, while they will not cause a variegated plant to return to its normal condition, will often stimulate the development of a normal green shoot that takes most of the nourishment and thus causes the variegated and disappearing parts. In practically all cases, as in codieums, modified chlorophyll is developed. Large yellowish oil-like drops occur in the substance of the chromatophores, and the various changes that these undergo under the action of light and the acids and oxidizing ferments of the leaf, produce the remarkable and beautiful colors of this group of plants. The coloration here, as in dracaenas and caladiums, is intensified by strong light and nourishing food. The more of the modified chlorophyll there is produced and the more rapid the changes in the modified chlorophyll brought about through the action of light and the acids and oxidizing ferments of the leaf, the more highly developed will be the colors, though here again high feeding is likely to cause the plant to revert to its normal condition.

Variegated plants or parts of plants are usually of slower growth and smaller than green plants of the same variety or the green parts of the same plant.

Variegation occurs either by bud-variation or by variations in seedlings. In the former, a variegated branch is likely to appear on an otherwise perfectly normal plant. Such variegations are easily reproduced by budding, grafting, or cuttings, but generally do not develop as seeds produced on such branches. On the other hand, when variegation develops in seedlings, the seeds of such plants usually give a number of variegated individuals, even the cotyledons being sometimes affected. In some cases the proportion of variegated plants from seeds is very large and can be increased by selection. As a rule, the form of
spotting or marking is not constant in seedlings, often being very different from the parent. In certain groups of plants which have for many years been selected on account of the horticultural value of these markings, the variegated condition has become almost a fixed feature of the plant, as in dracaenas, caladiums, and codieums. While the plants of these genera are not usually propagated from seeds, still when they are so propagated, a large number of seedlings show more or less variegation.

Darwin and many of the earlier investigators believed that these variations were started in the plant by unfavorable nutritive conditions, and much has been written on the subject as to whether or not variegation should be considered as diseased conditions.

The question as to whether a variegated condition could be transmitted to normal plants by budding and grafting has also been much disputed, but the weight of evidence indicates that in many cases such transmission certainly takes place. This has been thought to indicate the presence of some micro-organism, living either parasitically or symbiotically in the plant, and causing the changes known as variegation.

Investigations conducted by the writer on the so-called mosaic disease of tobacco, which is a form of variegation, and also on many other forms of ordinary variegation, show quite conclusively that the disease is not caused by micro-organisms, but is due to a deranged condition of the nutrition of the cells. Without going into the details of the matter, it may be said that the condition is characterized physiologically by a marked increase in the oxidation processes in the cells, caused by the presence of an abnormal amount, or an abnormal activity, of oxidizing ferment in the protoplasm.

These changes must, in most cases, therefore, be considered as pathological in their nature, as the vitality and vigor of the plants are reduced as a result. It is further evident that the initial causes of variegation may be quite diverse, some of the most usual being seed of low vitality; unsuitable nourishment, especially a lack of elaborated nitrogen; rapid growth in very moist soil; severe injury to the roots during a period of rapid growth of the upper parts of the plant; severe cutting back, and the like.

Though started at first through the influence of environment, variegation, when of value horticulturally, has in many cases been increased and fixed by selection till it has become almost a specific character in some groups of plants, and is considered in the botanical description of them.

A word might be said in this connection regarding autumn coloration. The production of color in autumn foliage is, as is well known, due in part to the gradual destruction of the chlorophyl when the leaves have reached maturity and approach the period of death, and in part to the action of acids on anthocyanin. Many of the destructive changes which take place in the chlorophyl are oxidation processes, the same as occur in the cells of highly colored variegated plants, and physiologically they are not very different from the changes occurring in calatheas, caladiums, codieums, and the like. The approach of maturity in the leaf, and the coming on of cool weather in autumn, stimulates the production of oxidizing ferments, and the action of these and the acids of the cell-sap on the chromogen, or color contents of the leaves, especially the chlorophyl and anthocyanin, causes many of the brilliant colors of autumn foliage (p. 431).

ALBERT P. WOODS.

VARNISH TREE: Calceolaria paniculata, Astrolabias alteissima, Rhus verniciflua, and other plants.

VEGETABLE-GARDENING. In horticultural usage a vegetable is an edible herbaceous plant or part thereof that is commonly used for culinary purposes. The product may or may not be directly associated, in its development, with the flower: the root, stem, leaf, flowerbud, partially developed seed-receptacle, mature seed-receptacle, or seeds (either immature or mature), may constitute the edible part. Some vegetables are edible only after being cooked, others (such as melons), are eaten either cooked or raw, while others, as melons, are used only in the fresh state, and are really dessert articles. In some countries, melons and tomatoes are regarded as fruits, though American usage classifies them as vegetables. Although it is difficult to make a general definition that will include all vegetables and exclude none, the use of the term "vegetable" is so well understood that there is little difficulty in making proper application of it in common speech.

All the art and science that has to do with the growing of the plants commonly called vegetables is popularly known as vegetable-gardening. The Latin term, olericulture, is sometimes used in formal writings as a synonym of vegetable-gardening, but has never become popular. Vegetable-gardening is usually considered as a branch of horticulture,
coordinated with pomology (fruit-growing) and floriculture. However, certain vegetables, such as potatoes, when grown in large areas in rotation with general farm crops, are sometimes looked on as agricultural rather than horticultural subjects. Some vegetable crops may be classified as horticultural or agricultural depending on the uses for which they are to be employed. For example, beans that are grown for the green pods are horticultural subjects, but if the same varieties were to be grown for the mature seed for sowing in the general market, they may be known as agricultural products. In like manner turnips may be horticultural subjects when grown in small areas for home or table use, but agricultural subjects when grown for fodder.

Vegetable-gardening may be divided into two great categories, depending on the disposition that is to be made of the products; namely, commercial gardening (see page 1967, Vol. IV, the article Market-Gardening), of which the purpose is to make money from the industry; and home- or amateur-gardening, in which the purpose is to raise a supply for family use. Commercial vegetable-gardening may be divided further into four fairly well-defined types: market-gardening proper, truck-gardening or truck-farming, forcing (see Vol. III, page 1254), and the growing of vegetables for canning or pickling purposes.

Market-gardening proper involves intensive methods of culture, and is most highly developed near large cities. Truck-gardening involves the growing of one or a few special vegetable crops, often as an adjunct to a system of general farming. These are usually grown in relatively large areas, and at considerable distance from market. Questions of climate, soil, and shipping facilities largely determine the location of truck-gardening areas. The South produces early vegetables for northern markets; the North produces cool-climate crops for winter storage, such as onions, cabbage, turnips, sweet corn, tomatoes, and peas for canning purposes, and cucumbers for pickling, are grown where the soil and climate are especially adapted to their culture.

Particular regions have become famous for the production of certain vegetable crops. Some examples are: Eastern Long Island for late cauliflower; Kalamaoozoo, Michigan, for celery; Rocky Ford, Colorado, and the Imperial Valley, California, for muskmelons; certain areas in Georgia for watermelons; southern Texas for the Bell pepper type of onion; Norfolk, Virginia, for spinach, kale, and early potatoes; Ontario for turnips and other root-crops. Long-distance transportation has revolutionized vegetable-gardening in this country (see Packing, Transportation), and crops which were formerly grown only near market and had a limited season are now shipped across the continent, and may be procured in the same market, from some source, twelve months in the year. Head lettuce is an example.

The practices.

While in commercial vegetable-gardening the location is determined to considerable extent by soil and climate, in the home-garden the climate and the soil are largely beyond the control of the gardener, since these matters are determined by the location of the homestead. The general effort in the home-garden is to secure products of high quality and to have a more or less continuous supply throughout the season. In market-gardening, emphasis is placed on a few varieties, whereas in home-gardening it is placed on a great variety of crops.

The old-time home vegetable-garden or "kitchen-garden" was generally unsuited to the easy handling of the soil and to the efficient growing of the plants. Ordinarily it was a small confined area in which horse-tools could not be used (Vol. III, page 1738). The rows were short and close together, so that finger-work was necessary. The custom arose of growing crops in small raised beds, probably because such beds are earlier in the spring than those that are level with the ground. With the evolution of modern tillage tools, however, it is now advised that even in the home-garden finger-work be dispensed with as much as possible. The earliest crops may be grown in raised beds to advantage, but in general it is better to secure earliness by means of glass covers or by ameliorating the entire soil by subsoil drainage and the incorporation of humus and by judiciously in the fall.

Vegetables are usually large users of manure. Near the large cities the manure is bought in carload lots or hauled with four-horse teams, and it is used every year or even two or three times a year. The reason for this frequent and heavy use of manure is the necessity of improving the physical texture of the land so that it will be loose, open, and mellow, "be early" or "quick," and hold an abundant supply of moisture. In intensive vegetable-gardening there is no "resting" of the land and no green crops to be plowed under. The vegetable matter, therefore, has to be almost entirely by barn-manures. In the larger and less intensive vegetable-growing farther removed from large cities, general agricultural practices can be employed to better advantage, such as rotation and green-manuring.

In intensive vegetable-gardening it is important to start many of the crops under glass to transplant the young plants to the open as soon as settled weather comes. See Transplanting. This is particularly true of tomatoes, very early lettuce, sweet potatoes, egg-plants, peppers, and the early crops of celery, cabbage, and cauliflowers. In the northern states muskmelons and sometimes watermelons and cucumbers are started under glass, being grown in pots, venereal "dirt bands," or upon inverted suds, whereby they are transferred to the open without disturbing the roots. Formerly the plants were started under hotbed or coldframes, structures, but of late years there has been a great increase in the extent of glass-houses or forcing-houses. These are primarily for the purpose of growing certain crops to maturity outside of their normal season in the given locality, but are often used a part of the season for starting plants intended for transplanting. In these structures conditions can be controlled better than in hotbeds, and they are especially valuable for the starting of very early plants in cold weather. However, hotbeds and coldframes are still exceedingly important adjuncts to the vegetable-garden. They are almost indispensable for the reception of early plants that have been started in a greenhouse and require "hardening-off" before transplanting into the open ground. They can be moved when the person shifts to other land, and the space that they occupy can be utilized for outdoor crops later in the season. They are extensively used for starting early plants. Much vegetable-gardening in large cities is producer, on rented lands, therefore it may not be profitable to invest in such permanent structures as forcing-houses. The first cost of hotbeds and coldframes is less than that of forcing-houses, and this is often a very important item. For management of glass structures, see Greenhouses, Coldframes, and Greenhouses.

The seed and variety problem is most complex. A mistake in the selection of a strain or kind may mean inability to meet a market demand either as regards characteristics or season. A round cabbage crowds out a pointed form. As soon as they mature, better varieties crowd out the Earliana tomato. Therefore the gardener must know varieties. Many seedsmen are making sincere efforts to provide good seed, and each
CXV. A market-garden of the modern type near a city; overhead irrigation.
year sees progress. Much remains to be accomplished in study and classification of varieties and types, and in the improvements of methods of seed-breeding and production. These problems are especially difficult because the crops are chiefly annuals, and changes take place with great rapidity. Experiment stations are now taking up this work on a sound scientific basis, a thing that could hardly be said of most early taxonomic studies. They are enjoying the cooperation of seed houses.

There are great numbers of insect and fungous pests that attack the vegetable-garden crops. See article on Diseases and Insects. The spray-pump has now come to be a necessary adjunct to any efficient vegetable-garden. However, there are many difficulties beyond the reach of the spray, particularly those that persist year by year in the soil or which attack the roots rather than the tops. For such difficulties, the best treatment is to give rotation in the cultivation and to avoid carrying diseased vines back on the land the next year in the manure. Even the club-root of cabbage can be starved out in a few years if cabbages or related plants are not grown on the area.

In its best development vegetable-gardening is essentially an intensive cultivation of the land. Often it is conducted on property that is too high-priced for ordinary farming. Land that demands rent on a valuation of $500 each, and 4,220,045 farms less than 500 each. Denning in the United States are those of the Thirteenth Census, 1910. According to the report of this census, based on the crop of 1909, the acreage devoted to vegetable production was 7,073,779 acres, including 3,698,856 acres of potatoes. The total value of all vegetables reported for that year was $418,110,154. Of the total number of farms in the United States, 4,969,540, or 78.1 per cent reported having farm-gardens; 4,261,776 gave the acreage devoted to vegetables and the value of the product, 41,731 farms reporting, vegetables to a value of over $500 each, and 4,220,045 farms less than $500 each. "Farms of the former group usually produce vegetables chiefly for sale, while on a large proportion of the other farms vegetables are raised only for home consumption." In 1909, the value of the vegetable crop (including potatoes) in the following states amounted to over 10 per cent of the total value of all crops in the respective states: Maine, New Hampshire, Massachusetts, Rhode Island, Connecticut, New York, New Jersey, Pennsylvania, Michigan, Delaware, Maryland, Virginia, West Virginia, Florida, Colorado, Nevada.

According to the figures, the production of vegetables between 1899 and 1909 increased from $237,000,000 to about $418,000,000. This includes the potato, which is grown partly as a farm crop and partly as a vegetable-garden crop. With this most important commodity omitted, the corresponding figures for the miscellaneous vegetables are $139,000,000 and $251,000,000. The increase in the production of all other horticultural products, including fruit, flowers, nursery products and nuts, is from $152,000,000 to $273,000,000. A map showing centers of vegetable production in the United States would show changes too less marked. New districts have been established almost without number in all sections of the country. The business is much more evenly distributed throughout the United States than formerly, and the states that have been regarded as great trucking states are no longer holding their preeminence without question. Thus, Illinois and Indiana have become great vegetable states, with the market-gardening for Chicago, trucking in southern Illinois for both Chicago and St. Louis, muckland trucking in the swamplands (see Muckland-Gardening, Vol. IV), and production of crops for the canny. Similar statements might be made of other states. Ten years ago, truck-farming was thought of principally as production of vegetables in the South for shipment North. The advance in the importance of vegetables in the dietary, together with the rapid growth of the more southerly cities, has brought about a marked development of the crop in the southern states and eastern parts for shipment southward, particularly the cool-season crops for consumption when the gardens of the warmer climates are practically unemployed on account of the heat. The production of cabbage and potatoes in the North for shipment southward has long been a great industry, but of recent years important centers in the growing of cucumbers, peas, beans, and of the muckland crops, celery, lettuce, and onions, have been developed. Improved transportation facilities have made California an important source of supply for eastern markets.

The canning industry as connected with vegetable-gardening has been an important factor in making possible a continuous supply of vegetables throughout the year, and this industry has recently made much progress. Three phases of this industry utilize vegetable-garden crops—factory, farm, and home canning. Factory canning, based on very extensively large acreage of crops on the truck-gardening or general farming scale. Corn, tomatoes, peas, and string beans are extensively handled by canning factories. Farm canning promises to be a means whereby the market-gardener or truck-farmer may turn his crops into greater profit when markets are glutted. Home canning is a means of preserving a supply of perishable vegetable products from one's kitchen-garden for home use.

The introduction of the ramification system of vegetables through all the months has made possible the construction of greenhouse ranges, many of which are now measured in acres. The crops are lettuce, cucumbers, tomatoes, and radishes in the order named. While the business is not so satisfactory in the autumn months, because of poor growth conditions and on account of light demand, the returns after the first of the year are sufficient to render the business profitable and to justify increases in the areas under glass. A market-garden has kept pace with the growth of the cities, although some of the famous centers are declining on account of the great increase in real-estate values. The auto truck is an important factor in making it possible for the gardener to take advantage of the lower interest charges incident to the use of more distant lands.

In the practice of vegetable production, the most conspicuous development has been the introduction of overhead irrigation. Hundreds of acres are now watered in this way. The value of this practice is evident when it is considered that moisture is more often than otherwise the factor which prevents the gardener from rea-
ing returns from improvements which are far more costly than in other lines of agriculture.

The present principle of cooperation in vegetable producing is becoming a larger factor in the selling of produce on distant markets, and garden districts not yet ready for cooperative selling are finding material advantage in unionization. In matters of the gathering of information as to their methods, in the purchase of supplies, the standardization of packages, the improvement of local market conditions, and of transportation facilities, in overseeing legislation and securing assistance through the national agencies in the solution of local problems. The Vegetable Growers' Association of America was organized in 1908 and has brought into contact with one another a large group of men from all sections of the country. The New York State Vegetable Growers' Association, formed in 1911, has been the pioneer in state organization. All of these societies, national, state, and local, are finding new fields of usefulness and are each year serving directly an increased proportion of the men in the business, while all find advantage through their promotion of the general welfare.

Education; literature.

For many years a course in vegetable-gardening has been included in the curricula of most of the agricultural colleges of the United States and Canada, and more or less attention has been given to research in vegetable-gardening problems on the part of agricultural experiment stations. However, until within the last few years, both the teaching and research in reference to this subject were in most institutions conducted as incidental matters by some member of the staff whose principal energies were demanded by other horticultural interests. At the present time much of the attention formerly is being given the subject of vegetable-gardening in educational institutions, and many of the agricultural colleges and stations now have one or more men devoting their entire time to vegetable interests. In some of the institutions several courses are offered in vegetable work, including an introductory course, an advanced course in market-gardening, and courses in vegetable-forcing, systematic vegetable crops, and under research. Professional graduate work in problems bearing on vegetable-gardening.

Vegetable-gardening is also found to be especially adapted for use as a basis for giving instruction in the fundamental principles of crop production in schools, especially in those having only a limited area of land available for "laboratory" purposes. The simple equipment involved, the possibility of using odd bits of ground, the relatively short time in which results can be expected, and the high value of the product to be derived from a small area, together with its easy adaptation to educational purposes, all render this phase of agriculture especially serviceable in such activities. The work is conducted on special plots laid out for that purpose, and on the home farms and back yards.

There is a large literature devoted to vegetable-gardening, although much of it applies chiefly to amateur or home growing. Leading current books on the general subject of vegetable-gardening are those by Greiner, Green, Landreth, Bailey, Warburton, Lloyd, and Corbett. For California one should consult Wickers' "California Vegetables in Garden and Field," and for the Atlantic South, Rolfs' "Vegetable-Growing in the South for Northern Markets," and Somer's "Farming at the South," and Rolfs' "Subtropical Vegetable-Gardening." There are many books devoted to special topics, and there are many others which in their time were of great practical value, but which are now chiefly known as recording the history of the epoch in which they were written. Only one or two works have been devoted to descriptions of varieties of vegetables, as the works of Downing, Thomas, and others have to varieties of other crops. The work is Fearing's "Field and Garden Vegetables of America," Boston, 1863, and the abridgment of it in 1866, called "Garden Vegetables and How to Cultivate Them." A list of the American vegetable-gardening literature to that date may be found in Bailey's "Principles of Vegetable-Gardening," 1901. See also Horticulture, Literature of, Vol. III. Persons who desire a cyclopedic account of vegetables should consult Vilimorin's "Les Plantes Potagères," an English translation of the first edition of which is published in London as "The Vegetable Garden." Odd and little-known vegetables are treated in Paillieux & Bois, "Le Potager d'un Curieux," Paris, 3d ed. 1899.

JOHN W. LLOYD.

PAUL WORK.

Vegetable-growing in California.

It is an interesting fact that although California's horticultural prominence now rests on fruit products, the first attraction to the new state, after the gold discovery, was the wonderful growth of garden vegetables. The reports of immense size, of acreage products, and of prices secured, were so much in advance of ordinary standards, but the statements were so fully authenticated that many were drawn to California by them. These horticultural pioneers, however, soon found that immigrants from Asia and the Mediterranean region, by their cheap labor and by doing their own work, could cut under American growers who had to employ high-priced labor, and so the latter retired from the field, leaving the opportunity to the frugal and thrifty foreigner. Thus vegetable-growing from an American point of view, came to be conducted on a basis of new, and largely retains such disadvantage at present. The result is that the American largely avoids market-gardening, while Asiatics and South Europeans are thriving on it. There has been a reflection of the same disfavor in the farm growing of vegetables for home use, and our farming population, including the fruit-growers who should know and do better, is largely dependent on alien vegetable peddlers or products of canneries instead of fresh home-grown esculents, which would be cheaper and inexpressibly better than canned or transported supplies.

Fortunately there arose about twenty-five years ago a large industry in growing vegetables for overland shipment and for canning, and for which clothed in some of the pride involved in this trade with a new dignity and importance attractive to American growers. Cabbage, cauliflower, and celery for eastern shipment, asparagus for canning and for shipment, tomatoes for canning, and the like, have all become large special crops, while some other plants, like lima beans, which are chiefly grown in gardens elsewhere, have become field crops in California covering very large acreage. Such enterprises have enlisted American citizens and changed the popular conception of the dignity and opportunity of vegetable-growing. A measure of this influence, as well as of the extent of the product, may be had in the average annual shipments of green vegetables beyond state lines for several years ending with 1914:

The canned-vegetable output of 1914 was 2,373,182 cases (each containing twenty-four 2½-pound tins).
VEGETABLE-GARDENING

VELOZIA

divided as follows: asparagus, 800,380; string beans, 81,552; beets, 1,905; tomatoes, 1,193,705; other vegetables, 119,525.

In addition to the foregoing there is the dry-bean product, which reached a total of 3,670,000 bales of 80 pounds each in 1915, and of sugar beets which was 203,260 bales in 1914.

California conditions affecting vegetable-growing are wide and various. Nowhere else perhaps is it more essential that certain things should be done just at the right time and in the right way. If these requirements are fairly met the product is large and fine; if they are neglected the failure is sharp and complete. This fact has given rise to the impression that California is a hard place to grow vegetables, which is not true unless one lacks local knowledge or the nerve to apply it. One of the chief causes of failure is in following seasons and methods which have yielded success under conditions prevailing in the states east of the Sierra Nevada Mountains. If one begins gardening in the springtime the plants do not secure deep rooting, which is necessary to carry them to success in the dry season, and the garden is likely to be a disappointment. If, on the other hand, all the harder vegetables are sown in succession from September until February or March, there will be continuous produce throughout the winter and into the early summer. The chief shipments of vegetables from California are made during the late fall and winter and are taken right from the ground to the cars without protection or storage. Tender vegetables, like corn, beans, tomatoes, and the like, however, can be grown in the winter only in a few frostless places. They must either be pushed to a finish in the fall or sown early in the spring and carried into the dry summer as far as necessary either by natural moist land or by irrigation. There are a few localities, however, where tomatoes fruit early in the spring from fall plantings, and peppers will live through the winter and bear a second season’s crop on the old plants.

The possession of an irrigation supply is the secret of full satisfaction in California vegetable-growing, but a small amount of water, if skillfully applied, will work wonders. Irrigation will enable one to have something crisp and delicious in the garden every day in the year in the California valleys. It is true, however, that much can be done without irrigation by beginning at the close of the rainy season in September, growing the harder vegetables while moisture is ample even on the drier lands during the late fall and winter, and keeping the lower leaves and cultivated to prevent evaporation until the tender vegetables can be trusted in the open air, and continuing cultivation assiduously afterward so that moisture can be conserved in the soil as long as possible for them. That this is thoroughly practicable is seen in the fact that the large luna-bean product is grown almost entirely without irrigation from plantings made as late as May and the whole growth of the plant is achieved without a drop of water except that stored in the soil. The same is true of the corn crop; perfect corn can be grown without a drop of rain or irrigation from planting to husking. In such cases, however, the winter rains are retained in the soil by cultivation. If winter growth is made by rainfall, summer growth can be had on the same land by irrigation. It is true that irrigation demands more labor in securing all-the-year growth, which cannot be had by rainfall. With good soil and abundant irrigation it is possible to secure four garden crops in rotation within the year—the hardy plants in the fall and winter months; the tender plants in the spring and summer. Hence the adjustment of all these means to desired ends requires good perception and prompt action, and explains why those who have been accustomed to plant at a fixed date and do little but cut weeds afterward may find it hard to secure the best results in California. And yet the Californian grower has great advantages in his deep rich soil, in freedom from many diseases (which thrive in a humid atmosphere) and in an exceedingly long growing season.

Local adaptations for different vegetables are sometimes quite sharply drawn and selection of lands for large specialty crops must be made with reference to them. The result is that the earliest vegetables come from practically frostless places in the Colorado River region of southeast California; almost all the lima beans are grown on a coast plain from Santa Barbara southward; the celery for eastern shipment is nearly all grown on the peat lands of Orange and San Joaquin counties; the cabbage comes largely from San Mateo County; asparagus and tomatoes from Alameda County and river islands of Sacramento and San Joaquin counties, and so on. Smaller areas of these products and others not mentioned are more widely scattered, but everywhere the local soil, exposure, and climate are chief considerations.

There is prospect of great increase in all the vegetable products of California. Fresh and dried vegetables enter largely into the foreign trade with distant Pacific ports. Interstate trade is constantly increasing and canned vegetables are contracted in advance to European distributors as well as to dealers in all the Americas.

E. J. WICKSON.

VEITCHIA (James Veitch, of Chelsea, famous English nurseryman). Palmaeae. About 4 species of pinate palms native to the Fiji IsIs. and New Hebrides. The genus belongs to that section of the Arecaceae tribe characterized by a parietal ovule which is more or less pendulous and ffs. spirally disposed in the branches of the spadix, and is distinguished from Hedyscepe and allied genera by the following characters: sepals of the male fIs. chartaceous, connate at base; female fIs. much larger than the males. It is doubtful whether any species is now in the trade. V. Jodornis, H. Wendl., was cult. early in 1880-90. Lf.-segs. with a wide and rather shallow notch at the apex or obliquely truncate; sheath, petiole and rachis a dark blood-color and covered when young with a gray tomentum interspersed with lanceolate, thin, dark red scales: fr. 2½ x 1¼ in., oval-liguloid, orange, with a red base. G.C. II. 20:205. R.H. 1883, p. 344. Has been cult. in S. Calif., but is tender there. It has been conjectured that Kentia Van Houttei advertised in 1885 by American dealers may be a species of Veitchia. The genus is imperfectly known and of minor importance horticulturally.

VELOZIA (Vellos, a Portuguese naturalist). Vellosiaceae; or Amaryllidaceae. Usually shrubs, sometimes arborescent, adapted to the warmhouse. Sts. fibrous-woody, usually dichotomously branched: lvs. linear, rigid, tufted at the ends of the branches: peduncles 1-ft.: ffs. usually white; perianth funnel-shaped; segms. subequal, ovate-lanceolate; stamens 6, sometimes many; ovary clavate, 3-celled; ovules many, supersoned: caps. coriaceous, dehiscing at the apex.—About 65 species, Trop. and S. Afr., Madagascar and Brazil. Vellozia is closely related to Barbadecia distinguished by having more than 6 stamens, whereas Barbadeccia has only 6. V. trichophylla, Hemsl. (V. equisetoides, W. Wats., not Baker. V. equisetoides var. trichophylla, Baker). Shrub having a thick caudex, 1 ft. or more diam. and short primary branches; lvs. numerous, grass-like, scarcely stiff, 3-9 in. long in cult. specimens (often 1-2 ft. long and more rigid in wild specimens), about ½ in. wide: peduncles usually in 3’s, 1-ft.: fls. reddish lilac, very fragrant, perianth-segments acute, 1½ in. long. E. Trop. Afr. B.M. 7982. G.C. III. 34:426. Very little known in cult.
VELTHEIUMIA (named for the Count of Veltheim, 1741-1801). *Litideae*. Greenhouse and half-hardy tufted bulbous perennials; spring and summer. Leaves radical, several, oblong or strap-shaped, rather thick, herbaceous, lower longer than the upper, sheathing the base of the simple leafless scape: fls. showy, pendulous, densely grouped in a terminal raceme or spike; perianth tubular, cylindrical, persistent, lobes 6, very short, tooth-like; stamens 6; ovary sessile or subsessile, oblong, 3-celled; caps. membranaceous-scarious, the angles strongly dilated and wing-like, locally ciliolate 3-valved.—Three species, S. Afr. They are easy of cult. and are but little known in Amer.

A. *Les. green,* 2-3 in. broad.

*VIRIDIFOLIA*, Jacq. Lvs. oblong-lunate, wavy-margined, finally 1 ft. long: scape mottled with purple; raceme very dense, 3-6 in. long, 25-30-fld.: fls. 1½-1¾ in. long, yellow or reddish, with greenish tips. L.B.C.

AA. *Lvs. glaucous,* 1½ in. broad.

*Glaucia*, Jacq. Lvs. oblanceolate-lunate, acute, glaucous: scape less stout: fls. "yellow or bright red," according to Baker. B.M. 1091 (fls. white, dotted red toward the tips); 3156 (fls. reddish purple, dotted yellow below).

F. Tracy Hubbard.

**VELVET BEAN**: *Seslabium*. V. Tree: *Gynura aurantiaca*.

**VENIDIOUM** (name not explained by its author). *Compositae*. Annual or perennial herbs, grown for ornament.

Rays female: receptacle honeycombed, mostly nude; involucral scales in several rows, the outer narrower and herbaceous, inner scarious: achenes glabrous, dorsally 3-5-winged or -ridged, the lateral ridges inflexed, the medial straight, narrower; no hairs at the base of the achenes: pappus either none or of 4-5 very minute, unilaterial scales.—Eighteen species, S. Afr., 7 of which are annuals. By Hoffmann (Engler & Prantl, Pflanzenfamilien) united with Arctotis.

The following account of *V. calendulacenum* of the gardens as a garden plant is adapted from Gn. 21, page 405. It is a graceful single-flowered composite which flourishes under the ordinary treatment accorded half-hardy annuals, making a compact rounded mass 2 feet high and 3 feet wide. There is considerable diversity in its seedlings both as regards habit and the size, shape and shading of its blossoms, and careful selection in seed-saving is needful in order to secure the best forms. It is admirably adapted for cutting, as the flowers open and shut as regularly as when on the plant. This species has also been treated as a greenhouse perennial, continuing to bloom until near midwinter. The flower-heads are fully 2 inches across.

**VAR.** Differences. Less. Diffuse canescent perennial, 1-2 ft. long: lvs. mostly lunate, the terminal lobe ovate or rounded, sinuate-lobed or rounded, at first cobwebbed, afterward nude and punctate above, white-tomentose beneath; petiole 2-2½ in. long, amply cared at base, the ear decurrent along the st.—The type does not seem to be cult. but the following variety is offered as a half-hardy garden annual with dark-centered sunflower-like golden yellow heads 1-2½ in. across:

*V. calendulacenum*, *Harvey* (*V. calendulacenum* Less.), differs in having the petioles not cared at the base or with only a small ear. R.H. 1857, p. 123. Gn. 21, p. 405. G. 5:345.—Opinions differ as to its merits, and it is variable in quality. Some consider it coarse and weedy. In pots it does well; for spring bloom, sow in Aug. to Oct. in a frame in light soil and prick off into pots; if well grown it is very free-flowering.

—William Miller.

**VERATRUM** (ancient name of hellebore). *Lilacée*. FALSE HELLEBORE.

VERATRUM (name not explained by its author). *Compositae*. Annual or perennial herbs, grown for ornament.

Rays female: receptacle honeycombed, mostly nude; involucral scales in several rows, the outer narrower and herbaceous, inner scarious: achenes glabrous, dorsally 3-5-winged or -ridged, the lateral ridges inflexed, the medial straight, narrower; no hairs at the base of the achenes: pappus either none or of 4-5 very minute, unilaterial scales.—Eighteen species, S. Afr., 7 of which are annuals. By Hoffmann (Engler & Prantl, Pflanzenfamilien) united with Arctotis.

the species will stand any amount of sun although some more showy and satisfactory species are rarely reproduce true. However, most of the hybrids naturally and freely they hybridize so readily that they question of height should be taken into account, as V. pyræntineum, 18.

Frcyntanum, 18.

VERBA-SCUM (old Latin name of the mullein used by Pliny). Scrophulariaceae. MULLEIN. Hardy biennial herbs, rarely perennial or subshrubs, more or less tomentose or floccose-lanate, sometimes grown in the garden or border for ornament.

Plants usually erect and tall: lvs. all alternate, usually soft, circinate, sinuate-dentate or pinnatifid: racemes or terminal, simple or branched: fls. yellow, fuscous, purple or red, rarely white; calyx deeply 5-cleft or parted, rarely shortly 5-toothed; corolla-tube about none, explanate-rotate, lobes 5, broad, slightly unequal; stamens 5: caps. globose, oblong or ovoid, septicidally 2-valved.—About 270 species, natives mostly of the Medit. region, widely intro. in other countries. Prop. by means of cuttings or division, although most of the mulleins usually self-sow freely. The mulleins are very easily cultivated, adapting themselves to almost any soil except a wet cold one. In America the name mullein calls to mind the common weed, V. Thapsus, but this same weed if massed in the wild border is a very showy plant and gives a tall columnar effect which is very pleasing when contrasted with looser, more open-growing plants such as farkspar, wild asters, and goldenrods. Another feature of the mulleins which makes them valuable in border planting is the generally predominating grey-green of the foliage, in fact of the whole plant, which contrasts with the bright or dark green foliage about it. The most serious drawback to the mulleins in general is that most of them are biennial and although they reproduce naturally and freely they hybridize so readily that they rarely reproduce true. However, most of the hybrids are as showy as their parents and as a whole they deserve a place in every border of size. Some of the more showy and satisfactory species are V. olympicum, V. phlomoides, V. Chaiiiii, V. nigrum, V. phlomoides, V. pannusum, and V. cupreum, although many others are almost equally as good. In choosing varieties the question of height should be taken into account, as some species grow much taller than others. Nearly all the species will stand any amount of sun although some of them, as V. phlomoides, do better in partial shade as the flowers do not open well in strong sunlight.

Section I. THAPSIUS

1. Thapsus, Linn. (V. Blättraria, J. A. Schmidt, not Linn. V. giganteum, Willk. V. Schreber, Mey.), COMMON MULLEIN. Fig. 3909. Biennial, 2-6 ft. high, densely yellowish tomentose; radical lvs. oblong-elliptic or elliptic-lanceolate, crenate, attenuate to the petiole; cauline lvs. narrowly decurrent from If. to If.; fls. yellow, in a spike, shortly half-decurrent, the wings violet-bearded. Caucasus. G.C. III. 14:785. Gr. 40, p. 76.

2. thapsiforme, Schrad. (V. densiflorum, Bertol.). Biennial, about 2-5 ft. high, densely yellowish tomentose; radical lvs. oblong-elliptic or elliptic-lanceolate, crenate, attenuate to the petiole; cauline lvs. narrowly decurrent from If. to If.; fls. yellow, in fascicles forming a long raceme; calyx tomentose, segms. lanceolate; corolla small, concave. Eu., especially N. and Cent., and Cent. Asia, also naturalized in N. Amer. Gn. 28, p. 148.—A familiar weed in rocks and uncultivated fields. Hybridizes very readily with other species. There is also a white form of the species. This plant varies considerably in the color and size of its fls. and probably occurs under several trade names in Eu. A first-year rosette in a pot makes an attractive plant (Fig. 3909).

3. phlomoides, Linn. Biennial, 4-6 ft. high, whitish- or yellowish tomentose: radical lvs. crenulate, elliptic or oblong-lanceolate, attenuate to the petiole; cauline lvs. amplexicaul, usually coriaceous or very shortly decurrent: fls. yellow, in very short fascicles forming a long raceme; calyx tomentose, segms. triangular-lanceolate; filaments white-tomentose. S. Eu. and Caucuses. Gn. 40, p. 501; 41, p. 555. Var. album, Hort., has cream-colored fls.—The species has become naturalized in E. N. Amer.

4. longifolium, Ten. Biennial, 3-4 ft. high, covered with white or yellowish flocculent tomentum: lvs. numerous, densely superposed; lower 1½-2 ft. long, narrowly ovate or oblong-lanceolate, acuminate, base narrowed to a short petiole; upper sessile, base amplexicaul; all undulate: infl. sessile, 1 ft. long, 3½ in. diam., with innumerable short appressed branches: fls. golden yellow, about 1 in. across; calyx stellate-tomentose, segms. lanceolate. S. Eu. B.M. 7707. Var. pannosum, Hort. (V. pannosum, Vell., no Linn. V. Blattarioidea, Lam. V. globarium, Willd. V. vieidulum, Poir.). Biennial, 1½-3½ ft. high, whole plant green, somewhat viscid-hispid or nearly glabrous: fls. golden-yellow or glaucous-green or glaucous-hispid, especially beneath, oblong; lower petioled, dentate or subulate-pinnatifid; upper sessile, coriaceous-clasping or shortly decurrent: raceme glandular-hisrate, segms. lanceolate-linear; filaments purple-bearded. Caucasus. G.C. III. 14:785. Gr. 40, p. 76.

5. crassifolium, Hoffm. & Link. Biennial, about 3-4 ft. high, densely yellowish tomentose: lvs. obovate-spatulate, 6-8 in. long, crenulate; cauline long-decurrent: fls. fasciated in a spicate raceme, yellow; corolla flat-topped; filaments glabrous. Portugal.—Closely allied to and possibly only a variety of V. thapsiforme. One of the few species said to thrive well in a light sandy soil.

Section II. LYCHNITIS

10. niveum, Ten. Biennial, about 2 ft. high, possibly more, white-tomentose: lvs. ovate-oblong, ovate, undulate; lowest petioled, the others sessile, acuminate, rather spoon-like, shortly half-decurrent, the wings narrowly ovate, acuminate; raceme simple and very dense: fls. yellow, rarely white, solitary, subulate; calyx-segms. ovate, acuminate; filaments white-tomentose. S. Italy.

11. Boerhaavia, Linn. Biennial, about 2 ft. high, snow-white, tomentose-floccose, finally deciduous: st. reddish, leafy; lvs. crenate-dentate; lower ovate, obtuse, petioled; upper coriaceous-clasping, acute or acuminate; fls. in a long rigid spike-like raceme, yellow, in subulate fascicles; calyx tomentose and glandular-viscid; segms. lanceolate; corolla-violet-spotted at the throat; filaments violet-bearded. Medit. region.

12. glomeratum, Boiss. Biennial, 4-6 ft. high, densely grayish yellow, ragged, tall and stout: lower lvs. 1 ft. or more long, 3-4 in. broad, subentire, subulate, oblong-lanceolate, base attenuate; upper lvs. ovate, acuminate from a cordate-subauriculate base: infl. thyrsoid, subumbellate: fls. subulate in 3-4-flowered glomerules, yellow; calyx-segms. lanceolate; corolla strongly tomentose outside; filaments yellowish bearded. Asia Minor.

13. simplex, Labill. Perennial, about 2 ft. high, many-stemmed, base shaggy, densely white or yellowish, ragged: st. leafy below then prolonged into a long (6-12 in.) simple, strongly interrupted, rarely

Section 1. EUTHAPSI

1. Thapsus, Linn. (V. Blättraria, J. A. Schmidt, not Linn. V. giganteum, Willk. V. Schreber, Mey.), COMMON MULLEIN. Fig. 3909. Biennial, 2-6 ft. high, densely yellowish tomentose: radical lvs. oblong, crenate, petioled; cauline lvs. decurrent from If. to If.; fls. yellow, in a spike, crenate or rather entire, attenuate to the petiole; cauline diminutive, oblong, sessile; fls. yellow, in a simple raceme or slightly branched panicle, large, 1½ in. across, indigo-blue to purplish lilac; calyx densely glandular-hisrate, segms. broad-lanceolate; filaments orange- or purple-woolly. S. Russia. B.M. 1037. B.R. 558.

7. Wiedemannianum, Fisch. & Mey. Biennial, 1-3 ft. high, appressed, arachnoid woolly; st. stout, tall, leafy below; lvs. lanuginose; radical oblong or elliptic, 3-5 in. long, crenate or rather entire, attenuate to the petiole; cauline diminutive, oblong, sessile; fls. yellow, in a simple raceme or slightly branched panicle, large, 1½ in. across, indigo-blue to purplish lilac; calyx densely glandular-hisrate, segms. lanceolate-linear; filaments purple-bearded. Caucasus. G.C. III. 14:785. Gr. 40, p. 76.

Subsection 3. BLATTARIA

8. virgatum, With. (V. Blättraria, Vell., not Linn. V. Blattarioles, Lam. V. globarium, Willd. V. vieidulum, Poir.). Biennial, 1½-3½ ft. high, whole plant green, somewhat viscid-hispid or nearly glabrous: fls. golden-yellow or glaucous-green or glaucous-hispid, especially beneath, oblong; lower petioled, dentate or subulate-pinnatifid; upper sessile, coriaceous-clasping or shortly decurrent: raceme glandular-hisrate; pedicels in 2's or 3's, rarely solitary; fls. yellow, throat violet; filaments violet-woolly. Cosmopolitan.

9. Blättraria, Linn. MOTH MULLEIN. Biennial, 8 in. to 4 ft., glabrous and green; st. usually tall; lvs. oblong or oblong-lanceolate, dentate; lower attenuate to the pedicle, undivided or subulate-pinnatifid; upper sessile, coriaceous-amplexicaul, acute: raceme very long and lax: fls. rather large, yellow, rarely white, borne on solitary pedicels; calyx glandular, segms. linear-lanceolate; corolla-throat violet: caps. globose, longer than the calyx. Eu., N. Asia.—Distinguished from V. virgatum, which it resembles, by the solitary pedicels.

Section II. LYCHNITIS

Subsection 1. THAPSOIDEA

6. ovalifolium, Don (V. formosum, Fisch.). Biennial, about 2-3 ft. high, gray-tomentose: lvs. large, ovate, petioled, coarsely and rather double-crenate, coriaceous, petioled, hoary beneath; upper lvs. coriaceous-clasping: fls. sessile or nearly so, solitary, large, 1½ in. across, bright yellow, in a spike; calyx densely white-tomentose, segms. broad-lanceolate; filaments orange- or purple-woolly. S. Russia. B.M. 1037. B.R. 558.
slightly branched raceme: radical lvs. 1–2 in.; long, crenate, ovate- or oblong-lancedolate, very obtuse, long-petioled; cauline lvs. sessile or nearly so, arranged in remote glomerules of 2–5: fls. yellow; calyx white-tomentose, segms. oblong, mucronate; filaments white-bearded. Syria. G.C. III. 36:2.

Subsection 2. GLOMERATA.

14. mucronatum, Lam. Biennial, several feet high, densely white, ragged-tomentose; st. erect, crowded, leafy, large-petioled; lvs. thick; radical lvs. long-petioled, sometimes somewhat lobed and somewhat petioled; cauline lvs. oblong, rather long-decurrent; uppermost subtubularc, glomerules of fls. globose, forming a long virgate, interrupted raceme: fls. sub-sessile, white; calyx silky-lanate, segms. broad-lanceolate; filaments white-woolly. Asi Minor and Crete.

15. sinuatum, Linn. Biennial, 2–3 ft. high, more or less densely yellowish or gray-tomentose; radical lvs. oblong-glanulate, sessile, sinuate-pinnatifid, usually undulate; upper cauline lvs. oblong, acute, entire and short-decurrent; panicle pyramidal; branches elongated, twig-like: fls. yellow, rarely white, in remote glomerules; calyx tomentose, segms. short-lanceolate; corolla small; filaments white-woolly. Medit. region and Canary Isls.

Subsection 3. PYRAMIDATA.

16. pyramidatum, Bieb. Biennial, 2–4 ft. high, tomentose; st. stout; lvs. green above, canescent beneath; radical lvs. large, oblong, base long-narrowed, doubly and obtusely lobed or crenate; upper lvs. sessile, ovate, auriculate-cordate, long-acuminated; panicle pyramidal, sometimes 2 ft. long, crenate; branches finally rather lax; fls. yellow, solitary or in pairs; corolla tomentose, segms. oblong or ovate; corolla long; filaments purple-woolly. Caucasus.

Subsection 4. LYCHNITIDEA.

17. nigrum, Linn. (V. Hinski, Friv.). Biennial, 2–3 ft. high; st. tall, angled above; lvs. green above, more or less tomentose beneath; lower long-petioled, ovate or oblong, base cordate; uppermost sessile, base rotundate; infl. a simple or slightly branched elongated raceme: fls. small, yellow, in many-fl., lax, filaments; calyx hirsute, segms. lanceolate-subulate; inferior ovary; filaments purple-woolly. Eu. and Asi Min. Gn. 27, p. 173. Var. album, Hort., has white fls. G. 15:159. Gn. 41, p. 551.

18. Chatzii, V. Biennial, usually about 3 ft. high, whitish tomentose; st. somewhat angled above; lvs. ovate to oblong, green or tomentose below, canescent; lower 3–6 in. long, petioled, base cuneate, more or less crenate or rather incised; upper lvs. sessile, base rotundate; racemes paniculate, fascicled and laxly several-fl.; fls. yellow; calyx-segms. lanceolate-subulate; corolla-lbs. nearly rotund, filaments purple-woolly. S. Eu. Gn. 27, p. 172; 78, p. 435. Var. album, Hort., is a white-fl. form.—This species is said to reach a height of 10 ft. and to act like a true perennial in warm soils. V. orientale, Bieb., is considered the same by some authorities; apparently not in cult. The vars. sublanceatum, Hort., and Fremynatum, Hort., are really hybrids.

19. pyramidalae, Host. (V. speciosum × V. orientale). Biennial, 3–4 ft. high, white-pilose: lvs. rugose-crenate, acuminate, radical and lower cauline lvs. oblong, broad, upper smaller, remotely crenate; fls. small, collected in glomerules, yellow; calyx densely tomentose; corolla-lbs. obovate, red-brown-maculate at base; filaments white or purplish hairy. Austria.—Neither of the parents are in cult. and it is questionable what the material in the trade under this name really is; possibly it is V. pyramidatum.

20. Lychnitis, Linn. Biennial, tomentose: lvs. green above, slightly acutely palmatifid or linear-oblong, beneath; radical lvs. oblong-elliptic, narrowed to the petiole; upper lvs. sessile, lanceolate; infl. panicked; branches erect-spread, angled: fls. small, yellow or white; calyx tomentose, segms. lanceolate, acute, tips glabrous; filaments white-woolly. I. 37:468.

21. pulvurulentum, Vill. Biennial, 3–9 ft. high, densely white-floccose-tomentose: lvs. entire or obliquely crenate; radical lvs. oblong or elliptic, attenuate to a short petiole; upper lvs. ovate or rotundate, clasping: infl. a pyramidal panicle: fls. yellow, in slightly remote fascicled racemes; calyx densely floccose, segms. linear-lanceolate; corolla small; filaments white-woolly. Eu. Gn. 73, p. 422.

22. sondarinum, Schrenk. Biennial, several feet high, white-tomentose: lower lvs. lanceolate, acute, narrowed to the petiole; cauline sessile, oblong, cordate-lanceolate; uppermost subtomentose, cuspitate; racemes panicled: fls. in fascicled, yellow; calyx-segms. lanceolate; filaments white-bearded. Sonnegara.

Subsection 5. LEVANTIA.

24. leianthum, Benth. Biennial, up to 14 ft. high, covered with a dense white felt; basal lvs. very large, sometimes 4 x 2 ft.; cauline lvs. oblong, crenate, rugose, base decurrent, lax, whitish tomentose on both surfaces: infl. much branched up to 7 x 3 1/2 ft., laxly many-fl.; fls. bright yellow, ¾ in. across; calyx-segms. small, oblong-lanceolate, rather obtuse. Asia Minor. G.C. III. 44:171. Gn. 72, p. 500.

Subsection 6. BLATTARHOIDEA.

25. rubiginosum, Waldst. & Kit. Biennial, about 2–3 ft. high; st. glabrous or pubescent above; lvs. green, supersedent beneath; cauline lvs. ovate, petioled; upper petioled; superior ovary; calyx-segms. obtuse or ciliate-clasping; racemes laxly branched, somewhat paniculate; pedicels in 2's or 3's, rarely solitary, twice or many times as long as the calyx: fls. reddish purple; calyx-segms. linear-lanceolate; filaments purple-woolly. S. Eu. and Caucasus.—Boissier Flora Orientalis suggest that this is a hybrid between V. pharnaceum and V. nigrum. Var. ferrugineum, Benth. (V. ferrugineum, Mill.), has a long simple raceme and slightly larger and longer-peduncled fls. than the type. Horticultural form, possibly a hybrid.

26. phoeniceum, Linn. (V. ferrugineum, And.) PURPLE MULLEIN. Biennial, about 5 ft. high: lvs. glabrous above, short-puberulent beneath; radical rosulate, ovate or oblong-hispid, attenuate to the short petiole, obtuse, obtusely crenate or repand; cauline lvs. ovate, oblong or lanceolate, acute; fls. purple or red, in a simple slender raceme; calyx glandular, obtuse segms. elliptical; corolla glabrous; filaments purple-woolly. S. Eu. Eu., Caucasus, and Persia. G. 15:185. Gn. 22, p. 377; 27, p. 173; 41, p. 556. A.G. 13:639. The name phoeniceum was undoubtedly suggested by the Phoenician purple and not by the habitat. One of the parents of nearly all the hybrids having fls. of purple, violet, rose, pink, and lilac shades. The fls. open poorly in sunshine, preferring to the habitat. One of the parents of nearly all the hybrids having fls. of purple, violet, rose, pink, and lilac shades. The fls. open poorly in sunshine, preferring to the
In propagating general stock, sow the seed in February and pot to 2-inch pots as soon as the seedlings are up an inch. A temperature of 45° to 50° will answer, but they should have full light. There is no place equal to a mild hotbed for young verbenas. About April 15 plunge the pots in a few inches of soil in a mild hotbed. Lift them now and then until the roots which go through the bottom of the pot, in order to check growth and hasten flowering. Customers want to see them in flower before buying, and most of them wait till the end of May. However, verbenas may be planted out early in May, as a slight frost will not injure them.

The evolution of the garden verbenas has taken place in about seventy-five years. Although the history can be made out with considerable clearness, yet the botanical origin of the present florist's race, as to the species involved and the extent to which they have contributed, is not satisfactorily recorded. It is probable that four species have been more or less fused in the race or group known as *Verbena hybrid*.—*V. chaixii*, *V. phlomoides*, *V. officinalis*, and *V. cneorum*. In Fig. 3910. For an historical account of the development of the garden verbenas, see Cowen, "Cyclopedia of American Horticulture," Vol. IV.

It is impossible satisfactorily to classify the hybrid garden verbenas according to their botanical derivation. They are conveniently classed according to color of flowers into: (1) Selfs, or one-colored varieties; (2) Oculatas, or eyed varieties; and (3) Italians, or striped varieties. As to habit they may be divided into: (1) Standards, those of the ordinary loose, spreading growth; and (2) Compacts, which are much reduced in stature and of more condensed form. Verbenas now in cultivation are shown in Figs. 3910, 3911.

Latin trade names probably mostly or entirely belong with hybrid race of verbenas, such as *compacts*, *coecina*, *grandiflora*, *monstrosa*, *carulea*, *candidissima*, *italica*, *auriculeflora*, *striala*.
VERBENA

Branches erect; lvs. oblong-triangular, base cuneately truncate or subcordately attenuate into the evident petiole, pinnatifid lobed or deeply serrated and incised, upper lvs. sublanateolate, sessile, incisedly pinnatifid; spikes terminal, pedunculate, subternate, flat or convex; bracts ovate: calyx 4 times as long as bracts, short-hairy, sprinkled with glandular hairs; corolla-tube glandular-pubescent, thrice as long as calyx; limb large, rose-purple, paler beneath, obovate lobes deeply emarginate. S. Brazil, Paraguay, and N. Argentina. B.M. 3628.

ccc. Fls. white.

4. teucrioides, Gill. & Hook. Fig. 3910. Characterized by fragrant white fls. in very long clusters: sts. cespitose, rooting at base, ascending, terete, openly and copiously hirsute; lvs. ovate to oblong-triangular, base entire, sessile or nearly so, obtusely serrate, margins revolute, veiny-rugose, glandular-pubescent above, subternately hispidulous on veins below; spikes terminal, solitary, glandular, hairy, lax, 5-9 in. long: bracts subulate-lanceolate, ciliate: calyx nerve, twice as long as bracts; corolla yellowish white or pinkish, long exserted, twisting in age, fragrant. S. Brazil, Uruguay, Argentina, Chile, and Peru. P.M. 5:243. B.M. 3904.

bb. Fls. purple or rosy purple.

c. Bracts half as long as calyx: plant a subshrub.

6. tenera, Spreng. (V. pulchella, Sw., not Hort.). Herbaceous perennial; sts. cespitose, decumbent, rooting; branches slender, 4-angled, ascending, sparsely hairy; lvs. deciduous into the short petiole, 3-parted and again pinnatifid into acute, linear, entire, subrevolute divisions, sprinkled with short hairs; spikes terminal pedunculate: calyx elongated, strigose pubescent or hairy, sprinkled at angles with short stipitate peltate-form glands, twice as long as bracts; corolla rose-violet; anther appendages barely exserted, clavulate, subcurved. S. Brazil and La Plata region. Var. Maonettii, Hort., by some supposed to be a hybrid between V. tenera and V. incisa and by others to be a form of V. tenera, has rosy pink or carmine fls. rayed with white-margined corolla-lobes. Intro. from Italy and some...
times called Italian verbena. The name is variously spelled. Gn. 73, p. 31.

cc. Bracts about as long as calyx or a little shorter: plant annual.

7. crinosoides, Lam. (V. multi{tida), Ruiz & Pav. V. pulchella, Hort., in part). Moase VERBENA. Annual or perennial: st. strigose hairy or somewhat hisrate, branching, decumbent, rooting; branches ascending; lvs. ovate in outline, cuneate base decurrent into the petiole, deeply 3-parted and the divisions pinnatifid into narrow linear acute lobes, subrevolute on margins.

Variable species characterized by distinct finely cut foliage and rosy lilac to deep purple fls., but the clusters and individual fls. are too small to make it popular.

bb. Fls. lilac: plants annual.

cc. Lvs. twice pinnatifid.

8. bipinnatifida, Nutt. (V. pulchella ssp. of some seeden. V. montana, Hort., in part). Perennial, prostrate and rooting at base; st. stout, upright, branched, 6-18 in. high: lvs. rather thick, petiolate, 1-2½ in. long, scabrous above, ovate in outline, bipinnately partited or 3-parted into numerous oblong, rather acute lobes 1-3 lines broad: spikes solitary, dense to rather lax, at first capitulate, becoming 2-4 in. long in fr.: corolla 5-8 lines long, purple or lilac, limb 4-5 lines broad, lobes emarginate to obsolete; throat of corolla provided with a palisade of short hairs; upper stamens bearing each a small oval to oblong purplish gland. S. D. to Mex. east of the Rockies.—Fls. become bluish purple in drying.

cc. Lvs. once pinnatifid.

9. canadensis, Brit. (Buchnera canadensis, Linn. V. Aubletia, Jacq. V. Aubletia var. Drummundi, Lindl. V. Drummondii, Hort. V. Lomberti, Sim's. V. mon­tana, Hort., in part). Fig. 3912. Perennial, pubescent, with rather stiff hairs or glabrate: branches ascending from a sometimes creeping rooting base, 6-18 in. high: lvs. ovate or ovato-oblong in outline, 1-3 in. long, truncate, broadly cuneate or subcordate at base and the petiole more or less margined, incisedly lobed and toothed, often deeply 3-lobed: spikes peduncled, dense, short and capitate in early fl., becoming 2-4 in. long in fr. :bracts subulate, mostly shorter than the calyx—these and the calyx densely glandular-appressed: calyx-teeth unequal, filiform-subulate; corolla 6-10 lines long, from bluish purple or lilac to rosy purple or white, frequently approaching blue in dried specimens; limb ½-¾ in. broad, lobes oblong or obovate, emarginate and more or less revolute near the sinuses, throat provided with palisade of short white hairs; upper anthers bearing each a light brown, oblong gland which is hardly exserted. Colo. and Mex. eastward across the continent. J.H. 308; 2200. B.R. 294; 1925.—Reported as producing many garden and spontaneous hybrids. Garden forms are of stouter habit, less inclined to root at base: lvs. larger, dark shiny green above, more conspicuously veiny, ciliolate and individual fls. larger, and the color variation more striking.

Many forms have a rich spicy fragrance quite different from that of the hybrid verbena. On account of the robust healthy nature of V. canadan­sis, it has been frequently recommended in horticultural literature as desirable for hybridizing with the hybrid verbena to improve their constitution. The cross would probably be too radical for best results. It is to be regretted that this charming species which is thought well of in Eu. should be neglected in its native country.

V. radicans is listed as an alpine species of trailing habit and with crimson fls., suitable for rock-gardens. The V. radicans of botanists (Gill & Hook.) is an Andean species with procumbent rooting st., glabrous divided lvs. with ultimate segments blan­colored fragrant fls. in short head-like spikes. J. H. COHEN. L. H. B.'

VERBENA, LEMON: Lippia. V., Sand: Aervaia.

VERBESINA (probably a meaningless alteration of Verbena). Composita. CROWNBEARD. Annual or perennial herbs, or some tropical species shrubby.

Leaves alternate or opposite, often decurrent: heads corymbose or solitary, of yellow or white fls.; rays sometimes wanting, pistillate or neutral: achene flattened or those of the rays 3-sided, their margins winged or not;
VERBASINA

pappus of 2 (1–3) awns, sometimes with 2 or 3 intermediate scales.—About 50 species, American. About a half dozen hardy perennial verbasinas have slight rank as garden plants, but the competition among yellow-flowered autumn-blooming composites is so great that verbasinas have little chance. They make acceptable wild-garden and back-border subjects.

occidentalis, Walt. (V. Siegbeschka, Michx. Phaethusa occidentalis, Brit.). Hardy perennial herb, 4–8 ft. high: lvs. ovate (uppermost oblong-lanceolate), acuminate, or rose, borne in the following species in terminal cymes: heads not glomerate, several to many exclusively tubular: involucre of dry or partly herbaceous, much-appressed, July–Sept. Rocky hills, W. Texas.

c. Plant about 1 ft. high.

Vernonia (after Wm. Vernon, an English botanist and traveler in North America). Compositae. Ironweed. Perennial herbs or in the tropics shrubs and trees.

Leaves alternate, pinnately veined: fls. usually purple or rose, borne in the following species in terminal cymes: heads not glomerate, several to many exclusively tubular-flowered: involucre of dry or partly herbaceous, much-appressed heads: peduncles not branched: involucre green, the filiform tips often red-dishe and the pappus often purplish. Plains, Mo., Kans. to Texas. July–Sept. Var. alba, Hort., has white fls.

a. Heads 60–70-fld.

b. Lvs. narrowly linear.

c. Plant about 1 ft. high.

cc. Plant 2–4 ft. high.

Lettmanii, Engelm. St. fastigiatly and cymosely much branched at the summit: lvs. 2–4 in. long, only 1 line wide, much crowded and very numerous; margins not revolute: fls. numerous, ½ to 1½ in. long, 10–14-fld. July–Sept. Sandy soil, Ark.

bb. Lvs. not narrowly linear.

c. Bracts of involucre tipped with slender awns.

noveboracensis, Willd. Fig. 3913. St. 3–6 ft.: lvs. oblong to oblong-lanceolate, 3–9 in. long: heads in an open cyme: involucre commonly brownish or dark purplish: fls. deep purple, rarely white. Usually in moist soil. July–Sept.—The only common species of the E. U. S. and often used in the wild-garden.

cc. Bracts not awned.

d. Plant tomentose.

Baldwini, Torr. St. 3–7 ft. high: lvs. oblong to ovate-lanceolate, 4–8 in. long, rather numerous: bracts greenish, acute or acuminate, tips spreading or reflexed: fls. purplish, blooming earlier than most species, in July and Aug. Prairies, eastern Mo. to Texas.

dd. Plant glabrous.

x. Lvs. thin.

altissima, Nutt. (V. maxima, Small). St. 5–10 ft. high: lvs. veiny, lanceolate or lanceolate-oblong, 4–12 in. long, usually long-acuminate and finely serrate: infl. loosely branched and open, the fls. purple: bracts obtuse or merely mucronate-tipped, closely appressed. July–Sept. W. Pa. to Ill., La., and Fla.

ee. Lvs. thickish.

fasciculata, Michx. St. 2–5 ft. high: lvs. somewhat obscurely veined, linear to oblong-lanceolate, 3–6 in. long: heads numerous and crowded on the branches of the cyme, 20–30-fld.: bracts obtuse or some of the upper mucronate-acut, closely appressed. July–Sept. Ohio and Ky. to the Dakotas and south to Texas. Grows on prairies and in moist soil; variable southward.

3913. Isolated specimen clump of ironweed. — Vernonia noveboracensis.
VERONICA

V. Arachnoidea, André. Glabrous shrub, 3-6 ft. high; lvs. sericeous, linear-lanceolate; f-ls. reddish violet. Uruguay.—V. glaucifolia, Hort. Robust: f-ls. in panicles, narrow of violet-tose.

P. W. BARCLAY.
N. TAYLOR.†

VERÓNICA (named in honor of St. Veronica). Scrophulariaceae. Speedwell. Annual and perennial herbs, shrubs, or rarely trees, one group of which, mainly European and American species, are hardy in the North, the other group, New Zealand species, are hardy in California and similar climates and are also somewhat used as greenhouse plants.

Leaves opposite, rarely whorled or rather few; cauline lvs. very rarely alternate; floral lvs. always alternate: fls. disposed in terminal or axillary bracteate racemes, or rarely solitary in the axes of alternate lvs., blue, purple, flesh-colored, or white, never yellow; calyx 4-6-parted, but they survive the winters outdoors, usually short, limb spreading, 4-5-cleft; stamens 2: caps. compressed or turgid, 2-grooved, loculicidally dehiscent, usually obtuse or emarginate.—About 300 species, mostly natives of the temperate and colder regions, a few in the tropics. Veronica was monographed by Bentham in DC. Prod. 10:453-491 (1846), 158 species being then known. About 200 species are now known, very widely distributed.

All are showy free-flowering plants, used, except the shrubs, as garden perennials or annuals, and are propagated by seeds, the perennials also by division, the shrubs by cuttings in spring or summer. They succeed in any good garden soil in a sunny situation. The low-growing forms are good rock-plants; the taller are adapted to the herbaceous border. The shrubby forms are greenhouse plants or grown only in warmer parts of the country, particularly California, where they are everblooming, and where they do well along the coast even in exposed places by the sea. The shrubby species are mostly natives of New Zealand. They are well reviewed in The Garden 45, page 506, and 28, page 292. Some of them have enjoyed a considerable popularity in England, where they are generally seen in cool conservatories, but they survive the winters outdoors in the most favored parts of the British Isles. The first hybrid was raised in 1848 by Isaac Anderson-Henry (then Isaac Anderson), a noted hybridizer. This gentleman continued his experiments for several years, using V. speciosa, V. salicifolia, and V. elliptica. His work was continued by others, and most of the hybrid veronicas of today have the parentage above indicated, with the blood of V. speciosa generally much in evidence. If a collective name for veronica hybrids is desired, V. speciosa var. hybrid is the best name for the whole group. Unfortunately all these hybrids are unfit for general cultivation out-of-doors in northern climes, but a harder race will probably be secured by using V. Traeriki and its allies, which have been introduced more recently. Some of these are V. Columnea, V. anomala, V. monticola, and V. pinelioleoides.—all well known to the American trade. A third and still harder group of the New Zealand speedwells is the truly alpine group known as whitepod veronicas. These should be hardy in many northern rockeries. They are unknown in America now. The best of the group is said to be a form of V. cupressoides, known to English trade as V. saliciniformis. Others in cultivation are V. Hectori, V. Armstrongii, and V. lycopeoides. (A. P. Wyman.)

The New Zealand veronicas (Cockayne).

In New Zealand the veronicas comprise a marked feature in the flora, being represented by many shrubby and semi-shrubby kinds. Several of these species are well-known evergreen garden plants in California and parts of Europe. The following comment on the New Zealand veronicas is by L. D. Cockayne, Wellington; and the systematic treatment of these species is also founded on manuscripts contributed by him.

Excepting the Tasmanian V. formosa, the shrubby species are natives of New Zealand where they occur in all kinds of stations and at all altitudes. In their native land, and in Great Britain and Ireland, they are now widely cultivated, but, unfortunately, none can be considered perfectly hardy in the northern states, though, where the cold of winter does not sink much below 12° F., many of the species should thrive admirably. All can be readily propagated from seeds or cuttings. If the latter are taken from adult plants in the autumn, they will bloom during the succeeding summer, and if boded out on the rockery are most effective.

The genus in New Zealand contains more than 100 species, while nearly all of these can be subdivided into several distinct varieties. There are also astonishing differences in their growth-forms. Some are trees and others shrubs, which latter are erect or prostrate, compact and ball-like or wide-spreading, densely leafy or the leaves reduced to adpressed scales so that the plant resembles a cypress (the whipcord veronicas). The flowers also differ considerably and may be in small heads, rosettes of different length, corymbbs, or long branched panicles. The usual color is white, but crimson, lilac, violet, and blue are met with. Usually the leaves are bright green and perhaps glossy, but in some species, and this is a sign of hardiness, they are of a pleasing pale glaucous hue.

The compact shrubby species lend an admirable effect to the garden landscape when massed together on banks, many looking as if trimmed into a ball-like form by the gardener's hand. Most forms tolerate clipping to any extent. Some, especially V. elliptica, V. angustifolia, and V. leptophylla, make excellent evergreen hedges. A small form of the polymorphic V. buxifolia can be used as an edging after the manner of the box.

The species are exceedingly difficult to determine and many are known in garden nomenclature, while unpublished names are frequent. Natural hybrids also occur and this brings in further confusion. Also, there are a number of garden hybrids in cultivation, mostly between V. speciosa and its nearer relatives. Much more important for colder countries are the
hybrids to crossing the more hardy alpine species. So far as American gardens are concerned the following, not introduced or rare in cultivation (some of them not here described), would be desirable novelties: V. Diefenbachii, V. gigantea, V. Barkeri, V. Lectiste, V. leucoxyla, V. Bolonii, V. anomala, V. ternerosa, V. monticola, V. Menziesi, V. decumbens, V. tetragona, V. Armstrongii, V. propinqua, V. loganioides, V. Lavaudiana, and V. Rauhii. Those desiring more information about the shrubby veronicas should consult Cheese­man’s Manual of the New Zealand Institute.

1. Bonarota, Linn. (V. chamadryfolia, Wetttat. Panderota Bonarota, Linn. P. chamadryfolia, Brign.) Perennial, pilose: sts. 4–6 in. high; lower lvs. orbiculate, scarcely 1 in. long; upper lvs. ovate or lanceolate, serrate or incised: spike globose or oblong, compact, 1–1 1/2 in. long; fls. blue, about 3 mm. across; calyx-segms. linear-subulate. Italian Alps and Tyrol.

2. virginica, Linn. (Leptandra virginica, Nutt. V. verticillata, Hort.) CULVER’S Root. Erect, simple, somewhat pubescent herb 2–6 ft. tall: lvs. in whorls of 4, lanceolate, 2 in. long. Stems above, pubescent below, acutely serrate, short-petioled; racemes terminal, erect, long, dense; fls. many, white or pale blue, short-petioled: caps. longer than broad, pointed, twice exceeding the calyx. Aug.–Sept. Eastern states. Gr. 79, p. 269.—Free-growing herb. Likes rich soil and much sun. While stiff and coarse, it is bold and stately. Var. alba, Hort. (V. verticillata var. virginica alba, Hort.) is offered in the trade as a form growing 4 ft. high, with erect spikes of white fls. Var. japonica, Makino (V. japonica, Steud. V. verticillata var. japonica, Hort.) has pedicelled blue or white fls., the pedicel equaling or exceeding the calyx. Var. sibirica, Makino (V. sibirica, Linn. V. verticillata var. sibirica, Hort.) has sessile or subsessile blue or white fls.; pedicels always longer than the calyx.

Section II. PSEUDOLYSIMACHIA.

1. A. Foliage and st. white-pubescent or white-tomento.
2. B. Base of lvs. cordate.
3. C. Foliage and st. nearly glabrous.
4. D. Lower lvs. petiolate.
5. E. Lower lvs. merely serrate or crenate.
6. F. Racemes panicled.
7. G. Racemes sericeous or fimbriate.
8. H. D. Lvs. lanceolate.
9. I. D. Lvs. ovate-oblong.

3. pinnata, Linn. Strong, upright plant 2–3 ft. high, glabrous or pubescent: lvs. sparse or somewhat clustered, finely cut, the lower lvs. with spreading segms., the upper pinnatifid, thickish, shining, smooth: racemes slender, many-fl., elongated: fls. blue, June, July. Open mountain slopes, Russia.

4. Bachofenii, Heuff. Perennial, white-pubescent: sts. several, ascending or erect, 1–2 ft. high: lvs. opposite, petioled, 1–2 x 1 in., cordate-oblong, acute, coarsely serrate; racemes terminal, 1–2, opposite, elongate: fls. blue; calyx-lobes < linear, subequal; corolla-tube inflated, lobes broad-lanceolate: caps. small, obcordate, slightly compressed, about equaling the calyx. Hungary.

5. spuria, Linn. (V. paniculata, Linn. V. augustifolia, Fisch., not Bernh. V. tinea, Soland. V. amethystina, Wild.) BASTARD SPEEDWELL. Upright, slender, densely pubescent species 2 ft. high: lvs. mostly opposite or ternate, 1 in. long, linear, acute, serrate-crenate toward the apex, entire below, smooth, narrowly at the base, thickish: racemes numerous, panicked, long, densely many-fl.: fls. blue, pedicellate: caps. nearly round, thick, exceeding the segms. May, June. G.W. 7, p. 337. Woods, S. E. Eu. and S. Russian Asia.—Becomes weedy late in the season. Var. elegans, Voss ex Wyman (V. elegans, DC. V. paniculata var. elegans, Benth.), has the lvs. pubescent on both surfaces and is more branched than the type. Belgium. Variants of this variety are known in horticulture as V. elegans var. cárnea, Hort., a form growing 1 ft. high and having spikes of rich pink fls. and the variegated form as V. elegans cárnea variegata.

6. longifolia, Linn. (V. maritima, Linn. V. hybrida, Georgi, not Linn. V. persicifolia, Schott. V. bracteata, Opiz, not Wild.) Strong, leafy, upright, densely growing species 2 1/2 ft. high, with usually a smooth st.: lvs. lanceolate or oblong-acuminate, sharply serrate. lower
VERONICA

opposite, upper more or less verticillate, pubescent below, very scaly. 2½-4 in. long; racemes long, erect, spiral, dense; fls. like, numerous; caps. longer than broad, notched, a little exceeding the linear sepals or sometimes exceeded by them. Becomes black in drying. July–Sept. Wet fields, Cent. and E. Eur. and N. Asia.–Much cult. and hybridized. Has several varieties. A fine border plant and the most common species, growing and flowering freely in any good soil. Var. alba, Hort. (V. maritima var. alba, Hort.), grows 1½-2½ ft. high; fls. white. Var. glauca, Hort., has glaucous blue foliage; fls. rich purple. Var. rosea, Hort. (V. rosea, Hort. V. hybrida rosea, Hort.). a probable variety with pink fls., 2½ ft. high and much branched. Hardy in Mass. Prop. by division and cuttings. Var. subsessilis, Miq. (V. subsessilis, Hoffm.). A Siberian form growing from a shortly creeping, almost woody root-stock: fls. smaller and narrower: raceme elongated, leafy, many-fid.; pedicels: caps. nearly round, slightly notched, exceeding the linear sepals or all material known as raceme usually somewhat elongated. (Subsection 3. Alpina.)

Plants 2½-6 in. high.

b. Fis. blue or violet. . . . . . . . . . . . 14. alpina
d. Fis. rose or white. . . . . . . . . . 16. repens

c. Plants ½-4½ ft. high (seldom less than 9 or 10 in.).

c. Fis. rose or white. . . . . . . . . . 16. repens

Subsection 1. Diffusa.

DD. Blades ovate, orbicular or oblong-spatulate.

DD. Blades linear-spatulate. . . . . . . 10. cespitosa

ER. Surface of leaf glabrous. . . . . . 9. Nummularia.

ER. Surface of leaf white-tomentose. . . 11. bombycina

CC. Inf. a very short (in fr. elongated)

raceme, few-fid. (Subsection 2. Fruticulosa.). . . 12. fruticulosa

Subsection 2. Fruticulosa.

12. fruticulosa, Linn. (V. saxatilia, Scop.). Perennial or shrubby; sts. diffusely branched, 2-6 in. high, woody at base: fls. ½-3½-in. long, oblong or ovate, entire or suberect; racemes lax, short, few-fid.; pedicels: fls. blue or flesh-colored; caps. ovate. July. Mountains of Eu. and Greenland. There is a white-flowered horticulturally known as V. saxatilia alba and also a form known in the trade as V. saxatilia Griseb.—Possibly not all material known as V. saxatilia belongs here.

Subsection 3. Alpina.

13. gentianoides, Vahl (V. gläber, Hort.). Erect, slender, tufted species 6–24 in. high, from creeping roots; lvs. ovate-oblong or ovate, some lanceolate or linear, thin-fibrous, entire or small crenate, smooth, 1–3 in. long; root-lvs. more or less in rosettes; upper lvs. bract-like, smaller and narrower; raceme elongated, leafy, many-fid., hairy; fls. pale blue, with darker streaks, on long pedicels; caps. nearly round, slightly notched, exceeding the calyx. Wet alpine fields, S. Eu. B.M. 1002. —A hardy species in any soil or location, shade-enduring though not necessarily shade-loving, blooming early. Prop. by division. Forms a mat and makes a good ground-cover for bare spots in midsummer; also a valuable border plant. One of the earliest. Var. alba, Hort., is a white-flowered form. Var. foliis variegatis, Hort.,
VERONICA

see var. variegata. Var. pallida, Hort., is offered in the trade as a variety with pale porcelain-blue fls. Var. pallidiflora, Hort., is a trade name, perhaps the same as var. pallida. Var. stenophylla, Hort., is a narrow-leaved form. Var. variegata, Hort., is offered in the trade as having lvs. variegated with creamy white. G.M. 54:575.

14. alpina, Linn. A slender delicate plant growing from a creeping stock, branching at the base, becoming ascending or upright, the fl.-st. often solitary, 2-6 in. high; lvs. opposite, occasionally alternate, subsessile, elliptic or oblanceolate, entire or dentate, about 1/4-1 in. long, of varying size, the lowest small, orbicular; raceme short, spikeform, dense; fls. small, blue or violet; caps. 1/3 in. long, oblanceolate, broader than long, hairy, exceeding the calyx. Mountains of Eut., Cent. and N. Asia, and alpine and arctic regions in Amer. B.M. 2975.—Adapted to the rock-garden. It blazzenes when dried.

15. serpyllifolia, Linn. (V. alpestris, Hort.). St. Paul’s Speedwell. Slender, ascending, nearly smooth plant, growing irregularly in clumps 2-4 ft. high, the base prostrate and rooting; lvs. ovate or oblanceolate, 1/2-1 in. long, smooth, variable; racemes loose, with conspicuous bracts; fls. pedicelled, white or pale blue with deeper stripes; caps. wider than long, obliquely notched, exceeding or equal to the sepal. May-July. Roadsides and fields, Asia, Eut., N. Afr., and S. Amer. 

16. repens, DC. Prostrate, slender, compact plant growing in dense masses; lvs. 1/2-3/4 in. long, ovate, slightly crenate, shining green and moss-like; racemes slender, few-fld.; fls. rose or nearly white, with a trace of blue; caps. broader than long, slightly papillose-pubescent: branches numerous, thin and long pedicels, of long duration: caps. broader than long, deeply notched, exceeding the sepals. May--July. Fields, Cent. and S. Eut., Asia and naturalized in N. Amer. F. 1846. p. 112.

17. syraca, Roem. & Schult. (V. pedunculata, Labill., not Vahl). Ascending, diffusely branched pubescent annual, 6-12 in. high; lvs. ovate or ovate-lanceolate, incised or dentate, smooth; lower petiolate, upper subsessile, 3/4 in. long; raceme terminal, slender, 4-6 in. long; fls. blue, with thread-like pedicels 1/3 in. long; caps. broader than long, notched two-thirds of its length, exceeding the sepal. June. S. W. Asia. B.O. 1897. p. 311. F.S. 12:1259. Var. flore-albo, Hart., is a trade name, perhaps the same as var. pallida. Ascending, diffusely branched pubescent annual, 6-12 in. high: lvs. ovate or ovate-lanceolate, suberectely truncate. Greece. B.M. 7759.

18. glauc4., Sibth. & Smith. Annual, suberect, ascending or upright, the fl.-st. often solitary, 2-6 in. long, short-petioled, elliptic-oblong, acute angled, 2-lobed to the middle. Base of caps. Totundate. South Africa and S. Afr., Mex. and intro. in Calif. Allied to V. serpyllifolia but dwarfer and more prostrate; grows in the sun. Will cover the ground where grass does not grow, forming a sod in a moderately dry soil. Var. alba, Hort., is offered in the trade as a variety with pale porcelain-blue fls. Var. pallida, Hort., is offered in the trade as a variety with white-puberulent fls. Var. stenophylla, Hart., is a narrow-leaved form.

Section V. BECCABUNGA.

A. Calyx 5-parted. (See also No. 40.) The species of this group are closely allied and often hard to distinguish. (Subsection 1. Pentasepalae.)

B. Lvs. bipinnatifid.

C. Base of caps. rotundate.

D. Calyx-seosem8. ovate-lanceolate.

E. Margin of blade sharply dentate.

F. Base of caps. obovate-orbicular, turgid and glandular. Persia.

Section VI. CHAMEDRYS.

19. Tournesfortii, C. C. Gmel. (V. Buxbaumii, Tenore). Prostrate annual, with elongated slender pubescent stems, the lower branching and often rooting; lvs. ovate, subcordate, coarsely crenate-serrate, pubescent, shortly petiolate, 3/4 in. long, the lower opposite, the upper alternate and similar; racemes axillary: fls. small, blue, crenate-tonged, on long pedicles, of long duration: caps. broader than long, very widely notched, exceeded by the sepal. April--Sept. Fields, Cent. and S. Eut., Asia and naturalized in N. Amer. F. 1846. p. 112.

Section V. BECCABUNGA.

21. Michauxii, Lam. Perennial, 4-5 ft. tall, everywhere pubescent: sts. erect, or ascending from rooting bases; lvs. ovate, crenate-dentate, lower and those of the sterile branches petiolated, the others clasping: racemes few, rather dense, from the upper axes: fls. pale blue (drying reddish); calyx-seosem8. oblanceolate, acute; caps. ovate-ornicular, turgid and glandular. Persia.
Subsection 1. Pentaspale

22. orientalis, Mill. Perennial, shortly and crisply pubescent, rarely glabrate: sts. from woody rhizomes, decumbent or prostrate: lvs. sessile, short, lower, at least long or lanceolate, dentate-incised, rarely entire; upper usually narrower, lanceolate: racemes 2-4, from the upper axis, second: fls. flesh-colored or pale blue; calyx-segments 4 or 5, linear-lanceolate, very unequal; caps. glandular-pubescent, obcordate or truncate. July. Asia Minor and Persia. L.B.C. 5:419. Var. tenutiloba, Boiss. (V. taitica, Willd.), has narrowly linear lvs., with the margins sometimes somewhat revolute, entire, rarely acutely toothed. S. Armenia and Persia. L.B.C. 10:911.

23. latifolia, Linn. (V. urticaefolia, Linn.). Perennial, sparsely and crisply hirsute: sts. erect: lvs. sessile, ovate, sharply serrate, base often cordate; upper long-acuminate: racemes opposite, laxy-pilose: fls. light blue or reddish; calyx-segments minute, lanceolate, rather acute, caps. ovate-oblong, base round. Eu.—Habitat of the cultural material under this name is apt to be a broad-leaved form of V. Teearum.

24. Telearium, Linn. (V. dentata, F. W. Schmidt. V. nitiata, Hort., ex Poir., not Ehrh.). Perennial, pubescent: sts. numerous, ascending, up to 20 in. high: lvs. ovate to lanceolate, nearly entire, crenate to even bluntly dentate-incised, mostly sessile: racemes opposite, elongated: fls. white, blue-veined, large; calyx-base: lvs. sessile, pinnatisect, opposite, laxly many-fid.: caps. ovate, blotched, sharply serrate, base often cordate; upper long-acuminate; lvs. sessile, petiolate, very broadly ovate, sometimes narrower, sub-acute; corolla-lobes lanceolate-linear, rather acute; corolla-lobes lanceolate: caps. obcordate, acute, puberulent. S. Eu.

25. austriaca, Linn. (V. multifida, Jacq., not Linn. V. orientalis, Willd., not Mill. V. prénia, G. Beck). Perennial, 1-2 ft. high, pubescent: sts. erect, rarely ascending: lvs. sessile, ovate in outline, pinnatisect, serrate with their base narrow or linear, entire or incised: racemes 2-4, from the upper axis, elongated, many-fid.: fls. large, blue; calyx-teeth 5, rarely 4, linear, strongly unequal: caps. hisrate, obovate-obcordate. S. Eu. and Asia Minor. B.M. 1679.—Probably not common in cult. and some at least of the material so named is probably V. austriaca.

26. multifida, Linn. Perennial, shortly and crisply pubescent: sts. decumbent and indurated at base or diffuse: lvs. sessile, pinnatisect in linear, entire or dentate-segments: racemes 2-4, axillary: fls. flesh-colored or pale blue; calyx-segments strongly unequal: caps. glabrous or short-glandular, transversely broader. June, July. Asia and Asia Minor. B.M. 1679.—Probably not common in cult. and some at least of the material so named is probably V. austriaca.

27. filifolia, Lipsky. Sts. several, ascending or erect, 6-12 in. high, crispily pubescent: lvs. sessile, bipinnatifid, divisions long, slender almost filiform: racemes 4-8, opposite, laxly: fls. white, blue, yellowed to brown; calyx-segments 4, almost equal, nearly linear, acute: caps. shorter than the calyx, strongly flattened, obcordate, transversely broader. Caucasus.—Near V. multifida.

Subsection 2. Strictiflorae

28. pectinata, Linn. Prostrate, white-pubescent, hairy, spreading plant rooting at the nodes, the ascending branches producing single elongated racemes: lvs. obovate or spatulate, sometimes pinnatifid: fls. narrow at the base, sessile, racemes elongated, many-fid.: lower bracts like lvs.: fls. deep blue with a white center: caps. larger, longer than broad, notched, puberulent, thick, exceeding the sepals. May-June. Dry, shady hills. Asia Minor.—Suitable for dry spots in a rock-garden. Grows in almost any soil and position. Var. rosea, Hort., has numerous small spikes of rose fls.

29. officinalis, Linn. (V. Allionii, F. W. Schmidt, not Vill.). COMMON SPEEDWELL. FLEUELEN. Ground-Horse. Prostrate, leafy native with a pubescent stem, rooting at the nodes, slender, 6-18 in. long: lvs. elliptic, oblong or broadly oblong, ½-1 in. and more long, hairy, serrate at base, evergreen, retaining color where most exposed: racemes slender, densely many-fid.: fls. pale blue, rarely pink, sessile: caps. broader than long, wedge-shaped, broadly notched, hairy, exceeding the hairy sepals. May-July. Forests and mountains of Eu. and N. Amer.—Grows under trees and in shade where no grass will grow, covering the ground with a permanent sod. Spreads rapidly and is easily grown. Prop. by cuttings.

Subsection 3. Multiflorae

32. piroleaformis, Franch. Perennial: sts. short, pilose below: lvs. nearly all clustered, petiolate, very broadly ovate, obovate or sub-spatulate, 3-fid.: corolla 3-fid.: fls. rose or pale violet; calyx-lobes glandular, ovate-oblong, obtuse: caps. rhomboid, broader than long. China.

34. scutellata, Linn. (V. angustifolia, S. F. Gray, not Bernh.). Perennial, 6-18 in. high, weak, glabrous or rarely puberulent: sts. slender: lvs. sessile, linear-lanceolate, acute, remotely and minutely denticulate: racemes filiform, flexuous, few-fid.: fls. whitish, bluish or flesh-color; calyx-segments oblong: caps. much wider than long, plano-compressed, 2-lobed, N. temperate regions.—Material offered in the trade as V. angustifolia should also be compared with V. austriaca and V. spuria.

Subsection 5. Petraeae

35. Baumgartenii, Roem. & Schult. (V. petrae, Baumg., not Stev.). Perennial, 3-6 in. high, possibly more, glabrous or minutely white-puberulent: sts.
slender, ascending: lowest lvs. minute; middle 6 lvs long, ovate or oblong, somewhat dentate; upper lanceolate, narrowed at base; fls. blue; calyx-segs. broadly lanceolate: caps. emarginate, glabrous. S. Hungary.—The material offered in the trade as V. petrea may belong here.

26. petraea, Stev. Perennial, cespitose, 4-5 in. high, minutely and crisply pubescent: sts. dwarf, diffuse and ascending: lvs. 6-10 lvs long, oblong or elliptic from a cuneate, subsessile base, few-toothed; upper lvs. sometimes entire: racemes axillary, solitary; peduncles rather long: fls. large and blue; calyx-segs. broad-oblong: caps. glandular-hirsute, 2-lobed, transversely broader, base rotund, apex retuse. Caucasus.—The material offered in the trade under this name may be V. Baumgartneri.

27. telephifolia, Vahl. Perennial, creeping or tufted, glabrous, glaucous: branches diffuse, filiform but rather hard and fragile, rooting: lvs. fleshy, bluish green, small, 2-3 lvs long, oblong-obovate or oblong, short-petioled: peduncles axillary, solitary, ending in a short sessile, obtuse, entire, both surfaces hispid; fls. solitary and axillary, pale blue (rich blue according to the trade); calyx 4-5-parted, segms. linear-oblong; corolla 4-lobed, lobes oblong: caps. small, broadly oblong, slightly compressed. Late-flowering. New Zealand.

3015. Veronica Andersonii (x3). No. 41.

30. Biddwillii, Hook. f. Perennial, about 3 in. high: sts. slender, prostrate and rooting, much branched, woody at base, 3-12 in. long; branches creeping, often matted, glabrous or pubescent: lvs. short-petioled or almost sessile, minute not more than 1/4 in. long, broadly oblong or ovate with 1 or 2 deep notches on each side or entire, coriaceous: peduncles axillary, slender, erect, 3-9 in. high, few- or many-fl.: fls. white, calyx-segs. 4, ovate or oblong, obtuse: caps. broadly oblong. June. New Zealand.

40. canescens, T. Kirk. Perennial, small creeping and rooting herb with intricately branched sts. 1-4 in. long, often forming broad matted patches, hispid with grayish white hairs: lvs. minute, short-petioled or nearly sessile, obtuse, entire, both surfaces hispid: fls. solitary and axillary, pale blue (rich blue according to the trade); calyx 4-5-parted, segms. linear-oblong; corolla 4-lobed, lobes oblong: caps. small, broadly oblong, slightly compressed. Late-flowering. New Zealand.

Section VII. Hebe.

a. Lvs. strictly scale-like, connate and appressed. (See also No. 54 which has somewhat scale-like but recurved spreading lvs.)

b. The lvs. densely imbricated ....... 50. Hectori

b. The lvs. in distant pairs ....... 60. cupressoides

AA. Lvs. not strictly scale-like and appressed. (No. 54 has somewhat scale-like but recurved spreading lvs.)

BB. Margin of lvs. coarsely serrate. ....... 58. Huileana

CC. Margin of lvs. entire or minutely incised.

d. Blades more than 3 in. long (occasionally less in No. 42).

d. Blades less than 3 in. long.

dd. Apeck of lvs. obtuse ....... 41. speciosa

dd. Apeck of lvs. acute or acutish.

ee. Caps. three length of calyx ....... 44. macrolepis

ee. Caps. twice or less length of calyx.

ff. Fls. 1/4 - 1/3 in. across.

ff. Fls. 1/2 - 1/3 in. across.

gg. Calyx-segs. narrow-oblong: fls. 1/4-1/3 in. diam. ....... 42. macrolepis

gg. Calyx-segs. lanceolate or wide-lanceolate to ovate-oblong: fls. 1/3-1/2 in. diam. ....... 43. salicifolia

hh. Apex of lvs. acute. ....... 51. buxifolia

hh. Apex of lvs. obtuse, red-margined. ....... 49. Balfouriana

ii. Fls. in a spike ....... 52. glaucophylla

ii. Fls. solitary in a spike; ....... 51. buxifolia

iii. Apeck of lvs. obtuse, red-margined. ....... 49. Balfouriana

iv. Apeck of lvs. not glossy.

v. Apeck of lvs. glossy; fls. in a spike ....... 51. buxifolia

vi. Calyx 4-parted. ....... 53. acaulis

vi. Calyx 5-parted....

vii. Calyx 5-parted....

viii. Calyx 5-parted....

ix. Color of fls. white ....... 50. pinguiifolia

ix. Color of fls. blue ....... 51. glauco-

x. Lvs. green. ....... [carolea

x. Lvs. green. ....... 55. chathamica

xx. The blades flat. ....... 53. chathamica

xx. The blades recurved. ....... 54. epacrida

xx. Blades broadly obovate. ....... 54. epacrida

xx. Blades broad-lanceolate. ....... 55. loganioides

41. speciosa, R. Cunn. Stout half-hardy shrub, 2-5 ft. high, with stout, spreading leafy branches and crimson-purple fls.: lvs. 2-4 in. long, ovate or obovate-oblong, sub sessile, dark green, thick, smooth, glossy, entire, rounded at apex: racemes axillary and opposite near tips of branches, stout, dense-fl.: fls. large, 1/2-1 in. diam., purple-crimson: caps. more than twice as long as the calyx. Summer. New Zealand. B.M. 4637. F.S. 1:19. R.I. 1844:60. H.U. 6, p. 349. Var. corombyfera, Hort., is offered in the trade as growing 2 ft. high with rosy fls. Var. rubra, Hort., is offered in the trade. Var. variagata, Hort., is offered as a form growing 6 ft. high with large lvs. variegated with creamy white; fls. light blue. Probably really the variegated form of V. Andersonii. Intro. into S. Calif.—V. imperialis, Hort. (V. speciosa var. imperialis, Boncharlat), seems to be merely a garden name for the true species. F.S. 22:
2317. *V. spectosa* hybridizes freely and there are several garden forms closely allied to it. The best known is *V. Andersonii*, Lindl. & Paxt. (V. salicifolia × *V. spectosa*. *V. spectosa* var. Andersonii, Hort. V. Hendersoni, Hort.)—Fig. 3915, is grown in the greenhouse and is also used as a bedding plant. It grows 18 in. high: lvs. oblong, sessile, entire or crenate, dark green above, bluish white beneath; racemes about 1 in. long, corymbosely branched; fls. white or pale lavender-blue, about 2 in. across; calyx usually 3-parted, rarely 4-parted; corolla 4-lobed: caps. ovate, turIDDLE. New Zeal. B.M. 7539. Gn. 43, p. 519.

47. *formosa*. Br. Evergreen corystemons, branching shrub, 2–4 ft. high, practically glabrous; lvs. rather crowded, thin, acute, narrowly oblanceolate, ½–1 in. long, acuminate, truncate at base, pale green, rather thick, margins with white pubescence, midrib prominent beneath; racemes near tips of branches, 1–1½ in. long, laxly 12-fl.: fls. large, blue for a brief period, then white, sweet-scented: caps. twice as long as calyx. Late summer. Sea-coast on rock or on ground mixed with other shrubs. Subantarctic S. Amer., Lord Auckland and Campbell Isls. and New Zeal. B.M. 242. J.H. III. 52:38.—V. Lévisii, J. B. Armstrong, a desirable half-hardy, late-blooming species is related to the above and may be a hybrid. It has larger lvs., denser-flowered racemes 2–2½ in. long and very large white fls.

49. *Balfouriana*. Hook. f. Erect, glabrous shrub, 3 ft. high: lvs. sessile, ½–¾ in. long, elliptic-ovate, subacute or obtuse, margins red-brown: racemes 2–3 in. long, many-fl.: fls. pale violet-blue, calyx-segments acuminate: caps. one-third longer than calyx-segments or less. B.M. 7556.—Raised in the Royal Botanic Garden, Edinburgh, from seed sent from New Zeal. but it has not been found growing wild as yet, nor is it cultivated in New Zeal.

50. *Traversii*. Hook. f. Fig. 3916. Shrub of dense habit forming a globose mass of leafy, slender sts. 3–4 ft. diam.: lvs. ½–1 in. long, elliptic-oblong to linear-oblong, green, leathery, acute: racemes near tips of branches, 1–3 in. long, generally tapering: fls. white, calyx-segments broad, ovate or oblong: caps. twice as long as calyx. Midsummer. New Zeal. B.M. 6390. G. L. 25:139. G.M. 45:84; 53:630. Gn. W. 12, p. 161.—V. monticola, J. F. Armstrong, includes a number of distinct plants much resembling *V. traversii*, but their lvs. are frequently obtuse and racemes much shorter. Gn. 43, p. 522. V. lúisii, Benth., is similar to *V. monticola* but it differs in its corymbosely-branched inflorescence. *V. subalpina*, Cockayne, has softer, brighter green lvs., shorter racemes and corolla-tube. It also blooms earlier than *V. traversii*.

51. *buxifolia*. Bentham. Under this name are included many most distinct plants, but all possess green, glossy, acute, thick, petioled lvs., truncate at the base and keeled beneath, which in one form are golden variegated when young, sessile fls. in spikes ½–1 in. long and if-like bracts as long as or longer than the calyx. Var. odória, T. Kirk (var. petens, Cheesem.), is perfectly globular in form. Var. prostrata, Cockayne, is quite prostrate with rooting branches.—Another form, not yet named, is erect, 2–3 ft. high, and sparingly branched. Late summer. New Zeal. V. anómala, J. B. Armstrong, distinguished from *V. buxifolia* var. odória by its sometimes 3-lobed corollas and its narrower lvs., with purplish tips is nevertheless a most distinct and handsome plant. B.M. 7360.

52. *glaucophylla*, Cockayne (V. Colésonii var. glaica, Hort.). Closely related to *V. Traversii* but at once distinguished by the small, narrow, not keeled, glaucous lvs., slender tapering racemes of white fls. short corolla-tube hairy with pubescent ovary. Summer. Dry montane and subalpine stations, New Zeal.
—There are several forms of this striking fairly hardy shrub quite distinct for garden purposes, one of which is known as V. Cotonea var. glauca fana, Hort. The species is not related to V. Cotonea, Hook f., a plant not yet in cult., which has been placed in section Chamredrys by some, in section Hebe by others.

53. Chamaecistis, Buch. A rather tender polymorphic species, the leaves of which are distinguished by the trailing, flexible branches, elliptic or elliptic-oblong, rather fleshy, pale green, often more or less pubescent lvs., and short, dense, obtuse racemes of violet lfs. Late summer. Chiefly in the southwest. (V. M. 7290).

54. Eperisubas, Hook. f. Prostrate, almost hardy shrub of spreading habit: lvs. closely quadriangularly imbricated, opposite pairs united at base, spreading, recurved, 3½–4 in. long, broadly ovate-oblong, leathery, cuneate, glabrous, keeled, rounded or subacute at apex: fls. small, white, in dense terminal ovoid heads. Early summer. Mountains, New Zealand. V. Halstonii, Hook. f., is closely related to the above but is a larger plant with the lvs. more fleshy and not recurved or keeled. Both are admirable rock-garden plants of a most distinct appearance.

55. Loganoides, J. B. Armstg. Dwarf shrub, 6–14 in. high: sts. woody, decumbent at base, erect above; branches grayish white-pubescent or almost villous: lvs. diam. ½–1½ in. long, glabrous, entire. or with 1 or 2 small teeth, dull green, keeled leathery: racemes forming a small corymb-like head: fls. ± in. across, white or white with pink veins; calyx deeply 4-parted, segms. ovate-oblong, ciliolate: corolla 4-parted, dillyom, turgid. New Zealand. B.M. 7404.—A species of doubtful systematic position, by some placed in section Chamaedrys.

56. Pinguifolia, Hook. f. (V. carnosula, Hort., not stricta, Bieb.). Branches stout, more or less decumbent, ringed with lfs.-sars. imbricating to erect-patent, sessile, narrow-oblong to almost orbicular, ½–3½ in. long, glabrous, usually thick, glaucous, generally margined red: spikes crowded near tips of branches, short, stout, dense-fl.: fls. white, ovary pubescent. Summer. Mountains, to 7000 ft., New Zealand. B.M. 6857.—A fairly hardy polymorphic species containing many most distinct plants admirably suited for rockeries. The forms with larger almost orbicular lvs. are generally termed V. cotonea in gardens, but this species, distinguished by its glabrous ovary and acute caps., is probably not in cult. V. amphicribalis, J. F. Armstg., is an extremely striking allied plant readily distinguished by its larger glabrous ovary, subacute, or serrate, rather obtuse, keeled; V. lyrripodium, Hook. f., branches acutely 4-angled, lvs. narrowed into a blunt point; V. Armstrongii, Koenig, branches filabellate, tereve, lvs. subacutate, fls. pale lilac; V. salicornioides, Hook. f., branches terete, lvs. united to much above middle, subtruncate, fls. white. V. prospina, Chelse. (V. cupressoides var. variabilis, N. E. Br.), was for many years cult., in gardens under the name of V. salicornioides but it is semi-dwarf, with slender branches about ¾ in. diam. and minute lvs.

V. amnica, Hort., not Bieb., is described as growing 1 ft. high, flowering early: fls. rose, in neat spikes. The true V. amnica is apparently not in cult.—V. angustifolia var. roena, Hort., is offered in the trade as shrubby with fls. bright rose in spikes; not determinable botanically as the specific name angustifolia has been used for several different forms.—V. bocholonomii, Hort., is offered in the trade as growing 4 ft. high: fls. white, ovary pubescent, possibly the same as V. Bischumii.—V. Bischumii, Hort., is offered as growing 1½ ft. high, of coarse texture, with the same name as V. Bischumii.—V. corymbosa, Don., is offered in the trade, but it is not now included in any of the Swiss botanists. The nomenclature passing under this name in the trade may be described as follows: Low, trailing perennial, growing in a dense mass: lvs. leathery, crenate to dentate, pubescent; corolla deep blue, racemes many, in 6 in. high, small, dark blue. May, June, Coneddest one of the best. Valuable as a ground-cover, or as a rock-plant, or at the front of an herbaceous border. Usually cultivated: V. tricolor, Don., is offered in the trade as a dwarf plant with small leaves, with pink, blue and white fls., growing less than ¾ in. high, with densely glomerate heads of dark blue fls. is offered in the trade under this name.—V. edeliana=V. Hectorii, Hort., 1835, pinneolidae.—V. elegansima, Hort., is a trade name.

—V. Fouchtii, Diels. Perennial, 6–10 in. high: stns. decumbent, creeping, branched and stoloniferous at base: lvs. petiolate, narrowly ovate or oblong, ½–3 in. long, glabrous, pubescent or almost pubescent, often purplish beneath: racemes terminal or axillary, fls. reddish, sepals oblong, chocolate-oblong, glandular-puberulent; calyx pubescent or hairless capsule oblong, rather oblong. Mountainous of W. Yunnan, China.—V. pinnatifida, Hort., is a trade name. V. galpinii, Hort., was a hybr1d, said to grow 9 in. high: fls. blue. V. keilbergii, Hort., is offered in the trade as having narrow foliages and starry blue fls.—V. koeini, Hort., is offered in the trade as having large trusses of pink fls.—V. Lithouardii, Hort., is a trade name. V. Listenfa, Hort., is offered in the trade under the name of V. salicifolia, Hort., 1835, pinneolidae.—V. elefantinae, Hort., is a trade name. V. Lavaudiana, Hort., 1840 presented as a dwarf variety, yellow, with strong racemes of purplish fls. borne in June and a four-parted calyx. The caps. are obconic. This plant has been offered by Rochester nurseriesmen ever since 1853. V. Lavaudiana, Hort., 1840, presented as a dwarf variety, yellow, with strong racemes of purplish fls. borne in June and a four-parted calyx. The caps. are obconic.
saries," which, when kept wet and placed in a current of air, cools and perfumes the atmosphere. The rhizome when laid away among them is said to keep clothing free from moths. For history of this grass, see Kew Bull. Misc. Inform. No. 8, 1906. A. S. Hitchcock.

**VIBURNUM** (the ancient Latin name). *Caprifoliaceae*. Ornamental woody plants grown for their attractive flowers, fruits, and foliage.

Deciduous or sometimes evergreen shrubs, rarely small trees, with opposite stipulate or cymose flowers; fls. small, in terminal panicle or mostly umbel-like cymes; calyx with 5 minute teeth; corolla rotate or campanulate, rarely tubular; stamens 5; ovary usually 1-seeded; fr. a drupe with a 1-seeded, usually compressed stone. In several species the marginal fls. of the cymes are sterile and radiate; such are *V. macrocephalum*, *V. tenumtosum*, *V. Opulus*, *V. americanum*, *V. Sargentii*, and *V. alnifolium*, and of the 3 first-named garden forms are known with all fls. sterile and enlarged.---About 120 species in N. and Cent. Amer. and in the Old World from Eu. and N. Afr. to E. Asia, distributed as far south as Java. For a key to the 65 species known from E. Asia, see Rehder, *The Viburnums of Eastern Asia*, in Sargent, Trees and Shrubs, 2:105-116.

The viburnums are upright mostly rather large shrubs or sometimes small trees with usually medium-sized deciduous or evergreen foliage and white or sometimes pinkish flowers in showy flat clusters or sometimes in panicles, followed by berry-like subglobous to oblong, red, dark blue, or black fruits. The viburnums rank among the most valuable ornamental shrubs. Besides showy flowers and decorative fruits they possess handsome foliage which mostly assumes a bright fall coloring. The plants are of good compact habit. Most of the deciduous species are hardy North, but *V. macrocephalum* var. sterile and *V. oblongum* are tender; also *V. tomentosum*, *V. Wrightii*, *V. theferum*, *V. cassinifolium*, *V. nudum*, and *V. dilatatum* are not quite hardy farther north than New England. Of the evergreen species, *V. rhytolphyllum* is the hardiest and at the same time one of the most distinct and handsome species of the genus, with its bold foliage and the large clusters of flowers and fruits; it is hardy as far north as Massachusetts in favorable positions; also *V. japonicum* stands several degrees of frost, but cannot be relied on north of Philadelphia; *V. odoratissimum* and *V. suspensum* are still tenderer. The viburnums are well suited for borders of shrubberies or planting along roads, and the more showy ones are handsome as single specimens on the lawn. They are mostly deciduous shrubs, 5-10 feet high, but *V. Lenoago*, *V. prunifolium*, and *V. rufidulum* sometimes grow into small trees, 30 feet high, while *V. cassinifolium* hardly reaches 5 feet. The most decorative in fruit are *V. Opulus*, *V. dilatatum*, and *V. Wrightii*, which mostly assume a bright scarlet or red berries which remain a long time on the branches. Besides the snowball forms, *V. dilatatum*, *V. tomentosum*, *V. Sieboldii*, *V. prunifolium*, *V. rufidulum*, *V. venosum*, and *V. den-
The familiar snowball is seriously attacked by aphids! Fortunately its place can be taken by a Japanese species that is even more satisfactory. (Fig. 3923.) The berries of its fertile type, V. tomentosum, are a brilliant scarlet, changing to black. The foliage of this snowball is also remarkably beautiful. The olive-green with brownish purple or bronzy margins, and their plicate character makes them very distinct and attractive. The bush is entirely free from insect pests. The single and double forms of the Japanese species differ as shown in Figs. 3922 and 3923. Unfortunately these "single" and "double" forms have been confused in many nurseries, and only the trained eye can tell them apart in the nursery row. The double or snowball type is, of course, the one destined to the greater popularity, though the single form is a shrub of great value, especially for large estates and parks. The double form is known to nurseries as V. prunifolium, but its proper name is V. tomentosum var. plenum. While it is hardy in New England, it is not a shrub that can be transplanted as easily as many other species. Hence it should be transplanted every second year in the nursery until it is sold. The double form may be propagated by cuttings of half-ripened wood in close frames, or by layers, which in some soils would better remain two years. French nurserymen propagate it by layering. The layers seem to suffer from winter and, to be on the safe side, it is best to cover them well with moss or leaves when the ground is somewhat frozen, so that the frost may be kept in until spring. The clusters are about as big as oranges and pure white. They are in great demand for Decoration Day in New York. The single form, unlike the double, is easily transplanted. It is also readily propagated by layers or cuttings. Both kinds are hardy in the North and make compact bushes 6 to 8 feet high.

VIBURNUM

1. Sięboldii, Miq. Fig. 3918. Deciduous shrub, attaining 10 ft., with stout branches, pubescent when young; lvs. oval to oblong-obovate, coarsely crenate-serrate except toward the base, acute, dark green and shining above, paler and stellate-pubescent beneath, 3-6 in. long; frs. white, rotate-campanulate, in panicles 2½-4 in. broad; frs. pink, changing to blue-black. May, June. Japan. G.F. 2:559 (adapted in Fig. 3918). S.I.F. 1:86. F.E. 23:345. —Hardy shrub of vigorous growth with handsome dark green foliage, large for the genus, exuding a disagreeable odor when bruised. The frs. drop soon after ripening. It is known in some nurseries as V. japonicum, V. latifolium, or V. japonicus latifolium. Var. reticulatum, Rehd. (V. reticulatum, Hort.). Smaller in every part: lvs. of lighter green, less pubescent: half-hardy. Var. variagatum, Hort. Lvs. variegated with white.

2. suspensum, Lindl. (V. Sandakowa, Hassk.). Evergreen shrub, attaining 6 ft., with slender warty branches: lvs. oval to oblong-obovate, acute or obtuse, usually remotely crenate-serrate toward the apex, shining and bright green above, paler beneath, glabrous, 2-4 in. long; frs. white, tinged pink, in dense semi-globose panicles becoming 1½ in. high; corolla ½ in. long, with cylindrical tube twice as long as limb: fr. red, subglobose. June, July. Liu-kiu Isl. B.M. 6172. —Tender.

3. odorifæsimum, Ker (V. Awabickii and V. Awafuki, Hort.). Evergreen upright shrub, attaining 8 ft., with stout warty branches, glabrous: lvs. elliptic to elliptic-oblong, acute, remotely serrate toward the apex or entire, shining and bright green above, paler beneath, glabrous, 2-4 in. long; frs. white, tinged pink, in dense semi-globose panicles becoming 1½ in. high; corolla ½ in. long, with cylindrical tube twice as long as limb: fr. red, subglobose. May, June. India to S. China and Japan. B.R. 456. S.I.F. 1:88.:—Tender.

4. Thymus, Linn. (V. Laurustinus, Hort. Thymus laur-リフォinus, Boreckh.). LAURUSTINUS (or LAURESTINUS) Bushy, 10 ft., with glabrous or somewhat hairy branches: lvs. ovate-oblong or oblong, acute, dark green, shining and glabrous above, pubescent beneath usually only on the veines, 2-3 in. long: fr. white or pinkish white, slightly fragrant: cymes somewhat concave, 2-3 in. broad: fr. ovoid, black, rather dry. May-
CXVI. Viburnum tomentosum.

brous above at length: fls. white or yellowish white: cymes rather long-peduncled, 3-5 in. broad: fr. globose, pink at first, changing to dark blue. June, July. Long Island to Fla., west to Ky. and La. B.M. 2281.—Not quite hardy. Var. nigricans, Zabel (var. angustifolium, Torr. & Gray). Var. nigricans, Willd. WITHE-ROD. Small. Large shrub or small tree, attaining 25 ft. or more, with rather stout branches: winter buds more pointed, obtuse, rusty-pubescent: petals often with narrow margin, rusty-tomentose: lvs. elliptic to ovalate, usually obtuse, glabrous or scurfy at the veins beneath, 2-4 in. long: fls. pure white: cymes sessile, 2-5 in. broad: fr. oval, bluish black, with bloom. May, June. Hudson Bay to Man., south to Ga. and Miss. S.S. 5:223, 224.—Handsome arborescent shrub, keeping its lvs. until spring. Sometimes as V. prunifolium and V. ferrugineum in gardens. A garden hybrid, originated in Germany, is V. Vellern, Zabel (V. Lentago x V. nudum), similar in habit to this species but the cymes on short peduncles over 1/2 in. long.

12. macrocephalum, Fortune. Shrub, attaining 12 ft. and occasionally more, with spreading branches: lvs. short-petioled, oval to ovate-oblong, rounded at base, acute, dentate, almost glabrous and dark green above, stellate-pubescent beneath, 2-4 in. long: fls. yellowish white, in peduncled cymes, 3-5 in. across, with the mar-

3919. Viburnum cassinoides. (X3/4)

brous above at length: fls. white or yellowish white: cymes rather long-peduncled, 3-5 in. broad: fr. globose, pink at first, changing to dark blue. June, July. Long Island to Fla., west to Ky. and La. B.M. 2281.—Not quite hardy. Var. nigricans, Zabel (var. angustifolium, Torr. & Gray). V. nigricans, Willd. WITHE-ROD. Small. Large shrub or small tree, attaining 25 ft. or more, with rather stout branches: winter buds more pointed, obtuse, rusty-pubescent: petals often with narrow margin, rusty-tomentose: lvs. elliptic to ovalate, usually obtuse, glabrous or scurfy at the veins beneath, 2-4 in. long: fls. pure white: cymes 3-5 in. broad: fr. oval, dark blue, glaucous, little over 1/2 in. long. April-June. Later than the following species. Va. to Fla., west to Ill. and Texas. S.S. 5:225 (as V. prunifolium, partly).—Handsome arborescent shrub with dark green shining foliage, showy fls. and decorative fr.; has proved hardy at the Arnold Arboretum, Boston.

12. macrocephalum, Fortune. Shrub, attaining 12 ft. and occasionally more, with spreading branches: lvs. short-petioled, oval to ovate-oblong, rounded at base, acute, dentate, almost glabrous and dark green above, stellate-pubescent beneath, 2-4 in. long: fls. yellowish white, in peduncled cymes, 3-5 in. across, with the mar-

8. cassinoides, Linn. (V. nudum var. cassinoides, Torr. & Gray. V. aquinatum, Willd.). WITHE-ROD. APPALACHIAN TEA. Fig. 3919. Upright shrub, 2-6, occasionally 12 ft. high: lvs. oval to ovate, acute or bluntly acuminate, usually obscurely dentate, almost glabrous, rather thick, dull green above, 1-3 in. long: fls. and fr. almost like those of the preceding species, but peduncle shorter, usually shorter than cyme; blooming a little earlier. June, July. Newfoundland to Man. and Minn., south to N. C. G.F. 9:305 (adapted in Fig. 3919). M. D. G. 1901:85, 86. Em. 2:411 (as V. nudum).—A good shrub for borders of shrubberies; hardy.

9. Lentago, Linn. SHEEP-BERRY. NANNY-BERRY. Fig. 3920. Shrub or small tree, attaining 12 ft., with spreading branches: winter buds short, 3-4 in. long: fls. white: cymes large, in peduncled cymes, 3-5 in. across, with the margins nearly like those of the preceding species, but peduncle shorter, usually shorter than cyme; blooming a little earlier. June, July. Newfoundl.
3460 VIBURNUM

The wild form with only the marginal fls. sterile and enlarged; has proved hardy at the Arnold Arboretum.
hardy than the type.
13. rhytidophyllum, Hemsl. Evergreen shrub, to 10 ft., with stout upright branches; branchlets densely
stellate-tomentose: lvs. thick, ovate-oblong to oblong-lanceolate, acute or obtuse, rounded or subcordate at
the base, dark green, glabrous and lustrous and deeply wrinkled above, covered with a thick gray or yellowish
tomentum beneath and reticulate, entire or indistinctly dentate, 3–7½ in. long: fls. yellowish white, ¾in.
across, in terminal cymes 4–8 in. across formed in autumn and expanding the following spring: fro ovoid,

most charming viburnums, opening its deliciously fragrant pink-and-white fls. early in spring with the
unfolding lvs.; it has proved hardy at the Arnold Arboretum. A closely related species which has been
confused with V. Carlesi is V. bichuiense, Makino. A slenderer, more straggling shrub: lvs. smaller, usually
obtuse and often subcordate; fls. in smaller cymes; anthers inserted near the base; filaments longer than
anthers. Japan. Less handsome than V. Carlesi.
15. Lantana, Linn. WAYFARING TREE. Upright shrub or sometimes small tree, attaining 20 ft.: young
branches scurfy-pubescent: lvs. ovate or oblong-ovate, usually cordate at base, acute or obtuse, sparingly stel-
late-pubescent and wrinkled above, tomentose beneath, denticulate, 2–4 in. long: fls. white, in dense terminal sub-
globose cymes 2–3 in. across, appearing with the lvs.; stamens included, inserted about the middle; filaments

16. cotinifolium, D. Don (V. multratum, C. Koch). Shrub, attaining 6 ft., with spreading branches, tomento-

case when young: lvs. orbicular-ovate to ovate, cordate or rounded at the base, usually obtuse, exscinde-
tenate or almost entire, wrinkled above and nearly gla-
brous at length, tomentose beneath, 2–5 in. long: fls.
white, tinged with pink, in cymes 2–3 in. broad, with
usually 5 rays; corolla rather larger, funnel-shaped cam-
panulate, tube longer than limbs: fr. ovate-oblong, red,
H.W. 3, p. 131. Gn. 61, p. 324.—Hardy shrub, especially for drier situations and limestone soil. Var.
rugosum, Hori. With larger and very wrinkled lvs.
and larger cymes. There are a number of other varie-
ties, including some with variegated lvs.
10. alnifolium, Marsh. (V. lantanoides, Michx.). HOMELINESS.-AMERICAN WAYFARING TREE. Fig. 3921.
Low shrub, sometimes 10 ft. high, with spreading branches, tomentose when young: lvs. orbicular-ovate to ovate, cor-
date or rounded at the base, usually obtuse, exscinde-
tenate or almost entire, wrinkled above and nearly gla-
brous at length, tomentose beneath, 2–5 in. long: fls.
white, tinged with pink, in cymes 2–3 in. broad, with
usually 5 rays; corolla rather larger, funnel-campanulate, tube longer than limbs: fr. ovate-oblong, red,
Not quite hardy N., requiring protection near Boston.
11. alnifolium, Marsh. (V. lantanoides, Michx.). HOMELINESS.-AMERICAN WAYFARING TREE. Fig. 3921.
Low shrub, sometimes 10 ft. high, with spreading branches, tomentose when young: lvs. orbicular or broadly ovate, cor-
date or rounded at the base, short-acuminate or acute, irregularly serrulate, minutely pubescent or almost glabrous

22. **wrightii**, Miq. Upright shrub, to 10 ft. high, with the branches almost glabrous: lvs. almost orbicular or broadly obovate to ovate, abruptly acuminate, coarsely dentate, almost glabrous except on the veins beneath, 3-5 in. long; fls. rather large, white, in usually short-stalked, 2-4-in.-broad cymes; corolla glabrous outside; stamens longer than the corolla: fl. globose, red. May, June. Japan. S.T.S. 1:19.-Hardy shrub, similar to the preceding, but of less dense habit, with larger fls.

---

above, subrally pubescent beneath, 3-8 in. broad: fls. white: cymes sessile, 3-5 in. broad; marginal fls. enlarged and sterile, long-pedicelled: fr. ovoid-oblong, dark purple. May, June. New Bruns. and Mich. to N. C. G.F. 2:635 (adapted in Fig. 3921).—Handsome shrub, with very large foliage, assuming a deep claret-red in fall. Var. *praeceptor*, Hesse. Said to bloom about 3 weeks earlier than the type. M.D. 1912, p. 370. G.W. 16, p. 495.

20. **fötáium**, Wall. (V. cœanohoides, C. W. Wright). Upright shrub with spreading branches, to 10 ft.: branchlets stellate-pubescent; lvs. obovate to rhombic-or obvate-oblong, acute or acutish, rarely short-acuminate, cuneate at the base, sinuate toothed above the middle, 3-nerved at the base and with 1 or 2 pairs more of lateral veins, glabrous above, pubescent on the veins beneath, 1½-2½ in. long; petiole ½-1⅛ in. long; fls. white, in cymes 2-4 in. across on lateral spreading branchlets: fr. scarlet, ovoid, ½ in. long. June. Himalayas, S. W. China. Var. *rectangulum*, Rehd. (V. rectangulum, Gnubra). Shrub, to 12 ft., with spreading, often pendulous branches: lvs. oblong-obovate to lanceolate, acuminate, remotely dentate or denticulate, usually nearly glabrous, 1½-3 in. long; cymes on slender, lateral branchlets often spreading at right angles. W. China.

21. **dilatátum**, Thunb. Fig. 3924. Upright bushy shrub, attaining 10 ft., with the branches hirsute when young: lvs. roundish or broadly ovate or obovate, usu-

25. venosum, Brit. (V. moUe, Auth., not Michx. V. Hanceanum, Dipp., not Maxim. V. nepalense, Hort.). Fig. 3925. Shrub, to 5 ft., with grayish brown branches; young branchlets stellate-pubescent; lvs. ovate to orbicular, coarsely and sharply dentate, glabrous or nearly so above, stellate-pubescent beneath, particularly on the veins, 2-5 in. long, with prominent veins beneath; petioles 1/2-1 in. long, pubescent; cyme long-stalked, slightly pubescent, 2 1/2-4 in. across; fr. globose or globos-ovoid, 1/2 in. long, bluish black. June, July; fr. in Sept., Oct. New Bruns. to Minn., south to Ga. G.F. 10:332.—Has proved hardy at the Arnold Arboretum.

26. pubescens, Pursh. Fig. 3926. Bushy shrub, 3-6 ft. high, with slender, upright branches; lvs. oval to ovate, rounded or cordate at base, acute or acuminate, coarsely dentate-serrate, glabrous or nearly so above, stellate-pubescent on the veins, 1 1/2-2 1/2 in. long; cymes short-peduncled, pubescent, 1 1/2-2 in. broad; stamens exceeding the corolla about one-half; fr. oval, almost black, slightly flattened. June, July. Que. to Ga., west to Man. and Ill. G.F. 3:125 (adapted in Fig. 3926). A.F. 12:1101. G.B. 5:311. M.D.G. 1903:404.—Handsome shrub of compact habit. Var. affine, Rehd. (V. affine, Bush). Lvs. nearly glabrous; petioles 1/2-1 in. long, sometimes shorter. Mo.

27. moUe, Michx. (V. Demetrians, Deane & Rob.). Shrub, to 12 ft.; bark separating in thin flakes; lvs. orbicular or broadly ovate, cordate, shortly acuminate, coarsely dentate, pubescent beneath or almost glabrous, 2 1/2-4 in. long; cymes long-peduncled, puberulous, about 2 1/2 in. broad; fr. oblong, almost 1 1/2 in. long, bluish black. May; fr. in Aug. Ky., Mo., Iowa. B.B. (ed. 2) 3:272.—Has proved not quite hardy at the Arnold Arboretum.

30. aucifolium, Raf. Straggling shrub, attaining 5 ft.; lvs. orbicular to oval, coarsely dentate, with 3 short lobes above the middle or often without, glabrous or slightly pubescent beneath when young, 2-3 1/2 in. long; cymes few-fl., small, on lateral, short usually 2-lvd. branches: fr. scarlet, subglobose. June. Lab. to Alaska, south to Vt. and Colo. in the mountains. G.F. 3:5.—It does not usually succeed well in cult.; requires shade and moist porous soil.

VIBURNUM

3463

Gug. 1:9. Gn. 56, p. 83; 76, p. 35. F.E. 15:319; 20:813. G.W. 6, p. 159.—This is a very showy variety, but it lacks the decorative frs. Var. xanthocarpum, Spach. Fr. yellow. There are also variegated forms of the type and of the sterile variety.

32. americanum, Mill. (V. Opulus var. americanum, Ait. V. Trilobum, Marsh. V. opuloides, Muhl. V. edule, Pursh. V. Oxyacum, Pursh.) CRANBERRY BUSH. HIGH CRANBERRY. Fig. 3928. Closely allied to the preceding species, but habit more open and spreading; lvs. with coarsely toothed or nearly entire lobes, pilose on the veins beneath or nearly glabrous, 2-5 in. long; petals with shallow groove and small, usually stalked glands; cymes with shorter pedicels; stamens somewhat shorter. May, June: fr. in Aug., Sept. B.B. (ed.) 2:270 as V. Opulus). New Brit. to Brit. Col., south to N. J. and Ore.—Handsome native shrub, very decorative in fr., which begins to color by the end of July, remains on the branches and keeps its bright scarlet color until the following spring. The berries are eaten by birds.

3927. Snowball.—Viburnum Opulus var. sterile. All the fertile flowers are changed to sterile, showy ones. (X4)

3926. Viburnum pubescens (X4)
VIBURNUM

Vicia (classical Latin name). Vetch. Tare.

Leguminosae. Mostly weedy or insignificant-looking plants, but a few are grown for the bright flowers, others of late for green-manure crops (see Cover-crops), and one (V. faba) is a garden bean.

Herbs, mostly climbing, with pinnate foliage, closely allied to Lathyrus, Pisum, and Lens, but differing in minute floral characters: wings adhering to the keel; style very slender; with beard or hairs all around the upper part or only at the apex; pod flat, 2- to many-seeded, 2-valved, and dehiscing, the seeds either globular or flatisht; stamens diadelphous (9 and 1): fls. mostly blue or violet, sometimes yellowish or white.- About 150 species widely spread in the northern hemisphere and some in S. America. About two dozen species occur in N. America, some of the species intro. The species are mostly cool-season plants of easy culture. The interest in the vetches in this country is mostly for their value as soil-covers and for foliage. V. sativa, V. faba, and V. villosa are the important species at present for agricultural purposes, and V. Cracca, V. Gerardi, and V. julgans are sometimes used as ornamentals. For literature, see Farmers' Bull. Nos. 515 and 529, Bur. Pl. Ind. Cir. No. 15, and U. S. Dept. Agric. Cir. No. 45.

INDEX.

a. Pods 1-1/2 in. broad with spongy septa between the seeds; seeds oblong, Umbellus attached at the end: st. thick, erect, 4-angled: fls. without tendrils.

1. Fabæ. Linn. (V. fabæ vulgaris, Moench. = faba, Bernh.) Broad Bean. WINDSOR BEAN. ENGLISH DWARF BEAN. HORSE BEAN. Figs. 478, 479, Vol. I. Strong erect annual, 2-4 ft., glabrous or nearly so, very leafy: fls. 2-6, the lower ones not opposite on the racemes, the terminal one wanting or represented by a terminalmentil, ovate to elliptic or obtuse and mucronate-pointed: fls. in the axils, dull white and with a large blue-black spot: pods large and thick, from 2 or 3 in. even to 18 in. long, the seeds large and often flat. Probably native to N. Africa and S. W. Asia. R. F. G. 22:238.—Much grown in the Old World, but the hot dry summers prevent its cult, in most parts of the U. S. It is grown successfully in parts of Canada, particularly in the maritime provinces, and also in California as a winter vegetable or green-manure crop. The plant is grown mostly for cattle-feeding in the U. S. But the beans are extensively used in Asia, both full grown and immature, for human food. This bean has been cultivated, from prehistoric times and its nativity is in doubt. The plant is hardy and seeds should be sown early, when the season is cool. The unripe seeds are reported to have caused cases of poisoning, but little is known as to the conditions of the poisonous production.

b. Infl. very short-stalked or sessile: fls. in medium to large, often 1-2 in. in the If.-axis.

c. Stipules very large, mostly toothed: fls. with 1-3 pairs of Sts.: plants annual.

2. narbonensis. Linn. FRANCE OF NARBONNE VETCH. Annual, pubescent, dark green: st. stout, erect or ascending, 4-angled, 2-4 ft. tall: lower fls. with a single pair of flts. without tendrils, upper with 2-3 pairs of flts. and branching tendrils; fls. 1/4-2 in. long, 1/4-1/2 in. broad, compressed; seeds flat or mucronate above, 1-2 (rarely 5)-fid.: fls. stalked, 1/2-1/2 in. long; calyx-teeth unequal, banner lilac to purple or bluish, wings and keel bluish; pod broadly linear to rhombic-linear, 2-3/2 in. long, 1/3 in. broad, compressed; seeds flat or mucronate above, 1-2 (rarely 5) -fid.: fls. stalked, 1/2-1/2 in. long; calyx-teeth unequal, banner lilac to purple or bluish, wings and keel bluish; pod broadly linear to rhombic-linear, 2-3/2 in. long, 1/3 in. broad, compressed; seeds flat or mucronate above, 1-2 (rarely 5)-fid.: fls. stalked, 1/2-1/2 in. long; calyx-teeth unequal, banner lilac to purple or bluish, wings and keel bluish; pod broadly linear to rhombic-linear, 2-3/2 in. long, 1/3 in. broad, compressed; seeds flat or mucronate above, 1-2 (rarely 5) -fid.: fls. stalked, 1/2-1/2 in. long; calyx-teeth unequal, banner lilac to purple or bluish, wings and keel bluish; pod broadly linear to rhombic-linear, 2-3/2 in. long, 1/3 in. broad, compressed; seeds flat or mucronate above, 1-2 (rarely 5) -fid.: fls. stalked, 1/2-1/2 in. long; calyx-teeth unequal, banner lilac to purple or bluish, wings and keel bluish; pod broadly linear to rhombic-linear, 2-3/2 in. long, 1/3 in. broad, compressed; seeds flat or mucronate above, 1-2 (rarely 5) -fid.: fls. stalked, 1/2-1/2 in. long; calyx-teeth unequal, banner lilac to purple or bluish, wings and keel bluish; pod broadly linear to rhombic-linear, 2-3/2 in. long, 1/3 in. broad, compressed; seeds flat or mucronate above, 1-2 (rarely 5) -fid.: fls. stalked, 1/2-1/2 in. long; calyx-teeth unequal, banner lilac to purple or bluish, wings and keel bluish; pod broadly linear to rhombic-linear, 2-3/2 in. long, 1/3 in. broad, compressed; seeds flat or mucronate above, 1-2 (rarely 5) -fid.: fls. stalked, 1/2-1/2 in. long; calyx-teeth unequal, banner lilac to purple or bluish, wings and keel bluish; pod broadly linear to rhombic-linear, 2-3/2 in. long, 1/3 in. broad, compressed; seeds flat or mucronate above, 1-2 (rarely 5) -fid.: fls. stalked, 1/2-1/2 in. long; calyx-teeth unequal, banner lilac to purple or bluish, wings and keel bluish; pod broadly linear to rhombic-linear, 2-3/2 in. long, 1/3 in. broad, compressed; seeds flat or mucronate above, 1-2 (rarely 5) -fid.: fls. stalked, 1/2-1/2 in. long; calyx-teeth unequal, banner lilac to purple or bluish, wings and keel bluish; pod broadly linear to rhombic-linear, 2-3/2 in. long, 1/3 in. broad, compressed; seeds flat or mucronate above, 1-2 (rarely 5) -fid.: fls. stalked, 1/2-1/2 in. long; calyx-teeth unequal, banner lilac to purple or bluish, wings and keel bluish; pod broadly linear to rhombic-linear, 2-3/2 in. long, 1/3 in. broad, compressed; seeds flat or mucronate above, 1-2 (rarely 5) -fid.: fls. stalked, 1/2-1/2 in. long; calyx-teeth unequal, banner lilac to purple or bluish, wings and keel bluish; pod broadly linear to rhombic-linear, 2-3/2 in. long, 1/3 in. broad, compressed; seeds flat or mucronate above, 1-2 (rarely 5) -fid.: fls. stalked, 1/2-1/2 in. long; calyx-teeth unequal, banner lilac to purple or bluish, wings and keel bluish; pod broadly linear to rhombic-linear, 2-3/2 in. long, 1/3 in. broad, compressed; seeds flat or mucronate above, 1-2 (rarely 5) -fid.: fls. stalked, 1/2-1/2 in. long; calyx-teeth unequal, banner lilac to purple or bluish, wings and keel bluish; pod broadly linear to rhombic-linear, 2-3/2 in. long, 1/3 in. broad, compressed; seeds flat or mucronate above, 1-2 (rarely 5) -fid.: fls. stalked, 1/2-1/2 in. long; calyx-teeth unequal, banner lilac to purple or bluish, wings and keel bluish; pod broadly linear to rhombic-linear, 2-3/2 in. long, 1/3 in. broad, compressed; seeds flat or mucronate above, 1-2 (rarely 5) -fid.: fls. stalked, 1/2-1/2 in. long; calyx-teeth unequal, banner lilac to purple or bluish, wings and keel bluish; pod broad
Vicia americana (Xvi)

4. pyrenaica, Pourr. Perennial, glabrous or nearly so: sts. 4-12 in. long, prostrate or ascending; angular; lower lvs. with only 1-2 pairs of lfts., the upper with 4-6 pairs of lfts. and unbranched or rarely 2-3-branched tendril; fls. solitary, large; calyx sparingly pubescent; corolla purple-violet; pod broadly linear, glabrous; seed smooth, brown, mottled. S. W. France.

V. americana. (Xvi)

tall: lvs. short-petioled, with 1-3 pairs of lfts., ending in a sharp point, without tendril; lfts. ovate, elliptic to oblong; infl. sessile, mostly 3-7-fld.: fls. ½-3¾ in. long, short-pediciled; calyx-teeth equaling or shorter than the tube; corolla yellowish white to golden; pod linear-oblong; 1-½ in. long; seed nearly spherical, brown, ½ in. diam. Moist lands across the continent and as far south as Ky. B.B. 2:2614.—Has been offered by dealers in native plants.

6. sativa, Linn. COMMON VETCH or TARE. Annual or biennial, not surviving the winter in the N., more or less pubescent, 2-3 ft. high; lfts. 7 pairs or less, elliptic, oblong or oblancolate, mostly truncate and apiculate at the top, the tendril part of the lft. extended: fls. usually 2 in. each axil, about 1 in. long, purple: pods 2-3 in. long when mature. Eu., and naturalized in some parts of the U. S. R. F. G. 22:248. B.B. 2:2621.—Much cult. abroad as a forage plant; in this country grown for similar purposes and also somewhat as a cover-crop for orchards. Best adapted to S. E. U. S. and the Pacific coast as a winter crop for green manure or sown with oats, wheat, rye, or barley for hay. As a spring crop it succeeds only where the summers are fairly cool. Not much injured by a temperature of 10° F. but zero weather results in much winter-killing. The name winter vetch is more commonly applied to winter vetches than those of V. sativa. In some parts of the S. it often makes up a considerable portion of the hay.

7. angustifolia, Linn. Annual, glabrous or pubescent: sts. slender, 1-2 ft. long; lvs. short-petioled or nearly sessile with 4-8 pairs of lfts. and an unbranched or 2-3-branched tendril; lfts. linear, lancolate or oblanceolate, up to 1½ in. long and 3/8 in. wide; fls. purple, ½-¾ in. long; pod glabrous, 1-2 in. long. Eu. R. F. G. 22:250. B.B. 2:2622.—Naturalized and established from Nova Scotia to Fla. The seeds mature earlier than those of V. sativa. In some parts of the S. it often makes up a considerable portion of the hay

V. villosa, the hairy vetch. (Xvi)
mucronate: fls. small, red or nearly scarlet and purple-striped, in a compact raceme or spike. Algeria.—
Adapted only to the Pacific and Gulf states. Usually of poor seed habits, but quite drought-resistant from spring sowings.

**Color of fls. purplish or violet.**

**Limb of banner not over half as long as its claw.**

**Pod glabrous.**

**V. villosa, Roth.** Hairy, Sand of Russian Vetch. Fig. 3930. Annual or biennial (sometimes perennial?), enduring the winters in the N., villous-pubescent: flts. 5-10 pairs, elliptic-oblong, rounded at the tip but usually ending in a very minute point: fls. violet-blue, in long 1-sided axillary about 30-fld. racemes. E. Asia. R.F.G. 22:234.—Now considerably used as a cover-crop. More hardly than V. sativa but the pods shatter more easily and the seeds are smaller. In N. Italy it can be cut early enough to produce a crop of millet the same season.

**Plant with short appressed pubescence: fls. only up to $\frac{3}{4}$ in. long.**

**V. dasycaepa, Ten.** Annual or sometimes perennial, slightly pubescent: st. slender, angled, climbing to prostrate: lvs. nearly sessile: fls. about 10 pairs, oblong-obovate to linear-lanceolate: fls. about 2-12-fld.: fls. about $\frac{3}{4}$ in. long; corolla whitish below, blue-violet above, becoming blue with age; pod $\frac{3}{4}$-1$\frac{1}{4}$ in. long, $\frac{3}{4}$ in. broad; seeds rather large, purplish brown. Eu. R.F.G. 22:235.—As hardy as V. villosa and matures earlier than V. sativa. Produces good seed crops Naturalized in W. Ore.

**Pod pubescent; plant with thick shaggy pubescence: fls. whistling below, purplish above.**

**ATROPERA, Desf.** Pteromcma. Annual, resembling V. villosa in habitat, sometimes with soft whitish pubescence: st. 8-30 in. long, angular, prostrate or climbing: lvs. with 5-8 pairs of flts. with branched tendrils; flts. oblong-linear to almost linear, apex pointed: infl. 2-12-fld.: fls. about $\frac{3}{4}$ in. long; corolla whitish below, purplish above: pod broadly linear to rhombic-linear, 1-1$\frac{1}{2}$ in. long, $\frac{3}{4}$-1$\frac{1}{4}$ in. broad, pubescent; seeds somewhat roundish, somewhat compressed, black. 8. Eu. R.F.G. 22:239. B.R. 871.—Of good seed habits. Best adapted to the Pacific and Gulf coasts and produces excellent yields from spring plantings in semi-arid regions.

**Fls. $\frac{3}{4}$ in. long or less: infl. 2-4-four-flld.: plants annual.**

**ERVILLA, Willd. (Erervm Erotica, Linn.).** Better Vetch. Annual, pubescent: st. erect, angular: lvs. with 8-12 pairs of flts. without tendrils; flts. oblong-linear to linear: infl. 2-4-flld.: corolla rose-colored, veined: pod broadly linear, smooth, yellowish; seed smooth, reddish brown. Eu. R.F.G. 22:261.—Extensively grown in Asiatic Turkey and seed shipped in large quantities to England and other countries for stock feed, especially sheep. Yields about 30 lbs. of seed to the acre. Plants not readily eaten by live stock but it has been found to be an excellent, winter green-manure crop in Calif.

**PL. RICKER.**

**VICTORIA (in honor of Queen Victoria).** *Nympheadora.* **ROYAL WATER-LILY.** The great water-lily of the Amazon, sometimes grown in large aquaria.

This remarkable aquatic genus may be recognized by its huge round floating lvs. often 6 ft. or more in diam., with the margin turned up at right angles to the water surface to a height of 3-8 in., making a basin-like object. Fls. (12-18 in. across) nocturnal, opening on two successive days about 5 P.M. and remaining unopened until the middle of the following evening. The first evening the inner floral fls. remain loosely closed over the stigma, the fl. is creamy white, and exhales a delicious fragrance somewhat like pine-sap; the second evening the floral lvs. spread wide open, and the color changes to pink or red; ovary inferior, densely prickly, and surrounded by a short broad tube, on the sides and summit of which the floral lvs. are situated; sepals 4; petals 50-70, obtuse, oblong-ovate to sublinear, rather thin and delicate in texture; stamens about 20; staminodes 150-200, linear-lanceolate; carpels about 25, forming a ring of thick fleshy bodies between the stamens and the styles; carpels 30-40; stigma forming a broad basin-like depression, 2-2$\frac{1}{2}$ in. wide, in the midst of the fl., with a central conical continuation of the floral axis, the basin filled with fluid on the first evening of opening; carpelary styles broad and fleshy in the lower part, produced upward to a fleshy subulate incurved process about $\frac{3}{4}$ in. long: in fr. all of the floral lvs. have decayed away, leaving the top of the torus at the top of a great prickly berry, half the size of one's head; seeds greenish or brownish black, about the size of a pea.—The genus is represented by 2 well-defined species, inhabiting still waters of S. America, from British Guiana to Argentina.

In its native haunts victoria grows in 4 to 6 feet of water, in great patches in extent, and is perennial. The tuberous rhizome stands erect in the mud, where it is anchored by innumerable spongy roots which spring from the bases of the leaves in groups of ten to thirty or forty. The tuber may be as much as 6 inches in diameter and 2 feet long. It decays below as it grows above. The leaves are arranged in 7 to 18 order, the flowers being extra-axillary. Each leaf after the first seedling leaf has a broadly ovate rounded stipule, these organs serving to protect the apex of the stem. The petioles and peduncles are terete, 1 to 2 inches in diameter, covered with stout fleshy prickles, and traversed internally by four large, and a number of smaller air-canals. The petioles attain a length much greater than the depth of the water, so that the leaves can adjust themselves to changes of the water-level, though Banks states that they may be completely submerged in times of flood. The gigantic leaves are covered beneath with a close network of prickly veins, the larger of which project an inch or more from the leaf-surface, the tissues are full of air-spaces and -canals, thus buoying up the mass of cellular matter. Besides many stomata on the upper surface of the leaf, which open into the air-chambers of the mesophyll, there are countless tiny depressions, in each of which one can see with a hand-lens that the leaf is perforated with a fine hole; these holes were called by Planchon "stomatae." (P.S. 6:240). He considered them to be useful as air-holes to let out gases which, rising from the water or mud, might be caught in the deep meshes of the netted veins on the under side of the leaf. It is also to be noted that, in spite of the cup-like form of the leaves, water from rain or other sources does not pass through the tiny perforations. This would be an indispensable protection against fungi and algae, and for the function of assimilation.

A single leaf, by its buoyancy, may sustain a weight of 150 or 200 pounds. Gurney at Tower Grove Park, St. Louis, covers the leaf with a large round quilted pad, then lays on an equally large frame of thin wooden
VICTORIA

slats, and on this a person can readily stand, as if in a boat. Not the least remarkable feature of these leaves is their rate of growth. Caspary found the maximum growth in length to be about 1 inch an hour when the leaf is just expanding; the surface increases 4 or 5 square feet in twenty-four hours, and a plant will produce in twenty-one to twenty-five weeks 600 or 700 square feet of leaf-surface. A great development of heat has been observed in the opening flowers of Victoria. About 8 p.m., when the anthers are shedding their pollen (in second-day flowers), the stamens may reach and maintain a temperature 10° F. above that of the surrounding air.

Though doubtless known to Spanish traders and missionaries, and certainly of use to savages as food in early times, Victoria was first noticed botanically by Haenke in Bolivia about 1801; but he died in the Philippines without recording his discovery. Bonpland, the companion of Humboldt, also saw it near Corrientes, Argentina, in 1819, and in 1825 sent seeds and a full description to Mirbel at Paris. In 1832 Poeppig found it on the Amazon, and gave the first published account of it in Forrie's "Notizen" in November of that year, under the name of Euryale amazonica. D'Orbigny saw the plant in 1827 at Corrientes, collected specimens, and sent them with drawings to the Museum of Natural History at Paris. In 1833 he saw it again in Bolivia, and several years later published accounts of his find. Robert H. Schomburgk, finding it again in 1836 on the Berbice River in British Guiana, sent home specimens and figures from which Lindley in 1837 (published in 1838) established the genus Victoria and described the species V. regia. This name has settled on the northern species, while the one found at Corrientes was named in 1840, by d'Orbigny, V. Cruziana in honor of General Santa Cruz, of Bolivia.

The struggle to bring the "queen of water-lilies" into captivity began with Schomburgk. He removed living plants from inland lakes and bayous to Georgetown, British Guiana, but they soon died. In 1846 Bridges obtained seed in the Bolivia locality, province of Moscos, and sent them in a jar of wet clay to England. Out of twenty-five seeds obtained at Kew, three germinated and grew vigorously as small seedlings until October, but died in December. In 1848 dry seeds were sent to England from the Essequibo River, along with rhizomes, the latter in Wardian cases; the rhizomes rotted, and the seeds refused to germinate. In 1849 an expedition from Georgetown succeeded in bringing back thirty-five living plants, but these all died. Finally some seeds were sent to Kew from the Demerara River in bottles of fresh water, by two English physicians, Rodie and Luckie. The first sending arrived February 28, 1849, and on November 8 a plant flowered at Chatsworth; the blossom was appropriately presented to Queen Victoria. From this stock Victoria regia was distributed to gardens in Europe, Asia, and America. Van Houtte of Ghent first flowered it on the continent.
the V. Cruziana of d'Orbigny. Its far southern habitat (27° south) explains its hardiness. At Riverton, New Jersey, seeds that have wintered in an open pond produce plants which flower by the end of August. The large starry seeds of this species are used as food in Paraguay under the name of ‘Mats del Agua,’ ‘water-corn.’ The form of Victoria originally introduced from British Guiana had leaves entirely flat until the plant attained considerable size; then a low rim appeared. The leaf was deeply purple-colored beneath. V. Cruziana differs markedly from this as V. regia, Randii approaches the latter; and Malme's recently described V. Cruziana forma mattogrossensis approaches V. regia in several details. Apparently the two species grade into one another in Matto Grosso, where the tributaries of the Amazon and the Parana rivers interlace.

For much interesting information on Victoria, see Hooker, 'Botanical Magazine' 4275-4278; Planche, 'Flora Brasiliensis' 4, part 2, page 143 ff. In 1854 John Fisk Allen published in Boston a four-page work (pages 21 by 27 inches) with colored plates, entitled: "Victoria regia, or the great water-lily of America. With a brief account of its discovery and introduction into cultivation; with illustrations by William Sharp, from specimens grown at Salem, Massachusetts, U. S. A."

**V. regia**, Lindl. Fig. 3931. Lvs. sparingly pubescent beneath, margins of lvs. of diam. above 40 in., turned up 2-4 in. high: fls. becoming dull crimson the second evening; sepals prickly almost or quite to the tips; prickles of the ovary about ½in. (10-11 mm.) long; seed ellipitico-globose, nearly 2½in. long, less in diam. (7-8 mm. long, 5½-6 mm. diam.); raphe indistinct; operculum elliptico-ornibiculare, with the micropyle at its central margin. Britiah Guiana, B.M. 4275 (poor); 4276-78 (incorrect in some details). F.S. 6:595-604. Kerner, Natural History of Plants, pl. 12, 1896. The seed may be planted soon in February, but there is great uncertainty as to how long one must wait for the seedlings to appear, and also as to what percentage of seeds will germinate. As soon as the seedlings appear they should be treated like seedlings of V. regia, except as to temperature, which should be kept as above stated for seedlings and small plants, and as the season advances may be raised to 75° to 80°. The rationality of the cool treatment here advocated is borne out by the fact that early in June quantities of seedlings appear in the pond in the open where a plant has grown the preceding season, the seed having remained in the pond during the winter. Planting in summer quarters may be done early in June or whenever it is safe to plant out tender seedlings, that is, when the pond is not artificially heated. When it is desired to plant out in unheated ponds it is not safe to plant before the middle or latter end of June. The conditions of the weather, early or late, and the advance of summer weather may be determined by the appearance of a few leaves in about ten days. These young plants late appearance in the pond or absence of the young plants late appearance in the pond or absence of leaves will vary with the seasons, and the like, must all be taken into account.

The best results are to be obtained from an artificially heated pond, or pots in the pond specially constructed to start the V. regia, these pots to be heated by hot water or steam and covered with frames and sashes. By this method plants may be set in their summer quarters.

Very gratifying results are obtained when the Victoria is grown under glass, as it is thus grown in several places in the United States, notably at Schenley Park, Pittsburgh, and Allegany Park; also at "Greystone," the estate of Samuel Untermyer, Yonkers, New York, also at many notable gardens in Europe. Plants grown under glass usually attain to larger dimensions, as they are protected against climatic changes and the elements, besides enjoying more of a tropical atmosphere. There is more than one disadvantage, however. Setting aside the costly construction, labor, and so on, it is by no means inviting even on a warm day to spend many minutes in such a structure. Compare this with a natural pond and its surroundings and a cool shady seat where these gorgeous plants may be viewed at leisure.

Whether grown indoors or out, these plants are only
annuals, and seedlings are of necessity raised every spring. They form no tubers as do the tender
ympheas, or rootstock as do the hardy ympheas.

Few, if any, insects are troublesome on these plants. The worst is the black-fly or aphid. The use of insecti­
ticides should not be resorted to, as they are most
likely to damage the foliage. The safest remedy is to
introduce a colony or two of the well-known "lady bug.
They and their larvae will soon clear off all the aphides
without any injury to the plant. WM. TRICKER.

VIGNA (Dominic Vigni, Paduan commentator on
Theophrastus in the seventeenth century). Legum­
ferae. Herbs grown mostly for the seeds and fodder;
the cowpea group.

The cultivated species of Vigna are annual bean­
like rambling vines with 3 rhomboid-ovate stalked
fls., the lateral ones unequal-sided, the petioles long:

<table>
<thead>
<tr>
<th>Species</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>V. sesquipedalis</td>
<td>Seeds elongated kidney-form, 8-12 mm. (1/2-1 in.) long, their thickness much less than their breadth; pods pendulous, much elongated, 1-3 ft. long, fleshy and brittle, becoming more or less inflated, flabby and pale in color before ripening, and shriveling about the widely separated seeds when dry. Probably S. Asia.</td>
</tr>
<tr>
<td>V. sesquipedalis</td>
<td>Seeds small, usually oblong or cylindrical and but slightly kidney-shaped, 5-6 mm. (1/16-1/4 in.) long, nearly or quite as thick as broad; pods small, not at all flabby or inflated when green, mostly 3-5 in. long, erect or ascending when green, remaining so when dry or at length becoming spreading or even deflexed. Probably S. Asia.</td>

</table>

sinensis. Endl. Seeds mostly 6-9 mm. (3-1/2 in.) long, varying from subreniform to subglobose; pods 8-12 in. long, early becoming pendulous, not at all flabby or inflated when green. Probably Cent. Afr.

Some species of Vigna are useful for ornament. V. strobilophora, Robs., from Mex. (Fig. 3932), is said by Pringle (G.F. 7:155, from which Fig. 3932 is reduced) to have abundant fls., that rival those of the wisteria in beauty. It is a twining woody vine climbing to tops of trees and shrubs; at. slender and fleshy, pubescent; fls. 3, ovate, acuminate, entire, rounded at base, 2½ in. long; fls. in dense axillary peduncled racemes, blue-purple, standard orbicular, slightly reflexed, with 2 small appendages at base; bracts large, closely imbric­ated. V. vexillata, Bent. (Phaseolus vexillatus, Linn.), widely spread in the tropics and warm parts of Old World, is intro. in S. Calif.: woody perennial with pink fls., the rootstock tuberous, hairy; fls. usually 4-vaned-lanceolate to ovate-lanceolate, 2 in a cluster on summit of peduncle; standard nearly 1 in. across, reflexed: pod 3-4 in. long, nearly cylindrical.

Geo. F. Freeman.

VIGUIÉRA (Dr. A. Vigüier, botanist of Montpellier,
France). Compositae. About 60 or 70 species of herba­
ceous or somewhat shrubby plants, found in the
warmer parts of the world, especially Amer. The fol­
lowing is a native of Low. Calif. and is offered in S.
Calif., but is little known otherwise. It is a tall bushy
VIGUIERA

plant with silvery foliage and small yellow fls. like single sunflowers, but borne in ample corymbs. Rays fertile, or more often sterile, in wild plants sometimes wanting; pappus of 2 chaffy awns: achenes usually pubescent. The plant blooms both winter and summer.

VILLARÉSIA (named for Matthias Villarez, a Spanish botanist). Iac. axillaries. Evergreen tall climbing trees or shrubs, adapted to the warmhouse: lvs. alternate, oblong, entire or spinulose-dentate, thick, leathery, shiny: cymes small, head-like, arranged in axillary or terminal racemose panicles or racemes: fls. white, hermaphrodite or polygamous; calyx 5-parted; petals 5, ribbed inside; stamens 5, disk inconspicuous; ovary 1-celled: drupe ellipsoid.-About 12-15 species, distributed in the islands of the Pacific, Trop. Austral., and Spanish botanist).

GRANDIFLORA, Fisch. Tree, smooth with subangular branches: lvs. sparse, petioled, coriaceous, ovate-lanceolate, narrowed toward the base, apex acuminate, glandless, pubescent; panicles terminal, clustered; fls. sessile, small, white; calyx tubular-campanulate, lobes 5, ovate; petals 5, spreading, lanceolate. Brazil. Gt. 6: 181.

muconotá, Ruiz & Pav. (Ilex gongônea, Mart.). Tree, usually 40 ft. high, rarely 50-60 ft.: lvs. short-petioled, ovate or elliptic-oblong, apex spinulose, leathery, dark green, shining above, paler and dull beneath: fls. 5-merous, in solitary shortly pubescent thyrses, terminal or in the upper axis, yellowish white; sepals wide and many-fld., sometimes iaxy paniculate, sometimes corymbose congested or capitate and involucrate: fls. yellow or white; calyx 5-parted or deeply 5-delt., segments lanceolate; corolla broadly campanulate or rather rotate; stamens 5: caps. 1-celled, subglobose, apex 4-valved.-About 10 species, S. Afr. and Austral.

VINCA (pervinca, old Latin name of periwinkle, used by Pliny). Apocynaceae. Erect or procumbent or trailing herbs or subshrubs, some used for bloom in the flower garden, others for decorative foliage in the greenhouse and in window-boxes and others for permanent ground-cover out-of-doors.

leaffulata, Smith. The name LEAFLESS RUSH-BROOM has been proposed for this. Leafless yellow-flowered shrub, attaining 10-20 ft., formerly cult. in European greenhouses as a small tender shrub: lvs. 3-8 in. long: pod 2-3 lines long. Austral. B.M. 1190. P.M. 14: 123.-Offered in S. Calif.

F. W. BARCLAY.

F. W. BARCLAY.
rainy weather. It is propagated by division or by cuttings, as seeds very rarely mature. The periwinkle will live in city yards under trees where grass will not thrive; rather is the commonest and perhaps most variable species. Varieties with white, purple, and double flowers are kept in most nurseries, as also a form with variegated foliage. V. major is larger in all its parts than the common periwinkle and not so hardy. It is very tender to frost. A variegated form of it is seen in nearly every veranda-box in the country. V. rosea is a tender plant of erect habit which is used chiefly for summer bedding. It grows about a foot high and has rosy purple or white flowers with or without a reddish eye, and often 2 inches across. The plants bloom continuously from the time they are set out until frost. It can be grown in large masses for public parks with somewhat less expense than geraniums. Mr. Stromback, head gardener of Lincoln Park, Chicago, has recorded his experience with V. rosea in Florist’s Review 1:141 as follows: “The seed is sown in January or February in flats of sandy soil in a temperature of 65° to 70°. When the seedlings show the second leaf, they are transplanted into 1-inch pots, and later shifted to 3-inch pots. The majority are bedded out from the 3-inch pots. The soil of the bed should be a sandy loam if possible, and the plants will not do well in a very heavy soil. In bedding, set the plants about a foot apart. They require more water than a geranium, and when the bed is watered it should be given a good soaking and then left alone for a few days. The plants require no trimming. The amateur will find V. rosea a satisfactory window-plant that can be grown with little trouble from seeds started as late as April, but of course such plants will not bloom as early as the bedding stock propagated in January or February. V. rosea is the largest-flowered species, and it seeds freely. (Wilhelm Miller.)

A. Plants trailing, herbaceous, hardy or nearly so, only the short flowering sts. ascending; fls. mostly blue or white.
B. Foliage evergreen.

a. Minor. Linn. Common Periwinkle. Blue, Ronnina. Fls. Fig. 3933. Hardy evergreen, trailing herb; fls. sts. erect, sometimes nearly a foot high; lvs. ovate or elliptic-lanceolate, not more than 1½ in. long, glabrous, petiole very short with 2 glands at the top; fls. lilac-blue; calyx-lobes narrowly lanceolate, acuminate; corolla-lobes ovate, very obtuse. Sube. G. 2:64.—Common in all country gardens and running wild in cemeteries and shady places. Some of the horticultural varieties are: Var. alba, Hort., which has single white fls. Var. alba variegata, Hort., a form with variegated lvs. and single white fls. Var. argentea variegata, Hort., has the lvs. silvery variegated. Var. strophurpea compacta, Hort., has single dark purple fls. Var. aurea, Hort., has been in the trade, a form with golden yellow florets. Var. aurea variegata, Hort., has golden variegated lvs. Var. cerisea, Hort. (V. cerisea, Hort. V. cerisea minor, Hort.), is a form with bright blue, single fls. There is also a form known as V. cerisea argentea marginata, Hort., which has the lvs. margined with silver white. Var. flore-pleno, Hort., probably the same as var. plena. Var. plena, Hort., has double fls., otherwise like the type. Var. purpurea plena, Hort., has double purple fls. Var. rosea, Hort., has single rosy fls. Var. rosea fl-pl., Hort., is like the last but double-flowered. Var. variegata, Hort., is a variegated-ldv., blue-flowered form offered in the trade. V. elegansina alba, Hort., and also ‘The Bride,’ a form with white fls. which are pink-centered belong to this species.

b. Minor. Linn. Storite sts. reclining; flowering sts. rather erect; lvs. subcorporate-ovate, rather obtuse, ciliate, shining, 2 in. long; fls. blue; calyx-lobes narrowly linear, ciliate; corolla-lobes obvate, very obtuse. Eu.—This species is larger throughout than V. minor. It is much used, especially the variegated forms, for veranda-boxes and hanging-baskets. Var. elegansina, Hort., is a showy form with the lvs. margined and blotched with yellowish white. Common form among the florists and easily prop. by cuttings. Var. reticulata, Hort., is offered in the trade. Var. variegata, Hort., is offered in the trade. G. 27:330.

C. Les. ovoite or ob-long-ovoite; corolla-lobes wedge-shaped; calyx glabrous.

a. Minor. Linn. Madagascar Periwinkle. Fig. 3934. Tender erect everlasting plant, somewhat shrubby or half-prostrate at the base: lvs. oblong, narrowed at base, veiny; petiole glandular at the base: fls. with a very small reddish eye, and often 2 glands at the top; fls. sterile or pubescent, calyx-lobes with pink or red center. As a matter of fact, these are the commonest and perhaps most useful species of Vinca that is realy native to Madagascar, viz., V. lanea, is not in cult. The plant is sometimes called “Cape periwinkle” and “old maid.” The three main types should be known as V. rosea, V. rosea var. alba, V. rosea var. oculara, the latter being a white fl. with pink or red center. As a matter of fact, these appear in American catalogues as V. alba, V. alba pura, V. alba nova, V. oculara, and V. varius, the last being a trade name for seed of mixed varieties. Var. delicata, Hort., is a trade name.

F. Tracy Hubbard.

VINCETOXICUM (compound meaning to conquer or subdue poison, alluding to supposed virtues). Acoeliadaceae. By some combined with Cynanchum (which see), but differing in anthers having only short scarios tips and bearing horizontal rather than suspended pollinia. There are about 75 species, all in Amer., mostly...
in warm or tropical parts: they are twining or trailing woody or perennial herbaceous vines, with opposite or verticillate simple lvs. and small greenish or purplish fls.; corolla campanulate or rotate, deeply 5-lobed and the parts sometimes reflexed; crown small, mostly ring-like or cup-like and thereby differing from the awned crowned-lobes of Gomolobus (Definition of Gomolobus, p. 1356, to be amended); follicles thick, pointed, mucronate or ribbed or both. Several species are native in the U.S. from Pa. and Va. southward, but apparently they are not in cult. The mosquito plant or cruel plant, sometimes named in this genus, is here treated as Cynanchum acuminatofolium.

VIOLAS: Planting, Vol. V. (Index p. 2657.)

VIOLA (classical name). Viola. Violet. Pansy. Usually perennial herbs with attractive spring or early summer bloom, and well adapted for colonizing in grounds and one species for forcing; in the pansy group, many species are handsome winter annuals or biennials; and in the Andes and the Sandwich Islands, and in southern Europe shrubby species occur, but they are scarcely cultivated. See Viola.

Either stemless, bearing lvs. and 1-fld. scape from the crown of the rootstock, or stemmed with manifest internodes between the lvs., from the axis of which arise 1-fld. peduncles: fls. usually of two kinds, those of spring with showy petals (Fig. 3935) and those of summer with petals rudimentary or lacking—fls. never opening but self-pollinated within the closed calyx (cleistogamous). (Fig. 3936.) The showy fls. of spring are 5-merous as to sepals, petals, and stamens, irregular and novel in structure as though contrived to prevent self-pollination; sepals nearly similar, persistent on the fr.; the lower petal of the nodding fl. spurred, the other 4 in 2 unlike pairs, the petals in each pair symmetrically alike; stamens short and included, the anthers more or less coherent in a ring about the style, 2 of them with nectar-bearing appendages projecting backward into the spur: fr. a caps. with several (up to 60) obovate seeds; caps. when ripe splitting into 3 boat-shaped valves with thick rigid keels; as the thin sides of the valve dry and contract the seeds within are more and more pinched, until they fly out, one or two at a time, to a distance often of 9 ft.: later cleistogamous fls. in some of the stemless species not growing in wet ground are borne on short horizontal peduncles concealed under soil and last-mold until the seeds are ripe, when the peduncle lengthens and lifts the caps. into the air, where it scatters the seeds within are more or less alike. (4) The hybrid is unstable in sexual reproduction; that is, the offspring of the self-fertilized hybrid are more or less unlike the parent and unlike each other; the offspring of pure species are not thus unlike.

By experimental cultures extending over twelve years, the writer has ascertained the existence of about eighty spontaneous hybrids among the violets of eastern North America—that is, more hybrids than there are pure species. In Wilhelm Becker's systematic treatise on the violets of Europe (published in 1910), eighty-three hybrids are reported among the one hundred and two species there recognized. Any reader caring for the details of the work on American violets will find a dozen or more papers in Rhodora and in the Bulletin of the Torrey Botanical Club (1904-1913); see also Science, June, 1907, and American Naturalist, April, 1910.

Violets are easily grown if an effort is made to imitate the conditions under which they naturally occur. They usually require abundant moisture and partial shade, and a light covering of fallen leaves or evergreen boughs in winter. The habitats are various: some are woodland species, others from bogs or borders of springs and brooks; still others, especially in the western United States, inhabit dry plains, remaining dormant during the drought of summer. They are propagated readily by division if the plant is fairly large, and in some nine of the American species by runners. Sometimes seeds are used, but not commonly. However, species of the northeastern United States germinate readily in April, if fresh seed is sown in autumn in boxes and exposed to a light covering of fallen leaves or evergreen boughs. Many species, that grow mostly to single stems in the wild, make large clumps under favorable conditions in the garden (Fig. 3942). But few of the native violets are grown to any extent as garden plants. V. pedata, the bird's-foot violet, a most attractive species, is
sometimes cultivated, as is the hardy grower, *V. papilionacea* (Fig. 3936). A partial alias of this, the petals white with a large blue center, is grown in southern gardens as "the confederate violet." It has been published as *V. Procana*, the type coming from Bowling Green, Kentucky; but it is perfectly hardy in the North, and multiplies abundantly. Many hybrids of *V. sororia* and of *V. pedatifida* are also hardy, some with violet flowers, others with white flowers, often fifty or more blooming at once in a large clump.

No attempt is made here to describe all the native species, as they are so numerous and so rarely horticultural subjects. For any desired information regarding them the reader is referred to the most recent editions of Gray's "Manual," of Britton & Brown's "Illustrated Flora," or of Small's "Flora of the South-eastern United States," the treatment of Viola in all three works being by the present writer. However, as a matter of record, a list of those that are or have been offered in the trade is here given, and references made to illustrations found in horticultural magazines. With the recent critical studies of Viola, it is found that two or more species were sometimes comprised under a single name; it is therefore difficult, in some cases, to determine what plant may be in cultivation under one of the older names. It is now considered that the European *V. canina* is not indigenous in America; probably the plant listed under that name is *V. conspersa*.

</tbody>
</table>

A. Species of exotic origin, comprising the florist's violets and the pansy.

b. Plant stemless, the peduncles arising directly from the base or crown.

c. Style truncate at apex.

1. hederacea, Labill. (Erpeton reniforme, Sweet. *E. hederaceum*, E. petiolare, and E. spathulatum, Don). AUSTRALIAN VIOLET. Tufted, and creeping by stolons, glabrous or pubescent: lvs. reniform or orbicular or spatulate, small, entire or toothed, usually not equaling the scapes; fls. small, usually blue, sometimes white, the spur almost none. Austral. G. 35:35.—Offered in S. Calif.

c. Style terminating in a slender hooked beak.

2. odorata, Linn. SWEET VIOLET. Fig. 3937; also Figs. 3947-49. Tufted, somewhat pubescent, producing long prostrate stolons flowering the second year; rootstock short: lvs. cordate-ovate to reniform, obtusely serrate; stipules ovate-lanceolate, acuminate, the fringed border usually not glandular: fls. deep violet, rarely rose or white, fragrant, the spur nearly or quite straight and obtuse. Eu., Aaf., and Asia.—It runs into many forms varying in stature, size of fls. and color. There are double-fl. forms. It is the parent of florists' violets. Fig. 3937, from G.C. III. 21:248, represents var. sulfuera, "reported to be a native of the south of France, and bears dull sulphur-coloured flowers." *V. californica* of gardeners on the Pacific coast is only the sweet violet of Eu. For cult., see *Violet*.

3. cyanes, Cebak. Stemless, stoloniferous: lvs. broadly cordate-ovate, crenate, bright green, glabrous or pubescent, long-acuminate, filbrinate: pedicels 2-4 lines long, about equaling or slightly shorter than the petals after flowering; sepal oblong, obtuse, with short appendages which are rotundate and appressed to the pedicel; corolla medium-sized; petals sky-blue-white below the middle, lower petals emarginate, the others about as long, scarcely emarginate; spur conical, rather straight; ovary short-conoid, very smooth. Eu.

4. alba, Bess. Stolons long, ascending, appearing in spring and sometimes bearing fls. the same season: lvs. nearly triangular, cordate, with deep and broad

sinus, obtuse; stipules lanceolate, long-acuminate, with glandular fringe; fls. fragrant, usually white, but sometimes in various shades of violet and rose. Cent. and S. Eu.

aa. Plants with evident sts., more or less branching, the peduncles arising some distance above the ground or crown.

c. Style slender throughout.

5. silvestris, Reichb. (V. silvestrica, Fries). Sts. reclining and ascending, glabrous or slightly pubescent: lvs. deeply cordate or nearly reniform, short-pointed or obtuse; stipules linear-lanceolate, fringed-toothed, and shining shorter than the petals; sepals lanceolate, acuminate; petals oblong, narrow, not overlapping. Widely distributed in Eu. G.W. 13:73.

6. elatior, Fries. Sts. tall and straight: lvs. lanceolate from a rounded or cordate base, when young with appressed pubescence; the middle stipules as long or

3937. Viola odorata. (X ½)
longer than the petals, the upper much surpassing it: corolla large, pale blue. Cent. Eu. and southeastward.

3938. Viola cornuta. (x 10)

7. calcarata, Linn. (V. valdaria, Huter). Rootstock producing filiform creeping branches: st. simple, 4 in. high: lvs. ovate, or the upper oblong to lanceolate, crenate; stipules nearly or quite pinnately divided; spur as long as the large violet corolla. Alpine region of Cent. Eu. G.W. 12: 709. Gn. 82, p. 97.

8. gracilis, Sibth. & Smith (V. olympica, Bois.). One of the V. calcarata group, and by some authors included in that species: entire plant hairy, internodes more or less elongated, 1 ft. high: lvs. oblong and narrowed to petiole, or broad-ovate to nearly round and abruptly contracted below, somewhat obtuse at apex, the margin crenate; stipules pinnately parted: fls. medium size, the petals violet or yellow; sepals lanceolate; spur exceeding calyx appendages. Macedonia to Asia Minor.

9. Munbyana, Boiss. & Reut. Another of the V. calcarata kind: plant about 1 ft. high, with long internodes, very short-pubescent: lvs. cordate-ovate, obtuse, crenate, glabrous or the margin ciliate, the upper ones somewhat acute; stipules pinnatifid: fls. 1–3, the petals violet or yellow; sepals lanceolate; spur straight, attenuate at the end, about twice longer than the calyx. Algeria.

10. lutea, Huds. Plant persisting by filiform pros­trate branching sts.: stipules digitately much divided, middle division linear and enlarged: sepals oblong­lanceolate, acute, shorter than petals; spur exceeding calyx appendages. Macedonia to Asia Minor.

11. cornuta, Linn. Horned Violet. Bedding Pansy. Fig. 3938. Plant tufted, glabrous or nearly so, producing evident lvs. with long peduncles in the fl.-axis: lvs. subcordate-ovate and usually acuminate, crenately serrate; stipules triangular, large, coarsely dentate: fls. normally violet, the petals ovate-obtuse, standing well apart, the spur slender, acute, shorter than the petals. Libea and the Pyrenees. B.M. 791. G. 32: 417. Gn. 73, p. 385.—Frequently seen in gardens and much prized for its large bright fls. Good for spring bloom. Hardy. There are several colors. Var. filosa, Hort. Gz. 78, p. 449. Var. purpurea, Hort. G. M. 52: 386. Var. Papilio, Hort. (Fig. 3939) has very large fls. violet in color, with small dark eye. Var. admirable, Hort., a garden group of various colors, is probably a hybrid offshoot of this species. V. munbyana is a form of this species.

12. tricolor, Linn. Pansy. Heartsease. Fig. 3940; also Figs. 2748, 2749. Glabrous or nearly so, the sts. becoming long and branched: basal lvs. cordate or round-cordate, those of the st. becoming ovate-oblong or lanceolate, all stalked and crenate-dentate; stipules large, pinnately parted toward the base: fls. large, usually about three colors represented (except in high­bred self varieties), the spur usually twice as long as the appendages of the calyx. Eu. G. Z. 27: 1. R.B. 38: 137.—When strayed from cult., the fls. become small and lose the markings characteristic of the high­bred pan­seys. A small-fl. field form, becoming common, is the common V. arvensis, Murray. A similar but more delicate species, distinguished by petals longer than the calyx, V. Rafinesqui, Greene (V. tricolor var. arvensis, American Auth., not DC.), is indigenous to the U. S. from N. J. southward and westward to Texas and Col. For cult., see Pansy.

AA. Species native in the U. S. and Canada, not do­mesticated but sometimes planted from the wild.

B. Plants stemless.

C. Petals normally violet or purplish.

D. Lvs. more or less dissected.

Gn. 65, p. 383. G. 13: 373; 22: 65.—In the typical form the 2 upper petals are dark violet, the 3 lower pale lilac; the concolorous form is by far the more common. A form with petals nearly white is known as var. filosa.

14. palmata, Linn. Fig. 3941. Rootstock stout, usually oblique rather than erect: first lvs. in spring sometimes less divided but later lvs. palmately 5–11– lobed or -parted, midle segm. largest, all of them variously toothed or eleft: fls. violet-purple, about ½–1 in. across; lateral petals bearded; sepals rather blunt, ovate-lanceolate; produces cleistogamous fls. on prostrate peduncles. Woodlands, Mass. to Minn. and to Fla.

15. pedatifida, Don. Rootstock short and erect: lvs. palmately multifid, primarily 3-parted or -divided, each segm. again 3-eleft or -parted into linear sub­divisions, these further often cut into 2–4 lobes; fls. showy, violet, on scapes surpassing the lvs.; produces cleistogamous fls. with yellowish caps. on erect pedunc. Woodlands, Ohio northwestward and south­westward.

DD. Lvs. lanceolate or oblong-lanceolate.

16. sagittata, Ait. A small species, with erect short rootstock, usually glabrous: mature normal lvs. lanceo­late or oblong-lanceolate, hastately or sagittately toothed
or incised at the base; earlier and later lvs. more deltoid and often only crenate at base; fls. violet-purple; sepal narrow-lanceolate, acute. Banks and fields, Mass. to Minn. and southward.

**DD**. *Les. cordate-ovata* to *cordate-reniform.*

17. *papilionacea,* Pursh (*V. cucullata* of older Manuals). Figs. 3935-6, 3942. Commonest and most variable violet in the N. E. "U. S. A robust plant, with a strong branching horizontal rootstalk, 3-6 in. high; lvs. deltoid-ovate to cordate-ovate, not lobed, bluntish, ovate, the long petiole somewhat pubescent; fls. normally deep violet but white or greenish yellow in the center; outer sepals ovate-lanceolate; petals narrow; spurred petal often narrow and boat-shaped; cleistogamous fls. usually underground but caps. erect. V. Priceana, Pollard, is probably a form of this, with white blue-centered fls. Ky. See remarks on p. 3475.

—Besides albinos there are striped and pied forms now in the trade known as *vari.* *striata,* *picta,* and *variegata,* Hort. All forms are easily colonized in the garden. C.M. 57:313. G. 3:323 (both as *V. cucullata*); GT 1:194.

18. *sororia,* Willd. Much like No. 17, but petioles and lower surface of lvs. villous-pubescent; a sturdy grower, in pubescence, shape of fl., and color of fl. resembling the European *V. odorata,* whence named by Willdenow in 1806 the "sister violet." (Latin *soror,* a sister.) Woods and moist meadows and about buildings, Que. to Minn. and southward.

19. *pratincola,* Greene. A prairie species of the Middle West, from Ind. to Minn. and Col.; like *V. papilionacea,* but less robust, and often united with that species: petals violet-purple but of a lighter shade than in No. 17, the petals broadly ovate.

20. *septentrionalis,* Greene. Scapes and lvs. more or less hisrutulous: lvs. ovate to reniform, cordate at base, somewhat attenuate but blunt at the apex, crenate-toothed and ciliate, the petioles slender: fls. large, of a rich violet-purple (rarely white or white); 3 lowest petals villose at base; sepals lanceolate, acuminate; 3 lower petals beardless or slightly bearded; cleistogamous fls. on shortish erect peduncles. Open moist ground, New. Bruns. to Fla. and La.

**DD**. *Les. ovata,* with either narrowed or rounded base.

21. *seckiriki,* Pursh. A very distinct small species with minute spreading hairs on the upper surface of the lvs.-blades: lvs. thin, ovate to nearly orbicular, deeply cordate with a narrow sinus, crenate: sepals lanceolate or ovate-lanceolate, usually acute; cleistogamous fls.

22. *Sékikiri,* Pursh. A very distinct small species with minute spreading hairs on the upper surface of the lvs.-blades: lvs. thin, ovate to nearly orbicular, deeply cordate with a narrow sinus, crenate: sepals lanceolate or ovate-lanceolate, usually acute; cleistogamous fls.

23. *lanceolata,* Linn. Small glabrous species, with erect habit: lvs. lanceolate or elliptical, obscurely crenulate, gradually narrowed into a margined more or less colored petiole; fls. white, but the 3 lower petals with purplish veins, all usually beardless; sepals lanceolate; cleistogamous fls. erect. Open moist places, Nova Scotia to Minn. and southward.—A distinct and interesting species.

**DD**. *Les. ovata,* with either narrowed or rounded base.

24. *primulifolia,* Linn. Usually glabrous but sometimes pubescent: lvs. oblanceolate, usually rounded at the base or cuneate, obscurely crenate-serrate, the petals often manifestly winged above: fls. white with purplish veins, on peduncles exceeding the lvs.; sepals lanceolate, acuminate; 3 lower petals beardless or slightly bearded; cleistogamous fls. on shortish erect peduncles. Open moist ground, New. Bruns. to Fla. and La.

**DD**. *Les. ovata,* with either narrowed or rounded base.

25. *pallescens,* Brainerd. Small neat species, for the most part glabrous, stoloniferous: lvs. broadly ovate or cordate-orbicular, sometimes only \( \frac{3}{2} \) in. wide, but usually 1½-2 in., crenate-serrate, obtuse: fls. faintly fragrant, white; lateral petals usually with small tuft of hairs, the upper ones broadly ovate. Springy land and along cold brooks, Que. and southward.

**DD**. *Les. ovata,* with either narrowed or rounded base.

26. *blanda,* Wild. Fig. 3943. A northern species extending southward in the mountains to N. Ga., has acuminate lvs. somewhat hairy on the upper surface, and narrow strongly reflexed petals. Probably not in cult.
3476

**VIOLA**

**DDDD. Les. kidney-shaped.**

27. renifolia, Gray. Pubescent to nearly glabrous; rootstock in mature plants mostly stout and scaly; mature lvs. of summer reniform; the 3 lower ones veined or tinged brownish; sepals narrowly-lanceolate; cleistogamous fls. purple, on horizontal peduncles: stolons absent. **Arboretia** swamps and cold woods, Newf. to the Mackenzie River, and southward in the Alleghany and Rocky Mts.

**ccc. Petals yellow.**

28. rotundifolia, Michx. Plant with long and stout scaly root-stocks, and making short stolons; lvs. in midsummer, oval, 2-4 in. wide, thick and prostrate, reniform, fls. bright yellow, with brown lines on the 3 lower petals; lateral petals bearded; cleistogamous fls. on de- 

30. eriocarpa, Schw. (V. scabriuscula, Schw.). Essentially glabrous or sparingly pubescent, the sts. ascending; root-lvs. usually 1-3, long-petioled, ovate to reniform, the base cordate or truncate, the apex usually rounded; st-lvs. all on upper half of st., broad-ovate, subcordate, apex acuminate; fls. yellow, the lateral petals bearded; sepals lanceolate or linear. From the Rocky Mts. eastward to Dak. and Mo.

31. pubescens, Ait. Markedly soft-pubescent; sts. 8-12 in. high, stout, often only one: root-lvs. usually wanting; st-lvs. near the top, short-petioled, broad-ovate to reniform, the base cordate or truncate, crenate-dentate, somewhat short-pointed; stipules large; fls. bright yellow; lateral petals bearded; spur short; sepals narrow-lanceolate. Dry rich woods, Nova Scotia to Man. and far southward.

**DD. Petals white inside with bright yellow base.**

32. rugulosa, Greene (V. Rydbergii, Greene). Plants widely spreading from long underground stolons; first lvs. broad and densely pubescent underneath, long-petioled, cordate-reniform and abruptly acuminate; fls. sometimes tinged with violet. Minn. and westward to Colo. and Brit. Col.

33. canadensis, Lam. Plants without stolons, glabrous or very nearly so; lvs. broad-ovate, cordate, at apex acute or acuminate, serrate, the stipules sharp-lanceolate: fls. solitary from the axis of the st-lvs., white inside with yellow center, the outside more or less tinged with violet, the 3 lower petals with darker stlfs., the lateral petals bearded; sepals subulate. Woods, New Bruns. to Sask. and Rocky Mts., to Ala. and Ariz.

**DD. Petals a uniform white or cream-color.**

34. striata, Ait. Plants cespitose, often 2 ft. high at maturity in summer, the sts. angular and leafy; lvs. nearly or quite glabrous, ovate to orbicular, cordate, mostly acuminate, closely crenate-serrate; stipules large and fimbriate; fls. white or cream-colored, long-stalked; sepals linear-lanceolate and ciliate; spur thick and blunt. Shady places, N. Y. to Minn., Ga. and Mo.

**DDDD. Petals usually violet-blue.**

35. conspersa, Reichh. (V. caulina var. Mühlenbergii, Gray). Plant glabrous, 3-6 in. high, with oblique often much-branched rootstock; lower lvs. cordate-ovicular, obtuse, crenate-serrate, not large (3½-4 in. wide); upper lvs. rather smaller and somewhat acuminate; fls. many, pale violet (running to white), overtopping the foliage; lateral petals bearded; spur 2-4 lines long; sepals acute. Que. to Minn. and Ga., in low or shaded places.

36. rostrata, Pursh. Fig. 3944. Glabrous or nearly so, 4-8 in. high, the sts. often numerous and plant forming a small clump; lvs. orbicular to broad-ovate, cordate, the upper ones acuminete, all serrate; fls. line with lighter spots; petals beardless; spur long (1½-2½ in.) and slender; cleistogamous fls. later on short axillary peduncles. A distinct and attractive species, in open woods and on hillsides, Que. to Mich. and southward.

3944. Viola rostrata. (X½)

3945. Viola Sheltonii. (X½)

**cc. Species western, or found east of the 100th meridian.**

**d. Lvs. not dissected:** petals yellow inside, the 2 upper madder-brown outside.

37. sarmentosa, Douglas. Prostrate plants with thickened rootstocks and numerous long leafy runners; lvs. small, roundish cordate, deep green above but often rusty beneath, closely crenate, shorter than the peduncles; fls. light yellow, the lower petal somewhat purple-veined; spur short and broad. Along the Pacific coast.
38. pedunculata, Torr. & Gray. Sts. ascending, often 2 ft. long, bearing normally in each If.-axil as the st. develops a large (1 in. across) fl. on a peduncle 2-5 in. long: rootstock thick and deep: lvs. round-ovate, the base usually truncate, coarsely crenate; stipules leafy: petals purple-veined inside, the lateral ones bearded. W. Calif., where often cult.; handsome.

39. glabella, Nutt. Sts. erect but usually weak, leafy only above: rootstock horizontal, more or less branching: lvs. cordate-reniform, glabrous or only puberulent, the lower ones on elongated petioles; stipules small; fls. bright yellow and somewhat purple-veined; lateral petals bearded; spur short and sac-like. Moist or shady places; widely distributed in the mountains of the N. W. and along the Pacific coast.

40. lobata, Benth. St. long and mostly naked at the base, the plant either glabrous or only puberulent: rootstock deep: lvs. from the base. Calif. and S. W. Ore.

41. Shétiôni, Torr. Fig. 3945 (adapted from Pacific R. R. Report). Nearly or quite glabrous; lvs. often a lar-reniform to cordate, 3-divided, the divisions 3-parted, lobed and cleft into narrow segms., not exceeding the peduncle: upper petals brownish, the 3 lower pale yellow. N. W. Colo. and N. E. Calif.

42. Beckwithii, Torr. & Gray. Fig. 3946 (adapted from Pacific R. R. Report). Plant pubescent or puberulent: lvs. palmately dect into 5-9 narrow lobes and the central lobe toothed: fls. yellow, the upper petals brownish purple on the outside. Calif. and S. W. Ore.

43. Hâlli, Gray. Plant glabrous; rootstock deep: lvs. 3-divided, the divisions 3-cleft, the segms. narrow; stipules leafy: fls. violet and yellow, the 2 upper petals dark violet and the 3 lower petals yellow or cream-colored; lateral petals bearded at base. N. W. Calif. and W. Ore.

44. trinervata, Howell. Plant glabrous; ultimate segms. of the If. lanceolate or ovate-lanceolate, tapering to an acute callous apex, thick and firm, prominently 3-ribbed; upper petals dark blue, the lower one pale blue to white with a yellow base. Cent. and S. W. Aus.

Ezra B. Shier.
work. Care should be taken not to have the beds too
covered with rustic siding. One walk 14 inches wide
some inconvenience involved in this work that most
In March, and selections
the time of planting varies somewhat in different
the same. The violet requires considerable water, but no very
rigid rules can be laid down as to the amount required. Every
effort should be put forth to keep the plants in
good growing condition without over-saturation of the
do not have the advantages that more favored ones like the
rose and carnation have had. Any good type of well-
cultivated houses is an ordinary even-span type, 12 feet wide.

For all practical purposes the commercial cultivation of the violet is limited to
growing in houses except in the South and
Far West, where for the most part they are
grown in the open or in coldframes.

Care should be taken not to have the beds too
wide, otherwise it will be difficult to reach all parts
of them from the walks. The best growers practice changing
the beds each year. At least 5 inches of fresh soil
should be put in before the young plants are set out.

The time of planting varies somewhat in different
parts of the country. Usually the flowers are not much
in demand after the middle of April, so that in prac-
tically all the violet-growing sections preparations may
be made in March, and selections may be made from these
for the planting, which is performed the latter part
of May.

Comparatively little at-
tention has been given to
proper houses for violet-
culture. Almost any kind
of house is believed to be
suitable, hence the crop has
not had the advantages that more favored ones like the
rose and carnation have had. Any good type of well-
lighted, well-ventilated house will suffice. For those
with a limited amount of capital to invest, one of the most economical and satisfactory
houses is an ordinary even-span type, 12 feet wide.
The height of such houses is about 6 feet, with a roof
5 feet 5 inches wide. Such beds are a
little wider for convenience in reaching the plants from
the walk, but by means of a board to be hooked onto the heating pipes, all plants may be conveniently reached. Coldframes for violet-culture are simple in construction. They are of the usual type, being 6 feet wide, 12 inches high in front, and 16 to 18 inches high at the back. Ordinary 3 by 6 inch may be used. These frames may be made any length in locations where the soil is porous and well drained; the frames may be lower than the surrounding soil. This gives some advantages in winter although it is back-breaking work at any time properly to care for the plants and pick the flowers in such frames.

In sections where the climate is comparatively mild, violets may be planted directly in the open ground and the frames, which may be movable ones, may be set over the plants about the middle of September. Violet houses do not need much heat, merely enough in fact to keep out the frost. The tendency is to overheat and there are probably more good crops spoiled by too much rather than too little heat. Hot water is usually depended on for heating both houses and frames. For the average houses a boiler capacity of 1,200 to 1,500 square feet will be required for every 10,000 plants. With the present cost of materials and labor it is safe to figure the cost of a plain style of house such as already described at about 50 cents a plant. A house 12 feet wide and 100 feet long will hold about 2,000 plants and should cost complete from $850 to $1,000.

Marketing is one of the most important factors connected with commercial violet-growing and is seldom understood in all its details. The grower should be thoroughly familiar with the many needs and requirements of the market and be able to supply these demands, for upon his ability to do this depends largely his success or failure from a financial standpoint. Violets are prized chiefly for their delicate perfume, and as this diminishes in proportion to the length of time they are picked, the best market, other things being equal, is the one which requires the least possible delay between picking the flowers and placing them in the hands of the customer.

The crop may be disposed of at retail or wholesale or through a commission merchant. Each method has its advantages and disadvantages, and in deciding

which one to adopt the grower must be guided by existing conditions. He must in any event have a thorough knowledge of the requirements of the market as regards quality of the flowers, size, shape, and arrangement of the bunch, and should at all times exercise the utmost care in picking, packing, and shipping, so that the flowers may reach the customer in the best and most attractive condition. The kind of bunch varies from year to year, and each large city is likely to have its own style. The various styles are wonderfully exacting in their requirements and great skill is required to bunch the flowers properly.

The cultivated violets are subject to a number of diseases, each of which is characterized by one or more distinct symptoms. The principal diseases are as follows, their destructive-ness being in the order in which they are discussed:

Spot disease (Alternaria violae) (Fig. 3951), also called leaf-spot, leaf-rust, and smallpox, is the most widespread and destructive known in America. It attacks principally the foliage, normally producing definite circular whitish spots, frequently with concentric rings, of a darker shade, very often with a light central portion resembling the bite or sting of an insect. Ceratoceras violae, Phyllosticta violae, and the like, produce spots very similar in outline and appearance to those caused by Alternaria violae, but only under conditions peculiarly favorable to these fungi do they cause any serious loss.

Root-rot (Thielavia basicola) is very troublesome and destructive in some localities, especially to young plants that are transplanted during hot dry weather. It causes the growing or blackening of the parts attacked and the final death of the plant. Wet-rot (Botrytis sp.) attacks leaves, petioles, flower-stalks, and flowers, causing a moist or soft rot. It is sometimes very destructive, especially with large plants growing in a damp stagnant atmosphere, where there is insufficient ventilation and light.

Leaf-fading or yellowing is induced by a variety of conditions, but as yet little that is definite has been ascertained regarding its cause.

It is difficult to exterminate any of the diseases named after they once gain a foothold. However, they can be held in check and often entirely prevented by selecting and propagating exclusively from strong vigorous disease-resistant plants, and by keeping them in the best possible growing condition. Careful attention must be given to watering, cultivation, and ventilation, and the dead and dying leaves and all runners should be destroyed as fast as they appear.

Although violets are attacked by a number of insects and other related enemies, only a few do sufficient injury to warrant discussion here.

Aphides (Aphis sp. and Rhopalosiphum violae) are generally known as the green- and the black aphid or green- and black-fly. They cause the young growing parts to curl and twist, resulting in a stunted deformed plant. They work their way into the young, unopened flower-buds, and, thrusting their bills through the overlapping petals, feed on the juice. Each puncture produces a greenish white blotch on the petal, and the flower becomes dwarfed, distorted, and worthless for market. Aphides can be easily controlled by fumigating with hydrocyanic acid gas, and this is now in general use. To each cubic foot of space in the house or frame use .15 gram of 88 per cent cyanide of potassium for double varieties and .10 gram for single varieties. Handle the cyanide and gas with utmost care, as both
are very poisonous. Divide the total amount of cyanide into as many equal parts as there are jars used, which latter should be one for every 50 to 75 linear feet of a house 12 to 18 feet wide. Put each part into a two-pound manilla paper bag and this into a second bag. Attach each package to a string or wire so arranged as to allow it to be lowered from the outside of the house into its respective jar. Pour into each jar an amount of water about equal to the bulk of cyanide in the bag, add commercial sulfuric acid until steam is evolved, then from the outside lower the bags into the jars beneath. Fumigate double varieties thirty minutes and single varieties twenty minutes, after which open ventilators from outside, leaving them open at least sixty minutes before entering the house. Aphides may also be combated by using tobacco in some one of its many forms, but tobacco is likely to weaken the leaves and make them more liable to the attack of fungi, and on this account is very objectionable.

Red-spider (Tetranychus telarius) lives on the under surface of the leaves, and, when present in sufficient number, causes considerable damage. It is widely distributed on a great variety of plants, and when established in the violet-house is most difficult to combat. It can be held in check, and often the plants may be kept entirely free from it, by frequent syringing with clear water under a pressure of twenty to thirty pounds to the square inch. Care must be taken to syringe early in the morning and on bright days, so that the plants may dry off before night. Neglect may be the means of inducing disease.

Eel-worms, or nematodes, are sometimes very injurious to the violet. This is a species, attacks the roots producing galls and distortions that check the growth of the plants. These may be controlled by judicious soil selection, the freezing of the soil in winter and the use of good clean grass sod. A very destructive nematode, Aphelenches spicatus, that appeared in this country twelve or fifteen years ago, is rapidly becoming one of the serious enemies of the violet. This nematode attacks the crown-buds, causing the plants to "go blind." Rigid selection of stock is the only remedy. Every "blind" crown plant should be taken out and destroyed. Extreme care should be exercised in introducing new stock. Nearly all imported plants are more or less affected with the pest. The bud nematode does more injury in this country than abroad. This may be due to the fact that while the pest has been imported, its enemies have not been brought in. Some very promising investigations are now being made by N. A. Cobb, of the Bureau of Plant Industry, United States Department of Agriculture, of a race of predaceous nematodes which destroy immense numbers of the harmful kinds.

In some parts of the country the larvae of gall-fly (Diplolepis eriosa), violet sawfly (Empyktus canadensis), greenhouse leaf-tufts (Phyllostreta rubigalis), and several species of cutworms (Agrotis et al.) injure the plants to some extent by feeding on the foliage. Fumigating with hydrocyanic acid gas is the best means of combating them.

Under certain conditions slugs, snails, sowbugs, and the like, do considerable damage, especially to the flowers. They also can be controlled by the hydrocyanic acid gas treatment.

**VITEX (ancient Latin name for this or a similar shrub).** Verbenaceae. Ornamental woody plants chiefly grown for their white, blue, or yellowish flowers produced in terminal spikes or panicles. Deciduous or evergreen shrubs or trees; lvs. opposite, digitate, with 3-7, rarely with 1 ft.; fls. in 1 or many-fld. cymes; calyx campanulate, usually 5-toothed; corolla tubular-funnel shaped, with 5 lobed, oblique and slightly 2-lipped limb; stamens 4, 2 longer and 2 shorter ones: fr. a small drupe, with a 4-angled stone. About 60 species are known, distributed through the subtropical and tropical regions of both hemispheres, few in the temperate regions. Some species, particularly *V. altissima* and *V. leucoxylon*, in S. Asia are important timber trees.
The two species most often cultivated are shrubs or small trees with deciduous digitate leaves and lilac-blue or white flowers in terminal spikes or loose panicles appearing in summer and autumn. The hardiest seems to be *V. Negundo* var. *incisa*, which stands most ordinary winters as far north as Massachusetts. *V. Agraueus* is hardly as far north as New York, in sheltered positions. These species are particularly valuable for their late-appearing flowers. They grow in almost any kind of soil and prefer rather dry sunny situations. Most of the species are inhabitants of tropical and subtropical regions and only a few can be cultivated outdoors in warmer temperate regions. None of these tender kinds seems to be in cultivation in this country; in the Old World they are sometimes cultivated as greenhouse plants. They thrive in a sandy compost of peat and loam. Propagated from seeds sown in spring and by greenwood cuttings under glass; also by layers.

**Agnes-cástus, Linn. CHASTE-TREE. HEMP-TREE.** Shrub or small tree, with a strong aromatic odor, grayish tomentose; lvs. long-stalked; lfts. 3-5, lanceolate, acuminate, serrate or entire, grayish tomentulose beneath, the middle one 3-4 in. long; the fs. in dense, sessile clusters, forming terminal, often panicled spikes 5-7 in. long; corolla usually pale or lilac, grayish outside, 1½ in. long; stamens and style exserted. July-Sept. S. Eu., W. Asia. Mn. 2, p. 44. G.C. III. 51:52. Var. *alba*, Rehd. (V. abiflora, Hort., *Agnes-cástus vulgaris* alba, Carr.). Fls. white.

**Negundo, Linn.** Shrub or small tree with quadrangular branchlets: lfts. usually 3, or occasionally 5, stalked, elliptic-ovate to lanceolate, acuminate, serrate or entire, grayish tomentulose beneath, 1½-4 in. long; fls. blue or lavender, small, scarcely ¼ in. long, stalked, in rather loose clusters forming slender spikes usually crowded into loose terminal panicles 5-8 in. long; stamens and style slightly exserted. China, Indi. Tender. Var. *incisa*, Clarke (V. incuse, Lam. V. laciniata, Hort.). Fig. 3952. Lfts. incised serrate or almost pinnatifid, ½-3 in. long; the more extreme form with deeply pinnatifid lfts. and narrow remote segms. may be distinguished as *V. multifida*, Rehd. (*Agnes-cástus incus var. multifida*, Carr.). July-Aug. N. China, Mongolia. B.M. 364 (as V. Negundo). This variety is much harder than the type; it is less showy in bloom than the preceding species, but a graceful shrub of loose and open habit, with handsome foliage.

3952. *Vitex Negundo var. incisa*. (X¼)

3953. *Vitis*.—Forms of leaf on the same vine.

**Vitis** (classical Latin name). VINE. GRAPE. *Vitis* or *Ampelidea*. Tendril-climbers (some members of the genus *Cissus* erect) grown as ornamental vines but particularly for the edible fruits or grapes. The genus is variously defined, but if *Cissus* is excluded it is distinguished as follows (Gray): Plants climbing by the prehension and coiling of naked-tipped tendrils; fs. polygamo-dioecious (i.e., some individuals perfect and fertile, others sterile with at most only a rudimentary ovary), 5-merous; corolla calyptrately caducous—the petals in anthesis cast off from the base while cohering by their tips (Fig. 3954); hypogynous disk of 5 nectariferous glands alternate with stamens; style short and thick, or conical; berry pulpy; seeds pyriform, with contracted beak-like base.—A widespread genus of the northern hemisphere, most abundant in temperate countries. In its stricter limitations, the genus includes less than 60 known species, but some authors unite *Cissus* and *Ampelopsis* in it. V. *Negundo* includes some 250 species. The standard monographer (Planchon, DC. Monogr. Phaner. 5), refers 30 or more species to *Vitis* in the main account and in the addendum, and more than 200 to *Cissus*. N. Amer. is particularly rich in *Vitis*, not only in number of species, but in the widespread distribution and the abundance of the plants. From the native species have been developed the outdoor grapes of this country except those of Calif. and the extreme S. W. (which are *Vitis riparia*). For an account of the evolution of these various cultural varieties, see Bailey, Sketch of the Evolution of Our Native Fruits; Hedrick’s Grapes of New York, a notable volume issued by the N. Y. Agric. Exp. Sta.; also Munson, Foundations of American Grape Culture, 1909. For a sketch of *Vitis* and similar plants as ornamental vines, with illustrations, see Veitch, Journ. Roy. Hort. Soc. 28 (1905–4). For cult., and control of insects and diseases, see *Grape*. For recent studies in var. in variation and in pollen sterility, see *Proc. Amer. Breeders’ Assoc., vol. 7* (1912), and Bull. No. 144, Minn. Exp. Sta. (1914).

Many of the species of *Vitis* are excellent ornamental plants, when it is desired to cover arbors, porches, or trees; a number of the recently introduced oriental species (some of them properly referable to *Ampelopsis* and *Parthenocissus*) seem to be particularly interesting for such use. All of them are readily grown from seeds, and most of them from hardwood cuttings. Only a few of the native species are regularly in the trade; but with the possible exception of *V. Treleasei* they have been offered for sale to experimental stations and amateurs by the late T. V. Munson, of Texas, a well-known authority on both the botany and horticulture.
VITIS

3054. Grape flowers, enlarged. 1, shows the bud; 2, shows the petals or "cap" falling; 3, shows the flower in full bloom, the petals having been cast off. In all the flowers the minute calyx is seen, and in 2 and 3 the disk is shown inside the base of the stamens.

North America north of Mexico; it is adapted from the writer's account in Gray's "Synoptical Flora," vol. I, 420-430. These American grapes are very difficult to distinguish in many cases; hence the subjoined descriptions are full, to bring out the contrasting characters. Some of the best recent systematic writing on American Vitis is from French sources, since the American species have come into prominence in France as phylloxera-resistant stocks for the wine grape. See, for example, the works of Millardet, and Viala and Ravaz; also "Ampelographie Universelle," by Viala and Vermorel. Many of the species listed in the trade under Vitis will be found in the genera Ampelopsis, Parthenocissus, and Cissus.

The grape-vines of eastern Asia, although apparently not yielding fruit of value, are interesting as ornamental vines, and some of them are likely to come into prominence for their good foliage and brilliant autumn coloring. They are little known with us as yet. V. Conjonctii and V. amurenensis are hardy in the northern states. Those tender at the Arnold Arboretum and more or less killed back in winter are C. capensis (V. capensis); C. gongylodes (V. murnenensis); C. hypoglauca (V. hypoglauca); C. oblonga (V. oblonga); C. quadrangularis (V. quadrangularis); C. rhombifolia (V. rhombifolia); C. Romanetii (V. rutilans); Cissus striata (V. sempervirens), page 776. The standard English authors incline to keep them distinct. Several of the species properly referred to Cissus are described in the present account (Nos. 1-5), not having found their place regularly under Cissus in Vol. II.

INDEX. 2.

Vitis capensis (preferably known as Cissus capensis), an evergreen species prized in southern California. (X 1/2)
nearly orbicular to reniform, 3-nerved, obtusely 5-angled, the margin repand-dentate, with ovate stipules; infl. thyrse-like, tomentose, with long peduncles, the fls. woody, with 5 triangular-ovate petals and 5 stamens, the ovary hirsute and style short; fr. globular, red-black and glossy, usually 2-seeded, about 2 in. diam., said to be excellent for sirups, jellies, and for stewing. S. Afr.—Tubers reported as making wholesome fodder for cattle.

3. C. hypoglaucia, Gray (Vitis hypoglaucia, Muell.). Scandent evergreen, the branches angled but not winged; lvs. 3-foliolate, petiolated; lfts. all long-petiolate, serrate, glabrous above, the lateral ones oblique and somewhat cordate, the middle one ovate to rhombic, petioled; lfts. 3-foliolate, petioled; lfts. all long-petiolate, acuminate, stalked, entire or toothed toward the apex: fls. white, with 5 triangular-ovate petals and 5 stamens, the ovary husute and style short: fr. globular, angled, the margin repand-dentate, with ovate stipules: bark without distinct lenticels, on the branchlets smoothish and glabrous; leaves large (4 in. or more diam.) with a distinct stipe-like beak. (Muscadinia; separated as a genus by Small.)

4. C. rhombifolia, Planch. (Vitis rhombifolia, Vahl). Bark without distinct lenticels, on the branchlets smoothish and glabrous; leaves large (4 in. or more diam.) with a distinct stipe-like beak. (Muscadinia; separated as a genus by Small.)

5. C. oblonga, Planch. (Vitis oblonga, Benth.). Erect tree-like evergreen species, the branches with a few tendrils, glabrous or the young shoots minutely tomentose: lvs. simple, broad-oblong to ovate-oblong, obtuse, about 1-2 in. long, entire, obscurely 3-nerved: fr. ovate, small, 2-3-seeded, in short-petioled cymes. Austral.—Allied to C. antarctica.

II. Species of Vitis, or true grapes; plants yielding the grapes of commerce, and some of them grown for arbors and for ornament.

A. Bark bearing prominent lenticels, never shredding; nodes without diaphragma; tendrils simple; fl.-clusters small and not much elongated; seeds ovoid or oblong, without a distinct stipelike beak. (Muscadinia; separated as a genus by Small.)

6. rotundifolia

B. Bark without distinct lenticels, on the old wood separating in long thin strips and fibers; nodes provided with diaphragma; tendrils forked; fl.-clusters mostly large and elongated; seeds pyriform. (Euovis.)

7. Munsoniana

B1. The wine-grape, grown extensively in Calif., as well as in Eu., and also in glass grapevines; skin and pulp mostly firmly adhering to the rpe fr.

8. vinifera

B2. The grapes of more modern domestication or intro., representing the commercial kinds in N. Amer. outside the Calif. region, and exotic species grown for ornament; skin of the mature berry usually separating freely from the pulp.

9. Davidii

C. Sta. stiff-hairy or bristly, or pricky. (Spinottis.)

D. Lvs. becoming glabrous beneath: sta. glabrous and prickly.

D1. Lvs. floccose or loosely pubescent beneath: sta. glandular-bristly and pubescent.

10. Romanetti

C1. Sta. glabrous or pubescent, not aculeate or armed.

D. Vitis species of N. Amer., some of them giving rise to pomological races and the others of botanical interest. (Nos. 21-32)

E. Class of green-leaved grapes, mostly marked at maturity by absence of prominent white, rusty, or blue tomentum or scar or conspicuous bloom on the lvs. beneath (under surface sometimes thinly pubescent, or minute patches of floccose wool in the axils of the veins, or perhaps even cobwebby): foliage mostly thin: tendrils intermitent, i.e., every third joint bearing no tendrils (or infl.). V. cinerea and V. arizonica are partial exceptions and are much less so than most in the genus. V. Champinii, with a long or at least a prominent point and usually long and large sharp teeth or the edges even jagged.

G. Lvs. broader than long, with truncate-oblique base. (V. Treleasei might be sought here.)

11. rupestris

G1. Lvs. ovate in outline, with a mostly well-marked basal sinus.

12. monticola

H. Diaphragm (in the nodes) thin: young shoots not red: lvs. not deeply lobed.

13. Champinii

II. Lvs. margin not lobed or only obscurely so, the teeth small or else not elongated.

14. Longii

J. Young parts pubescent or floccose.

15. vulpina

K. Tendrils prominent and persistent.

16. Trelasei

KK. Tendrils small and deciduous.

17. rubra

FP. Group of cardofolia-like grapes, with thickish and dull-colored or grayish green lvs. often holding some class dull paleness below at maturity and the shoots and lvs. nearly always more or less pubescent when young, the teeth mostly short, the point mostly red and more conspicuous.

O. Plant strong and climbing, with stout persistent tendrils.

H. Young shoots tere and slender, and glabrous or very slightly becoming so.

18. cordifolia

HI. Young shoots angled, and covered the first year with tomentum or wool.

I. Under surface of lvs. glabrous or essentially so at maturity.

J. Blade of l. lustrosa or glossus when full grown.

19. Berlandieri

JJ. Blade of l. dulli.

20. Baileyana

K. Under surface of lvs. glaucous or pubescent.

21. cinerea

GG. Plant scarcely climbing, the tendrils perishing when failing to find support.

22. arizonica

FPP. Group of orbicular-scallop-led. species of the Pacific coast.

23. californica

EB. Class of colored-leaved grapes, marked by thick or at least firm foliage, the lvs. prominently rusty or white-tomentose or glaucous-blue. V. eipheri, V. arizonica, and possibly V. californica might be sought here; and leaf-patented forms of V. bicolor might be looked for in Eu.
VITIS

V. Lus. only flocculently or coarsely or glabrous below when fully grown (i.e., not covered with thick, dense, felty-hairiness, except sometimes in V. Doniania).

G. Ends of the growing shoots are, under the surface of the leaf, which by gray: the white-tipped.

H. A. Grape of S. Calif., with thick diaphragms and short, pointed lvs.

II. Grape of Okla.-Texas region, with thin diaphragms and prominently pointed lvs.

GG. Ends of shoots (except in V. bicolor), and the unfolding leaves distinctly rusty-colored, and the mature leaves, either rusty or bluish beneath (or sometimes becoming green in V. bicolor): the variscan grapes.

H. Leaves usually prominently floccose or tomentose.

HH. Leaves pubescent or becoming nearly as smooth as glabrous.

I. Under surface of lvs. mostly glaucous-blue.

II. Under surface not glaucous-blue (except in variety of V. bicolour): the variscan grapes.

J. Berries small, 0.5–1 in. long, shaped something like a coffee berry. River banks, swamps, and rich woodlands and thickets, S. Del. to N. Fla. and west to Mo., Kans., Texas, and Mex.

3956. Vitis cinerea. (X4)

7. Munsoniana, Simpson (Muscadinia Munsoniana, Small). MUSTARD GRAPE OF Fla. BIRD, EVERBEARING, OR EVERLASTING GRAPE.

Very slender grower, preferring to run on the ground or over low bushes, more nearly evergreen than the last, flowering more or less continuously: lvs. smaller, thinner, and more shining, more nearly circular in outline and less prominently pointed, the teeth broader in proportion to the blade and more open or spreading; clusters larger and more thyrse-like: berries a half smaller than in the last and often more numerous, shining black, with a more tender pulp, acid juice, no muskiness and thinner skin; seeds half smaller than in the last. Dry woods and sands, Fla. at Jacksonville, Lake City, and southward, apparently the only grape on the red keys; also in the Bahamas. Difficult to distinguish from V. rotundifolia in herbarian specimens, but distinct in the field. The plant often bears fis. and both green and ripe fr. into Dec.

8. vinifera, Linn. WINE GRAPE. EUROPEAN GRAPE.

Fig. 3956. Young growth smooth or floccose, the plant
not so high-climbing as most American species; tendrils intermittent: lvs. mostly thinish, rounded, with a deep sinus and the basal lobes usually overlapping, tomentose or glabrous beneath, the margins coarsely nicked or jagged; clusters large and long, the berries usually oval or oblong, although wide in some varieties; globular-fruited. Probably native to the Caspian or Caucasus region and W. India. Cult. from the earliest times, and the grape of history; now greatly varied. The hothouse grapes, as Black Hamburg, Barberossa, are of this species; also the vineyard grapes of Calif. Not hardy in the northern states and very subject to phylloxera (root-louse) and mildew. Regel, a Russian botanist, considered the wine grape to be a hybrid of 2 species that he characterized as V. Labruscana and V. vulpina, but this view is not accepted. Var. apiifolia, Loud. (V. laciniata, Linn. V. vinifera var. laciniata, Dipp.), has the lvs. cut into 5-7-9-odd segments; ornamental: known as "parsley vine," and "cicat."

9. Davidi, Fée (Syvadésis Davidi, Romant. Vitis Davidiaina, Dipp. V. armata, Diels & Gilg. V. vinifera var. Davidi, Hort.). Sts. and petioles armed with straight or slightly recurved prickles, glabrous; tendrils interrupted: lvs. long-petioled, large, papery, somewhat glaucous and becoming glabrous; stem vertically broadly ovate, obscurely angled, the base cordate, the apex acuminate and acute, the margin finely and feebly serrulate, the teeth acute or obtuse, the base cordate, the boldly rounded top bearing a short, abrupt point and sometimes 2 lateral teeth enlarged and suggesting a crenate-tint, the sides turned up so as to expose much of the underside, broadly ovate, obscurely angled, the base cor­

10. Romanéthi, Romanet (V. rutilans, Carr.). Petioles and young sts. floccose-pubescent and bearing spreading gland-bearing purplish hairs or bristles; sts. and young shoots bare; fr. bluish: perhaps a hybrid.

11. rupestris, Scheele. SAND, SUGAR, ROCK, BUSY, CURRANT, or MOUNTAIN GRAPE. Shrub 2-6 ft. high, or sometimes slightly climbing, the tendrils few or even none, diaphragm plane and rather thin: lvs. reniform to reniform-ovate (about 5-8 in. wide and two-thirds as long), rather thick, smooth and glabrous on both surfaces at maturity, marked by a characteristic light glaucous tint, the sides turned up so as to expose much of the undersurface, the base only rarely cut into a well-marked sinus, the margins very coarsely angle-toothed, the boldly rounded top bearing a short, abrupt point and sometimes 2 lateral teeth enlarged and suggesting lobes; stamens in fertile fls. recurved laterally or rarely ascending, those in the sterile fls. ascending; cluster small, slender, open and branched; berries small (1/4-1/2 in. diam.), purple-black and somewhat glaucous, pleasant-tasted, ripe in late summer; seeds small and broad. Sand banks, low hills, and mountains, S. Pa. to Tenn., Ind., Mo., Okla., and S. W. Texas. Var. dissicata, Eggert, is a form with more ovate lvs. and very long teeth, and a strong tendency toward irregular lobing. Mo.

12. monticola, Buckl. (V. texana, Munson. V. texicana, Planch). SWEET MOUNTAIN GRAPE. Fig. 3957. A slender trailing or climbing plant (reaching 20-30 ft. in height, with very long and slender branches, the young growth angular and floccose (sometimes glau­

13. Champaui, Planch. Probably a hybrid of V. rupestris or V. Berlandieri and V. candicans, bearing medium to large reniform or reniform-cordate lvs, which are variously pubescent or cobwebby but become glabrous, the growing tips mostly white-tomentose; berries very large and excellent. S. W. Texas. A.G. 12:579.——-In some places associated with V. candicans, V. Berlandieri, and V. monticola only, and in others with the above and V. rupestris. Often composing dense thickets in the wild.
found about fifty years ago by Engelmann in the Botanic Garden of Berlin under the name of *Vitis* Solonis, without history. Engelmann guesses (Bushberg Cat. ed. 3, 18) the name to be a corruption of "Long's." It is probable that the plant was sent to European gardens as *Vitis* Longii—very likely from Prince's nursery—and the name was misread on the label. The original name, which was duly published by Prince with description, may now be restored.

Var. *microsperma*, Bailey (V. Solonis var. microsperma, Munson), is a very vigorous and small-seeded form, which is very resistant to drought. Red River, N. Texas.

15. *vulpina*, Linn. (V. riparia, Michx. V. odoratissima, Donn. V. odorata, Hort. V. silvarum, and V. missouriensis, Prince? V. cordifolia var. riparia, Gray). RIVERBANK or FROST GRAPE. Fig. 3958. A vigorous tall-climbing plant, with a bright green cast to the foliage, normally glabrous young shoots, large stipules, and plane very thin diaphragms: lvs. thin, medium to large, cordate-ovate, with a broad but usually an evident sinus, mostly showing a tendency (which is sometimes pronounced) to 3 lobes, generally glabrous and bright green below, but the veins and their angles often pubescent, the margins variously deeply and irregularly toothed and sometimes cut, the teeth and the long point prominently acute: fertile fis. bearing reclining or curved stamens, and the sterile ones long and erect or ascending stamens: clusters medium to large, on short peduncles, branched (often very compound), the fis. sweet-scented: berries small (less than \( \frac{1}{2} \) in. diam.), purple-black with a heavy blue bloom, sour and usually austere, generally ripening late (even after frost); seeds rather small and distinctly pyriform. Nova Scotia and New Bruns. to Man., Kans., and Colo. and south to W. Va., Mo. and Texas. B.M. 2429.

The commonest grape in the northern states west of New England, abundant along streams. Variable in the flavor and maturity of the fr. Forms with petioles and under surfaces of lvs. pubescent sometimes occur. It apparently hybridizes with *V. Labrusca* eastward, the hybrid being known by the tomentose young shoots and unfolding lvs., and the darker foliage, which is marked with rusty tomentum along the veins of the less jagged lvs.

Var. *præcox*, Bailey, is the JUNE GRAPE of Mo., the little sweet frs. ripening in July.

16. *Trelæsei*, Munson. Plant shrubby and much branched, climbing little, the small and mostly short (generally shorter than the lvs.) tendrils deciduous the first year unless finding support, internodes short, the diaphragms twice thicker (about \( \frac{3}{2} \) in.) than in *V. vulpina* and shallow-biconcave: stipules less than one-fourth as large as in *V. vulpina*: lvs. large and green, very broad-ovate or even reniform-ovate (often wider than long), thin, glabrous and shining on both surfaces, the basal sinus very broad and open and making no distinct angle with the petiole, the margin unequally notch-toothed (not jagged as in *V. vulpina*) and indistinctly 3-lobed, the apex much shorter than in *V. vulpina*: fertile fis. with very short, recurved stamens, sterile with ascending stamens: cluster small (2-3 in. long): berries \\( \frac{1}{2} \) in. or less thick, black with a thin bloom, ripening 3 weeks later than *V. vulpina* when grown in the same place, thin-skinned; pulp juicy and sweet; seeds small. Brewster Co., S. W. Texas and New Mex. to Bradshaw Mts., Ariz.—Little known, and possibly a dry-country form of *V. vulpina*. In habit it suggests *V. arizonica* var. *globa*, from which it is distinguished, among other things, by its earlier flowering and larger lvs. with coarser teeth and less pointed apex.

17. *rubra*, Michx. (V. monosperma, Michx.). RED or CAT GRAPE. Fig. 3959. A slender but strong-growing vine, with small long-jointed angled red glabrous herb-like shoots and red petioles: lvs. small to medium, ovate-acuminate, dark green and glossy, sometimes indistinctly pubescent on the nerves below, the sinus obtuse, the blade either nearly continuous in outline or (commonly) prominently lobed or even parted, coarsely notched: stamens in the sterile fis. long and erect: clusters loose and long-peduncled, branched, the fis. opening very late: berries small and late (\( \frac{3}{4}-\frac{3}{8} \) in. diam.),
acute, sinus more open; petioles shorter and often smaller, the larger ones shortly but distinctly prolonged and often muticous, the teeth comparatively small and notch-like and not prominently pubescent at maturity only on the veins, the point only on the surface of the IVB.

3-lobed or 3-angled, the basal sinus rather deep and ending in a short mucro. Kerr Co., S. Texas, 1,600-2,000 ft.

Var. fécilis, Engelm., has fétidly aromatic berries, and grows in the Mississippi Valley.

Var. sempervirens, Munson. A glossy-leaved form holding its foliage very late; lvs. sometimessuggesting forms of V. rubra, deltoid with a truncate base: clusters small, the fr. ripening later than in the type. S. Fla.

Var. Helleri, Bailey (V. Helleri, Small). Lvs. more circular (i.e., lacking the long point), and the teeth round-obtuse and ending in a short mucro. Kerr Co., S. Texas, 1,600-2,000 ft.

19. Berlandieri, Planch. MOUNTAIN, SPANISH, FALL, or WINTER GRAPE. Fig. 3960. A stocky moderately climbing vine, with mostly short internodes and rather thick diaphragms; lvs. medium large, broadly cordate-ovate or cordate-orbicular (freely as broad as long), glabrous and glossy above, covered at first with gray pubescence below but becoming glabrous and even glossy except on the veins, the sinus mostly inverted-U-shaped in outline but often acute at the point of insertion of the petiole, the margin distinctly angled above or shortly 3-lobed and marked by rather large, open, notch-like acute teeth of varying size, the apex mostly pronounced and triangular-pointed: stomens long and ascending in the sterile fls., laterally recurved in the fertile ones: clusters compact and compound, mostly strongly shouldered, bearing numerous medium to small (½ in. or less diam.), purple and slightly glaucous very late berries which are juicy and pleasant-tasting; seed (frequently only 1) medium to small. Limestone soils along streams and hills, S. W. Texas and Mex.—Well marked by the gray-veined under surface of the lvs.

20. Baileyana, Munson. POSSUM GRAPE. Less vigorous climber than V. cordifolia, rather slender, with short internodes and very many short side shoots; lvs. frequently smaller, the larger ones shortly but distinctly 3-lobed (lobes mostly pointed and much spreading), bright green but not shining above, gray below and pubescent at maturity only on the veins, the point only slightly prolonged and often muticous, the teeth comparatively small and notch-like and not prominently acute, sinus more open; petioles shorter and often pubescent; floral organs very small, the stamens reflexed in the fertile fls.: pedicels short, making the bunch very compact: berries about the size of V. cordifolia, black and nearly or quite bloomless, late; seed small and notched on top. Mountain valleys, 800-3,000 ft. altitude, S. W. Va. and adjacent W. Va. and W. N. C., Tenn., and N. Ga.; also at common levels in the uplands of W. Cent. Ga.—The eastern counterpart of V. Berlandieri.

21. cinerea, Engelm. SWEET WINTER GRAPE. Fig. 3961. Climbing high, with medium to long internodes and thick and strong diaphragms; lvs. large, broadly cordate-ovate to triangular-cordate-ovate (generally longer than broad), the sinus mostly wide and obtuse, the margin small-notched (teeth much smaller than in V. Berlandieri) or sometimes almost entire, mostly distinctly and dextracordately 3-angled or shortly 3-lobed toward the apex, the triangular apex large and prominent, the upper surface coarsely pubescent and the lower dark green (not glossy), the under surface remaining ash-gray or dun-gray, pubescent: stomens in sterile fls. long, slender, and ascending, in the fertile ones short and laterally recurved: cluster mostly loose and often straggling, containing many small black berries, these only slightly, if at all glaucous, ripening very late, and after frost becoming sweet and pleasant; seeds small to medium. Along streams, mostly in limy soils, Cent. Ill. to Kans. and Texas; also N. Fla., also in Mex.—Readily distinguished from V. austriaca by the triangular-topped sharply 3-lobed ash-gray lvs. and the gray tomentum of the young growth.

Var. floridana, Munson (V. austriaca, Small). Growing tips rusty-tomentose, as are sometimes the veins on...
the under sides of the lvs.: cluster longer-peuncled and more compound. Manatee Co., Fla.; and apparently also in Ark.; possibly a compound with *V. sativula*, but the lvs. have the characteristic shape of *V. cinerea*. Not to be confounded with any form of *V. cariba*, because of the lobed triangular-topped lvs. and much larger teeth.

Var. canescens, Bailey. A form with rounded or heart-like lvs., the upper half of the l. lacking the triangular and 3-lobed shape of the type. St. Louis, Mo., and S. Ill. to Texas.

22. arizonica, Engelm.  (*V. arizonensis*, Parry). CAÑON GRAPE. Plant weak, much branched, with short internodes and thick diaphragms, branchlets angled: lvs. mostly small, cordate-ovate and with a prominent triangular-pointed apex, the sinus broad or the base of the blade even truncate, the teeth many and small and pointed or mucronate, the margin either continuous or very indistinctly 3-lobed (or sometimes prominently lobed on young growths), the lvs. and shoots white-woolly when young, but becoming nearly glabrous with age: stamens ascending in sterile fls. and recurved in the fertile ones: bunches small and compound, not greatly; if at all, exceeding the lvs., bearing 20-40 small black berries of pleasant taste; seeds 2-3, medium size. Along river banks, W. Texas to New Mex. and Ariz., mostly south of the 35th parallel, to S. E. Calif. and N. Mex.

Var. glabra, Munson. Plant glabrous, with glossy and mostly thinner and larger lvs. In mountain gulches, with the species and ranging northward into S. Utah. Distinguished from *V. monticola* by its triangular-pointed and small-toothed lvs. Perhaps a form of *V. Treleausii*.

23. californica, Benth. Fig. 3962. A vigorous species, tall-climbing on trees but making bushy clumps when not finding support, the nodes large and diaphragms rather thin: lvs. mostly round-reniform (the broader ones the shape of a horse's hoof-print), rather thin, either glabrous and glossy or (more commonly) cottony-canescent until half grown and usually remaining plainly pubescent below, the sinus ranging from very narrow and deep to broad and open, the margins varying (on the same vine) from finely blunt-toothed to coarsely scallop-toothed (the latter a characteristic feature), the upper portion of the blade either perfectly continuous or rounded or sometimes indistinctly 3-lobed and terminating in a very short apex: bunches medium, mostly long-peduncled and forked, the numerous small berries glaucous-white, seedy and dry but of fair flavor; seed large (2½-in. long), prominently pyriform. Along streams in Cent. and N. Calif. and S. Ore.—Lvs. becoming handsomely colored and mottled in autumn. Very susceptible to mildew.

24. Girdiana, Munson. VALLEY GRAPE. SOUTHERN CALIFORNIA GRAPE. Strong climbing vine, with thick diaphragms: lvs. medium to large and rather thin, broadly cordate-ovate, with a rather deep and narrow sinus and nearly continuous or obscurely 3-lobed outline (sometimes markedly 3-lobed on young shoots), the teeth many and small and acute, the apex short-triangular or almost none, the under surface remaining closely ashy-tomentose: clusters large and very compound, each one dividing into 3 or 4 nearly equal sections, which are in turn shouldered and thyrse-like: berries small, black and slightly glaucous, the skin thin but tough, pulp finally becoming sweet; seeds medium in size, pyriform. S. Calif., south of the 36th parallel. —Diffs from *V. californica* in the more pubescent shoots and foliage, smaller and sharp teeth, decom-pound clusters, smaller less glaucous berries, and smaller seeds, Shoots of *V. californica* often bear lvs. with small and muti-cous teeth, and such specimens without the fl.-clusters are diff-icult to distinguish from this species. Some of the forms which have been referred to *V. Girdiana* are apparently hybrids with the wine grape, *V. vinifera*; the plant is imperfectly under-stood and its merits as a species are yet to be determined. It bears the name of H. H. Gird, of Calif.

25. Doaniiana, Munson. Plant vigorous, climbing high or remaining bushy if failing to find support, with short internodes and rather thin diaphragms: lvs. bluish green in cast, mostly large, thick, and firm, cordate-ovate or round-ovate in outline, bearing a prominent triangular apex, the sinus either deep or shallow, the margins with very large, angular, notch-like teeth and more or less prominent lobes, the under surface usually remaining densely pubescent and the upper surface more or less floccose: cluster medium to small,
The plant would pass as a hybrid of  V. culpina and  V. cande-
cans, except that these species do not often occur in its range. It bears the name of Judge J. Doan, of Wil-
barger Co., Texas. It gives promise as a parent of pomological grapes. The Arnold Arboretum reports it as
"a fast-growing plant and appears to be perfectly at home in New England. The leaves are large, thick and firm, and rather pale bluish green in color. The fruit, which grows in small clusters, is blue covered with a pale bloom and of fair quality."

26.  carib rea, DC. Fig. 3963. Climbing, with floccu-
cent-woolly (or rarely almost glabrous) and strPointF
shoots; tendrils rarely continuous; lvs. ovate-ovate or even oval and mostly acuminate-pointed, some-
times obscurely angled above (but never lobed except now and then on young shoots), becoming glabrous above but generally remaining rufous-tomentose below, the margins set with very small, mucro-tipped sinuate teeth; cluster long and long-peduncled, generally large and very compound; berry small and globose, purple; lvs. large, round-cordate-ovate in outline, glabrous and dull above and very heavily glaucous-blue below, but losing the bloom and becoming dull green very late in the season, those on the young growth deep blue-
lobed and on the older growths shallowly 3-lobed, the
basal sinus running from deep to shallow, the margins mostly shallow-toothed or sinuate-toothed (at least not so prominently notch-toothed as in  V. aestivalis); cluster mostly long and nearly simple (sometimes forked), generally with a long or prominent peduncle; the purple and densely glaucous berries of medium size (½in. or less diam.), sour but pleasant-tasted when ripe (just before frost); seeds rather small. Abundant
northward along streams and on banks, sometimes taking the place of  V. aestivalis. Ranges from New England and Ill. to the mountains of W. N. C. and to W. Tenn.

—Well distinguished from  V. aestivalis (at least in its
northern forms) by the absence of rufous tomentum,
the blue-glaucous small-toothed lvs. and long petioles
and tendrils. It has been misunderstood because it
loses its glaucous character in autumn; an excellent
species as a covering for arbors and trellises.

28.  aestivalis, Michx. (V. Nortoni, Prince. V.
Labrusca var. aestivalis, Regel. V. bracteata and V.
arméensis, Le Conte). SUmmer, BUNCH, or PIGEON
GRAPE. Strong tall-climbing vine, with mostly long inter-
nodes and thick diaphragms, the young growths
rusty or red-brown pubescence which clings
to the under side retaining a covering of copious
astringent to juicy and sweet; seeds 2–4, medium size (½in. or less long). S. N. Y. to
Cent. Fla. and westward to the Missouri and Misso-
rouri rivers.—A marked type readily
distinguished from other species by the red-
dish fuzz of the under side of the lvs.

Var. Bourquiniana, Bailey (V. Bourquiniana, Munson). A domestic offshoot, represented in such cult.
varieties as Herbermont and Le Noir, differing from  V.
aparvula in its mostly thinner lvs. which (like the young
shoots) are only slightly red-brown below, the pubes-
cence mostly crenate or dun-colored or the under sur-
f ace sometimes blue-green; berries large and juicy,
black or amber-colored.—A mixed type, much out
S. It is probably exotic, but may have been modified
by hybridization. Probably to be associated botanically with *V. vinifera*.

29. *Linsecomii*, Buckl. (*V. diversifolia*, Prince. *V. xantii* var. *Linsecomii*, Munson). Post-Oak, Pines, or Turkey Grape. More stocky than *V. xantii*, climbing high upon trees but forming a bushy clump when not finding support: lvs. densely tomentose or velvety below: berries large (1½-3½ in. diam.), black and glaucous, mostly palatable; seeds mostly much larger than in *V. xantii* (often ½ in. long). High post-oak (*Quercus stellata*) lands, S. W. Mo. to Texas and La.—Munson distinguishes it from *V. xantii* by larger berries and seeds, larger lvs. which are bluish in the var. glauca, greater endurance of drought. A promising species for the pomologist. It bears the name of Dr. Gideon Linsecom, and is oftenwritten *V. Linsecomii*, but if such original spellings as Wisteria, Zanthorizia, Deditis, Stewartia and many others are to be retained, consistency requires that we hold to Buckley’s original spelling, *V. Linsecomii*.

Var. glauca, Munson (*V. xantii* var. glauca, Bailey). Lvs. and mature wood glaucous-blue on the body beneath, but the veins rusty: berries and seeds larger. S. W. Mo. to N. Texas.—Much like *V. bicolor*, but lvs. thicker and more pubescent below, and tips of shoots rusty-tomentose: berries larger and the clusters strongly shouldered.

30. *candicans*, Engelm. (*V. mustangensis*, Buckl.), Mustang Grape. Plant strong and high-climbing, with densely woolly young growth (which is generally rust-tipped), and very thick diaphragms: lvs. in large in size and more or less poplar-like, ranging from reniform to cordate-ovate or triangular-ovate, dull above but very densely white-tomentose below and on the petioles, the basal sinus very broad and open or usually none whatever (the base of the leaf nearly truncate), deeply 3–10 lobed (with enlarging rounded sinuses) on the strong shoots and more or less indifferently lobed or only angled on the normal growths, the margins wavy or sinuate-toothed: stamens in the fertile lfs. long and strong, those in the fertile lfs. very short and laterally reflexed: clusters mostly branched, bearing 12–20 large (½ in. or less diam.) purple or light-colored or even whitish berries, which have a thick skin and a very disagreeable fiery flavor; seeds large, pyriform. W. Ark., Okla., N. Texas, mostly on limestone soils.

Var. coriacea, Bailey (*V. coriacea*, Shuttlew.). Leather-Leaf or Callosa Grape. Fig. 3965.

Differ from the species chiefly in bearing much smaller (about ½ in. diam.) thinner-skinned and more edible grapes with mostly smaller seeds, and perhaps a less tendency to very deep lobing in the lvs. on young shoots and possibly rather more marked rustiness on the young growths. Fls. chiefly southward, in which range various Texan plants reappear.—The more agreeable quality of the fr. is perhaps the result of a more equable and moist climate.

31. *Simpsonii*, Munson. Distinguished by mostly much-cut lvs. on the young shoots and comparatively thin berries, and large-toothed ones on the main shoots; rusty white tomentum below and very prominently brown-tomentose young growths—the character of the lvs. and tomentum varying widely, the foliage somewhat becoming almost blue-green below. Fls.—This is perhaps a hybrid of *V. xantii* and *V. candicans* var. *coriacea*. Some forms of it are very like *V. Labrusca*, and might be mistaken for that species. Its botanical position is yet to be determined.

32. *Labrusca*, Linn. (*V. Blandyi, Prince*). Fox Grape, Skunk Grape. Fig. 1705, Vol. III. A strong vine, climbing high on thickets and trees: young shoots tawny or fuscous, with much scurfy down: lvs. large and thick, strongly veined (especially beneath), broadly cordate-ovate, mostly oblong or triangular, heart-shaped to the top (on strong growths the sinuses sometimes extending a third or even half the depth of the blade, and rounded and dentate at the bottom) or sometimes nearly continuous in outline and almost deltoid-ovate, with the petiole usually shorter than the blade and very open (tending to narrow and half or more the length of the petiole), the margins shallowly scallop-toothed with mucro-pointed teeth (or sometimes almost entire), and the apex and lobes acute, the upper surface dull green and becoming glabrous but the lower surface densely covered with a tawny white, dun-colored or red-brown tomentum: stamens long and erect in the sterile lfs. and (in wild forms) short and recurved in the fertile ones: raceme short (berries usually less than 2 in wild types), generally simple or very nearly so, in anthesis about the length of the peduncle: berries large and nearly spherical, ranging from purple-black (the common color) to red-brown and amber-green, generally falling from the pedicel when ripe, variable in taste but mostly sweetish musky and sometimes slightly astringent, the skin thick and tough; seeds very large and thick. Cent. New England and southward in the Allegheny region and highlands to W. Cent. Ga. Not known to occur west of E. N. Y. in the N., but occurs in S. Ind. and Tex.—The parent of the greater part of American cult. grapes (probably largely through hybridization). It is often confounded with *V. xantii* in the S., from which it is distinguished by the habitually continuous tendrils, the more felt-like lvs. which are not floccose, and especially by the small-toothed lvs., very short clusters, and large berries and seeds.

33. *Pissazkii*, Maxim. (*Ampelopsis Davidiana*, Mott.). A species with variable foliage: dioecious; young branches, petioles, and under surface of lvs. rufous-pubescent: lvs. membranaceous, terebrate; lfts. petiolulate, the central one rhomboid and more or less divided into segments, the lateral ones obliquely ovate, the central one rhomboid and more or less divided into segments, the lateral ones obliquely ovate, the top (on strong growths the sinuses sometimes extending a third or even half the depth of the blade, and rounded and dentate at the bottom) or sometimes nearly continuous in outline and almost deltoid-ovate, with the petiole usually shorter than the blade and very open (tending to narrow and half or more the length of the petiole), the margins shallowly scallop-toothed with mucro-pointed teeth (or sometimes almost entire), and the apex and lobes acute, the upper surface dull green and becoming glabrous but the lower surface densely covered with a tawny white, dun-colored or red-brown tomentum: stamens long and erect in the sterile lfs. and (in wild forms) short and recurved in the fertile ones: raceme short (berries usually less than 20 in wild types), generally simple or very nearly so, in anthesis about the length of the peduncle: berries large and nearly spherical, ranging from purple-black (the common color) to red-brown and amber-green, generally falling from the pedicel when ripe, variable in taste but mostly sweetish musky and sometimes slightly astringent, the skin thick and tough; seeds very large and thick. Cent. New England and southward in the Allegheny region and highlands to W. Cent. Ga. Not known to occur west of E. N. Y. in the N., but occurs in S. Ind. and Tex.—The parent of the greater part of American cult. grapes (probably largely through hybridization). It is often confounded with *V. xantii* in the S., from which it is distinguished by the habitually continuous tendrils, the more felt-like lvs. which are not floccose, and especially by the small-toothed lvs., very short clusters, and large berries and seeds.

35. flexuosa, Thumb. Sts. slender and usually flexuous, glabrous at maturity, the new ones more or less rufous-tomentose: lvs. petiolate, cordate-ovate or truncate-ovate, entire or angular-3-lobed, short-cuspidate, unequally dentate, at maturity glabrous above and more or less hairy or floccose beneath (at least on the veins): fl-clusters peduncled and branching: fr. very small, 2-3-seeded. China, Korea, Japan. Var. parvifolia, Gagnep. (V. parejolola, Roxbg. V. flexuosa var. Wilsonii, Veitch), is a small, indv. form, cult. for the color of the lvs., which are purple beneath and bronzy with metallic luster above. China.

36. amurensis, Rupr. (V. vulpina var. amurensis, Regel). A hardy species, well known to botanists but little planted although found in growing colonies: sts. obliquely angled and striate, the young shoots loosely floccose or webby, later glabrous or nearly so: lvs. green above and beneath, nearly or quite glabrous, cordate-ovate, some of them more or less 3-5-lobed: fl-cluster shorter than lvs. or about equaling them: fr. very small (½-⅔ in. long), 2-3-seeded, purplish black. China, Japan. B.M. 8558. —It is the E. Asian representative of V. labrusca. The plant sometimes cult. under this name is probably V. pentagona. A form of V. Coignetiae passes as V. Thunbergii in England.

37. Thunbergii, Sieb. & Zucc. (V. Sieboldii, Hort.). A variable species resembling V. labrusca: sts. angled, those and other parts rufous-tomentose: lvs. glabrous above, tomentose or pubescent on the nerves beneath, cordate, 3-5-lobed or deeply cut, unequally mucronate-dentate: fl-cluster shorter than lvs. or about equaling them: fr. very small (⅔-⅔ in. long), 2-3-seeded, purplish black. China, Japan. B.M. 8558. —It is the E. Asian representative of V. labrusca. The plant sometimes cult. under this name is probably V. pentagona. A form of V. Coignetiae passes as V. Thunbergii in England.

38. pentagona, Dick & Gilg. Climbing the tundra regions of the small, 2-3 seeded. China, Korea, Japan. outside the southern parts: sts. and lvs. less or more pubescent or tomentose: lvs. 3-6 in. or more long (sometimes very large), sometimes nearly glabrous but usually soft-pubescent or tomentose beneath, membraneaceous, cordate-ovate, short-acuminated, not lobed: fls. small and green, in a paniculate cyme, the petals rarely separating at the top: fr. purple, size of large pea, 4-seeded. Himalaya to China.

heterophylla var.—V. Poinsettiana, Balf. Climbing, the tendril spiral, red-tasty; lvs. persistent, coriaceous, long-stalked, digitate with usually 5 elliptical coarsely dentate lfts. which are glabrous above and bright green; fls. in axillary short-peduncled cymes, hermaphrodite; sepals 4, oval, shorter than the 4 oval-lanceolate separate petals; carpels woolly, with a short 4-lobed style, the 2 carpels bouralate. Tonkin. R. H. 1902. pp. 56, 57. R. B. 28-3. Genus doubtful.—V. somereni, Hort. "observed in a nice villa garden" robust, etc. brown-felted; lvs. large and leathery, deeply cut into fine lobes, brown-tomentose, deep olive-green at maturity.

L. H. B.

VITTAGDMIA (Dr. C. Vittadini, an Austrian who wrote on fungi, 1826-1842). Compositae. Herbs with a thick caudex, or branching subshrubs.

Leaves alternate, entire or variously cut; heads rather small, with a yellow disk and white or blue rays, terminal, solitary or in loose leafy corymbs: involucre of several rows; rays pistillate, numerous, crowded, in more than one row: achenes narrow, compressed or flat, with or without ribs on the faces; pappus of numerous, often unequal capillary bristles.—About 14 species, natives of Austral, New Zealand, S. Amer., and Hawaiian Isls. The genus is closely related to Erigeron, differing in habit and in the appendages of the style-branches, those of Erigeron being short, while those of Vittadinia areawl-shaped. For V. triloba, Hort., not DC., see Erigeron mucronatus.

australis, A. Rich. (V. triloba, DC., not Hort.). Herbaceous plant of uncertain duration, 1 ft. high or less, tomentose lvs. obovate or spatulate to linear-lanceolate, entire or coarsely 3-toothed or lobed; heads solitary: rays narrow: said to be revolute (which may apply only to dried specimens). G.W. 11, p. 129. Austral, Tasmania.—There are botanical varieties.

V. tricolor, Hort. is apparently V. australis, A. Rich.

WILHELM MILLER.

VITTAHIA (Lat. a fillet or head-band or in vita, a line). Polyphideae. A genus of about 40 species of tropical ferns mostly with narrow cord-like lvs. growing pendent from trees: sporangia borne in 2 lines along the margins. V. lineata, Swartz, Old Man’s Beard, is a tropical American species which is found as far north as Cent. Fla., where it grows on the cabbage palmetto. Rare in cult. and interesting only as an oddity.

V. filifolia, Féc. Fig. 3967. A small species, 10-12 in., which is representative in appearance and habit of most of the species; sometimes found in choice collections. Trop. Amer.

L. M. UNDERWOOD.

VOANDZÉA (from a native name). Leguminosae. One species, V. subterranea, Thouars, cult. widely by the natives of Cent. Afr. for its underground peanut-like seeds. It is a prostate herb with a creeping pubescent rhizome from which arise slender-stalked compound lvs. Illts. 3, oblong or lanceolate, 3 in. or less long, with minute obtuse stipels: fls. yellow, ½ or ⅓ in. long, papilionaceous, 1-3 on flexuous peduncles; calyx very small; standard obovate; wings equaling standard, oblangelate; keel boat-shaped; nut or seed diapholous; fr. a tuber-like roundish pod, about ½ in. or more long, with 1 or 2 small seeds; the peduncle elongates after flowering and the ovary is buried in the earth, where the fr. ripens; seeds globose-ellipsoidal, about ½-⅓ in. long, yellow-mottled. Until very recently the plant has been unknown in a wild state, but it has now been found natively in Nigeria and German Adamaua (see Kew Bull. 1912, p. 213; and in this article the plant is distinguished from Kerstinella geniculata, page 1737. another underground legume widely cult. in Trop. Afr.). Voandzea appears not to have been intro. in this country.

L. H. B.

VOCHSIA (Vochy is the name of one of the species in Guiana). Vochysiaceæ. Glabrous or tomentose usually resinous trees, frequently tall shrubs, occasionally grown in the warmhouse: lvs. decussately opposite or verticillate, usually leathery; stipules small, subulate: fls. rather large, yellow, odorous, in elongated composite racemes or panicles; pedicels 2-bracted; sepalas 5, connate at base, lateral and anterior very short, posterior largest, usually spurred; petals 1-3, linear or spatulate, anterior commonly larger than the others; stamen 1, fertile; ovary ovary 3-celled; capsule, leathery or woody, 3-celled, loculically 3-valved.—About 60 species, natives of Brazil, Guiana, E. Peru, and Colombia. The spelling Vochysia is later.

V. ferruginea, Mart. (V. tomentosa, DC.). Tree, 25 ft. or more high: lvs. ovate-oblong, long-acuminated, acute at base, glabrous above, ferrugineous-tomentose beneath: fls. in terminal racemes, which are loose and slightly noding. Guiana.—V. guianensis, Aubl. Tree, 12 ft. or more high: lvs. obvate-oblong, shortly acuminate, glabrous on both surfaces: fls. in simple racemes, which are erect, terminal and close-fld.; sp. spreading. Guiana.

VOLKAMÉRIA: Clerodendron.

VOLUTARÉLLA (diminutive of Volutaria). Syn., Amberboa. Compositæ. Erect or divaricately diffuse valious or glabrous annual herbs, sparingly grown in Calif.: lvs. alternate, crenate-dentate or remotely pinnatifid: heads heterogamous, outer fls. 1-row, neuter, disk-fls. fertile; involucre ovoid or globose; bracts in many rows, imbricate; corolla purplish, violet, or blue, regular tube slender and very short, limb cylindrical, deeply 3-lobed; achenes obvoid or oblong, prominently 10-15-ribbed. About 7 species, Medit. region, W. Asia, and India. This genus is treated as a part of Centaurea by Hoffmann in Engler and Prantl, Pflanzenfamilien IV, pt. 5. V. murielae, Benthi. & Hook. f. (Amberboa murielae, DC.). St. erect, 1-2 ft. high: basal lvs. lanceolate, attenuate to the petiole; cauline sessile, middle ones auricled, upper and lowest not auricled, linear- or obovate-lanceolate: fls. purple. Spain and Morocco. According to the Brussels Congress, Amberboa is placed in the list of "nomina conservanda," and if this ruling is followed, the species above mentioned will retake the name A. murielae, DC.

VOUAPA (native name in Guiana). Leguminosae. Unarmed trees, rarely cult.: lvs. abruptly or somewhat, old-pinnately-compound; llfs. sometimes 1 or few-paired, sometimes many-paired; stipules leafy or auricled, uppermost clawed; 2-4, lower small, scale-like or none;
VOUAPA

perfect stamens 3; ovary stipitate, 3- to many-ovuled; pod obliquely orbiculate, ovate-oblong or tubate, plano-compressed, leathery, 2-valved. About 45 species, Trop. Amer. and Trop. Afr. This is the oldest generic name, but the name Macrolobium is retained by the list of "nominis conservanda" accepted at Vienna. Macrolobium bifolium, Pers. (M. Vouapa, J. P. Gmel. Vouapa bifólia, Aubl.). Tree, about 10 ft. high; lvs. sessile, ovate, acuminate, oblique: fls. violet; calyx lobes spreading; stamens nearly equalling the corolla. Guiana.

VRIÉSIA (named for Dr. W. de Vriese, of Amsterdam). Bromeliáceae. Often spelled Vriesia, but not so spelled by Lindley, who founded the genus. Tropical American stiff-leaved plants, with mostly distichous spikes bearing large and showy bracts. According to Mez (DC. Monogr. Phaner. 9), 84 species are to be referred to this genus. They are very like tillandsias, with which they are united by Bentham & Hooker and others. The chief technical difference is the presence in Vriesia of 2 ligules or a single cleft or erarginate ligule on the inside of the base of petals. Culturally, vriesias are like tillandsias. They run to forms with marbled and banded lvs. Several species have been intro. in recent years, and many garden hybrids have been produced. Few kinds are offered in the American trade, and only these kinds are described here. For other kinds, see the monographs of Baker and Mez; also the accounts from time to time in horticultural publications. For cult., see Tillandsia.

A. Stamens longer than the petals.
   b. Infl. branched.

bb. Inf. simple.
   c. Bracts of infl. strongly imbricate.

speciosa, Hook. (Tillandsia splendens, Hort. T. plicata, Hort. T. zebrina, Hort., in part). Fig. 3968.

Strong-growing plant, with broad, strong, arching-ascending lvs. 1 ft. or more long, which are bright green and marked with dark brown transverse bands: spike with densely imbricated bright red acuminate bracts, the scape spotted: fls. exerted, yellowish white. Guiana. B.M. 4382. F.S. 2:107; B. p. 102. R.H. 1846: 41. F.W. 1874:33 (as V. brachystachys).—One of the best and most showy species. A robust form is var. major, Hort. See supplementary list below for additional note on T. zebrina.

AA. Stamens shorter than the petals.
   b. Lvs. not barred, mottled, or tessellated.

heliconoides, Lindl. (V. bellula, Hort. Tillandsia heliconoides, HBK.). Dwarf and tufted, with many rosetate recurving or arching lanceolate lvs. (about 12 in. long) which are bright green above and purple-tinged beneath: scape overtopping the foliage, simple and erect, with wide-spreading distichous boat-shaped bracts that are light red at the base and greenish at the tip, showy: fls. white. Colombia. I.H. 30:490. G.C. II. 21:140.

bb. Lvs. tessellated (marked in small checkered pattern) or minutely variegated.

fenestralis, Lind. & André (Tillandsia fenestrailis, Hook. f.). Robust, densely tufted, the lvs. stout (1-2 ft.
VRIESIA

bbb. Lvs. marked with strong transverse bands.

hieroglyphica, Morr. (Tillandsia hieroglyphica, Bull.). Fig. 3970. Lvs. many, rosulate, stout, recurved, short-acute, very strongly and irregularly marked and banded with dark green above and brown-purple beneath: infl. paniculate, the bracts broadly elliptic-ovate, the fls. yellowish. Brazil. I.H. 31:514; 42, p. 318. R.H. 1891:400. Gm. 37, p. 244 (adapted in Fig. 3970).—A very striking and showy plant. Sometimes known as a Massangea.

V. Blakii, Hort. (Tillandsia Blakii, Hort.). Infl. crimson, pinnately plicate, 4-6 ft. tall; floral bracts ovate; fls. in 2 rows, 4 in long; petals yellow, linear, about 4 in. long. S. Amer. B.M. 8192. G.C. III. 45-558.—V. filipes, Hort., has been catalogued in this country. It is a garden hybrid (V. incurvata × V. Duvalii). It has short green lvs. and an exerted simple spike with distinct bright red imbricated bracts. I.H. 35:67.—V. glaucophylla, Hook., in Tillandsia fasciculata.—V. Leopoldiana.—V. splendidissima.—V. Malpighii, Gm. 54:1539.—V. mucronata.—Grammonia.—V. regina, A.D. Lvs. very long-acute: infl. large; bracts elliptic-ovate, rounded at apex; fls. dirty yellow. Brazil.—V. Rez. Hybrid. R.H. 1907:570.

VUYLSTEKEARA

—V. zebrina, Hort., is sometimes V. splendidissima and sometimes Cryptanthus sonatus.
L. H. B.

VULNERARIA: Anthyllis.

VUYLSTEKEARA, a multigeneric orchid hybrid embracing Cochlioda, Miltonia, and Odontoglossum. It bears the name of Charles Vuylsteke, of Ghent, Belgium, and the name is conformable with Adamara, Linneana, Lowiana, Wilsoniana. Only two species or species-forms (very recent) are recorded, the first of which has been in doubt as to parentage. These are V. insignis, Hort., recorded (G.C. III. 56:14) as a hybrid of Milliotioda Bleuana and Odontioda Charlesworthii, bearing cream-white fls. with brownish spots; and V. Hyama, Hort., a hybrid between Odontonia Laeversia and Cochlioda Noezlana, with fls. 2 in. across with a cinnabar tint suffusing the greater part of the surface of the sepals and petals after the color of C. Noezlana, but with the form of fl. approaching O. Laeversia especially in the center of the labellum, which is white tinged rose-color, and the base having a crest of yellow ridges on a red ground in front of which is a large shining brownish yellow raised blotch similar to that in Milliotio Warcewiczii.
WAHLBORGIA (named after Georg Wahlberg, 1780-1851, Swedish botanist). Including Edræanthes (Hedranthus). Campanulaceae. Annual or perennial herbs, base of the stems sometimes woody, used as greenhouse and border plants, mostly the latter.

Leaves alternate, rarely opposite: ind. usually irregularly centriugal: peduncles terminal, lateral or axillary, solitary or rarely paniculate: fls. usually blue and nodding; calyx-tube adnate, hemispherical, turbinate or obconical-oblong, limb 5-parted, very rarely 3-4-merous; corolla-campanulate, funnel-shaped, tubular or rather rotate, 5-lobed, very rarely 3-4-lobed; ovary inferior or semi-inferior, 2-5-celled: caps. erect, loculicidally 5-valved.—About 110 species, Eu., Medit. region, S. Af., and Trop. Amer. This treatment includes Edraianthus, which is often kept as a distinct genus. The species are used mostly as rock-garden plants, and receive the treatment given campanulas.

A. Plants with clustered tubers.

b. Lvs. alternate or opposite and narrow, scattered along the sts.: plants usually annual.

c. Blades nearly rounded.

d. Pedicels of flowers about 1 in. long, calyx a little shorter, oblong, obtuse, calyx-lobes more or less equal, 5-7-angled, nearly rotund, about 1/2 in. diam.: fls. few, terminal, pale blue-lilac; calyx glabrous, tube hemispherical, lobes linear-subulate; corolla-lobes ovate, acute. Eu.

c. Blades linear to lanceolate or narrowly ovate.

g. Scapiflorus, L. (G. saxicola, A. DC.). Sts. simple or branched, 6-12 in. high, erect or somewhat decumbent: lvs. alternate or subopposite, linear-lanceolate, sinuate-dentate, about 1/2 in. long; peduncles terminal or axillary: fls. blue; calyx rather glabrous, tube ovoid, lobes acuminate; corolla-lobes ovate, acute. Trop. and south temperate regions of the Old World. G. C. III. 52:215.

aa. Plants without clustered tubers.

n. Lvs. basal clustered, narrow: plants perennial. (Section Edraiantha.)

c. Fls. solitary on the peduncles.

cc. Fls. several to numerous on the peduncles.

3971. Wahlenbergia serpyllifolia. (X1/2)

W. gentianoides, Hort., is offered in the trade as a rock-plant growing a foot high, with erect wiry sts. and bright blue fls.—W. grandiflora, Schrad., is Plateyrootis grandiflorum.

F. TRACY HUBBARD.

WÀTZIA (F. A. C. Waitz, born 1768, at Schauenburg, Germany, state physician to the Dutch at Samarrang, Java; wrote on Javanese plants). Compositae. Includes one of the rare "everlasting flowers," a half-hardy annual which bears flat-topped clusters of yellow flower-heads, with a golden disk.

Mostly annuals: lvs. alternate, linear or nearly so: fls.-heads in terminal corymbs or rarely in oblong leafy racemes; involucral bracts: the bracts over-lapping in many rows, all colored and petal-like: receptacle flat, without scales: anthers provided with tails of very small size: achenes somewhat compressed, glabrous or papillate, terminating in a slender beak; pappus of capillary bristles usually cohering at the base, simple, barbelate or plumose.—Seven species from Australia. The genus is distinguished from Helipterum and Helichrysum by the beaked achenes.
It seems to have replaced *W. aurea*, Steetz, the favorite of a former generation, being larger-flowered, more robust, and rather easier of culture.

*Wilhelm Miller.*

**WAKE ROBIN:** In England, *Arum maculatum*; in America, *Trillium*.

**3972. Yellow or barren strawberry.—**Waldsteinia fragarioides. (X½)

**WALDSTEINIA** (named after Franz Adam, Count of Waldstein-Wartenburg, born 1759 at Vienna; wrote with Kitaibel an illustrated work on rare plants of Hungary; died 1823). Rosaceæ. Creeping herbs with the habit of Fragaria, perennial and hardy, used in the border as an edging and on rockeries.

Leaves mainly radical, 3-5-lobed or -divided; fls. small, yellow, borne on bracted scapes; calyx-tube inversely conical, limb 5-cleft, with 5 often minute and deciduous bractlets; petals 5; stamens many, inserted into the throat of the calyx: achenes 2-6, minutely hairy.—About 5 species, Cent. and E. Eu., N. Asia, and Temp. E. N. Amer. Of simple cult.

The yellow or barren strawberry, *W. fragarioides*, is a little plant that looks much like a slender strawberry but it has yellow flowers and bears no edible fruit. It is a hardy North American tufted perennial herb, about 4 inches high, with glossy leaves composed of three wedge-shaped leaflets, and five-petaled flowers less than ½ inch across. It comes with the first rush of spring, and continues to bloom until summer. There is little satisfaction in growing only a few plants of this wild flower. The plant is appropriate to the rockery, where every effect should be made to induce it to form a large mat. Masses of the yellow strawberry have been used with good effect for edging shrubbery borders, and the plant is listed in the trade.

**WALKS, PATHS, AND DRIVEWAYS.** That gardens and grounds may be reached at all times in any weather, walks are introduced to afford dry comfortable routes. They should be laid out to conform to and emphasize the garden design. However, too much gravel or a too complicated system will mar the purpose and scale of the garden and detract from its charm. It is necessary, therefore, that the paths be kept in proportion by adopting various widths according to the amount of travel expected and the importance of certain lines in the design. Principal lines or “axes” of the design may be emphasized by widths of 6 to 14 feet; secondary by 4 to 8 feet; minor, 2½ to 4 feet. It may be added that straight paths should be wider proportionately than curving ones. Paths may also be maintained in scale by use of different materials, using stone or brick for the principal ones; gravel, tanbark, or stepping-stones for secondary; grass for the least important. The color of path material also influences the garden appearance, and the simpler the garden character the less pronounced should be its path-colors. Turf is the least and cement the most conspicuous of materials.

Grass paths should be designed for unusual wear, and a depth of at least a foot of well under-drained soil provided. Many simple gardens have turf paths only, but these are at a disadvantage in wet weather or dew. If the wear is more than grass will stand, or the garden lines need more emphasis, stepping-stones may be introduced in the grasses. (Fig. 3973.)

Stepping-stone paths are simplest made of native rock of irregular shapes (Fig. 3974); more refined if of native rock, hammer-dressed; and still more refined if of regular blocks, slate, flag, or cement, (12 by 12 inches square, or (12 by 24 inches) of regular (Fig. 3974). The stones should be set 20 inches apart,
WALKS

WALKS

3974. A, Stepping-stones in the grass—the simplest dry path in the natural style. B, The same, conventionalized for the formal style.

design as to demand greater width, the character should change, and gravel or crushed stone be used.

For macadam paths (Fig. 3975) excavate 8 inches at the sides, 6 inches in center, and lay 5 inches of stone or "spawls" on edge across the path. Over this spread 2 inches of crushed stone the size of a hen's egg (1/2-inch stone) and a sprinkling of clayish soil, and roll firm, a hand roller being used. An inch of crushed limestone or hard shale should then be spread and rolled until a firm hard surface results. The walk should be raised 1 inch at the center for each 2 feet of width. These hard walks must be contained by borders of grass sod, boxwood, stone, brick, or cement curb. The curb should stand only 1 inch above the walk-surface; it should be 2 1/4 inches wide for a 4-foot path and 2 1/2 inch wider for each added foot width of the walk up to 4 inches, which is sufficient for a highway.

Gravel paths appear well up to any width, but as they are widened their color increases in design importance. Many garden designers use red gravel only; others prefer blue trappe rock; few use washed beach gravel or other white surface material because of its glare.

This fault is a grievous one with respect to cement as a walk material; it also seems too artificial and not gardenesque.

Many garden designers use red gravel only; others prefer blue trappe rock; few use washed beach gravel or other white surface material because of its glare. This fault is a grievous one with respect to cement as a walk material; it also seems too artificial and not gardenesque.

Brick in various colors and textures is an old and valuable path material which meets the requirements of color, texture, interest, drainage, and neatness, as well as anything yet devised. The pattern of laying should not be complicated to the degree of attracting attention which should be bestowed on the garden itself. In front of seats or steps, about a pool or a garden dial, it may be embellished by special design or by tile introduced into the pattern. Usually the patterns are three, or adaptation of those shown in Fig. 3976. A tile effect can be secured by using extra-wide joints, but glazed tile will be found too slippery for out-of-door use. Brick walks should be laid over a foundation of 16 inches of cinders or broken stone, for drainage and to prevent-heaving by frost. To lay "dry," an inch of sand is spread upon this foundation, the bricks laid and afterward swept over with sand until joints are filled. If a cemented job is desired, spread 3 inches of concrete upon the "frostproof" foundation; lay the brick upon a layer of cement mortar spread above the concrete, and pour the brick joints afterward with cement (one part), sand (one part); scour the bricks with muriatic acid, one part to ten of water.

Much may be said in favor of stone paths. It is a material full of interest and generally harmonizes well in garden or lawn. The stones, as a rule, should be larger if the walk or terrace is wide or long. They may be laid regularly or irregularly (Fig. 3977); smooth or rough of surface; cemented joints over foundations as for bricks; or laid with grass joints. These last are very gardenesque, particularly if the joints are filled with low-growing plants, like Sedum acre, Armeria vulgaris, certain saxifragas, and Veronica rupestris. Such a walk is not easy to keep free of either snow or heavy dew, so that it must not be laid where service demands dryness.

In the English or natural landscape style, lawns and informal gardens are made up of grass, shrubs, trees, and vistas. Paths are introduced for the sole purpose of giving easy access to various points or objects of interest and are not relevant, as in formal gardens, to the design. On the other hand, it is easy to intercept and spoil a vista, subdivide charming greensward, or mar a graceful slope by introducing a walk. Considerable study is required to lay out paths which will be direct, serving the practical needs of the place without interfering with esthetic considerations. Usually it is best accomplished by keeping paths somewhat toward boundaries, and consisting of graceful long curves in harmony with the general rounded outlines of foliage, foregrounds, and slopes in hillsides, rather than by more conventional straight lines, directed through centers. These paths must not seem circuitous or precipitous, however, and the interest must be satisfying to the traveler by presenting special vistas, close examination of interesting plantings, providing good restful benches, passing through arches or otherwise made interesting and seemingly short. Paths of this character must not be laid out in an unrelated system nor built simply to break up lawns and afford aimless strrolls. It should not often be necessary for the traveler to return the way he came along a path, at least any distance, and even in small
grounds a full circuit should be devised, or else no path-scheme laid out at all. When crossing a vista, as is often necessary to secure directness or continuity, the path may be graded lower to obscure its course (Fig. 3978), or it may be of an inconspicuous material such as a blue slate, brown stones, or dark stepping-stones with grass joints (Fig. 3973).

The materials of such lawn-paths may be simply of turf when passage is through woods or meadows. This latter charming device is secured by moving a strip through the longer meadow grass and daisies. Macadam or gravel is usually the method of construction.

For crowded parks, the width should be 8 to 12 feet or more. The construction may be heavier by 2 inches, and special care given to drainage. Oiled macadam, valuable for roads, is not suitable for paths unless top-surfaced with fine screenings to prevent tracking the oil.

Asphalt paths are sometimes used and are best if the residuum used in the flux of the surface coat be reduced to the minimum in order to leave as hard a pavement as possible. Concrete is being more generally used because of its wearing properties. It should be colored with red ochre, and the usual whiteness of cement surface. These walks may be constructed in the usual way (3 inches concrete, 1 inch cement float), except that the surface should be rough finished—neither troweled nor rolled. Wing walks at each side of the cement may often be provided to good advantage. They are 2 to 4 feet wide, made of 4 inches of gravel (or crushed stone) laid upon 6 inches of cinders or broken stone.

Drainage should be provided for all paths. Brick, asphalt, or cement walks should be crowned in the center or on the high side. Three-fourths of an inch is sufficient for an 8-foot cement walk. At each side, or at the upper side at least, of paths on a slope, drainage should be provided by sod gutters. This will carry the surface water to park inlets which discharge into sewer lines.

**3977. Forms of stone paths of a gardenesque appearance.**

A, grass or flower joints; B, cement joints; C, cobbles and stones in cement.

**3978. Walk crossing a lawn in slight depression for concealment.**

Driveways.

If walks and drives were not necessary to a human use of the informal type of landscape, they would never be put into it. Drives should be regarded as secondary, not primary elements of beauty in this style of gardening and they should remain unobtrusive by direction, width, and material. But as the landscape becomes more formal, drives become increasingly important and prominent in the design. It is simpler to plan the driveway in the formal balanced lawn of a house with terrace and gardens in a straight line swung on evident axes than to observe the indefinite lines, the less apparent unity and balance of informal gardening and incorporate therein a wide roadway. A straight formal drive should not be intruded through an informal lawn, or an irregularly curved and planted road through a formal place.

As elements of beauty, roads are tolerable only as they serve their purpose thoroughly well. This purpose may be a service-way to the kitchen, when directness is the first consideration; or to the front door, when good views of the house and lawn may warrant more indirectness; or a pleasure-drive, where directness is lost sight of, and good views, interest of scenery, and gradient become all-important. Success in laying out driveways depends on skill in applying the principles of landscape design, with a true regard for grades and excellence of construction. More engineering skill will not attain good private or park drives, for part of the function of such roads is to harmonize as far as possible with the other elements of the created or natural landscape.

Practical reasons urge a principal entrance toward the most-used corner of the property. As far as possible, the natural inclination for "short cuts" should always be recognized. Neither straight lines nor tiresome turnings are esthetically pleasing; grades must be considered and fine existing natural features, trees, rocks, and the like usually avoided. The driveways should command interesting views ahead and to the side and attract attention to handsome plantings in the curves. The curves should always be directed toward and not away from the objective point, and circuitousness for sake of adding mere length to the approach should be avoided.

To be comfortable as well as practicable, the gradient should be low, of about 6 per cent (6 feet of rise in 100 of length), at turns never over 7 per cent, although 10 or 12 may be required elsewhere to accomplish the ascent. Transition from one slope to another must be carefully arranged so as to avoid sharp jolts (Fig. 3979); this is accomplished by filling the hollows or cutting off the crests where the grades reverse. There should always be a flat place in front of doors and at entrances. Road-curves should be long, at least equal to 60 feet radii. It is an advantage to plot the curves at least roughly upon the ground first and transfer them to paper rather than vice versa, as their true artistic and practical effect may be perceived better. Long stakes should be used to aid the sight or a coil of rope laid upon the ground, and moved about until the desired line is attained, then the rope staked.
By tying colored twine around the stakes and moving it up and down while sighting, the new grades may also often be visualized. In cleared ground this method is very sure. It is better than the engineer's method of regular curves connected by straight tangents.

Precaution should be exercised at curves and intersections to secure safety as well as appearance and convenience. The fast-moving almost noiseless modern vehicles emphasize this precaution; therefore the view ahead at sharp turns should always be unbroken by banks or dense, tall plantings (Fig. 3980). Drives should branch on the outside (A) not inside (B) of curves (Fig. 3981). Danger lurks in narrow branchings and may be avoided by widening the intersecting triangle (Fig. 3982). Small triangles at right-angle intersections are not to be advised. When used at all they should be large and clear of tall planting which obscures the view. Triangles with less than 50-foot sides may better be omitted altogether (Fig. 3983).

At the turn-in from the public road especial care must be exercised to avoid danger. The acute angle (A) is bad (Fig. 3984), and the corner entrance (B) is not much better, or is absolutely fool-hardy when arranged as C. The best turn-in is shown at D. When possible, enter from an outward bend of the public road (Fig. 3985) or at the head of the street (Fig. 3986), and always at nearly right angles to the public road (Fig. 3988), making a gradual bend, if desired, to an angle within the property. Avoid if possible the street entrance at the foot of a steep hill as it is the point of greatest speed. Formerly entrances were heavily emphasized by gate-piers, lodges, and tree-plantings; now they are recessed and the planting is less high.

The road-surface should be smooth, dry, elastic, clean, and of good color. All this is to be obtained by various constructions. The gravel roadway is always pleasing as to color and wear, but the present-day macadam, although somewhat lacking as to color, better withstands modern traffic. Brick, concrete, and asphalt are too noisy and seem too hot and formal for private roads in the country, although for short distances in the city they may be used properly.

The construction of any roadway is begun by grading the level for the bottom of the road. This is called the sub-grade and is made higher in the center than at the sides by 1/2 inch or more to each foot width. The sub-grade should be rolled before the stone is laid. For private drives generally a light Telford consisting of native stone, about 6 inches wide and 1 to 3 inches thick, is laid by hand upon edge crosswise of the road. Over this a sprinkling of clay soil is thrown and covered 2 inches deep with crushed stone of the 1/4-inch grade; this in turn is covered by an inch of crushed limestone screenings. Each course as laid is sprinkled and rolled with a six- to ten-ton steam roller. This is a water-bound macadam. (Fig. 3987 A.) Since it does not withstand automobile traffic without dust, various oil-binding treatments of the surface are on the market. Bitulithic macadam is an excellent method of binding the top courses together, with hot pitch applied under pressure. There is no tracking of oil when this method is practised and the color and texture are satisfactory. Local conditions so influence materials and methods that it is necessary to investigate before applying any general specification in detail.

A cheaper road (Fig. 3987 B) may be built of spawls, or other broken stone, spread evenly, rolled, and surfaced with the other two courses of crushed stone, each thoroughly rolled wet. Where gravel of a cementitious quality is obtainable, or a hard shale, it may be substituted for crushed limestone surfacing.
The earth road has its country uses. Its success depends on dryness, and this is brought about by wide ditching at the side, a rather high crown in the center, and puddling the surface by repeated dragging while in a wet condition. The turf road (Fig. 3987 C) in country estates, for occasional travel, is made by laying roundish stone without "chinging in" the interstices. Cover with soil 1 inch thick over top of stone and seed with grass.

Whatever material the road is made of, it should be of convenient although not of unnecessary width, 9 feet for a single suburban lot being sufficient, 13 to 16 feet, including gutters, for more pretentious places, 14 feet for the little-traveled by-roads in parks, and 22 to 30 feet for the principal drives, and 60 to 80 for boulevard widths. The roads should also partake of the decoration suited to the large feeling of the place. Such accessories as gutters and inlets, signs and light-posts, entrance-piers and gates, should be rustic or more refined, carved or conspicuous in proportion as the surroundings have been conventionalized. Roads must harmonize and obey the demands of unity in design. The use of roadside shrubbery and arrangement of taller-growing trees is the means whereby the designer may tie together an artificial road to the landscape.

ARTHUR W. COWELL.

WALLFLOWER. The vernacular name of Cheiranthus Cheiri, which see. A favorite spring bloom in Great Britain, and sometimes secured as early as Christmas; in this country it is little known, probably because of climatic reasons.

3987. Types of road construction: A, macadam; B, broken stone; C, turf; 1, cob gutter; 2, gutter; 3, stone curb; 4, cinders; 5, screenings; 6, 1½-inch crushed stone; 7, Tedford; 8, screenings over gravel; 9, spawls.

WALNUT

The wallflower is a perennial, blooming profusely the second year, but needing to be renewed frequently. The compact forms grow only 1 foot or 18 inches high, but some kinds are taller than this. There are single-flowered and double-flowered kinds, and colors in yellow, orange, blood-red, maroon-red, yellow-brown, light brown, ruby-purple, pink. The yellows are most commonly seen in English gardens, and make a most attractive show about cottages in early spring. The double kinds are propagated by cuttings taken in spring, and they make good blooming plants the following spring if not allowed to become stunted; double wallflowers are also grown from carefully selected seeds. The seeds of wallflowers may be sown in spring and plants are kept in vigorous condition until protected for the winter; they are transplanted when young into permanent beds. If seeds are started in late winter, bloom may be had in the following holidays, in a climate mild enough to carry them.

WALLICHA (Nathaniel Wallich, 1788-1854, Danish botanist; wrote on plants of India). Palmae. Stove palms, one of which, the first described below, is cultivated outdoors in southern Florida and southern California and in Europe under glass, and the second, while not advertised in America, is probably in a few northern greenhouses.

Low palms, esoposite, with short branching caudices, or in 1 species tall: lvs. densely fasciculate, terminal, distichous, scaly, unequally pinnatisect; segms. solitary or the lowest in groups, cuneate at the base, oblong-oblanceolate, cross-dentate, the terminal one cuneate; midnerve distinct; nerves fibrillose; margins recurved at the base; petiole slender, laterally compressed; sheath short, split, with the margins deeply crenate; spadices short-terminated, the staminate drooping or recurved, ovoid, much branched, densely fdl., the pistillate looser, erect; spaths very numerous, slender-conicossaious, the lower ones the narrower, tubular, the upper ones cylindrical, entire, imbricated: fls. symmetrical, the pistillate much smaller than the staminate, yellow: fr. ovoid-oblong, red or purple.—Three species, Himalayas. Wallichia is allied to Didymosperma, Arenga, and Caryota, differing in having 6 stamens instead of an indefinite number. Caryota is the only one of this group with ruminate albumen. Didymosperma has a cup-shaped 3-holod calyx, and in Arenga the calyx has 3 distinct sepals.

disticha, T. Anders. Fig. 3988. Caudex 10-15 ft. high, about 5-6 in. diam.; vs. graceful, 6-10 ft. long, alternate, erect; Hts. 1-2 ft. long, 2½ in. wide, fascicled, linear, narrowed to the base, denticulate at the apex, with a large tooth on each side above the middle, glaucous beneath; petiole and sheath short, scurfy; lvs. disposed in a one-third spiral: spadix 3-8 ft., the staminate usually twice as long as the pistillate; fls. in many spiral series, green. Himalaya.

caryotoides, Roxbg. (Harina caryotoides, Buch.-Ham. Didymosperma caryotoides, Hort.). St. very short or none, often sheathed with the persistent H.-base: lvs. oblong or linear-oblong, pinnatifidly excisate and acutely toothed, white beneath: spadix about 18 in. long, the fls. purple or yellow, according to sex. F. 1874, p. 161. R.H. 1870, p. 368.

V. densiflora, Mart., a palm like W. caryotoides and differing only in technical ovary characters, is offered in Flora of Unknown in Amer. J.F. p. 233, 234.—W. peraphrodes, Mart. See Didymosperma.

JARED G. SMITH.
N. TAYLOR.

WALNUT (formerly sometimes written walnut, but the name has no connection with wall, being rather of Anglo-Saxon derivation signifying "foreign nut," as the product came from the continent). A name applied to Juglans regia and its fruit, to us known mostly as
English walnut because the supply yearly reached America through England; also, by extension, to other species of the genus Juglans. The name is sometimes, but provisionally, given to hickory-nuts.

The walnuts may be thrown into three horticultural groups: (1) The Persian or English domesticated species, *Juglans regia* (Fig. 3988), the walnut of commerce and of extensive cultivation in California and other parts of the United States. (2) The North American walnuts, of several species but chiefly known in the black walnut, *J. nigra* (Fig. 3990). (3) The East Asian walnuts, represented by *J. sieboldiana* and allies, promising but yet little grown in this country. To the genus also belongs the butternut, *J. cinerea* (Fig. 2901), sometimes called white walnut. There is much promise of important cultural races in the species of Juglans, but the markets yet know practically only the nuts of *J. regia*. See Juglans, Vol. III.

L. H. B.

**Walnut in California.**

The extent of the present Persian or English walnut (*J. regia*) industry of California amounts to between 45,000 and 50,000 acres, or about 1,250,000 trees. An average crop for the past few years is about 12,000 tons, valued at $4,500,000. The crop for the year 1915 equaled 14,300 tons, valued at approximately $4,250,000 to the growers. The investment in the walnut industry of California represents about $15,000,000.

English walnuts may have first been planted in California by the Mission Fathers. However, it was not until after the coming of the first Americans that the walnut attained any commercial importance. The present walnut industry is of comparatively recent origin and owes its establishment to the early efforts of Joseph Sexton, of Santa Barbara, and the late Felix Gillet, of Nevada City. The Santa Barbara Soft Shell seedlings and the several grafted varieties of this type are usually planted immediately after harvest, the French varieties, such as the Mayette, Franquette, and the like, owe their popularity to the tireless work of the late Gillet in promoting the production of this type of walnut.

Commercial walnut-growing is largely centralized in the following counties mentioned in their order of importance: Orange, Los Angeles, Ventura, Santa Barbara, San Joaquin, and Contra Costa.

This industry is almost everywhere a specialized crop. It is seldom seen as one of two or more general farm crops, but, on the contrary, nuts are the one and only crop produced by many of the orchardists engaged in this industry. Success with this crop depends on the climate and climatic conditions and the availability of irrigation water. A deep rich alluvial loam containing plenty of humus is desirable. Groves planted on the light sandy loams or soils underlain with a fluctuating water-table or a hardpan within 4 or 5 feet of surface are usually short-lived and unsatisfactory in the end. Although good drainage is imperative to a depth of at least 6 or 8 feet, irrigation water is necessary throughout most of the walnut areas of California for the black walnut.

The walnut industry has been most successful throughout in the coast regions. In general, the high humidity and frequent fogs, together with a relatively small daily range in temperature, seem favorable to this crop. Walnuts grown inland are subject to sun-scald injury on both the nuts and the trees. The inland regions are subject to a very low humidity, an extreme maximum temperature and a wide daily range. Some of the more recently introduced varieties seem to endure the inland conditions better than the Santa Barbara Soft Shell seedlings. It seems very likely that the inland valleys may yet be devoted to this crop with the proper choice of varieties.

Clean culture, with the use of a winter cover-crop, is the most prevalent type of soil-management practiced by the progressive growers. Such cover-crops as melilotus clover, vetch, and rye are often seen. These crops are usually planted immediately after harvest, the latter part of September or October, and should be nearly waist-high at the time they are plowed under, in the latter part of March or April.

Irrigation water is applied by the furrow system in most cases, although occasionally a grove is watered by the basin method, where the land is level or where possibly a sod is grown in the grove throughout the year. From one to five or six applications of water are made in a season, depending on the moisture-holding capacity of the soil and local climatic conditions. Each irrigation should penetrate from 6 to 8 feet from the surface of the ground in order to reach the entire root-system. If the trees are irrigated a week or two before harvest, the shucks will open and remain on the trees. Dropping the clean nuts to the ground. In case the trees are drought-stricken at harvest, the shucks are likely to become sunburned, stick to the nuts, and thus cause an increase in harvesting expense.
The larger number of growers do very little systematic pruning of the walnut except to remove the lower limbs which interfere with cultivation. Occasionally, however, a grove is to be seen in which the branches are annually thinned out. Such trees usually bear more nuts on the main limbs near their centers than the unpruned ones.

In general, the first two men-others combined: Placentia, Eureka, Franquette, industry. At the present time the following five varieties are being propagated to a greater extent than all discarded even thus early in the development of the luwe been introduced and many of these have been this time, a comparatively large number of varieties today, with fewer adaptations to this crop.

The older plantations are composed entirely of seedlings, most of which are of the Santa Barbara Soft Shell type and trace directly or indirectly to the original trees grown by Sexton at Santa Barbara. It is only within a most of which are of the Santa Barbara Soft Shell type and in fact young groves, before they reach a bearing age, are sometimes handled with clean cultivation. The interplanting of young walnut groves with lima beans or other broad vegetable crops, small-fruits, alfalfa, and occasionally apricots and peaches, is a common practice. Certain intercrops, as beans, if properly handled, will commence making returns immediately, without detriment to the future walnut grove. Vegetable crops are preferable to tree crops for interplanting. Peaches and especially apricots have an apparent dwarfing effect on the young walnut trees. Their use may be profitable, however, in the end in spite of the injury caused.

The older plantations were set too close together. Although 40 to 50 feet apart seemed ample room for development, it is very evident now that a distance of 60 feet is none too much for the larger-growing varieties on the rich loam soils which are best adapted to this crop. It is a matter of common observation to see the outside trees in a grove produce considerably more than the trees in the center. This leads one to believe that perhaps some of the older plantations might produce more walnuts today with fewer trees to the acre.

The older groves are composed entirely of seedlings, most of which are of the Santa Barbara Soft Shell type and trace directly or indirectly to the original trees grown by Sexton at Santa Barbara. It is only within a comparatively recent time, during the last ten to fifteen years, that the walnut has been propagated by budding and grafting in commercial quantities. During this time, a comparatively large number of varieties have been introduced and many of these have been discarded even thus early in the development of the industry. At the present time the following five varieties are being propagated to a greater extent than all other sorts combined: Placentia, Eureka, Franquette, El Monte, and Prolific. In general, the first two mentioned varieties compose nearly 70 per cent of the trees propagated at the present time in southern California nurseries.

The several black walnuts are used as rootstocks. The northern California species (J. Hindsii) is held in the greatest favor at present. This is a strong vigorous tree which will withstand adverse soil conditions much better than the Persian walnut itself. Very few eastern black walnuts (J. nigra) are used for propagation, as they are usually thought to be less vigorous than California species. The southern California black walnut (J. californica) is little used at present, although it was once popular (Fig. 3992). This species starts growth so much earlier in the spring than the Persian walnut that it suckers profusely when used as a rootstock. It is not so rapid-growing as the J. Hindsii. Some of the nurserymen are using the Royal hybrid as rootstock. The Royal hybrid is the name commonly given to a cross between J. nigra and either of the California species. Some observers think the Royal hybrid root more resistant to excessive soil-moisture and general adverse soil conditions than any other rootstock. The Paradox hybrid, which is a cross between J. regia and any of the black species, is an exceedingly vigorous rapid-growing tree. This hybrid can be obtained by planting black walnuts which were produced in the neighborhood of J. regia trees. Such nuts will produce from 50 to 90 per cent hybrid progeny. Although this hybrid makes an excellent root and produces exceptionally large and vigorous tree, it is rather impractical for general use as it cannot be obtained in wholesale quantities.

The nursery propagation of walnuts is usually by crown-grafting in place. The black walnut root is grown one year in the nursery and grafted the second spring just before the leaves start to come out. A short whip-graft is used, tied in place by soft cotton twine or raffia. After tying, the graft and top of the cion are covered thoroughly with hot wax. Some additional protection is usually given to prevent the cion drying out excessively. This is done by covering with a paper bag or by hilling the soil over the union until growth starts. The young trees are staked in the nursery, as they are very supple, due to their rapid growth. The one-year-old trees are preferred by most planters and should be 6 to 10 feet high at this age. As the trees are set in the orchard, they are usually cut back to about 5 feet. Some growers in the inland sections, however, prefer to cut the trees back to 18 inches and then train one sprout from the trunk of the tree. This sprout is pinched back when it reaches a height of 5 feet. The method necessitates staking the trees. At the end of one season's growth such severely headed-back trees may be as large as though they were left 5 feet high in the beginning. The trees cut back to 18 inches grow much more vigorously than trees only moderately pruned.

The harvesting of walnuts is done largely by Mexican families who camp in the groves through the picking season. A portion of the nuts fall naturally to the
ground and the remainder are shaken off by means of hooks attached to long poles. The picker receives from 80 cents to $1 for 100 pounds for gathering the nuts and placing them in barley sacks. The nuts ripen through a period of a month or six weeks; therefore two or three pickings are made, followed by a cleaning of scattered nuts.

The nuts are washed, dried (Fig. 3993), culled, and sacked. There are then delivered to a central packing-house to be bleached. This is accomplished by spraying with electrolyzed salt-brine, or dipping in a solution of chloride of lime and sal soda, to which sulfuric acid is added. Ether process removes all discoloration from the shells and gives them a bright light tan color, attractive in appearance. There are many ways of handling the nuts after bleaching to hasten their drying. Some packing-houses pass the nuts through a warm air-current in long drums, thence they are elevated to the bins, where they arrive nearly as dry enough to suck. Other houses dry the nuts for about twenty-four hours in wire or lath bins. By putting each grower's nuts into several bins as they come from the bleacher, and then drawing from several bins at the time the nuts are sacked, a thoroughly mixed uniform product is packed in each bag. Each bag contains 100 pounds of nuts.

The grading of California walnuts has developed rapidly within the last decade, as compared with sales in the past of seedling nuts ungraded and unbleached, as plain walnuts; the grading has gradually reached a stage where part of the nuts are sold under their variety name and another larger portion is disposed of after being bleached and strictly graded according to size, shape, color of the meat, and quality of same.

The California Walnut-Growers' Association has recently introduced a one- and two-pound carton that has standardized the product handled in this package as strictly as breakfast foods and canned goods are graded and packed.

Although the walnut industry has not an established reputation for profitability which is comparable with citrus fruits of California, it has nevertheless maintained its position as a stable, conservative, permanent crop within this state. The income to the acre for this product will vary, widely according to variety, soil, and climatic conditions as well as the personal element of management. Such incomes will fluctuate from $100 to $300 an acre. Whereas the average yield of walnuts for the state is between 800 and 1,000 pounds, the better groves will average from 1,500 to 2,000 pounds to the acre annually.

The future development of this industry seems to be drifting gradually inland, giving way in Orange and Los Angeles counties to citrus culture. The inland valleys were formerly thought to be poorly adapted to walnut-production because of the darkening of the meats by the intense hot sunshine; however, there are several sections which give promise for development along these lines with the proper choice of varieties adapted to these particular environments.

The walnut industry enjoys one of the most notable features of any fruit industry of the country, inasmuch as its product may be successfully stored awaiting disposal for a period of at least twelve months if necessary. This has given the industry a very stable character and has freed this product from the speculative manipulations which are frequently found in connection with the perishable fruit products. It is interesting to note that the importations of walnuts into the United States have gradually increased during the last ten years and within this same period the total production and the prices to the growers of California have also gradually increased. This may be taken as only one of many indications that the walnut is being looked on more and more as a necessary food by the people of this country.

From present indications, this industry is less liable to the dangers of over-production than almost any other agricultural or horticultural crop within the borders of the state.

The chief insect and fungus troubles of the walnut are the walnut aphis, and also the walnut blight or bacteriosis (Pseudomonas juglandis). The aphis may be controlled by means of tobacco sprays; this is rarely done, however, as the damage is only occasional. There is no means of control known at present for the blight or bacteriosis (Fig. 3995). The wide variation among seedling trees in their susceptibility to the disease gives promise of eventual relief through the selection of blight-resistant varieties. Minor losses are due to red-spider, codlin-moth, and melasmula.

Bibliography.

culturists, there are at least four substantial reasons for doing so: (1) the species might well be planted at one-half or one-quarter the usual orchard distances apart, with the idea of allowing them to become forest trees, if for any reason the nuts should not justify their retention for orchard purposes. It is very doubtful whether any other species of walnut could be recommended for such use, as with the possible exception of the two forms of hybrids common in California, Paradox and Royal, no other species of walnut is now being seriously considered for forest planting and, except in rare instances, neither of these species would be developed into useful trees at practically no further expense. If one-quarter of the American farmers were to plant even two walnut trees about their premises, it is difficult to estimate what would be the aggregate increased value to such farms by the end of a
quarter-century, but certainly it would be very appreciable.

Among the species of walnuts not usually under cultivation, but which give promise of commercial possibilities, some are discussed in the following:

The American black walnut, Juglans nigra.

As a producer of marketable nuts, this species now gives greater promise than does any other secondary species of Juglans. Its natural range extends from middle New England to north Florida, in the east, and from Minnesota to Texas on the west. Although best suited to deep fertile loams, moist yet well drained, it readily adapts itself to conditions less favorable. It attains its best development in the basin drained by the Ohio River but is common at practically all altitudes in the eastern states up to about 1,400 feet where it is superseded by the butternut. The tree is a symmetrical and fairly rapid grower; usually moderately productive and very useful both in the landscape and as a forest tree. The nuts usually are thick-shelled, and it is seldom that the kernels can be separated from the cracked shell in perfect halves. A few varieties, the kernels of which crack out more or less perfectly, are now listed by the nurseries. The two best known are the Thomas, introduced from Pennsylvania in the early eighties, and the Stabler from Maryland in 1915.

The butternut, white or long walnut, J. cinerea.

In many respects, this species is similar to the preceding. Its northern range is somewhat more extensive than is that of the black walnut and its southern and western limits are less by about 300 miles. The tree is short-lived, not as symmetrical in form, nor as capable of adapting itself to unfavorable conditions, and the timber is of inferior value to that of black walnut. The nuts have thicker and rougher shells and are more difficult to crack but the kernels are more readily separated from the broken shells in perfect halves than are those of the former species. By many, the kernels of the butternut are much preferred to those of any other nut.

The Japanese walnut, J. Sieboldiana.

This species and its variety cordiformis, described in Vol. III, page 1723, as there explained do not breed true to type and revert to each other or to intermediate forms, but typically are broadly rounded at the base, conical, and smaller than are those of J. nigra. When struck with a hammer, they tend to open at the suture, thereby breaking both half-kernels into quarters. Frequently, nuts of the cordiformis type open automatically at the apex, and with the aid of a knife-blade, the half-shells may be separated entirely and the whole kernel removed without breaking. In color, texture, and flavor of kernel, the Japanese walnuts are very similar to those of the butternut, J. cinerea.

Miscellaneous species of Juglans.

A species from northeastern China (J. mandshurica), the nuts of which are intermediate in form between those of J. cinerea and J. Sieboldiana, was introduced into the United States some years ago but is not yet sufficiently well tested to make possible a definite report. It should be hardy and therefore of value in the northern states. Aside from those already included, there are a number of species of Juglans which are more or less common in parts of the United States, but all are of minor importance, so far as nut production is concerned, and apparently of use only in sections where the better species are unadapted and as stocks for superior varieties. Among such are included J. Californica, J. Hindsi, J. major, and J. rupestris. For full accounts of these species, see Vol. III, pages 1721 to 1724.

Juglans hybrids.

The various walnut species so freely interpollinate, when grown in close proximity to each other, that when pure strains are desired it is not safe to plant the nuts where there is danger of such pollination having taken place. The familiar Paradox and Royal of California, crosses of J. regia with any species of black, and of any California black with the eastern black, respectively, are typical examples of such natural hybridity. In the East, there are numerous crosses of J. regia with other species, viz., J. intermedia (J. regia x J. nigra); J. quadrangulata (J. regia x J. cinerea); and one between J. regia and J. Sieboldiana, which apparently has not yet been described. Frequently, individual trees of these forms are sturdy growers and make valuable stocks for other species, as already noted, but usually they are practically nonproductive and of little value to the orchardist.

C. A. Reed.

WANDERING JEW: Zebrina pendula and Tradescantia fluminensis. The common purple-leaved wandering jew of greenhouses, with pink flowers that open in sunshine, is Zebrina pendula, often confused with Tradescantia.
WARDIAN CASE. A nearly air-tight case with glass sides and top, used for transporting growing plants on long sea voyages, invented about 1836 by N. B. Ward, who wrote a book of ninety-five pages "On the Growth of Plants in Closely Glazed Cases," published at London in 1842. It provides the best and safest method of transporting potted and living plants across the ocean, as it insures the necessary light, protects the plants from salt spray and foul gases, and requires a minimum of care, as the plants need no watering. Such cases maintain nearly uniform conditions of temperature, moisture, and atmosphere. Similar cases are used in greenhouses for growing filmy ferns, dwarf foliage plants, and other small specimens that require a very moist and close atmosphere and invariable conditions.

WARPÜRIA (named after G. Warpur, who collected the genus). Acanthaceae. Low perennial greenhouse herb, branching from the base: lvs. opposite, approximate, entire or nearly so: fls. minute, white, in dense many-fld. cymes, head-like, long-peduncled, collected in the axis; calyx hyaline, 5-parted, segms. narrow, posterior 3 distinct nearly to their base, anterior 2 con-
CXVIII. Washingtonia filifera var. robusta.
WASHINGTONIA

Banning, Riverside County, California. This is the largest group of indigenous fan palms in the United States, and the only grove of important size on the Pacific side of the United States. The grove contains thousands of trees, some of them nearly 100 feet high. There are many young ones of all sizes and the other trees are still vigorous. Most of the canons of the desert basins of San Jacinto, according to Parish, contain these palms; and a few grow in the canyon of the White Water River, which is the western limit of the species. The southern limit is probably Carrizo Creek, San Diego County, and the northern at Corn Springs in San Bernardino County. Except in trees protected in cultivation, old specimens are rarely seen bearing the great shaggy mass of dead hanging leaves, for they are burned off by Indians or take fire by accident; even in cultivated trees, the mane is usually cut away to give the plants a neater appearance but much of the characteristic beauty of the palm is then lost. Parish writes that "the functional life of a leaf is about one year. How long the dead leaves would remain attached to the trunk if undisturbed cannot be stated; probably for a very long period."

The Washingtonias are much planted in California, thriving even in the climate about San Francisco Bay. In southern California they attain great size and comprise a characteristic feature of the landscape. They grow readily from seeds, but the trunks rise slowly. Two species are commonly planted, W. filifera var. robusta, with leaves bearing many filaments or threads on the edge and in the sinuses, and W. gracilis which is practically devoid of filaments.

A. Petiole prolonged into the blade with an acuminate point. acuminata
b. Blade of if. abundantly supplied with threads or filaments. filifera
bb. Blade nearly or quite destitute of filaments or threads. gracilis

filifera, Wendl. (Brachea filamentosa, Hort. B. filifera, Hort. Pritchardia filamentosa, Wendl. P. filifera, Hort.). Margins of the petioles armed up to the middle or somewhat beyond with stout hooked spines, but naked above: st. cylindrical, 20-40 ft., enlarged at the base, covered with persistent petiole-bases: blades 3-5 ft. long, 1-2½ ft. wide at the summit, glabrous, plano-convex; ligule large, glabrous, lacerate; blade circular, tomentose on the margins of the many segms., 3-5 ft. long, erect until old, 2 in. wide at base, % in. at apex, somewhat glaucous, very filiferous; peduncle declined, exceeding the lvs.: frs. nearly sessile; seed broad-ovate, about ½ in. long, somewhat rugose or wrinkled on the raphal face. Probably native in northern Low. Calif.—From the W. filifera group this tree is distinguished by its slender trunk, smaller and less deeply divided shorter-stalked lvs., which bear no filaments or threads except now and then in the sinuses of some of the folds.

Var. robusta, Parish (W. robusta, Wendl. W. filifera, Hort., not Wendl. Neovashingtonia filamentosa, Sudw.). Fig. 3997. The palm usually cult. in this country as W. filifera, whereas the one cult. as W. robusta is really W. gracilis: margins of petiole armed throughout: trunk stout, enlarged at base, 60-90 ft. tall: petioles stout and erect until old, 3-5 ft. long, the upper surface concave; ligule paper-like, acuminate and torn; if.-blade 3-5 ft. across, with 60-70 folds, cleft two-thirds to the base, the margins with abundant threads; panicle declined, exceeding the lvs., the involucre dense, but in fr. becoming diffuse or open: fls. with heavy odor: seed excavated on raphal face. Probably for a very long period.

Sonora, Wats. (Neovashingtonia Sonora, Rose) Top of petiole obtuse where it joins the blade, the latter abundantly supplied with filaments: st. 25 ft. high, 1 ft. diam.: lvs. 3-4 ft. diam., somewhat glaucous, very filiferous; peduncle 3 ft. long, very slender, 2 in. wide at base, % in. at apex, floccose-hairy along the margins and with stout curved spines: frs. % in. long, edible. Guaymas and Low. Calif., Mex.—Yet imperfectly known in cult. L. H. B.†

WATERING

The watering of plants usually exhibits the skill, or the lack of it, of the gardener. It is a practice that cannot be well explained in print, although a few general statements may be made.

An abundant and convenient supply of pure fresh water should always be a first consideration in locating a garden or greenhouse. Having this, the next matter is knowing how to use it. For here, good gardeners say, lies nine-tenths of the elements of success. Certain it is, especially in the indoor cultivation of plants, that more depends on knowing when to give or withhold water than on any other single matter. The art of watering is untouchable; it requires experience, judgment, skill. Some knowledge of the commoner facts of vegetable physiology, physics, and soil physics will be helpful, but even then experience will be necessary.

In American gardens watering is usually performed with a hose from a stored water-supply. Two common types of watering-cans are shown in Fig. 3908.

A fairly safe guide to watering is: never water plants until the soil has become dry, though not "powder-dry," and then give them a thorough soaking. Plants dislike a continuously wet soil. In the care of plants in earthenware vessels, a useful test is to thump the jar. If it rings the soil is dry; if the sound produced is dull the soil is sufficiently moist. Such rules, however, are only for the novice. They presuppose activity of growth, and even into account only one consideration aside from this, and that is the condition of the soil as regards moisture. The experienced gardener reads his practice in his plants and the conditions under which they are being kept. The following suggestions are based on the most important considerations.

Actively growing plants may be watered very freely, as a rule, whereas in a dormant or semi-dormant state the same plants will require only occasional waterings. Soft-stemmed or rapid-growing plants ("soft-wood" and "herb-like" plants), and those with large leaves, need, as a rule, an abundance of water when growing actively. Hard-wood or slower-growing plants, with smaller leaves, must be watered with greater care. Soft-wooded plants, with some exceptions, may at times even flag somewhat for want of water, and recover without permanent injury when a fresh supply is given. Hard-wooded plants, as camellias, azaleas, and heaths, on the other hand, suffer permanent injury from becoming too dry. It is safest to allow no plant in active growth to flag.

The amount of foliage affects the plants' capacity for using water. Plants which have been cut back, or which from disease, insects, or other causes, have lost most of their foliage, must be kept drier until they have regained their foliage. Unhealthy plants are benefited, as a rule, by being kept rather dry until they begin to show signs of renewed vigor.

Small cuttings, or any plants freshly potted or newly transplanted, are not in condition to use much water until the root-hairs have attached themselves to the soil-particles and growth has begun. A thorough watering at the time of potting or repotting the plants, especially if they are subsequently shaded for a few days, is usually sufficient until they have become established.

The character and bulk of soil should be kept in mind. Porous and warm soils dry out much sooner, while heavier clay soils are in danger of becoming water-logged and sour unless watered with care. When there is a large mass of soil in proportion to root-development, as in the case of greenhouse beds newly set with young plants, care must be used in watering until the soil is occupied with roots.

Serious trouble often begins in the greenhouse from a heavy watering at the beginning of a period of dark muggy weather. Not only does such watering do damage to the soil and roots, but the excessive humidity of the air about the plants and its weakening effect on their tissues invite the attacks of various mildews, fungi, and insect pests.

The time of day is important. In the greenhouse in winter free ventilation is usually impossible. At night there is a tendency toward a damp atmosphere. Careful florists, therefore, water in the early part of the day at this season, so that the house will have become somewhat dried out by nightfall. It is seldom advisable to let plants under glass go into the night with wet foliage. It gives the fungi a chance. Especially hazardous is it to water cutting benches or boxes of young seedlings late in the day in the winter season. The various damping-off fungi find under such treatment the condition suitable for their development. Excessive humidity on the interior of a closed plant-house is most likely to occur in moderate weather. During severe weather the condensation upon the glass is large and renders the air of the house drier. During summer, when there is free ventilation, the watering may advantageously be done late in the day. Midday watering at a season when the sunshine is very bright is often followed by scalding of the foliage unless the plants are well shaded. Ferns, Rex begonias, Chinese primroses and richardias are among plants easily injured in this way.

Consider the temperature at which the plants are kept, the position of the heating-pipes, the amount of light, and the freedom of ventilation permissible in watering plants in glasshouses. It is better, as a rule, to have the watering conform to these conditions; but frequently the practice must be reversed.

The temperature of the water exerts a marked effect on the growth, flowering, and fruiting of plants. It is now held that, in general, the water should be of a temperature close to that of the air in the house where the plants are growing, or about 10° F. below.

Watering may be indirect. Shading the glass of greenhouses in summer with some suitable material is much practised by florists for the purpose of sheltering plants from too great intensity of light, and for the purpose of reducing evaporation and transpiration. Certain kinds of plants, as palms, and some kinds of ferns, require this; also newly potted plants. Syringing of walks, by reducing the temperature and increasing the humidity of the air, also tends to reduce transpiration and save watering. Watchfulness and attention to ventilation are necessary, however, to avoid excess.
sive humidity, which tends toward a soft watery growth and extreme sensitiveness and susceptibility to disease. Watering is best practised in the early morning or early evening, when the air is cool and the leaves can absorb the moisture from the spray without wilting. The amount of water required will depend on the size, shape, and direction of spread of the plant. Excessive watering should be avoided, especially in hot weather, as this can lead to the formation of soft, watery growths and increase susceptibility to disease.

Watsonias are particularly sensitive to overwatering, and their roots can become waterlogged and damaged. It is recommended to water the plants in the early morning or evening when the air is cool and the leaves can absorb the moisture from the spray without wilting. The amount of water required will depend on the size, shape, and direction of spread of the plant. Excessive watering should be avoided, especially in hot weather, as this can lead to the formation of soft, watery growths and increase susceptibility to disease.

It is important to avoid watering at night, as this can cause the plant to become waterlogged and damaged. It is also important to avoid watering during the heat of the day, as this can cause the plant to become wilted and damaged. The best time to water Watsonias is in the early morning or evening when the air is cool and the leaves can absorb the moisture from the spray without wilting. The amount of water required will depend on the size, shape, and direction of spread of the plant. Excessive watering should be avoided, especially in hot weather, as this can lead to the formation of soft, watery growths and increase susceptibility to disease.

Another important aspect of watering Watsonias is to avoid overwatering. This can cause the roots to become waterlogged and damaged, and can lead to the formation of soft, watery growths and increase susceptibility to disease. It is recommended to water the plants in the early morning or evening when the air is cool and the leaves can absorb the moisture from the spray without wilting. The amount of water required will depend on the size, shape, and direction of spread of the plant. Excessive watering should be avoided, especially in hot weather, as this can lead to the formation of soft, watery growths and increase susceptibility to disease.

In general, it is recommended to water Watsonias in the early morning or evening when the air is cool and the leaves can absorb the moisture from the spray without wilting. The amount of water required will depend on the size, shape, and direction of spread of the plant. Excessive watering should be avoided, especially in hot weather, as this can lead to the formation of soft, watery growths and increase susceptibility to disease.
WATSONIA

WEEDS

WEDELLA (Georg Wolfgang Wedel, professor at Jena, Germany, 1645–1721). Compositae. Scabrous-pubescent or hirsute, annual or perennial herbs or subshrubs, suitable for growing in the greenhouse: lvs. opposite, usually decussate, rarely 3-cleft or entire; head heterogamous; ray-fls. male, disk-fls. fertile or the innermost sterile; involucral ovoid, campanulate or somewhat hemispherical, in 2 rows; corolla yellow, male ligulate, spreading, apex entire or 2-3-toothed, female regular, tubular, 4-5-toothed and chiloid; achenes glabrous or pilose, smooth or tuberculate, cuneate-oolong or obovate.—About 70 species, natives of the warmer regions of the world.

oblonga, Hutchins. Glabrous-hairy herb, up to 3 ft. high: lvs. strongly cuneate. Hemispherical heads, male acute, 3–3 1/2 x 1–3 in.; peduncles 1 1/2–2 in. long: flower heads yellowish–white, 1 1/2–2 in. diam.; outer bracts leaflike, inner somewhat scarious; ray-fls. about 12, 3-toothed. British E. Afr.

To this genus, Passalis is referred by recent authors. P. glauca, Ortg., is from Chile, probably not in cult. The plant cult. under this name in England, and once or twice in this country, is probably the plant shown in P.M. 8:125, which is thought to be a Helianthus. It is not hardy and there seems to be little reason for cultivating it here where there are so many other sunflowers. P. glauca is an herbaceous perennial, with opposite linear-lanceolate lvs., the upper ones entire and lower ones irregularly dentate; heads terminal and solitary, yellow-rayed.

WEEDS. A weed is a plant that is not wanted. There are, therefore, no species of weeds, for a plant that is a weed in one place may not be in another. There are, of course, species that are habitual weeds; but in their wild state, where they do not intrude on cultivated areas, they can scarcely be called weeds. The common weeds are sometimes valuable, in which case potato plants would be weeds if they grew among them.

It would have been a sorry thing for agriculture if there had been no weeds. They have made us stir the soil, and stirring the soil is the foundation of good farming. Even after we have learned that crops are benefited by the stirring of the land, we are likely to forget the lesson or be too neglectful of it unless the weeds constantly remind us of it. Necessity is always the best schoolmaster; and of these necessities, weeds are among the chief.

The one way to destroy weeds is to practise good farming. Judicious tillage should always keep weeds down in cultivated lands. In idle lands weeds are likely to become a serious nuisance. In sod lands they are also likely to take the place of grass when for any reason the grass begins to fail. The remedy for weeds in grass lands, therefore, is to secure more grass. In order to do so, it may be necessary to plow the land and reseed. In some cases, however, it is only necessary to give the land a light surface tillage, to add clean and quickly available fertilizers, and to sow more grass seed. This is the fundamental remedy for weeds on lawns. When the land for any reason is fallow—when it is waiting for a crop—surface tillage with harrows or cultivators will serve to keep down the weeds and to make the land clean for the coming crop. Often lands that are perfectly clean in spring and early summer become foul in the fall after the crops are removed. Cleaning the land late in the season, therefore, may be one of the most efficient remedies for riddling the place of weeds. Coarse and rough stable manure, which is not well rotted, may also be a coveryer of weed seed. The seeds of weeds are sometimes carried in the seed with

WATTLE: Acacia.

W.-work: Celsia sp. soundae.

EE. Fls. rose-red or white.

F. Lvs. 1/2–3/4 in. wide: spikes about 12-fld.

Meriana, Mill. This seems to be the dominant species of the genus and hence the most variable and the one most interesting to the plant-breders. In its widest sense it includes W. tridifolia, but for horticultural purposes it will be convenient to consider a distinct species. W. Meriana is best restricted to the commonest type at the Cape, which is a rose-fl. species 3–1 ft. high, the st. usually branched, lvs. lanceolate, spikes 12–20-fld. This is the plant figured in B.M. 1194 as Antholyza Meriana. Gn. 17:390 is more typical in color. The white-fl. form, which is rarer in nature, is treated under W. tridifolia.

Baker says that there are scarlet-fl. forms of this species, but he gives them no name, and it is probable that all such should be referred to W. angustia.

F. Lvs. wider: spikes denser, 20-fld. or more.

tridifolia, Ker-Gawl. (W. Meriana var. tridifolia, Baker). This is treated by Baker as a variety of W. Meriana characterized by broader lvs. than the type: fls. closer and more numerous, white or pinkish. For horticultural purposes it will be convenient to treat it as a distinct species and restrict the name to the pink or rose-colored type.

dd. Spikes dense, 30–50-fld.

densiflora, Baker. This very distinct and handsome rose-colored species more nearly resembles a gladiolus than any other by reason of the density and regularity of its pyramidal inf.: sts. unbranched, 2–3 ft. high: spikes 4–6-fld.: corolla-tube elongated, wider at the base, nearly 1–2 in. wide, and the spikes 12–20-fld. This is the widest sense it includes W. Meriana var. ardernei. This showy scarlet-fl. species differs from W. Meriana in its st. being shorter and unbranched, the spikes fewer-fld., and the styles a trifle longer: lvs. 1–2 ft. high: spikes 3–4-fld.: corolla-tube elongated, longer than the limb, the lobes spreading, obovate, acute or rounded: involucre ovoid, campanulate or subhemispherical, many-bracted. B.M. 1194 (W. Meriana variety). J.H. III. 33:61.

dd. Tube 1 1/2–2 in. long.

humilis, Mill. This species has rose-red fls. apparently the same size and color as W. densiflora but only 4–6 in a spike and the st. only a foot or so high: corolla-lobes oblanceolate, acute. B.M. 631.—A variegated form figured in B.M.1193 as W. roseo-alba has a spike of 5 flesh-colored fls. with broad bands and splashes of scarlet.

a. Upper part of tube short and broadly funnel-shaped.

WILHELM MILLER.

E. TRACY HUBBARD.†

WATTEL: Acacia.
WEEDS

which the land is sown, particularly in grass and grain
seeds.

It does not follow that weeds are always an evil, even
when they are abundant. In autumn a good covering
of weeds may serve as an efficient cover-crop for the
orchard. They are likely to entice some extra care the
next year in order to prevent them from gaining a
monopoly, but his extra care benefits the orchard at the
same time. It is, of course, far better to sow the cover-
crop oneself, for then the orchardist secures what he
wants of the proper quantity and at the right
season; but a winter cover of weeds is usually better
than bare earth.

From the above remarks it will be seen that weeds are
scarcely to be regarded as fundamental difficulties
in farming, but rather as incidents. In the most
intensive and careful farming the weeds bother the
least. There should be a careful oversight of all waste
areas, as road sides and vacant lots. The greatest
difficulty arises on commons and waste land, not on
farms.

Weeds are often troublesome in walks, particularly in
those made of gravel. If the walk were excavated 2
feet deep and filled with stones, rubber, or coal-ashes,
weeds cannot secure a foothold. It is particularly
important that gutters be not laid directly on the soil,
either in the city or in the sewage channel. There are
various preparations that can be applied to walks to kill
the weeds, although, of course, they also kill the grass
drigings if carelessly applied. Strong brine, applied hot, is
one of the best (one pound of salt to one gallon of water).
They are also very good to use in the preparation of arsenic, vitriol, lime, and sulfur, known as herbicides. For identification of
weeds and means of control, see Georgia's "Manual of

L. H. B.

WEIGELA, WEIGELIA: Diervilla.

WELDENIA (for Ludwig von Welden, an Austrian
army officer, wrote on natural history; 1780-1833).
Commelinaceae. Tube-rooted herb, suitable for the
greenhouse: lvs. numerous, grouped at the top of the st.,
forming a sort of involucre about the figure; cymes very
densely fasciated, sessile among the lvs.; calyx sessile,
15-25 mm. or less long, membranous, long and laxly
tubular, often atrophe-like, split, apex shortly 3-cleft;
corolla-tube slender, much longer than the calyx, lobes
broad, spreading, subequal; stamens 6; ovary ovoid.

One species. W. candida, Schult.

WELLINGTONIA: Sequoia.

WELWITSCHIA (Dr. Friedrich Welwitsch, 1806-
1872, botanical traveler, who brought this remarkable
plant to notice). Gnetaceae. One of the most singular of
plants, sometimes seen in the dried state in museums
and rarely grown in botanic gardens.

The plant consists essentially of 2 persistent woody
lvs. lying near or on the ground, the ends becoming
much frayed (at one time supposed to be persistent cotyledon), and from the center or crown the cone-
like fructification arises. It may be described as follows: A low woody plant, sometimes grown as an
oddity; st. or trunk thick, cone- or top-shaped, usu-
ally somewhat raised above ground, more or less 2-
lobed, said to be sometimes 14 ft. in circum.: lvs. 2,
lasting the life of the plant, linear at first, later spatter-
ing into many sections: inf. axillary, paniculate,
dichotomously branched, the branches ending in 4-
angled ament-like spikes which are colored: fls. diac-
icious; male fls. with 4 perianth-segms. in the shape of a
cross, stamens 6, joined at the base; perianth of female fls. tubular, inclosing completely
the fertile seed.—One species, arid places Trop. and
S. W. Afr.

The oldest actual name for this strange plant is
Tumboa, which was mentioned incidentally in the
Gardeners' Chronicle, 1801, page 75, in a running
account of a meeting of the Linnean Society; and the
name T. Bainesii, Hook. f., was similarly mentioned
on page 1008 in an account of a meeting of the Royal
Horticultural Society. In the same journal in 1802 the
name T. strabilifera was also mentioned. Neither the
genus nor the species was botanically defined. In
Gardeners' Chronicle for 1802, the name Welwitschia
was proposed, and under that name the plant was
carefully drawn and the plant regularly described in
Trans. Linn. Soc., 1803, and in the same year in B.M.
5368, 5369. Under this name the plant has passed; but
in Engler & Prantl, Pflanzenfamilien Nachtr. (1897),
attention is called to the older Tumboa as the proper
name, and this name is taken up in Cat. Welwitsch
Afr., pl. II, pt. 1 (1899). All the preceding literature
is under Welwitschia and all the horticultural refer-
ces; and inasmuch as the name in nomenclature is,
should be, stability rather than priority, the principle
of long-accepted usage should be invoked in this case
and the name Welwitschia retained, particularly as
the name Tumboa was not formally founded and as the
revival of it contributes nothing to clearness or
definition. (It is retained by the Brussels Congress.)

In respect to the cultivation of Welwitschia, W.
Watson, Curator of the Royal Botanic Gardens, Kew,
England, writes in 1916: "We have a plant here
which was raised from a seed in 1880. It lives, but
growth is very slow, so slow that a full-sized plant,
such as we have in our Museum, might at this rate be
reckoned a thousand years old. We grow it in a
tropical house devoted to succulents, where it gets all
the sunlight, the usual amount of water, except for
about three months in winter, when it gets very little,
and it is potted in sandy loam. There may be a set of
conditions that would suit the plant better, though
experiments with other plants raised here since did not
reveal anything better."

mirabilis, Hook. f. Lvs. 6 ft. or more long, the split
ends reclinign on the ground, flat and long-narrow,
attached at the base to the crown of the wrinkled brown
and hard trunk: plant said to persist a century. G.C.

L. H. B.

WESTRINGIA (J. P. Westring, Swedish physician
and author; died 1833). Labiatae. Shrubs, suitable for
greenhouse cult., although apparently not now in com-
mom cult.: lvs. in whorls of 3, 4, or rarely more, entire,

3511
WESTRINGIA

fls. axillary or rarely in terminal leafy heads; calyx campanulate, 5-toothed; corolla-tube short and dilated at the throat, limb 2-lipped, upper lip flat, broadly 2-lobed, lower spreading, 3-lobed; stamens, 2 upper perfect, 2 lower sterile; nutlets reticulate-rugose.—About 12 species, natives of extra-Trop. Austral.

WHIPPLEA (in honor of Lieut. A. W. Whipple, commander of the surveying expedition to the Pacific Ocean in 1853–1854). Saxifragaceae. Two low shrubs in W. N. Amer. with small opposite nearly sessile lvs., 3-nerved and entire or sparingly dentate, appressed-hairy on both sides, and with small white fls. in terminal cymes: fls. 5- or rarely 6-merous; receptacle turbinate, adnate to the base of the ovary; sepals lanceolate; petals small, oblong-elliptic, 5-lobed, lobes imbricate; stamens 5, or rarely 6-merous; ovary half inferior, with small white or brick-colored, solitary in the axis of opposing bracts, arranged in a terminal raceme; calyx 6-lobed, segments membranaceous, colored, oblong or lanceolate; corollas tube swollen almost from the base or slender-cylindrical and abruptly inflexed above widening to a campanulate throat, 5-lobed, lobes ovate or oblong-lanceolate; stamens 4, in pairs.—About 17 species, Trap. Afr. This material which has been offered in Amer. as W. lateritia is really Jacobinia cornnea (see Vol. III, p. 1714): the true W. lateritia, Hook., is rarely cult. and is a tender evergreen shrub about 3 ft. high; lvs. ovate or oblong-ovate, wavy; fls. red; corolla bell- or funnel-shaped. W. Trop. Afr. B.M.4153, F.S. 1:36.

WIGANDIA (named after Johannes Wigand, Pomeranian bishop; wrote on plants; 1523–1587). Hydrophyllaceae. Tall hispid perennial herbs or subshrubs, used for subtropical bedding, or may be grown in the greenhouse.

Leaves alternate, large, rugose, doubly dentate, cymes terminal, large, dichotomous: fls. sessile, 1-sided along the branch; calyx-segments linear; corolla-tube shortly and broadly campanulate, sealed inside; limb broad, spreading, 5-lobed, lobes imbricate; stamens 5; ovary rather perfectly 2-celled: caps. 2-valved.—About 3 or 4 species, widely dispersed in the mountains of Trop. Amer. Monographed by A. Brand in Engler's Pflanzenreich hft. 59 (IV. 251). The species of Wigandia are very much confused in current reference books, as well as in the trade. The following account is based on André's revision of the genus in R.H. 1861: 371, with an important change in the name of one species. In respect to W. urens, André follows the previous revision by Choisy in DC. Prod. 10:184. The combination Wigandia urens was first used by Kunth, who applied it to a Mexican plant. Before this, however, another plant of the same family but a native of Peru had been called Hydrocleys urens. When Choisy came to monograph the whole family he transferred Hydrocleys urens to the genus Wigandia and called it Wigandia urens, Choisy. He therefore had to rename the Mexican plant. This he did as W. modesta, Kunth.

Wigandias are chiefly valued as foliage plants for subtropical bedding, because of their very showy character. Their leaves are covered with stinging hairs, similar to nettles. Many large specimens may be seen in California, but the plants are considered to be rather coarse and straggling. They are generally raised from seed every year, the seed being started indoors as early as January. The plants attain a height of 8 to 10 feet in a single season. They are unsatisfactory greenhouse plants, as they do not grow vigorously indoors. The roots may be kept over winter in a frostless place and stock may be secured in spring by cuttings. In general, the plants are not much used in North America.
caracasana, HBK, Fig. 3999. Erect robust subshrub, 1-2 ft. high, softly golden or silvery-pubescent; lvs. rather long-petioled, ovate, obtuse, base subcordate, 18 x 10 in., coarsely, doubly and irregularly crenate, white-tomentose beneath; inf. golden silvery-pubescent, terminal, elongate, strict (a thymoid cincinnus); corolla violet, tube white; caps. equaling or a little longer than the calyx. S. Mex. to Venezuela and Colombia. B.M. 4575 (adapted in Fig. 3999). B.R. 1866; F.S. 8:755. Ga. 4, p. 502; 8, p. 198. R.H. 1859, p. 635, J.F. 2:132. Var. macrophylla, Brand (W. macrophylla, Choisy & Schultes.), is a larger-sized form which also grows rather taller than the type and has the infl. white-silvery-pubescent. R.H. 1861:371.—It is the Mexican form of the species and the one mostly in cult.

Kanthii, Choisy (W. arenus, HBK, not Choisy). Very hirsute subshrub, not golden pubescent, about 6-15 ft. high; lvs. doubly sharp-serrate, not white-tomentose; infl. not at all thyrsoid but paniculate, very hirsip, rarely pubescent or dirty tomentose; corolla violet, tube white: caps. slightly longer than the calyx, very densely hirsute. Mex. to Honduras.

Arenus, Choisy, not HBK. (W. peruviana, W. Mill. Hydrolea arenus, Ruiz & Pav.) Stout erect subshrub up to 12 ft. high, very densely dirty white-hirsute; lvs. short-petioled, 8-12 x 6-7 in., broadly ovate, dentate or truncate, apex obtuse; fls. arranged in a broad terminal raceme (cincinnus); sepals lanceolate-acute, hirsute; corolla violet, parted to the middle, lobes elliptical, densely silky outside: caps. oblong, twice shorter than the calyx. Peru. R.H. 1867, p. 470.

W. imperialis is listed as a very ornamental plant, but it is not treated by Brand.—W. Podleri, Carr., is not treated in Brand's monograph and is apparently a horticultural form, perhaps of W. caracasana. Carriere merely said it was a silvery plant instead of somber and plumy like W. caracasana. It is frequently listed in the trade and is said to have blue-black or wine-colored fls.

F. TRACY HUBBARD.

WIKSTRÉMIA (named after J. E. Wikstrom, professor of botany at Stockholm, 1789-1856). Thymelaeaceae. Shrub or trees, occasionally grown in the warmhouse or greenhouse; lvs. opposite or rarely alternate; fls. in short terminal or axillary racemes, spires or heads; perianth tubular, limb spreading, 4-lobed, without scales in the throat; stamens 8; ovary villose, 1-celled: fr. a berry-like drupe.—About 40 species, Trop. Asia, Austral., and the islands of the Pacific.

Poséigera, Brit. & Rose (Echinocereus tuberosus, Rümpl. Cereus tuberosus, Posel.). Roots black, several, borne near the surface: stems 2 ft. or less high, with about 8 ribs, the lower and older part naked, spiny above, the spines almost hiding the ribs; spines appressed, yellowish or golden-pubescent, radially and ascending, black-tipped: fls. purple, 2 in. long: seeds pitted or rugose, 1/4 in. long.—This species, although often cult., does not do well under glass when grown on its roots, but when grafted on various species of Selenicerus, it does extremely well.

J. N. ROSE.

WILD FLOWERS: Their appeal and conservation. In many countries some kind of wild flower grows first place in the love and sentiment of the inhabitants. The rose, the thistle, the shamrock, the iris, the edelweiss and alpine rose, the chrysanthemum, the poppy and the lotus have all contributed their share to the literature and art of the Old World. Typically of the states have adopted some native American plant for the state flower, including the arbutus, bitter-root, black-eyed Susan, columbine, gentian, goldenrod, laurel, lupine, magnolia, mistletoe, mountain-flower, Oregon grape, pukea flower, golden poppy, pine cone, rhododendron, rose, Sago lily, sunflower, syringa, and violet. Of these the goldenrod and violet lead in popularity, with the arbutus, magnolia, and rhododendron next in public favor. Nine states have chosen either cultivated plants of economic value or introduced weeds like the daisy. Thus far, no national flower has been adopted, principally because no wild flower grows or could be grown in all the states and territories, owing to the diversity of climate and flora. An attempt has been made recently to adopt the mountain laurel, but as this is a plant which grows only in the Appalachian regions of the eastern states it has not met with unanimous approval.

That a widespread interest in native plants exists there can be no question. Local and popular floras abound, poems and songs appear frequently, yet the people as a whole are still barbarians when it is a question of real love and protection. Arrows pulled up from the roots and sent through the mails in frail and broken pasteboard boxes, having been nearly or quite exterminated where formerly it was abundant. Orchids and lilies are gathered by the basketful to adorn college commencements and church services. Ropes of laurel and ground-pine are used at balls and Christmas festivities, and the holly which used to be abundant is rapidly becoming scarce, and hard to find. All these supplies come from wild sources and few of them will pay to cultivate. Moderation and protection are recommended for all of them. Some few of our wild flowers take kindly to cultivation, and are grown for their beauty: laurel, rhododendron, azaleas, dogwood, and magnolias perhaps lead in popularity, but some of the smaller herbaceous plants such as bloodroot, hepatica, columbine, lilies, jack-in-the-pulpit, forget-me-nots, and many of the native ferns may be readily grown if given suitable conditions of soil, moisture, and shade. Most wild flowers prefer an acid soil with plenty of leaf-mold to the ordinary garden soil, and should be planted in some place by themselves where natural conditions can be maintained. A hopeful sign of advancing appreciation is that the best landscape architects and park superintendents are recommending the planting and preservation of native plants and in many of the national parks and public reservations the native flora is protected from depredation. With the increase of motors has come an interest in good roads and roadside planting, but some of the railroads in Colorado still run "flower excursions" where a lot of vandals are taken to some beautiful spot and come home loaded with wild flowers which they promptly throw away. It is sad to think of selfish and thoughtless destructiveness which should be combated by all true lovers of native plants, and various organizations have been formed to try to accomplish it. Arbor Day might fitly be called Conservation Day and used to impress on school children the importance of this work.

The following associations are interested and will supply information to those wishing to cooperate: Conservation Department, General Federation of Women's Clubs; Conservation Society of National Educators; American Association of Forestry; State Associations of Forestry; Garden Clubs of America, Philadelphia; Lincoln Highway Commission; Society for the Protec-
tion of Native Plants, Boston; Stokes Fund for the Preservation of Native Plants, New York Botanical Garden; American Association of Park Superintendents, Portland, Oregon; Wild Flower Preservation Society of America, Brooklyn Botanic Garden.

List of state and provincial flowers.

- **Alabama**: Goldenrod.
- **Alaska**: Forget-me-not.
- **Arkansas**: Apple blossom.
- **California**: Golden poppy.
- **Canada**: Sugar maple.
- **Colorado**: Blue columbine.
- **Connecticut**: Mountain laurel.
- **Delaware**: Peach.
- **Florida**: Orange blossoms.
- **Georgia**: Cherokee rose.
- **Idaho**: Syringa.
- **Illinois**: Native violet.
- **Indiana**: Carnation (pink).
- **Iowa**: Goldenrod.
- **Kansas**: Sunflower.
- **Kentucky**: Goldenrod.
- **Louisiana**: Magnolia.
- **Maine**: Pine cone and tassel.
- **Maryland**: Black-eyed Susan.
- **Massachusetts**: Arbutus, Mayflower.
- **Minnesota**: Moccasin flower.
- **Mississippi**: Magnolia.
- **Missouri**: Goldenrod.
- **Montana**: Bitter-root (Lewisia).
- **Nebraska**: Goldenrod.
- **New Jersey**: Violet.
- **New York**: Rose.
- **North Carolina**: Daisy.
- **North Dakota**: Wild rose.
- **Nova Scotia**: Arbutus.
- **Ohio**: Red carnation.
- **Oklahoma**: Mistletoe.
- **Oregon**: Oregon grape (Mahonia).
- **Pennsylvania**: Laurel.
- **Rhode Island**: Violet.
- **South Dakota**: Pasque flower (Anemone).
- **Tennessee**: Daisy.
- **Texas**: Blue bonnet, lupines.
- **Utah**: Sage lily (Calochortus).
- **Vermont**: Red clover.
- **Washington**: Rhododendron.
- **West Virginia**: Rhododendron.
- **Wisconsin**: Violet.
- **Wyoming**: Gentian.
- **Hawaii**: Lehua (Metrosideros).

**WINDBREAK**

In horticultural usage, windbreaks are plantations of trees or other plants designed to check the force of the wind or to deflect it to other directions. Windbreaks are often of the greatest use, and at other times they are detrimental. In regions of very strong prevailing winds, they may be necessary to prevent injury to the plants. This is true along seashores. In the dry interior regions, windbreaks are often useful, also, to check the force of parching winds that would take the moisture from the land. In other cases, they are employed for the purpose of sheltering the homestead, to make it more comfortable for human occupancy: such breaks are usually known as shelter-belts. See Hedges.

Whether windbreaks shall be used for orchard plantations depends wholly on circumstances. In regions of very strong prevailing winds, as near large bodies of water or on the plains, such breaks are usually necessary on the windward side of the orchard. However, if the prevailing winds are habitually warmer than the local temperature, the winds should not be stopped or wholly reflected, but they should be allowed to pass through the windbreak with diminished power in order that, while their force may be checked, they may still prevent too low temperature. In regions that are very liable to late spring and early fall frosts, a tight break is usually a disadvantage, since it tends to confine the air—to make it still—and thereby to increase the danger of light frosts. If windbreaks are employed in such cases, it is best to have them somewhat open so that atmospheric drainage may not be checked. In most regions, the greatest value of the windbreak for orchard plan-
if their velocity is not too great; care must be taken to allow of adequate atmospheric drainage.

Windbreaks for orchards require much land, and crops near them are likely to suffer for lack of food and moisture, and also from shade. In small places, therefore, it may be impossible to establish large breaks. It is well to plant the windbreak at some distance from the first row of orchard trees, if possible. It is usually planted for shelter-belts, because they thrive under most conditions, grow rapidly, and are hardy.

WINDOWFLOWER: *Anemone*.

WINDOW-GARDENING. The growing of plants in windows and similar openings, particularly when conducted as a regular and systematic undertaking.

Although not strictly a part of the planting of the property, window- and veranda-boxes give color and tone to the place as well as provide pleasant and satisfaction for the inmates of the residence. For those who live in crowded localities or are unable to care for a garden, these outside boxes offer an opportunity for a display of flowers, not only in the summer months, but, in the case of window-boxes and by the substitution of other kinds of plants, through the winter months as well. The illustrations (Figs. 4001-4003) show good forms of window-boxes. The first two are drawn from illustrations in Gardening, May 15, 1916. See House Plants, Vol. III.

These boxes may be purchased and may be highly ornate, having pattern tiling or made of finely finished wood and suspended by fancy brackets; but such boxes are not necessary. A stout pine box of the required length, from 10 to 12 inches wide and at least 6 inches deep, if painted a suitable color serves quite as well as the others, for the side and ends of the box should be soon covered by the drooping vines. Provision for drainage should be made by boring holes in the bottom of the box, these holes being covered with pieces of broken pots, coal-cinders or gravel-stones. This allows for the drainage of water while holding the earth from escaping. The soil for these window-boxes should be rich in plant-food, as the roots will be restricted. The most desirable soil is one that does not pack hard when watered, or contract much when dry, but remains porous and springy.

The soil may be made by mixing two parts of garden loam, one part of leaf-mold or wood earth, and one part of sand. To this mixture should be added well-decayed manure, preferably cow-mature, at the rate of one peck to two bushels of soil.

Many kinds of plants may be used in window- and porch-boxes, but in planting one should choose the subjects most suitable for the particular exposure. If the boxes are to be placed in full sunlight, it will be necessary to choose vigorous-growing sun-loving plants. For

a shady corner or a northern exposure, more delicate plants may be used. For the former, such plants as geranium, coleus, achyranthes (iresine), Paris daisy, double petunias, may be used; or, if a more pretentious display is desired, crotona, colored-leaved dracenas, acalypha, aspidistra, or small palms may be employed. Low-growing plants for the front of the box may consist of the dwarf white-leaved geranium Madame Sal­leroi, the golden feverfew, lobelia, sweet alysium, and the white-leaved cineraria. For the drooping vines, nothing excels the variegated-leaved vines, nasturtiums, tradescantia, and German ivy. If the position is shady, vigorous-growing ferns, such as the nephrolepis, a few of the pteris, and perhaps the hardiest of the adiantums are effective. The narrow-leaved dracena (Cordyline indivisa), grevillea, and Rex begonias are all good plants for shady places.

After the plants have filled the box with roots, it will be necessary to work into the soil more plant-food, either a light coating of bone-meal or a thicker layer of well-rotted manure; still better would be a watering about once each week with dilute liquid manure.

One of the objections to veranda-boxes, especially those that are fastened permanently in place, is that in winter they are usually bare of foliage and therefore unsightly. This disadvantage may be overcome and a seasonable appearance given by the use of small conifers, broad-leaved evergreens, dwarf box, mahonia, Eony­mus radicans and pachysandra or Vinca minor are all available. To lighten the somber effect of the solid green, small shrubs bearing bright-colored fruits may be introduced, such as dwarfed plants of barberry, either Berberis vulgaris bearing long clusters of dark red fruits or B. Thunbergii with bright scarlet berries borne along the gracefully bending branches. Privets, either Ligustrum vulgare or L. Regelianum, are good for berries, both bearing clusters of blue-black fruits con­trasting well with the green of the conifers or the reds of the barberry; these fruits are held through the winter without change in color. Wisteria sinensis in a striking setting.
Those who wish to give a young wisteria an extra-good start may sink a bottomless tub in the ground and fill it with good soil. When a wisteria is to be trained to a tree, choose an old tree, if possible, which is past the height of its vigor; but good results are to be expected only when sunlight and opportunity are ample, and these can rarely be secured under a living tree-head.

The Japanese wisteria (W. floribunda) is one of the best and commonest of hardy climbers. It has pale green pinnate foliage and bears profusely of dense drooping clusters of purplish pea-shaped flowers. The clusters are about a foot long. This is the commonest and best form. The variations furnish the connoisseur with variety in habit, color, and season of bloom, but they are not as prolific, and doubling adds nothing to the beauty of the flowers. Moreover, the double flowers decay quickly in wet weather.

The wisterias bloom in May and usually give a smaller crop of flowers in August or September. The spring crop is borne on spurs, while the autumn crop is borne on terminal shoots of the season. There are several ideas about training a wisteria. A good way is to let it alone. This produces rugged twisted and gnarled form. The vines should be pruned back every year in early spring to a height of 6 or 8 feet and pruned in for some years, the stem will stiffen until it is able to stand alone, and the top will spread out into a broad head.

INDEX.

KEY TO THE SPECIES.

A. Standard of the fl. with distinct calices or appendages at base (Wisteria proper).
B. Fls. 7–9 pairs ........................................ 1. floribunda
B. Fls. usually less than 7 pairs.
C. Lei. smooth or nearly so on both surfaces of calix
D. Racemes long, 6–12 in. or more. 2. sinensis
E. Fls. large (more than 1 in. across at full expansion).
F. Fls. small (less than 1 in. across): American ........................................ 3. macrostachys
G. Racemes short, 4–6 in. or less: American ........................................ 4. frutescens
H. Racemes long, 6–12 in. or more: American ........................................ 5. venusta
I. Standard lacking auricles at base (transition to Millettia) ........................................ 6. japonica

1. floribunda, DC. (Glycine floribunda, Wild. Wisteria brachybotrys, Sieb. & Zucc. Krauthia brachybotrys, Greene). JAPANESE WISTERIA. Young lvs. densely covered with straight appressed hairs, but foliage soon glabrous; lfts. 7–9 pairs, ovate-elliptic, rather abruptly acuminate, acute, rounded at base; fls. violet or violet-blue, rather small, in moderately long racemes (or sometimes in short racemes, particularly later in the season, whence the name brachybotrys); standard oblong-oblanceolate, subcordate at base and auriculate, with a short stipe-like claw; calyx hairy, the upper teeth very short and broad. Common on

diagram: Wisteria covering for a porch.
sinensis, Makino). CHINESE WISTERIA. Fig. 4005. Lvs. smooth or nearly so at maturity, the petiole swollen at base; lfts. about 5 pairs, ovate-acuminate or ovate-lanceolate, short-stalked, 2–3 in. long, the margins ciliate but entire; racemes pendulous, 6–12 in. long, terminating the branches; calyx villous; corolla large, blue-violet, not fragrant, showy. Low altitudes in China, and much cultivated there. Apparently little grown in this country and not so hardy as W. floribunda. B. M. 2083 (from which Fig. 4005 is adapted). B. R. 650. L.B.C. 8:773. P. M. 7:127. Var. alba (forma alba, Lindl. var. alba, Kuntze) has white fls. I.H. 5:166.

3. macrostachys, Nutt. (Kraunkia macrostachys, Small). Slender vine 20–25 ft. high or long: lfts. usually about 9, ovate to elliptic-lanceolate, about 2 in. long, acuminate at base or acute, cordate or rounded at base, racemes 8–10 in. long, drooping, loosely flded, the pedicels and calyx glandular-hairy; fls. light blue or purplish, the standard about ¼ in. across and not prominently auricled; calyx-teeth half or more the length of the tube. Swamps, Ill., southward. Probably rarely if at all cult.

4. frutescens, Poir. (Glycine frutescens, Linn. Kraunkia frutescens, Greene. Bradilia frutescens, Brit. W. speciosa, Nutt.). Tall stout climber, the trunk attaining several inches in diam.: not glandular, smoothish or somewhat downy at maturity; lfts. 4–6–7 pairs, ovate to ovate-lanceolate, acuminate but obtuse, glabrous above: racemes 4–6 in. long, densely flded; fls. lilac-purple; auricles of the standard rather prominent; calyx-teeth very short. Low grounds, Va. to Fla. and Texas. Sometimes planted. Var. alba, Hort., with white fls., has been listed. Var. magnifica, Herneq (W. magnifica, Hort.), supposed to belong here, has racemes 50–60-fld. and 6–8 in. long; fls. 1 in. across, lilac with a yellow spot, earlier than the type. F.S. 11:1151.

5. venusta, Rehd. & Wils. (W. brachypoda var. alba, Mill.). SILKY WISTERIA. Tall, reaching 30 ft. or more, the young growth pubescent: lfts. usually 5 pairs (from 4–6 pairs), velvety both sides, oblong-lanceolate or elliptic to ovate-oblong, short-acuminate, at the base subcordate or rounded or truncate, entire; racemes pendulous, 6 in. or less long including the short peduncle, broad, the rachis densely appressed-villous; fls. very large, white, on nearly horizontal spreading pedicels; standard suborbicular, truncate at the apex and acuminate at base, clawed; upper calyx-teeth subulate; pod compressed, densely velvety. China, province Chi-hi.—

More or less planted in Eu. and U. S., but only recently distinguished. Var. plena (forma plena), Rehd. & Wilson. With double white fls., occasionally offered by Japanese dealers; the only double-flld. white wisteria known.

6. japonica, Sieb. & Zucc. (Miliédicta japonica, Gray. Phaseolos japonicus, Kunze). Kraunkia japonica, (Taub.). Glabrous throughout: lfts. 4–6 pairs, petiolate, narrow-ovate or ovate-lanceolate, acuminate but obtuse at point, entire, light green: fls. small, white, in long drooping simple racemes to 8 in. long; calyx cylindrical urn-shaped or cup-shaped, pubescent; standard obovate, lacking the callouses at base; ovary and style glabrous; pod linear-oblong, mucronate at apex, woody, not large. Japan, Korea. Little known in this country, and not hardy in the northern parts. By some authors this species is kept in the genus Milletia, where it was placed by Asa Gray; and under that name it is described in Vol. IV, page 2051.

L. H. B.†

WITCH-HAZEL. Hamamelis.

WITHANIA. See note under Salpichroa.

WITLOOF (Dutch, “white-leaf”) is a salad vegetable comprised of the compact blanched leaf-head produced by certain forms of chicory. The large thick roots of chicory produce leaves when forced in absence of light, and these leaves may be further blanched by forcing them through sand or other covering. See Covi.

The vegetable known as barbe-de-capucin, often shortened to barbe, is very similar to witloof, being produced by forcing either wild or improved roots of chicory and having a looser more leafy head. Witloof is usually forced from a special variety, grown for this purpose. As seen in the market in its best form, it is a firm oblong-pointed head about 6 inches long of white crisp undeveloped leaves. (Fig. 4006.) This vegetable is imported into this country in large quantities, being much prized as a delicate salad with a slightly bitter and characteristic flavor. It is frequently known as French endive.

There seems to be no reason why witloof can not be produced in this country. The New York Agricultural Experiment Station (Geneva) has recently published the results of tests (J. W. Wellington, Bulletin No. 418, from which the following directions are adapted: The seed (sold by many American seedsmen) from which to grow the forcing roots may be sown any time in May in open ground, in rows 18 inches apart and the plants later thinned to 6 inches apart in the row. Ordinary garden culture only is needed, but the plants should make a steady luxuriant growth, resembling large smooth-leaved dandelions. The roots should be lifted just before the ground is liable to freeze, the leaves trimmed to within 2 inches of the crown, and the roots stored. When needed for forcing in winter, the roots should be placed in boxes or boxes where moderate heat can be applied, first cutting them off at the bottom to a uniform length of 8 or 9 inches. For holding the roots any soil or sand will do, since the growth of the heads is from the food stored in the roots and does not depend at all on the soil fertility. The roots may be set quite close together, but not touching, upright in the soil, and
covered to the crowns. Various materials may be used for holding and bleaching the heads during their growth; 8 inches of clear sand is a good medium. This may be placed on the bedding material, as long as the roots are set. One or more free applications of water should be made. From 50° to 60° F. in a desirable temperature, the latter probably preferable since growth is slower at the lower temperature. Higher temperature than 60° for any considerable period causes the leaves to shoot up rapidly and decreases the proportion of solid heads. At these temperatures the leaves begin to show through the 8 inches of sand in about two weeks, when the heads are ready for harvesting.

In the Geneva tests four grades of sizes of roots were used, ranging from 0.25 inches, medium, 0.9 inch, and small, 0.6 inch. Of these the large and medium roots gave more than 70 per cent of marketable heads, while the extra roots produced too many divided and loose heads, or heads too large to serve satisfactorily as individual portions at table. The small roots produced many small heads, too slender for market purposes. The heads should be 4 to 6 inches long, and weigh two to three ounces to suit the market best. In Europe they are packed in baskets holding ten kilograms; but a three-pound Climax basket serves satisfactorily as individual portions at table. The heads are ready for harvest at these temperatures.

In the tests at these temperatures the leaves should begin to show through the 8 inches of sand in about two weeks, when the heads are ready for harvesting.

In Europe they are packed in baskets holding ten kilograms; but a three-pound Climax basket makes a satisfactory package for American markets. L. H. B.

WITTLÖOF (named after Nicholas Witsen, Dutch patron of botany in first half of 18th century). Iridaceae. An ornamental greenhouse shrub with erect ensiform lvs. which are equitant, subsessile fls. with a very definite tube; petals free, linear, acuminate, without scales; fr. a dry berry. About 5 species, Cent. and S. Amer. This genus has sometimes been referred to Asphodelaceae; see Bilbergia for cult. W. lingulata, Mez. Lvs. about 10 in a rosette, firm, strap-shaped, rounded, shortly cuspitate, about 2 ft. long, 2½ in. wide, spines short, broad-based, about 3 lines apart; scape floccose when young; sepals lanceolate; pani­* ple pinnately branched; fls. numerous, sessile; sepal white, ovate, bearing an awn nearly 1 line long; petals yellow, ovate from an oblong base; ovary glabrous, rather cylindrical. W. Indicus. B.M. 8066.

WOODBETONY (after Joseph Woods, an English botanist, 1776–1864). Polypodiaceae. A genus of mainly rock-loving ferns characterized by their inferior indusium, which is attached beneath the sorus, inclosing it at first but soon splitting into star-like lobes, and later hidden beneath the sorus. – Some 15 species are known, of which 7 grow wild in this country. The following native species are sometimes cult. in borders. Treatment given other hardy ferns will suit them well. Both grow best among rocks.

A. Lvs. of two sorts, the veins everywhere forming areoles areolata, Moore (W. angustifolia, Smith). Sterile lvs. deltoid-ovate, with numerous oblong-lanceolate sinuate pinna; apophylls with narrowly linear pinna 3–4 in. long. Mich. to Fla., mostly near the coast. – Often and probably better separated under a distinct genus, Lorinseria, on account of its characteristic trichomes, which have been offered. They are of interest only as rarities in large collections. R. C. BENEDICT.

WOODWARDIA (Thomas J. Woodward, an English botanist). Cystopteris. A group of rather coarse-foliated ferns of diverse habit and structure, but all bearing the sor in rows arranged parallel to the midrib like links of sausages. See Fern.

A. Lvs. of two sorts, the veins everywhere forming areoles areolata, Moore (W. angustifolia, Smith). Sterile lvs. deltoid-ovate, with numerous oblong-lanceolate sinuate pinna; apophylls with narrowly linear pinna 3–4 in. long. Mich. to Fla., mostly near the coast. – Often and probably better separated under a distinct genus, Lorinseria, on account of its different lvs. and habit of growth. AA. Lvs. uniform.

B. Veins forming one or more series of areoles.

radicans, Smith. Lvs. rising from a short erect st., 2–3 ft. long, gracefully curved; pinnae 8–15 in. long, 2–4 in. wide, pinnatifid nearly to the midrib. The true W. radicans from Eu. bears scaly buds toward the apex of the fl. and roots to form new plants. The Californian and Mexican species, which has often been referred to

4008. Fruiting lobe of Woodwardia virginica.
ents. According to Blythe, the green color of this liquor is due not to wormwood but to the chlorophyll of anise, parsley, or nettles. The plant may be grown without trouble in light dry rather poor garden soil from seed which, owing to its small size, should be started where it may not be washed out or packed down by rain. When large enough to set out, the few specimens necessary to furnish a family supply should be placed not closer than 15 inches each way the first year. If alternate plants be removed with a good ball of earth early in the following spring and planted 30 inches apart, they will be sufficiently close together and the transplanted ones should suffer from no check. Ripened cuttings taken in March or October may be used for propagation. Clean cultivation and slight annual dressings of manure are the only other requisites. In the middle western states there are several localities where wormwood is grown for export.

Wormwood is used very extensively in the manufacture of certain medicines. The oil is produced largely in southern Michigan, and Wisconsin supplies a large acreage.

M. G. KAINS.

WYETHIA: *Ixia elephas*, Regel, is *Ixia columellaris*.

**WULFENIA** (named for F. X. Wulfen, 1778-1825).

*Scrophulariaceae.* Hardy perennial glabrous or slightly pubescent herbs, suitable for the border or rock-garden.

Leaves nearly radical, petiolate, crenate; peduncles scape-like, simple: fls. racemose at the top of the scape or spike, solitary at the axil of the bracts, nodding, blue; calyx 5-parted, segments narrow; corolla-tube exserted, cylindrical, limb 4-lobed, erect-spread; stamina 2: caps. acute, septicidally and loculicidally dehiscent, 4-valved.—About 8 species. Eu. and Asia.

**Amherstiana, Benth.** Lvs. obviate-oblong or obovate-spatulate, 2½ in. long; coarsely crenate or lobulate, narrowed at base and subplanitiate; petals ½-1½ in. long: scape 5-10 in. long, slender; racemes long, many-fl.: corolla ½ in. long. Himalayas. G.W. 9, p. 375.

**carinithaca, Jacq.** About 9 in. high; lvs. oblong or oval-oblong, doubly crenate, slightly lobed, narrowed at base, radical few, 3-8 in. long: scape 1-2 ft. long; raceeme dense, spike-like, at length elongated; corollata ½ in. long, limb shorter, upper segments bifid, lower somewhat crenate. Mountains of Carinthia. *W. cordata*, Greene, = *Synthyras reniformis*.

F. TRACY HUBBARD.

**WYETHIA** (named for N. J. Wyeth, North American botanical collector). *Compasita.* Hardy perennial herbs, probably adapted to the wild-garden or border. Caudex stout: sts. usually simple, 1-headed: lvs. radical or alternate, entire; heads large, heteroagamous; ray-lvs. pistillate, in 1 row, disk-lvs. perfect and fertile; involucre hemispherical; 2-5 rows of bracts; corolla yellow, rays ligulate, spreading, entire or minutely 2-toothed.—About 7 species, N. Amer. *W. mólis*, Gray. Plant floccose-woolly when young, more or less glabrous when old, 1-3 ft. high, bearing solitary or few heads: lvs. oblong or ovate, base rounded, truncate or cuneate; rays 10-15, over 1 in. long; achenes minutely pubescent at summit. Nev. and Calif. B.M. 7772.
XANTHISMA (Greek, dyed yellow, referring to the color of the flowers). Compositae. Summer-blooming yellow-flowered composites.

Annuals or biennials, with alternate, usually entire, narrow lvs.: fls. all fertile, exclusively radiate; achenes top-shaped, 4-5-ribbed or angled; pappus persistent, composed of 10 or 12 rigid bristles which are minutely scabrous above, gradually chaffy-dilated toward the base, and longer than the disk-corolla, as many more one-half shorter, and usually 5 still smaller and shorter external ones.—Two species, of easy cult. texanum, DC. (Centaurium Drummondii, Torr. & Gray). Fig. 4011. Nearly glabrous biennial or annual, 1-4 ft. high: lvs. narrowly oblong to lanceolate; st.-Ivs. entire or with a few teeth toward the apex: fls. attaining a diam. of 2 in. even in the wild, very showy, composed of a small disk and about 20 rather slender rays. On prairies, Texas.—Suitable for dry open places. In cult. treated like a hardy annual, the seed being sown in the open border early in spring. The second species, X. Berlandieri, Small (X. texanum var. Berlandieri, Gray), also of the prairies in Texas, is probably not cult. N. TAYLOR.†

XANTHOCRAS (Greek, xanthos, yellow, and keris, horn, alluding to the yellow corn-like processes of the disk). Sapindaceae. Ornamental shrub planted for its showy racemes of white flowers and also for the handsome pinnate foliage.

Deciduous: lvs. alternate, odd-pinnate, with narrow serrate lfts.: fls. polygamous, the upper ones of the terminal raceme pistillate, the lower ones staminate, those of the lateral 6-8; ovary superior, 3-located, with a rather short, thick style: fr. a caps., with thick walls dehiscent into 3 valves, each locule with several globose, dark brown seeds.—One species from N. China, allied to Ungnadia and Koelreuteria. A very handsome shrub or sometimes a small tree with rather finely pinnate dark green and glossy foliage which is not attacked by insects and retains its bright color until frost sets in, and with showy white flowers appearing in upright profusely produced racemes with the leaves on last year's branches. The large greenish fruits are similar to those of the buckeye. It is hardy as far north as Massachusetts and is well suited for solitary planting on the lawn. Xanthoceras is also sometimes used for hedges. It is not very particular as to soil. A porous loamy soil and a sunny position seem to suit it best. Propagation is by seeds, stratified and sown in spring, and by root-cuttings, which succeed best with moderate bottom-heat.

XANTHORHIZA: Zanthorhiza.

XANTHORRHEA (Greek, yellow flow, referring to the resin which exudes from the trunk). Liliaceae. Persistent perennials with a thick woody caudex, adapted to greenhouse culture and which have been tried out-of-doors in the extreme South. Caudex very short to arborecent: lvs. in a dense tuft at the top of caudex, long-linear, brittle, spreading or recurved: scape or peduncle terminal, often several feet long, terminating in a dense cylindrical spike: fls. greenish, numerous, sessile; perianth persistent, segments 6, 3 outer glume-like, erect, concave or almost hood-shaped at the top, 3 inner much thinner, erect with the

4011. Xanthisma texanum. (X⅓)
outer but more or less protruded beyond them; stamens 6; ovary sessile, 3-celled; caps. protruding from the perianth, ovoid or acuminate, 3-valved, hard, brown and shining.—About 14 species, Austral.

The "grass trees," "grass gums," or "black boys," form a conspicuous feature of the Australian landscape. These picturesque desert plants are well worth trial in the warmer and more arid regions of the United States. The trunk varies from almost nothing in some species to 15 feet in the case of aged specimens of X. Preissii. The tall and palm-like trunks are thickly covered with the bases of the old dead leaves, which are cemented together by the black or yellow resinous gum that flows freely from the stems. In Australia the trunks are often charred and discolored by bush fires. The following species have been offered in southern Florida and southern California, but are practically unknown to cultivation in this country. All the species are long-lived perennials native to dry and rocky places. They are said to thrive in a compost of peat and loam and to be propagated by offsets. X. Preissii seems to be the most desirable species.

XANTHOSOMA

4012. Xanthoceras sorbifolia. (X 1/2)

Xanthoceras sorbifolia, R. Br. Lvs. 1–2 ft. long, 1–2 lines wide; scape shorter than the lvs.: spike less than 3/4 in. wide. B.M. 6297. —Belongs to the group in which the inner perianth-segments, have a white blade conspicuously spreading above the outer ones, while in the next two species the inner segments have a short whitish tip, little longer than the outer and scarcely spreading.

AA. Trunk becoming 5–6, or even 15 ft. long.

BB. Spike 1 1/2–2 ft. long.

hastiflora, R. Br. Lvs. 3–4 ft. long, 2–3 lines broad: scape often 6–8 ft. long, not counting the spike. Readily distinguished by the dense, rusty tomentum covering the ends of the bracts and outer perianth-segments. B.M. 6933. G.C. III. 39:228.

undulatifolia, Tod. ex Riccobono. Trunk 8 ft. or so high, 12 in. diam.: lvs. in a large crown, 5 ft. long, fragile, sword-shaped, reflexed, rhomboidal in section: scape quite erect, cylindric, about 12 ft. long, with a dense spike of golden yellow fis. Austral.

F. Tracy Hubbard.

XANTHOSOMA (Greek, yellow body, referring to the stigma). Araceae. This group is interesting to the horticulturist as containing the handsome variegated stove foliage plant known to the trade as Phyllostachis Lindeni, and part of the vegetables known as yautia, malanga, and tanner, a crop to which much of the arable land in Porto Rico is devoted.

Milky herbs of S. and Cent. Amer. with a thick sometimes elongated corm: lvs. arrow-shaped, 3-cut or pedately cut: fis. unisexual, naked; males with 4–6 stamens connate in an inversely pyramidal synandrium with 5 or 6 faces; ovary 2–4-loculed; ovules anatropous.—A genus of 25 species, according to Engler, who has given an account of them in DC. Mon. Phaner., vol. 2 (1879).

Many species of the arum family are noted for their huge corms, some of which are edible after the acrid and more or less poisonous properties are destroyed by cooking. Of this class the best known are the taros (Colocasia esculenta), Schott, the common taro of southern Asia and the Pacific islands, and C. antiquorum, Schott,
the Egyptian taro, and the auyatas, taniers, or malangas (Xanthosoma sagittifolium, and other species of this genus) of the West Indies. The botany of the species of Xanthosoma is confused. The corms and cormels (offsets) of some taros, and the cormels of some varieties of auyatas, are free from acridity even in the raw state.

as cultivated in southern United States. Auyata corms are strong-flavored and are seldom eaten. The young leaves of colocasia and xanthosoma when properly cooked are said to be equal or superior to spinach.

A. Caudex a short, thick, erect rhizome.

sagittifolium, Schott (Arum sagittifolium, Linn.).

YAUTIA. MALANGA. Fig. 4014. A tropical vegetable. "Young plants of this are stemless, but in age, from the decay of the old lvs., an annulated caudex or corm is formed some inches in height, each throwing out stout fibers from the base, and from time to time producing offsets by which the plant becomes tufted, and numerous lvs. are produced from the summit of the short, yet st.-like trunks" (B.M. 4089). Lvs. 1-2 or almost 3 ft. long, broadly sagittate-ovate, suddenly and shortly acute at apex, basal lobes obtuse: spathe large, with a creamy white tube; spadix bearing club-shaped neutral organs. Bntish Guiana.-X. belophyllum, Hort. Lf.-stalk whitish with dark purple blotches: spathe with green tube, purple inside, the limb white. Costa Rica. —X. maculatum, Nichols. is described as having immense pale green lvs. variegated with creamy yellow, the petiole violet-tinted. —X. Mauffa, Schott (Colocasia Mauffa, Hort.). Closey allied to X. belophyllum, has a similar caudex and a coradate-ovate If... but the posterior costa are separated by a right or acute angle, the angle in X. belophyllum being obtuse.—X. Michelia is said to be a very rapid grower, with green lvs. and dark sts.—X. maculatum, H. Offmanni, Hort. Lf.-stalk whitish with dark purple blotches: spathe with green tube, purple inside, the limb white. Costa Rica. —X. maculatum, Nichols. is described as having immense pale green lvs. variegated with creamy yellow, the petiole violet-tinted. —X. Mi

ROBERT A. YOUNG.

XANTHOXYLUM: Zanthoxylum.

XENIA. When sweet corn is fertilized by pollen from a starchy variety, the grains which result from this union become smooth and hard because packed with starch. In like manner the pollen of a purple-seeded variety like the Bt. Miller produces purple seeds on ears which would otherwise have white or yellow seeds, and pollen from a yellow-seeded variety produces yellow seeds on the ears of a white-seeded variety. Such direct effects of the pollen are known as xenia (Focke, 1881). While the phenomenon is best known in Indian corn, it has been demonstrated recently also in rye (von Rümker), in which a green-seeded variety bears yellow seeds if pollinated by a yellow-seeded variety. In both maize and rye, the xenia character affect only the endosperm (albumen) of the seeds, while characters of the seedcoat show no xenia. The correct interpretation of xenia in maize was given by de Vries (1899) and Cornens (1890), and almost simultaneously by Weber (1900). This explanation is briefly as follows: The pollen-tube contains two male nuclei, one of which fertilizes the egg, while the other units with certain other nuclei of the embryo-sac to form the endosperm-
nucleus from which the whole of the endosperm is developed. The direct effect of the pollen on endosperm characters is due to this participation of one of the male nuclei in the production of the endosperm. A slightly different phenomenon is seen in peas, in which pollen from a yellow-seeded variety produces yellow seeds in the pods of a green-seeded variety, for here the xenia character resides not in the endosperm but in the embryo itself. Physiological effects of pollen in causing local disturbances of nutritive or other functions in tissues surrounding the style or ovary, thus affecting the size and quality of the fruits, are not properly included under xenia. Many reported cases of xenia in plants other than those here mentioned are undoubtedly mythical and will not stand the test of careful experimental investigation. The deterioration of melons supposedly caused by growing in the proximity of pumpkins or cucumbers, is double-less a case of this kind.

Geo. H. Shull.

XERANTHEMUM (Greek, dry flower: it is one of the "everlastings"). Compositae. Annual erect herbs, densely pubescent or tomentose, of which X. annuum is one of the oldest and best known of the "everlastings" or immortelles.

The rays are yellow, but the large involucral scales are petal-like and persistent, giving the plant its value as a subject for dry bouquets: outer fls. few and sterile, inner ones fertile; receptacle chaffy; involucral scales in many series, glabrous; heads solitary on long naked peduncles.—Four or 5 species, Medit. region.

The culture of xeranthemums is very simple. Seeds are usually sown in the open, where the plants are to stand; but they may be started outdoors and the seedlings transplanted. Hardy or half-haIf-annual.

annuum, Linn. Fig. 4016. Annual, 2-3 ft. tall, erect, white-tomentose: lvs. alternate, oblong-lanceolate, acute: heads purple, 1½ in. across, the longer scales wide-spread and ray-like. S. Eu. G. 4: 74, 75.—Runs into many varieties. Var. ligulosum, Voss (X. plenissimum, and X. imperiale, Hort.). A double or half-double form. Var. purpurascens, Voss (X. superbussum, Hort.), has very full double heads. In these and the single types there are white-fld. (var. albus), rose-fld. (var. ramosum), and purple-fld. (var. purpureum) varieties. There are also violet-fld. forms. Var. multiflorum, Hort. (var. compositum) has a more compact and bushy habit, with somewhat smaller heads. X. edrus, Hort., is a trade name for mixed varieties. Xeranthemums are considerably used for a certain type of bedding, but they are mostly grown for cutting.

X. repandum, Mill. (X. erucinum, Presl), has white heads, of which the scales are little or not at all open or spreading. S. Far. to S. W. Asia.

L. H. B.

XEROCRÁDIA (dry branch, from the character of the growth). Loguminosae. One species, X. viridiramosa, Taub. (X. Zygieri, Harv. Actina viridiramosa, Burch.), of S. Afr., likely to be planted in warm dry regions in choice. The variations differ from Acaena paper only (rather than indefinite) stamens, powdery pollen, 3 free petals, and other technical characters. It is described as a small, dry, and very rigid bush 1-2 ft. high, with pale bark, spurious stipules, deciduous bipinnate lvs., and fls. 8-12 in nearly or quite sessile heads: petals oblong; filaments not much exceeding the petals; anthers with a very minute sessile gland; pod or legume seminiferous, indehiscent, 1-seeded, about 3½ in. long, winged.

The turkey’s beard of the eastern states (X. asphodeloides) is a strong herb, 3 to 4 feet high, resembling asphodel. It has a dense tuft of numerous long, wiry leaves from the center of which springs a stately shaft sometimes 5 feet high, with an oval or oblong raceme, 6 inches long, crowded with yellowish white 6-parted flowers, each ½ inch across. It blooms from May to July, flowers with delicate fragrance lasting a long time. The species is a native of the dry pine barrens from southern New Jersey to eastern Tennessee and Georgia. The chief species of the Pacific coast, X. tenax, has white and violet flowers, the latter color supplied by the stamens. Each region should cultivate its own species. The forms are too much alike for the same garden. A third species, X. douglasii, Watson, is a rare plant ranging from Montana to Oregon. It is distinguished by its six-valved capsule and is said to be inferior as a garden plant to the other species.

asphodeloides, Nutt. (Hedhinias asphodeloides, Linn. X. sejófólum, Michx.). Fig. 4017. Tall hardy perennial, 1-4 ft. high: lvs. 1 line or less wide: raceme 3-4 in. long: perianth-segms. exceeding the stamens. Pine barrens, E. U. S. B. M. 748. L.B.C. 4: 394. Gn. 27, p. 224; 39: 526 and p. 527; B. Y. R. 1: 3524. XENIA

There are also violet-fld. forms. Var. multiflorum, Hort. (var. compositum) has a more compact and bushy habit, with somewhat smaller heads. X. edrus, Hort., is a trade name for mixed varieties. Xeranthemums

4016. Xeranthemum annuum. (×50)
**XEROPHYLLUM**

Stems short, with many sheaths, soon thickened into fleshy pseudobulbs, which are 1-2-lvd.: lvs. large or elongated, petiole-vineated, contracted to the petiole: scapes erect, simple, arising from the base of the pseudobulb: fls. racemose, medium-sized or rather large, very shortly pedicellate: bracts linear, usually rather long; petals subequal, erect, finally spreading, lateral broader than the dorsal, forming a chin; petals similar to the dorsal sepal if not smaller; labellum somewhat articulate with the foot of the column, lateral lobes erect, surrounding the column, midlobe short, broad, surface smooth, lamellate or callous at the base; pollinia 4,Avoid: ovum: ovoid: —About 30 species, natives of Trop. Amer.

**XYLOBIUM**

Stems short, with many sheaths, soon thickened into fleshy pseudobulbs, which are 1-2-lvd.: lvs. large or elongated, petiole-vineated, contracted to the petiole: scapes erect, simple, arising from the base of the pseudobulb: fls. racemose, medium-sized or rather large, very shortly pedicellate: bracts linear, usually rather long; petals subequal, erect, finally spreading, lateral broader than the dorsal, forming a chin; petals similar to the dorsal sepal if not smaller; labellum somewhat articulate with the foot of the column, lateral lobes erect, surrounding the column, midlobe short, broad, surface smooth, lamellate or callous at the base; pollinia 4, Avoid: ovum: ovoid: —About 30 species, natives of Trop. Amer.

**XYLOPIA**

Stems short, with many sheaths, soon thickened into fleshy pseudobulbs, which are 1-2-lvd.: lvs. large or elongated, petiole-vineated, contracted to the petiole: scapes erect, simple, arising from the base of the pseudobulb: fls. racemose, medium-sized or rather large, very shortly pedicellate: bracts linear, usually rather long; petals subequal, erect, finally spreading, lateral broader than the dorsal, forming a chin; petals similar to the dorsal sepal if not smaller; labellum somewhat articulate with the foot of the column, lateral lobes erect, surrounding the column, midlobe short, broad, surface smooth, lamellate or callous at the base; pollinia 4, Avoid: ovum: ovoid: —About 30 species, natives of Trop. Amer.
with 3 valvate sepals connate for some distance from the base; outer petals elongate, thick, valvate, and connivent, or scarcely opening, and triquetrous above, inclining the 3 inner linear petals, which are concave at the base; after anthesis the receptacle undergoes a transformation, its center becomes depressed so as to form a cone-like sac, while its margin grows in such a way as to form a dome with an orifice at its apex; through this orifice protrude the styles, while the ovoids occupy the cavity, and the surface of the dome in most species is covered with the crowded stamens, the expanded connectives of which form a sort of tile-like covering to the pollen-sacs; carpels vary in number and the ovoids have a central placenta bearing an indefinite number of ovules primordially arranged in 2 vertical rows: fr. consists of clusters of berries either sessile or shortly stipitate, more or less elongate, often constricted between the seeds, which have a ruminant endosperm, like other members of the Annonaceae, and in many cases there is an aril on both sides of the terminal umbilicus. In the African species, sometimes separated as a distinct genus under the name Habzelia, instead of a central cavity there is only a slight depression in the orifice or even none at all. The genus Pseudannona, treated by Baillon as a section of Xylopia, but given generic rank by the writer (see Journ. Wash. Acad. Sci. 3:16. 1913), both the corolla and the fr. differ radically from those of Xylopia. The aromatic, acute, expanded and shell-shaped peduncles often 2 in. to 3 in., peduncles pilose, very short, bracteolate, solitary, or in 2's or 3's, growing from the axils of the lvs.: calyx connivent, or scarcely opening, and triquetrous above, petals oblong, acute at the apex; petals erect, the outer ones linear, tomentose above; the inner ones shorter and narrower, linear and triquetrous, acute, expanded and shell-like at the concave base, so as to cover the essential linear and triquetrous, acute, expanded and shell-like at the concave base, so as to cover the essential parts; receptacle hollowed in the center, forming a cavity in which the ovoids are included, the styles protruding beyond its opening. A wide geographical range, which has undoubtedly been extended through human agency. It is spread in S. Amer. from Brazil to Panama and also occurs in Cuba, where it is known as Malagueta brava, or "wild melegueta," and Guacima Maria, or St. Mary's guacima."—Varies considerably in the size and pubescence of its lvs. According to Baillon the frs. of this species, together with those of X. frutescens and X. sericea, are often offered for sale in the pharmacies of Brazil. They contain large cells filled with a volatile aromatic oil, having a pepper-like flavor, but more agreeable and delicate than pepper. Martius regards these frs. as worthy of intro. into the pharmacopoeia, on account of their tonic and carminative properties.

2. carminativa, R. E. Fries. (Unana carminath, Aruda da Cañada. X. sericea, St. Hill.). Pao d' Embr. Pindaíba. Pimenta de Macaco. A tree closely allied to X. frutescens, but with grandiflora, but with the petals forming a cone-like sac, while its margin grows in such a way as to form a dome with an orifice at its apex, in comparison with their length, and with the apex more attenuate and the base more acute, but the latter varies and is sometimes rounded; if-blade clothed with appressed silky hairs longer than those of X. grandiflora, and usually smaller, but often longer, but also varies in size: fls. much smaller than those of X. grandiflora, scarcely exceeding 1/4 in. in length, and serving at once to distinguish the two species: frs. either rounded at the tip or pointed, shorter than those of X. grandiflora, and usually contain 2 seeds, but sometimes only 1 or 2, in the latter case they resemble the frs. of X. frutescens, from which, however, they may be distinguished, when dry, by their black color and rough surface. Found from Minas Gerais in Brazil to British Guiana.—The seeds are commonly found in apothecary shops in Brazil, where they are sold as carminatives. According to St. Hilaire the bark is strongy and tenacious and is excellent for cordage, especially for boat-cables. The frs. have the odor and taste of pepper and are used as a condiment, but are not so pungent as pepper. Specimens were purchased at Januaria, state of Minas Gerais by Messrs. Popowecz, Shawel, and Dorsett, of the U. S. Dept. of Agr. during their recent mission to Brazil.

3. frutescens, Aubl. Malagueta hembra. Malagueta chico. Coumnerjav (Carib name). Jerejerecov (Cayenne). Embira. Pindaíba (Brazil). Fig. 4018. A shrub or small tree with dichotomous branches; new branches pilose, red-brown: lvs. oblong-lanceolate, acuminate at the apex, when mature suggesting the frs. of our common Asimina triloba. It is intended here to describe only the species of economic importance.

INDEX

| a. American species (Nos. 1-7) |
| b. Lvs. acut or acuminate |

1. grandiflora, Aubl. (X. cubensis, A. Rich. X. longifolia, A. DC.). Malaguetia macho. Malagueta grande. Zemfira. Fruta do Lum. Achon. Fig. 4018. Tree with younger branches rufous-tomentose near extremities: lvs. approximate, distichous, elliptical-lanceolate or oblong, acute at the apex, usually obtuse at the base, puberulous above, tomentose and rufescent beneath, the blade 2 in. or more in length, the petiole about 1/4 in. long, grooved above, tomentose and rufous: peduncles axillary, very short, 2-fl.; pedicels incurved, bracteate, villous, ferrugineous: fls. oblong, 2 in. long; calyx short, cup-splayed, shortly 3-parted; petals erect, the outer ones linear, acumen, concave at the base, silky near the base, sub-tomentose above; the inner ones shorter and narrower, linear and triquetrous, acute, expanded and shell-like at the concave base, so as to cover the essential

4. muriçata, Linn. (X. jamacaeinsis, Griseb.). Smaller Bitter-wood. Fig. 4018. A shrub with ovate or lanceolate, long-acuminate lvs., with "the slender acumen often obtuse at the tip, clothed beneath with...
XYLOPIA

strigose hairs, and bearded at the tip: fls. small, in axillary clusters; berries punctate.—This species, the type of the genus Xylopi, was described by Linnaeus on a plant growing in the mountains of Jamaica described and figured by Patrick Brown in his Natural History of Jamaica, and called by him Xylopiacum, on account of the bitter taste of its wood. The vernacular name was applied to it to distinguish it from X. glabra, Linn., a species based on Pluknet's Xylopecus, or Lignum anarum, of Barbados, commonly called bitter-wood.

5. discrētā, Safford (Unōna discrētā, Linn. f. Habzēlia discrētā, A. DC.). PETROCOBOLUS. A shrub or small tree with privet-like, or willow-like Ivs. and

available for the name of a second genus. The generic name Desmos is therefore valid, and must be used for the Asiatic plants commonly called Unōna. (See Desmos, Vol. II, p. 991 of this work.)

6. aromatica, Baill. (Habzelia aromatica, A. DC. Unōna zeylanica, Aubl.). MANIGUETTE, BOIS d’ ECOECE. POIVRE DES NEIGRS. A tree with a trunk 20 ft. high or more, with a spreading crown and leafy branches: lvs. ovate or oblong-globose, mucous, puberulent; fls. axillary, solitary or in pairs; calyx-divisions subrotund-ovate, acute, fleshy; petals 6, 3 outer ones longer, ovate-oblong, on the outside villos, numerous, on the inside glabrous, violet-colored, the 3 inner ones smaller, glabrous, violet-colored; berries reddish, numerous (12–25 in a cluster), oblong, suberete, shortly stipitate, with a longitudinal seam down one side; constricted between the seeds; seeds 3–6, orbiculate, reddish.—A species of doubtful relationship, owing to its broad petals and orbiculate seeds. It has been referred to Unōna concolor, Wildl., and may possibly be congeneric with Desmos or Unōnopsis. The type, described by Aublet under the name Unōna zeylanica, was collected in the forest of Timoutoll, French Guiana.

7. obtusifōlia, A. Rich. (Habzelia obtusifōlia, A. DC.). GUIMBA. GUAVICA. GUAVICO DE SAVANA. PICO DE GALLO. Fig. 4018. A shrub or small tree with numerous crooked branches, the extremities of which are ferrugineous-pubescent when young. It differs from all other species here described in its perfectly glabrous Ivs., which are quite obtuse or rounded at the apex and obovate or subobovate in outline, coriaceous, pale green and glossy above and paler beneath, and about 1–1 1/2 in. long; fls. axillary, solitary, very shortly peduncled, suberete by small scale-like bracteoles; calyx-divisions broad, subacute, and ciliate along the margin; outer petals narrowly linear, acutish, dilated and concave at the base, covered on the outside with rufous silky hairs; inner petals shorter and narrower, triquetrous above, expanded and concave: at the base, covering the essential parts; carpels included in the cup-like hollow of the receptacle, numerous, but usually only 2–8 developing into fr.; the latter a cluster of terete follicles more or less constricted between the 2–4 seeds, which have a whitish fleshy aril on each side of the hilum.—This plant is known only from the Island of Cuba, where it is prized for its fine wood. Its local name Pico de gallo (cock’s beak) is suggested by the form of its sharp elongated fl-buds.

AA. Asiatīc species.

8. parvifōlia, Hook.f. & Thom. (Patonia parvifōlia, Wight. Unōna tripetalaidea, Moon). NETAWU. ATUKETIYA. A tall aromatic tree of Ceylon, with a straight trunk, smoothish bark, and silky shoots and young branches: lvs. oval, acuminate, acute at the base, 3–5 in. long, glabrous; petiole 1/2–1 in., finely pubescent: fls. axillary, solitary or in clusters of 2 or 3 on very short peduncles bearing several short imbricated scale-like bracteoles; calyx-divisions small, broad, united half-way up, acute, pubescent; petals hairy, the outer ones linear, strap-shaped, acute, hollowed at the base; the inner a little shorter, thick, trigonous, expanded and hollowed at the base, covering the essential parts; stamens truncl’ed carpels 5, sunk in the center of the receptacle; ovules 4–8 in two rows; fruiting carpels 1–4 on very short thick stalks, broadly ovoid, 1–1 1/2 in. long, containing several smooth brown oblong seeds.—This species is common in the moist low country near Ceylon. Its bark, as that of the root, its yellow fls., and the fr. are all delightfully sweet-scented and aromatic, and are chewed by the natives with their betel. The wood is
XYLOPIA

yellowish gray and soft. Two other Ceylon trees with
fragrant yellow fls. are X. nigricans, with the calyx-
divisions divided almost to the base; and X. Cham-
ploni, with blunt ovoid fl.-buds.

AAA. African species.

glabrous and glossy above, finely appressed pilose
beneath, oblong-elliptic or oblong, obtuse or narrowed
at the base and more or less acuminate at the apex:
fls. solitary or in clusters of several, short-pedicelled;
calyx with the segms. broadly triangular and acute;
petals on the outside fulvo-sericeous, linear, subcon-
cave at the dilated base, the outer ones with thick
margins, the inner ones narrower, trigonous; stamens
with the dilated connective puberulous, outer circle
of stamens sterile, a little broader than the fertile ones;
carpels numerous; ovules 6-8 in a single series; mature
carpels subsessile, slender, cylindrical, somewhat in-
curved, about 2 in. long, slightly constricted between
the seeds, glabrous, vermilion-colored within; seeds
6-8, of medium size, ellipsoid, about 1⁄2 in. long; fr. globose, 1⁄2–3⁄4 in.
Japan, Korea, E. China. S.Z. 188. Var. pubescens, Rehd. & Wilson. Tree, to
80 ft.: branchlets pubescent:
lvs. ovate to oblong-ovate, glabrous, 1⁄4 in. long.
Cent. and W. China. —Only this variety seems to be
in cult. and Wilson pronounces it one of the handsomest
evergreen trees of China; it has proved hardy in S.
England and probably will do well in the southern
states and Calif.

Sälznannii, Eichl. Shrub, to 15 ft., glabrous, the
sts. and older branches armed with stout branched
spines: lvs. chartaceous, ovate to ovate-oblong, obtuse
or obtusely acuminate, cuneate at the base, crenate-
dentate, 3–4 in. long; fr. black, 3-4-seeded. Brazil,
Argentina, Paraguay.

X. Aquifolium, Sprague. Lvs. holly-like or occasionally nearly
entire, having pair of glands at base of blade, 3–4 in. long; racemes
short, axillary, of very small fls.: styles 5–7. Habitat unknown,
probably Polynesia or Austral.

XYLOSMA

(Greek, xylos, wood, and osme, odor; alluding to the aromatic wood of some species). Syns.,
Myroxylon, Hisingera. About 45 species

of evergreen, often spiny, trees or shrubs distributed
throughout the tropical and subtropical regions of both
hemispheres except Afr. Lvs. alternate, short-petioled,
usually dentate, extipulate: fls. small, in axillary ra-
cemes, usually daisy-like, apetalous; sepals 4–5, slightly
connate at the base; stamens many, distinct, surrounded
by a disk; ovary superior, surrounded by a disk and
sometimes by staminodes, 1-celled with several ovules;
styles 2–3, usually connate. Little known in cult.;
prop. by seeds and probably by cuttings of half-
ripened wood under glass.

racemosa, Miq. (Hisingera racemosa, Sieb. & Zucc. Myroxylon racemosum, Kuntze). TENG-CHING TREE. Small tree or shrub, unarmed or spiny, glabrous:
fls. ovate, acuminate, rounded at the base, serrate, 11⁄2–2
in. long; fls. yellow, fragrant, scarcely 1⁄4 in. across, in
axillary racemes 1⁄2–1 in. long; fr. globose, 1⁄2–1⁄2 in.
Japan, Korea, E. China. S.Z. 188. Var. pubescens, Rehd. & Wilson. Tree, to 80 ft.: branchlets pubescent:
lvs. ovate to oblong-ovate, glabrous, 11⁄4–3 in. long.
Cent. and W. China.—Only this variety seems to be
in cult. and Wilson pronounces it one of the handsomest
evergreen trees of China; it has proved hardy in S.
England and probably will do well in the southern
states and Calif.

ALFRED REHDER
YAM. The name yam properly belongs to the members of the genus Dioscorea, although unfortunately it has been applied for many years in the United States to the large varieties of the sweet potato, *Ipomoea Batatas*. The name as applied to the sweet potato is thought by some to be a corruption of an African word pronounced "nyam," brought by the negroes who were transported to America in the early days. This word was used for the true yam or other large roots or tubers used for food in Africa and was bestowed by the negroes on the large sweet potatoes in America.

The botany of the cultivated yams has not been cleared up. Many varieties are of mediocre quality, while some are excellent, being superior in flavor and mealliness to almost any other starchy vegetable. Single roots or tubers of some varieties, particularly of *D. alata*, attain great size, occasionally even reaching 100 pounds or more in weight, and several feet in length. The best varieties, however, are of small size, often less than a pound in weight. Among the best known of these are the yampis of Jamaica and the Isthmus of Panama, and other varieties of small quality, such as the cush-cush of the Island of Trinidad. The Chinese yam or cinnamon vine, *D. Batatas*, is of excellent flavor, but on account of its deep-growing habit is very difficult to dig. Several kinds of yam are grown scattering in Florida. For further discussion, see *Dioscorea*.

ROBERT A. YOUNG.

YARROW: *Achillea*.

YELLOW-WOOD: *Cladrastis*.

YEW: *Taxus*.

YÚCCA (*Yuca*, native name for the manihot or cassava, erroneously applied to the present plants by Gerarde). *Liliaceae*, tribe *Yuccoae*. Bold stiff-leaved plants suitable for lawn planting, subtropical massing, and a few of them for flower-garden use. Acaulescent to arborescent endogens with fibrous evergreen sword-shaped lvs. usually pungent and often dentilicate or fibrous on the margin; fs. white or shaded with cream or violet, cup- or saucer-shaped, usually pendent in large usually erect panicles, opening at night and then somewhat sickishy fragrant; pollination rarely occurs except through the aid of a small white moth, *Pronuba yuccasella*, found wherever yuccas occur wild on the continent, which deliberately gathers the pollen and thrusts it into the stigmatic chamber, its larvæ feeding exclusively on the maturing seeds of these plants: fr. either capsular and erect or fleshy and hanging in the principal groups or subdivisions.—About 30 species, confined to N. Amer. and the W. Indies, most of them native to the arid S. W. U. S. and the Mexican tableland. A few species have been cult. for centuries, and within the last decade a large number of artificial hybrids have been produced and intro. into cult., especially along the Medit. There are recent monographs by the writer in Rep. Mo. Cot. Gard., Vol. 13, pp. 42-116, with illustrations, and by Molon in a small manual "Le Yucche," Milano, 1914, in which many of the Sprenger hybrids are also figured. See *Hesperocereus*, Samuela.

Propagation is by seeds, offsets, stem-cuttings or rhizome-cuttings. These should be planted in well-drained sandy loam, usually in the succulent house. The only species hardy where frost is severe are *Y. glauca*, *Y. filamentosa*, *Y. flaccida*, *Y. baccata*, *Y. recurvifolia*, and *Y. gloriosa*, which flower in the sequence given, the last-named often blooming late in autumn. *Y. Treculeana* shows considerable resistance to frost. The tender species are kept in the cactus house. Well-drained sandy loam suits yuccas best, but with good drainage they are tolerant of a large range of soil and exposure. *Y. Treculeana* blooms usually in March in plant-houses, as when wild, and the Mexican species when brought to flower are usually spring bloomers but they often refuse to flower for long periods and then suddenly and unexpectedly produce an abundance of simultaneous bloom, even on the smaller plants. Of the hardy species, *Y. glauca* flowers in June and it is quickly followed by *Y. filamentosa* and *Y. flaccida*, while the forms of *Y. gloriosa*, which usually flower only at intervals of several years, bloom from late August to so late in the autumn as to be cut down by frost. The only well-known yucca in northern gardens...
YUCCA

is the common Adam's needle, *Y. flaccida*. This persists for years, sending up a tall panicle of cream-white flowers in late spring or early summer. All yuccas are suited to bold and formal effects in gardening; as tub specimens they may be used effectively in subtropical bedding or massing. Most yuccas may be fertilized if fresh pollen is transferred directly from the anther to the stigmatic cavity of a newly opened flower, preferably one seated directly on the main shaft, where nutrition is more certain. *Y. aloifolia* commonly fruits freely, but the others rarely fruit spontaneously in cultivation except *Y. filamentosa* and *Y. flaccida*, which are pollinated by the small white moth (*Prom thuộc yucca-sella*) that accompanies them when it emerges in the western states, but rarely when they are cultivated in the eastern states. This "Joshua tree" is now known in the more flaccid recurved lvs. var. concava, Baker (Y. concava, Haw.). See Rep. Mo. Bot. Gard. 13:10, 83.

The great yuccas, or "yucca palms," of southern California are chiefly *Y. arborescens*. They grow in the higher lands bordering the Mojave and adjacent deserts, reaching a height of 15 to 20 feet. The old plants are exceedingly weird and picturesque. Occasionally this species is transferred to gardens, but it is apparently not in the trade. This "Joshua tree" is now known in the more flaccid recurved lvs. var. concava, Baker (Y. concava, Haw.). See Rep. Mo. Bot. Gard. 13:10, 83.

WILLIAM TRELEASE.
Three of the species are known as night balsams or star balsams, from their night-blooming habit. The name night-blooming phlox would be better, as the flowers are silver-shaped and five-lobed, each lobe being deeply cut. These plants are generally treated as half-hardy annuals, the seed being sown indoors in early spring. The plants bloom in about ten weeks after being set out and continue in flower through July and August. Some cultivators declare that this method is very unsatisfactory and urgent that the seed be sown in the autumn and the young plants wintered in a coldframe. They will then begin to flower by June. The blossoms are closed by day and are fragrant by night.

A. **Corolla-tube slightly pubescent.**

b. **Duration perennial; bracts oblong-lanceolate; lvs. linear or the lower ones lanceolate.**

**lychnidea**, Walp. (**Nycterinia lychnidea**, D. Don. **Erinus lychnidea**, Linn. **E. gracilis**, Lehm., not Hort.). Subshrub, about 2 ft. high; lvs. oblong-linear, sessile, entire or few-toothed; corolla-tube 1-1 1/2 in. long, limb 1/2-3/4 in. across, white inside, purplish or red outside. B.M. 2504; 8215 (the latter as **Z. martitima**). B.R. 748. G.C. III. 42:162 (as **Z. martitima**).—Usually acts much like an annual and is generally treated as such when cult.

bb. **Duration annual; bracts oblong-lanceolate; lvs. linear or the lower ones lanceolate.**

**capensis**, Walp. (**Nycterinia capensis**, Benth.). Differers from the above, as described by Bentham, in stature, duration, strict sts. and smaller lvs.; same picture as Gn. 24, p. 89) the lvs. are commonly short and 4-8-fld., sometimes long and 15-20-fld. There is some evidence that this species and the next are confused in the trade. In R.H. 1851:221 the fls. are 3/4-1 in. long and less than 1/2 in. across.

AA. **Corolla-tube glabrous.**

**selaginoides**, Walp. (**Nycterinia selaginoides**, Benth.). Dwarf annual, branched at the base, 3-5 in. high, rarely 6 in., with spatulate lvs. and fls. 3-1/2 in. long, color of fls. not stated by Bentham, but in R.H. 1896, p. 308 (same picture as Gn. 24, p. 89) the fls. are said to range from white to lilac and darker depending on their stage of development, with an orange-colored eye, which becomes crimson later. This suggests the preceding species, and it is evident that the two must be distinguished by technical characters until the colors can be verified. G.C. III. 45:173.—The plant once advertised in America as **Nycterinia selaginoides** is said to be a pink-flit. half-hardy perennial, growing 9 in. high, which does not agree with authentic descriptions. A species passing under this name is hardy at San Francisco.

WILHELM MILLER

F. TRACY HUBBARD.
ZAMIA (name used by Pliny, meaning L. 7.

dies or dam.

cate, and first applied to pine cones, and trans

defined to these plants apparently because of the cone-like fruit). Cycadaceae. Perennial, tropical and subtropical plants, resembling palms and in some respects ferns.

Caudex sometimes a low trunk, simply lobed or branched, standing above or almost below ground; lvs. few, developing one after the other, pinnately compound; pinnae broad or narrow, articulate at base, entire or serrate, parallel-veined; petiole smooth or spinulose: cones rather small for the order, globose or rarely sub-lobate, male cone oblong-cylindrical, female cone similar but larger and thicker: ovules sessile, ovoid.—About 36 species, Trop. and Subtrop. Amer. One of the 9 genera of the C y c a n e family, as constituted by Alphonse De Candolle (Prodr. 16, pt. 2, pp. 522–47). Other genera of horticultural interest and discussed in this Cyclopedia are Ceratozamia, Cycas, D i o o n, E n c e p h a l a r t o s, and Macrozamia. The lvs. of cycads are d i e c e cious, without envelopes; the pistillate fls. are mere naked ovules inserted under scales in cones, and the staminate fls. are simple anthers under similar scales. The plants are therefore gymnosperms (seeds not horned) and form a cylindrical cone; the anthers are numerous, and the ovules pendulous in pairs. The fecundation of Zamia has been studied by H. J. Webber (Bull. No. 2, Bur. Pl. Ind., U. S. Dept. Agric.). His conclusions respecting the Floridian species are accepted below.

The zamias are stocky short- and usually simple-stemmed cycas-like plants, the trunk sometimes subterranean, with long-pointing evergreen leaves or fronds; the leaflets being thickened and usually broadened at the base, and jointed. Zamias are warmhouse plants, to be treated like species of Cycas or E n c e p h a l a r t o s, which see. The plants are propagated by means of seeds and offsets; also by division when there is more than one crown.

a. Petiole prickly.

furfuracea, Ait. Trunk cylindrical, 1–2 ft. tall; peti

olate dilated and concave at the base, with several small prickles; lfts. about 10–12 pairs, opposite or alternate, oblong-lanceolate, entire on the lower half but serrate or jagged toward the top, acute or obtuse, nearly so, and narrowly linear, the base not narrowed, 6–8-nerved: pistillate cone oblong, 5–6 in. (12–16 cm.) long, marked by umbonate (projection on the scales), densely tomentose.—Abundant in S. Fla. on the coast below latitude 26° 30′, in open comparatively dry pine woods, sparingly.

pumila, Linn. Differs, according to Webber, in having shorter and broader lfts. which are less twisted and not so erect and rigid and in its shorter and non-umbonate cones with seed-bearing scales thinner and more flattened at outer end.—Abundant in Cent. Fla., ranging from 28° 30′ north for 1° of latitude, in dense moist woods.

Z. cordifolia, Versch., is Macrozamia spiralis.—Z. Désenoi, Auth., in Macrozamia P a r a f l o r a;—Z. pumila, Hort.—Cycas Rumphii (?).—Z. pumila, Ait.—E n c e p h a l a r t o s pumila.—Z. spinosa, Lod. = E n c e p h a l a r t o s A l t e n a s t e n i .

L. H. B.

ZAMIOCULCAS (Zamia and C ulcas). A r a c e a e. One species, sometimes grown in the warmhouse for ornament and curiosity, it being one of the very few aroids with pinnate lvs. Z. zamiifolia, Engler (Z. Loddigesi, Schott. C d u l t u r a zamiifolia, Lodl.), grows in Trop. Afr. It is an evergreen perennial herb, with stout creeping rootstock, and erect glabrous radical lvs. standing 1½–2 ft. high; lfts. about 12, opposite or alternate, oblong-lanceolate, acute, jointed to the petiole and forming small tubers at the base after falling; s a t h e convolute at base with spreading or reflexed blade, green, glabrous; spadix club-shaped, with female fls. below and male fls. on the longer upward part, whiteish, about 1½ in. long and ½ in. thick. B.M. 5985. L.B.C. 15:1408. Prop. by the If.-tubers and by division.

ZAMIOCULCAS 3533

4025. Stamin ate cone of Zamia floridana.

4026. Pistillate cone of Zamia floridana.

4027. Aggregate fruit of Zamia floridana. Cone not mature.
ZANNICHELLIA (named in honor of G. G. Zannichelli, a Venetian botanist). *Naidaeeae.* Horned Pondweed. Slender branching herbs, growing under water, of little horticultural value for ponds: lvs. mostly opposite, long and linear, thread-like, entire; stipules membranaceous, sheathing; fls. monocious, sessile, naked, usually both kinds from the same axil. About 5 species, scattered throughout the world. *Z. palustris*, Linn. Style at least half as long as the fr., which is flatish, somewhat incurved, or occasionally more or less toothed on the back (not wing-margined), nearly sessile. Cosmopolitan in fresh or brackish water.

ZANÒNIA (Jacob Zanoni, 1615–1682, botanist of Bologna). *Cucurbitaceae.* Under this genus, one species, *Z. sarcophylla*, Wall., is sometimes listed among cult. plants. This plant is now placed in the genus *Alismatix* and becomes *A. sarcophylla*, Hook. f. It is native of Burma: climbing shrub with very flaky 3-foliate lvs.; lfts. oblong, entire; fls. small, white, axillary, in compound panicles; corolla rotate, 5-parted, with obtuse segs.; calyx rotate and 5-parted, with acute segs.; male fls. with 5 stamens; females with a 1-celled elongate 3-4-styled ovary: fr. a medium-sized 3-valved caps.; seeds black, narrowed at base, with 2 flat curved horns at apex.

ZANTEDESCHIA (Francesco Zantedeschia, who wrote on Italian plants in 1825). Syn., *Richardia.* Calla of horticulturists. Perennial herbs grown for their ornamental corolla-like spathes and sometimes for spotted foliage; greenhouse subjects in the northern regions, but grown permanently in the open in California and other warm parts. The genus comprises the "calla lily." Herbsaceous plants with many long-peduncled lvs., all from a thick rhizome; peduncles appearing with the lvs.; pedicels spongy, often bristly below; blade sagittate, hastate, or lanceolate to cordate-ovate, the numerous primary and secondary nerves excurrent: peduncle as long or longer than the lvs.; spathe large, open, with a flaring, pointed, recurved tip; spadix staminate above, and pistillate below (Fig. 4029): fls. many and small, naked, crowded, staminodes sometimes mixed with the ovaries: fr. a 1–3-celled berry.—Engler assigns 8 species in his latest monograph (Das Pflanzreich, hft. 64, 1918), in Trop. and S. Afr. The common calla-lily is long known in commerce as *Calla athiopica*. Later it was known as *Richardia africana*, it having been found that the genus Calla, as more closely defined, could not include it. The *Richardia* of Kunth, 1819, under which the plant has been named, is antedated by another *Richardia*, and *Zantedeschia*, 1826, is considered by latest authorities to be the tenable name and is retained in the "nomina conservanda" of the International Rules as against both *Richardia* and *Aroides*. The genus *Calla*, as understood by modern botanists, comprises a single species, *C. palustris*, native in swamps in the northern hemisphere, including N. E. U. S. and Canada; see Fig. 742, Vol. II. For the black calla, see *Arum*.

When grown for the flowers only, *zantedeschias* may be planted out permanently on a bench, using very rich soil and giving an abundance of water while growing. They may be kept growing continually or given a season of rest, as desired. Plants in pots are usually started late in summer from dry tubers. The species having yellow or pink spathes seem to do best when grown without a resting-period.

**Culture of callas.** (T. D. Hatfield.)

The so-called calla of gardens (*Zantedeschia athiopica*) has been a favorite for generation. Although often grown as a window-plant, it is very unsuitable and seldom blooms under house treatment. When grown for winter flowers, it is customary to give the roots a rest during summer-time. They may be dried and stored if necessary. It is in this condition that Californian callas are received. It is the opinion of the writer that summer-resting would be the best treatment for those grown as house-plants, as well-grown dried roots are more likely to bloom. But rest must be enforced, for callas will grow all the year round, increasing in size and numbers when planted out. The largest blooms are always secured from summer-grown plants. They are taken up in the autumn, given good loam and plenty of root-room, with a liberal allowance of liquid fertilizer when well established. They thrive best under good light, and in a minimum temperature of 55°.

Some are said to be more odoriferous than others, although all are fragrant. Besides being invaluable pot-plants, they can be used with good effect in indoor water-gardens, growing luxuriously when partly submerged; and also in bog-gardens, and on the margins of ponds, to give sub-tropical effects. Although introduced to cultivation but twenty-five years ago, *Z. Elliottiana* is yet of secondary importance. Although an acquisition. It is a South African species, about which comparatively little is known in the wild. (N. E. Brown writes in "Flora of Tropical Africa," Vol. 8, 1902: "This species is stated to have been raised from seeds received from South Africa, but I have reason to believe that its habitat is somewhere in the northern part of the Transvaal." The plant was described as *Richardia Elliottiana* in Garden and Forest, New York, 1892.) When introduced, it was thought difficult to grow. It was first grown in this country by William Robinson, gardener to F. L. Ames, North Easton, Massachusetts, Mr. Harris, gardener to H. H. Hunnewell, Wellesley, Massachusetts, and Joseph Tailby, of Wellesley. The last named is a commercial grower, who looked on his importation as an investment. The bulbs (corms or roots) were expensive—a guinea or thereabouts—and about as big as marbles. Tailby's experience is interesting and it may be of interest to the reader. He came near losing his whole stock by cutting out the eyes, with the object of getting separate plants. There had been no sign of natural division, nor has there since; although some are still of the opinion that by proper manipulation they may be increased by division, as we now do potatoes, but the wounds must be given time to heal over. The roots are kept over in a cellar at a temperature of 45° F., or thereabouts, until
April, when they will show signs of starting. They should be potted then, but kept rather dry until the roots develop. The pots will be fairly well filled with roots before much growth shows, and they can be kept under benches in a coolhouse, or even in the cellar, for two weeks after potting. With the roots well started, they come along quickly, coming into bloom in ten to twelve weeks. A good bright intermediate house suits them best, and some liquid fertilizer will help them when the flower-stems appear. The blooms last a long time, opening greenish yellow, turning to pure orange-yellow, and finally green when aging. Seeds are formed plentifully; and by these, though slow, is yet the surest and quickest method of propagation. During the ripening period of seeds, they must have the very best attention. They usually do not become thoroughly ripened until August. Pot-grown plants are better stored in pots. The whole culture is easy when it is known.

Seeds of Z. Elliotiana sown in November usually come up strong, but the plantlets are difficult to handle and liable to go off when very young. It is the safest way to let them stay in the seed-boxes, ripen there, and plant them farther apart next season. Seeds have been sown outdoors with very gratifying results. Almost a year is gained in this way, as the roots (or bulbs) are considerably larger than box-grown seedlings. Older roots held over until settled weather and planted like potatoes bloomed freely all summer, making fine roots; they were green when cut by frost in October, but ripened seeds. To do this successfully takes a longer season, and the plants must be started indoors.

The calla in California. (Ernest Braunton.)

In considering the calla in California, it is necessary to note two general heads first, as an ornamental; and second, as an article of commerce. The popular and growing demand for calla bulbs (or tubers) speaks much for the plant as an ornamental. Many, indeed, are the uses to which it is put. It is, perhaps, most commonly used as a belt along fences, and not infrequently as a hedge between two properties; or nearly as often is found along one side of a house in a long narrow bed. For effective planting it is much in demand for grouping around hydras and unsightly objects in damp places, at watersides; sometimes as a border around a fish- or lily-pond, oftentimes growing in bunches or masses in the water itself; or massed on a slope near water; mixed with other tropical vegetation; or as a border to tropical jungles; and very effective, indeed, in the lower tiers of basins around a large fountain with myriophyllum hanging down from the base of the callas. For all of these purposes the foliage is of even more importance than the flowers. As it grows luxuriantly here in almost any location, it is very seldom seen as a pot-plant either in the dwelling or on sale at the nurseries. In the most favored places only is it entirely secure from the frost, although the damage to it from this source is not serious in or around Los Angeles. Although dozing fairly well in the full sun, summer climate is too dry for it to attain its greatest beauty and luxuriance wholly without protection, and it may therefore be seen in perfection only when grown in partial shade. A good supply of water and manure is taken as an important factor in its proper development.

The spathe is subject to many variations in form, both in size and shape, some being long, rather narrow and pointed, ending in a decidedly recurved awn, while others are nearly circular, with the sharp point almost wanting and standing upright the same as the remainder of the spathe. It frequently happens that the spathe is double and even triple, sometimes in its entirety but often only partially so. In the latter case it often assumes some very strange forms. The spadix is not so variable and seldom departs from the type, although an occasional double or abnormal spadix is found. Most other species or varieties than Z. ethiopica are found but sparingly in California gardens, the most common ones being the spotted-leaved and the dwarf form known as the Little Gem, but Z. Elliotiana is grown extensively in certain areas, especially about Santa Cruz, which is the center of the bulb-growing industry in California.

Commercially, the growing of the bulbs for eastern and foreign markets is a sure source of revenue, and is conducted extensively throughout southern California. The local market for the so-called flowers is of course neglected, but if grown in a practically frostless belt, the blooms will more than pay for the cultivation of the winter field, as in that season of the year flowers of all kinds are scarce. The average retail price for good blooms in midwinter is 50 cents a dozen; the wholesale price about $1 a 100. Bulbs at retail cost about one-half, or even less, what they do in the East. The commercial growers get at present (January, 1916), $25 to $60 a 1,000, according to size, the market calling for tubers 1½ to 3 inches in diameter. Larger sizes are quoted as “fas” and command extra prices. Although they can be grown in almost any soil with some success, a free cool blackish loam is best, and they do not thrive in a hot gravelly or stony soil. The lands near the coast, where swept by the cooling sea-breeze, are productive of the best results, both in bloom and flavor. Land containing sufficient alkali to prevent the growth of many common crops will produce good callas if other requirements are present. In field-planting it is much better to put in small bulbs about 4 inches apart than to sow the offsets promiscuously in the row; when the sets are thus sown, they should be taken up the following year and the small bulbs properly planted. Offsets sown as above and left four to six years (the usual time for a good crop) have never produced satisfactory results. No pest seriously attacks foliage or bloom, but in dry years more especially, the common sow-bug eats into the tubers very seriously and at times quite destructively. Both of these pests are a considerable nuisance to the California nurseryman and gardener.

INDEX.

4031. Zantedeschia rethiopica var. DEN CALLA. Lvs. about 6 in. long: berries about 3/4 in. diam., nearly subulate margined, about as large as those of Z. albo-maculata: spathe yellow, the tip erect, black-purple at the base. B.M. 7436.

4. melanoléca, Engler (Richardia melanoléca, Hook. f. R. Spréngeri, Comes). BLACK-TROTHED CALLA. Scape and petioles briefly below: lvs. 6-12 in. long, hastate-ovate-acute, the basal lobes obtuse, marked all over with oblong, white, translucent spots: spathe pale straw-colored, widely flowering and open from the base, the margins and cuspidate tip recurving, with an ample black-purple blotch at the base within. Natal, 1868. B. M. 5762. Var. tropicalis, Engler (Richardia melanoléca var. tropicalis, N. E. Br.), of Trop. Afr., differs in larger size and absence of bristles at base of petiole.

5. Elliottiana, Engler (Calla Elliottiana, Knight. Richardia Elliottiana, W. Wats.). GOLDEN CALLA. Lvs. glabrous; petiole 2 ft. or more long, lacking bristles; blade hastate, narrow, the basal lobes one-fourth the length of the apical one 20 in. long, 3 in. wide at the base; peduncle 4-1/4 ft. long; spathe about 3 in. long, yellow, red inside at the base. Angola.-R. Elliottiana: spathe cup-shaped, 4-5 in. long (with a tail 1 in. long), purple at the base, the margins and cuspidate tip recurving, with a black-purple blotch at the base within. Basutoland, S. Afr. B.M. 7397. Hooker writes (in B.M. 1857) that "R. Elliottiana is much the largest-leaved species, and is the only one with a deeply gamboge yellow spathe within, which is much the largest and broadest of any." First flowered in 1892 by R. Whyte, Pentland House (Lee, England).

4. melanoléca, Engler (Richardia melanoléca, Hook. f. R. Spréngeri, Comes). BLACK-TROTHED CALLA. Scape and petioles briefly below: lvs. 6-12 in. long, hastate-ovate-acute, the basal lobes obtuse, marked all over with oblong, white, translucent spots: spathe pale straw-colored, widely flowering and open from the base, the margins and cuspidate tip recurving, with an ample black-purple blotch at the base within. Natal, 1868. B. M. 5762. Var. tropicalis, Engler (Richardia melanoléca var. tropicalis, N. E. Br.), of Trop. Afr., differs in larger size and absence of bristles at base of petiole.

5. Elliottiana, Engler (Calla Elliottiana, Knight. Richardia Elliottiana, W. Wats.). GOLDEN CALLA. Lvs. glabrous; petiole 2 ft. or more long, lacking bristles; blade hastate, narrow, the basal lobes one-fourth the length of the apical one 20 in. long, 3 in. wide at the base; peduncle 4-1/4 ft. long; spathe about 3 in. long, yellow, red inside at the base. Angola.-R. Elliottiana: spathe cup-shaped, 4-5 in. long (with a tail 1 in. long), purple at the base, the margins and cuspidate tip recurving, with a black-purple blotch at the base within. Basutoland, S. Afr. B.M. 7397. Hooker writes (in B.M. 1857) that "R. Elliottiana is much the largest-leaved species, and is the only one with a deeply gamboge yellow spathe within, which is much the largest and broadest of any." First flowered in 1892 by R. Whyte, Pentland House (Lee, England).
**ZANTHORHIZA**

*Zanthorrhiza* (Greek, yellow root). Often spelled *Xanthorrhiza*. Shrubby plants cultivated mostly for their handsome foliage, which is much like that of *Actea*, and which changes to a beautiful golden color in the autumn.

Leaves pinnate or bipinnate: fls. in drooping racemes or panicles; sepals 5, petal-like, deciduous; petals 5, smaller than the sepals, and 2-lobed; stamens 3-10; carpels 20, sessile, forming only 1-seeded follicles, 1 ovule of each usually not maturing.—One species, *Z. americanum*, Mill. *Z. fraxinum*, Michx.). *PRICKLY ASH*. Fig. 4033. Shrub or small tree, to 20 ft.; lvs. 3-7 in. long, glabrous; lfts. 13-21, elliptic-lanceolate to lanceolate, narrowed into a short stalk, minutely emarginate at the apex, crenate-erucent, ½-1½ in. long; fls. minute, with sepals and petals in terminal, short-stalked clusters, 2-4 in. across; fr. greenish or brownish. June; fr. in autumn. Japan, Korea. *S.I.F. 2:33.*—Sometimes cult. under the name of the following; handsomer in foliage and harder.

**ZANTHORHIZA** 3537

**ZANTHORHIZA** (Greek, *zanthos*, yellow, and *xylos*, wood). Also spelled *Zanthoxylum*. Including *Pagara. Rudceae.* Ornamental woody plants chiefly planted for their handsome foliage and for their ornamental fruits.

Deciduous or evergreen shrubs, sometimes sarmen­tose, or trees, with usually prickly branches; most parts, particularly the frs., emitting a strong aromatic odor when bruised: lvs. alternate, odd-pinnate, 3-foliolate or rarely simple; fls. dioecious or polygamous, small, in cymes or panicled; sepals, petals, and stamens 3-8; sepals often wanting; pistils 3-5; fr. composed of 1-5 separate small dehiscent caps, each with 1-2 shining black seeds.—The genus contains about 150 species in the tropical and subtropical regions of both hemispheres, and a few in temperate regions. Several species are used medicinally. The wood of some W. Indian species and that of the Australian *Z. brahyanthinum* is considered valuable. The frs. of *Z. pipertum* are used like pepper in Japan.

The zanthoxylums in cultivation are prickly shrubs or rarely small trees with mostly deciduous odd-pinna­te, medium-sized or rather small foliage and small greenish or whitish flowers in small, rarely large, axillary or terminal clusters, followed by usually reddish small pods disclosing lustrous black seeds at maturity. *Z. americanum* is the only species which is hardly North, while the species from eastern Asia, as *Z. schinifolium*, *Z. Bungei*, and *Z. alatum var. planispinum*, have proved fairly hardy in favorable positions as far north as Massachusetts, the first being the hardiest, but they probably will be perfectly hardy in the Middle Atlantic states. They do not seem to be particular as to the soil, but grow best in a well-drained soil and sunny position. Propagation is by seeds and by suckers or root-cuttings.

a. Rachi not or very narrowly winged.

b. Fls. before the lvs., in axillary fascicles.

c. Prickles solitary.

d. Schinifolium, Sieb. & Zucc. Shrub or small tree, to 20 ft.; lvs. 3-7 in. long, glabrous; lfts. 13-21, elliptic-lanceolate to lanceolate, narrowed into a short stalk, minutely emarginate at the apex, crenate-erucent, ½-1½ in. long; fls. minute, with sepals and petals in terminal, short-stalked clusters, 2-4 in. across; fr. greenish or brownish. June; fr. in autumn. Japan, Korea. *S.I.F. 2:33.*—Sometimes cult. under the name of the following; handsomer in foliage and harder.

c. Prickles in pairs.

**pipertum**, DC. Shrub or small tree; prickles rather slender, ascending: lvs. 2-6 in. long, with puberulous rachis; lfts. 11-19, ovate to oblong-ovate, narrowed into a short stalk, emarginate at the apex, remotely toothed, with conspicuous glands at the base of each tooth, midrib pubescent above, ½-1½ in. long; fr. with simple perianth, in small corymbs ½-1½ in. across, on short lateral branchlets; style slender; fr. reddish, glandular-dotted. Japan, Korea, N. China. June; fr. in Sept. *S.I.F. 1:32.*—The wood, according to Issa Tanimura, is dense and heavy with deep yellow grain; tree common cult. in Japan for ornaments, to make utensils, and for food; the seeds and inner bark are cooked or pickled; the fresh lvs. are added to soup; and the dried fr. used on roasted fish as a fragrant pepper.

**Büngel**, Planch. (*Z. Bungeanum*, Maxim.). Spreading shrub or small tree; prickles stout, flattened, very broad
ZAUSCHNERIA (named for a professor of natural history at Prague). *Onagraceae.* Low perennials, some of them subshrubby, few of them used in the flower garden.

Leaves, the lowest opposite, others alternate: fls. racemose, large, scarlet, fuchsia-like; calyx-tube globose, inflated just above the ovary, then becoming funnel-form, 4-lobed, bearing 8 small scales within; petals 4, obovate, or deeply cleft; stamens 8: caps. slender-uniflorous, obtusely 4-angled, 4-valved, many-seeded.—About 7 species, W. N. Amer.

**californica**, Presl. **CALIFORNIA FUCHSIA. HUMMINGBIRD’S TRUMPET. BALSAAM.** Half-hardy perennial with the fl. of a fuchsia and the fr. of an epilobium: height 3½-2 ft.; lvs. linear to oblong, ½-1½ in. long, pubescent or tomentose; fls. scarlet or vermilion, the trumpet-shaped calyx ½ in. long; calyx-lobes ovate; petals obovate, spreading; fr. 4-valved, imperfectly 4-loculed. Calif. P.M. 15:195. F. 1847-8:241. Gn. 31: 28 and p. 29. R.H. 1849:141. Var. splendens, Hort., is perhaps a little more luxuriant plant, otherwise not differing from the type. Var. inflata, Hook. Often nearly glabrous; lvs. broad-ovate to ovate-lanceolate, markedly feather-veined. B.M. 4493. F.S. 4:404.—Varieties have been made based on linear, lanceolate, or ovate lvs., but they run into one another. The plants also vary from glabrous and pubescent to tomentose. As a bedding-plant it has been occasionally used for novelty effects by European gardeners. To overcome its thin and leggy habit, it is well to set the plants rather close and pinch out the young shoots until compact bushes are secured. The plant is sometimes grown in pots for greenhouse decoration in late autumn. There are said to be forms that vary considerably in hardness. The plant is hardy in most parts of England.

**ZAUSCHNERIA** (named for a professor of natural history at Prague). *Onagraceae.* Low perennials, some of them subshrubby, few of them used in the flower garden.

Leaves, the lowest opposite, others alternate: fls. racemose, large, scarlet, fuchsia-like; calyx-tube globose, inflated just above the ovary, then becoming funnel-form, 4-lobed, bearing 8 small scales within; petals 4, obovate, or deeply cleft; stamens 8: caps. slender-uniflorous, obtusely 4-angled, 4-valved, many-seeded.—About 7 species, W. N. Amer.

**californica**, Presl. **CALIFORNIA FUCHSIA. HUMMINGBIRD’S TRUMPET. BALSAAM.** Half-hardy perennial with the fl. of a fuchsia and the fr. of an epilobium: height 3½-2 ft.; lvs. linear to oblong, ½-1½ in. long, pubescent or tomentose; fls. scarlet or vermilion, the trumpet-shaped calyx ½ in. long; calyx-lobes ovate; petals obovate, spreading; fr. 4-valved, imperfectly 4-loculed. Calif. P.M. 15:195. F. 1847-8:241. Gn. 31: 28 and p. 29. R.H. 1849:141. Var. splendens, Hort., is perhaps a little more luxuriant plant, otherwise not differing from the type. Var. inflata, Hook. Often nearly glabrous; lvs. broad-ovate to ovate-lanceolate, markedly feather-veined. B.M. 4493. F.S. 4:404.—Varieties have been made based on linear, lanceolate, or ovate lvs., but they run into one another. The plants also vary from glabrous and pubescent to tomentose. As a bedding-plant it has been occasionally used for novelty effects by European gardeners. To overcome its thin and leggy habit, it is well to set the plants rather close and pinch out the young shoots until compact bushes are secured. The plant is sometimes grown in pots for greenhouse decoration in late autumn. There are said to be forms that vary considerably in hardness. The plant is hardy in most parts of England.
ZeA (an old Greek name for some common cereal, probably spelt). Gramineae. *A large annual grass with monocous inflo, the staminate fls. in the tassel at the top and the pistillate fls. in one or more ears in the axils of the lvs., each ear inclosed in several reduced lvs. or husks, the numerous styles protruding from the tip as the silk. As now limited the genus is founded on the single polymorphous cult. species, *Zea Mays*, maize or Indian corn (Figs. 4034, 4035, 4036), whose origin is unknown but is suspected by some to be teosinte (*Buch­lena mexicana*). Most of the evidence points to Mex., as the region in which it originated and from which it spread.

After a prolonged study of maize, teosinte, and hybrids between them, Collins advances the hypothesis (Journ. Wash. Acad. Sci. 2:520. 1912) that maize originated as a hybrid between teosinte and an unknown grass belonging to the Andropogoneae. This grass is thought to have been not unlike the earless varieties of pod or husk corn (*Zea Mays* var. *tunica*, Figs. 4037, 4038). The chief distinction between pod corn and the ordinary varieties of maize is that the glumes of the pis­glumes are reduced to minute scales at the base of the tillate spikelets are developed in pod corn and com­pletely inclose the grain, while in ordinary maize the same spikelet, or in perfect florets.

Plants will appear in some plant radically dif­ferent from teosinte, for only such a parent would account for the appearance of characters which characterize Eu­chima. Under the article *Corn* are given the botanical characters of the genus, a classification of the subspecies, as proposed by Sturtevant, and a discussion of sweet corn and pop-corn.

The following varieties of *Zea Mays* are grown for ornamental:

Var. gracilima, Koern. (Z. gracilima and Z. minima, Hort.). Very dwarf, slender form with green lvs., some­times cult. in Eu. A var. variegata is also mentioned.

Var. Curagua, Alef. (Z. Curagua, Molina), is described as a very robust green-lvd. form. Sturtevant places it in the pop-corn tribe. G. 42, p. 207.

A. S. Hitchcock.
equal; fls. few, sessile, in 2 conduplicate bracts.—Two species, Mex. and Texas.

 Pendula, Schnizl. (Tradescantia zebrina, Hort. T. tricolor, Hort., in part. Cynoglossus villosa, Lindl. Combretum zebrinum, Hort.). WANDERING JEW, in part. Fig. 4041. Trailing, half-succulent, perennial herb rooting at the joints: lvs. lance-ovate, sessile, the lf.-sheath about 1/2 in. long and hairy at top and bottom and sometimes throughout its length; under surface of lf. red-purple; upper surface silvery white, suffused with purplish, the central part and the margins purple-striped; fls. about 2, rose-red, contained in 2 boat-shaped bracts, one of which is much smaller than the other. Mex.—Commonly confused with Tradescantia fluminensis, Fig. 3828, and sometimes with Commetora nudiflora, See Tradescantia. The lvs. of Z. pendula seem never to be green. They vary somewhat in color. All forms are easily grown, and they prop. readily from pieces of st. Var. quadricolor, Bailey (forma quadricolor, Voss. Tradescantia quadricolor and T. multiflora, Hort.). Lvs. with metallic green undertone and striped with green, red, and white. Handsome. L. H. B.

ZELKÓVA (after the vernacular name Zelkoua in Crete, or Selkwa in the Caucasus). Syn., Abelica, and including Hemiptélon. Ulmácex. Ornamental trees grown for their handsome foliage and attractive habit.

Deciduous: lvs. alternate, short-petioled, penninerved, serrate, stipulate; fls. polygamous, the perfect ones solitary in the axis of the upper lvs., the staminate ones clustered in the axis of lower lvs. or bracts; calyx 4-5-lobed; stamens 4-5; styles 2: fr. a 1-seeded drupe, usually broader than high, oblique, with the style eccentric.

Five species in Crete, the Caucasus, and E. Asia. They are closely related to Celtis and Aphananthe and are chiefly distinguished by the connate sepal and the eccentric and oblique fr. Z. serrata is an important timber tree; the wood is very durable, and considered the best building material in Japan.

The young wood is yellowish white in color; the old wood is dark brown and has a beautiful grain.

The zelkovas are trees, sometimes shrubby, in general appearance much like some of the small-leaved elms, but either smaller or less two-ranked short-stalked leaves, with insignificant greenish flowers appearing at the base of the young branches and followed by inconspicuous fruits. Z. serrata and Z. Davidii are hardy North, while Z. ulmoides is hardy only as far north as Massachusetts, at least only in sheltered positions. Z. serrata is a very graceful round-headed tree and well adapted for avenues or as single specimens on the lawn. Z. Davidii, which is of recent introduction, may be useful as a hedge-plant on account of its upright rather stiff stems armed with spines. They do not seem to be very particular as to soil and position. Propagation is by seeds soon after ripening, also by layers and by grafting on Ulmus.

A. Fr. not winged; branches not spiny.

branches forming an oval or oblong head: lvs. oval or ovate to oblong, slightly cordate or rounded at the base, coarsely toothed with obtuse teeth, with 6–8 pairs of veins, usually almost glabrous above at length, pubescent on the veins beneath, 5½–3 in. long. April, May, of the Caucasus. Gn. 24, p. 571.

ALFRED REHDER.

ZEPHIRANTHES (Greek, flower of the west wind). Syn. Atemáceo Amaryllidaceae. ZEPHIR FLOWER. FAIRY LILY. Half-hardy tunicate-bulbous herbs, grown in the greenhouse, in window-gardens, and in the garden for summer- and autumn-blooming.

Leaves narrow, usually contemporary with the fls.: peduncle elongated, slender, hollow; spathe membranous, tubular, apex bifid: fls. white, red, or yellow, solitary in the spathe; perianth funnel-shaped, erect or slightly inclined, tube short or elongated, segms. subequal; ovary 3-celled: caps. subglobose, loculicidally 3-valved.—About 53 species, natives of the warmer regions of Amer. A general revision of Zephyranthes is found in Baker’s Handbook of the Amaryllidaceae, 1888, where the following subgenera are made: Subgenus ZEPHIRANTHES proper. Fl. erect; tube short; stamens inserted near its throat. Subgenus ZEPHIRITES. Fl. slightly inclined; tube short; stamens inserted near its throat; style more declinate than in the other two subgenera. Subgenus PROZANTON. Fls. erect; tube longer, dilated in the upper half; stamens inserted at the middle of the perianth-tube. For the further separation of the species, Baker uses the characters which appear in the key below, except the foliage-characters and the color of the fls. However, the genus may be readily separated into 2 sections based on the color of the fls., and this arrangement is here used as being more convenient to the horticulturist. The seasons of bloom indicated herein are those for localities where the plants will thrive outdoors the year round. For an account of bigeneric hybrids of Zephyranthes and Cooperia, see Lancaster, Journ. Roy. Hort. Soc. 35, p. 631.

The zephyr lilies must be wintered in a place free from frost, and as the best kinds are natives of swampy places it is fair to presume that they will need more...
moisture during the resting-period than the generality of bulbous plants. The best four species are: Z. candida (Fig. 4045), white, autumn; Z. Atamasco, white, spring; Z. carinata, rosy, summer; Z. rosea, autumn. All of these will probably survive the winter out-of-doors in the middle states if given a fair degree of protection.

INDEX.

Atamasco, 13.
Atamasco, 1.
Aurea, 10, 15.
carinata, 12.
candida, 14.
carinalis, 15.
carinalis, 8.

KEY TO THE SPECIES.

2. Zephyranthes rosea, S. Species closely allied to Z. Atamasco and best distinguished by the lvs. as indicated in the key; perianth-segments sometimes keeled with rose, but in both species the fls. turn pinkish with age. It is a Fla. species, found in damper localities and blooming several weeks later than Z. Atamasco. V. 6:299. Gn. 33, p. 11. G. 10:1003. J.H. III. 53:273.

3. Zephyranthes tubispatha, Herb. Bulb globose, 1 in. diam.; lvs. narrow-linear, flaccid, bright green, sometimes 1 ft. long; peduncle slender, 6 in. long; spathe 1½-2 in. long, slit at the tip only: perianth 1½-2 in. long, white, slightly tinged with green, never with red, tube scarcely any, segms. obovate. W. Indies, Venezuela, and Colombia.

4. Zephyranthes erubescens, Wats. (Amaryllis erubescens, Horsford). Rare white-flowered August-blooming species supposed to be native to sandy plains of Texas, but perhaps from N. Mex.: distinguished from the 2 preceding species by the larger, longer-necked bulb, shorter perianth, and fls. strongly tinged with rose outside: bulb over 1 in. thick; neck as long: spathe bifid above: tube equaling and closely embracing the pedicel (about 1 in. long).—Intro. by Horsford 1888 and probably lost to cult.

6. Zephyranthes Conzattii, Greenm. Bulb globose, about 1 in. diam.: lvs. produced after the fls.: peduncle 6-9 in. high, slender; spathe produced about 1 in. long; perianth (dried) rose-colored or crimson-purple, tube short, segms. oblanceolate, style deciduate. Mex.

7. Zephyranthes Lindleyana, Herb. Rare summer-blooming rose-colored species from the mountains of Mex., inferior to Z. carinata for general cult.: bulb globose, ¾ in.
thick; neck short: fls. 1½-2 in. long; ovary stalked; stigma 3-fid; spathe 3-fid only at tip.

8. **rösica**, Lindl. Autumn-blooming rosy-fl. species, with much smaller fls. than *Z. carinata* but, according to American catalogues, the most popular rosy-fl. species: fls. only about 1 in. long and 1½ in. broad; bulb globose, ½ in. thick; neck scarcely any: spathe 2 fls. at tip only; ovary stalked; stigma 3-fid. Oct.

9. **longitória**, Hemsl. Summer-blooming, yellow-fl. species, distinguished from the next by characters of pedicel and spathe: bulb ovoid; neck 1½-2 in. long; spathe tubular in the lower half; pedicel much shorter than spathe: fls. yellow, coppery outside, ¾-1 in. long. New Mex.—Intro. 1889, and probably lost to cult.

10. **texina**, Herb. Yellow-fl. Texan species: bulb globose; neck 1-1½ in. long: spathe bifid only at the tip: pedicel much longer than the spathe: fls. yellow, coppery outside, ¾-1 in. long. New Mex.—Intro. 1889, and probably lost to cult.

11. **veréndi**, Herb. (Z. strüita, Herb.). Rare spring- and summer-blooming species, distinguished from other white-fl. species cult. by the sessile ovary and long-necked bulb: bulb 1 in. or less thick; neck 1-2 in. long: fls. 1½-2 in. long; greenish white, more or less tinged outside or keeled with rose. Highlands of Cent. Mex. B.M. 2583; 2593.—Offered by Dutch dealers.

**Subgenus ZEPHYRITHE.**

14. **cardinalis**, C. H. Wright. Lvs. ligulate, acuminate, about 6 in. long, above shining green, slightly canaliculate, below keeled: scape cylindrical, rose below, green above; spathe rose; perianth cardinal-red, tube funnel-shaped about 1 in. long, green, segms. broadly oblong-ob lanceolate, subobtuse. Amer. B.M. 8553.

**Subgenus PYRILLION.**

Z. alba, Hort., with pure white fls. is offered in the trade.—Z. forbesii, Hort., is a trade name.—Z. sulphurea, Hort., is offered in the trade.

**ZICHA**

**ZINGBER (name ultimately derived from a Sanskrit word meaning horn-shaped; probably referring to the ginger root). Zingiberaceae.** Gingers. Perennial herbs sometimes grown as warmhouse plants, and also for summer bedding in the southern United States for their decorative value; source of ginger. Rhizomes horizontal, tuberous: stts. leafy, the flowering and sterile differing: lvs. oblong-lanceolate, clasping the st. by their long sheaths: infl. thyrsoid-spike-like, dense cone-like or rather long, terminal or lateral; bracts usually 1-fl.: calyx cylindrical, shortly 3-lobed; corolla-tube cylindrical, segms. lanceolate, upper concave; later staminodes none or adnate to the obovate-cuneate lip; anthers-contiguous, crest narrow, as long as the cells; ovary 3-celled, ovules many, superposed; caps. oblong, finally dehiscing.—About 120 species, natives of the tropics of the Old World. Monographed by K. Schumann in Engler’s Pflanzenreich, hft. 20 (IV. 40). It is said by gardeners that in Zingiber the leaves tend to roll up or inward and in Hedychium downward.

The ginger plant is a small reed-like plant 2 feet or more high, as cultivated in greenhouses, with tuberous rhizomes, aromatic leaves and dense cone-like clusters of bracts. The flowers, however, are very rarely produced in cultivation, and Roxburgh wrote that he never saw the seeds. The plant is supposed to be native to India and China, but, like many other tropical plants of economic importance, its exact nativity is uncertain.

Some idea of the importance of ginger to the world may be gained by the fact that as early as 1884 Great Britain imported 5,600,000 pounds valued at $620,000. Medicinal ginger is prepared from the dried root; condimental ginger from the green. Candied ginger is made from carefully selected succulent young rhizomes which are washed and peeled and then preserved while scraping the roots or they will 'burn' for days. Ginger probably could be cultivated commercially in southern Florida and California. In Florida it thrives in rich soil and partial shade, and the roots can be dug and used at any time. The plant is cultivated commercially even in localities where it is necessary to lift the roots and store them over the cool season, as in the lower Himalayas. In the West Indies ginger may be cultivated up to an altitude of 3,500 feet.

Zingibers are occasionally cultivated as warmhouse
decorative plants. The shoots having a reed-like appearance, they may often be used to good advantage in arranging plants for artistic effects. They are of the easiest culture. Propagation is effected by division of the rhizomes in spring. These should be potted in fibrous loam to which a third of well-decomposed cow or sheep-manure has been added. Water should be given sparingly until the shoots have well developed, when they should have an abundance. They are also benefited by an occasional watering with weak liquid manure water. Toward the end of summer the shoots will begin to mature, when the water-supply should be diminished, and as soon as the plants are ripened off the pots may be stored either under the greenhouse stages or in some other convenient place, where they should be kept almost dry for the winter.

A. Margins of lvs. colored creamy white or often pink.

D. récei, Hort.; also spelled d' récei and d' Arqüé. About 2-3 ft. high: lvs. lanceolate, 6-8 x 2-21/2 in., bright shining green with a broad creamy white or often pink margin and oblique stripes of the same color: fls. deep red, bull-like.—Intro. into Fl. This species is not treated by Schumann and is probably of horticultural origin.

AA. Margins of lvs. not colored.

b. Leafy st. different from the flowering st.: spike from the rhizome.

Mígsa, Roscoe. About 3 ft. high: lvs. moderately or shortly petioled, linear-lanceolate or nearly linear, attenuate-acuminate and caudate at base, both surfaces glabrous, 10-15 x 1-21/2 in., membranaceous: spike elliptoidal, 2-31/2 in. long: fls. white; calyx tubular, acuminate; corolla-lobes lanceolate or oblong-lanceolate, lip obovate, entire: heads terminal. Japan. B.M. 8570.—It is said to be still a saying in Japan that those who eat this plant forget everything, although no one has yet demonstrated it.

bb. Leafy st. not differing from the flowering st.: spike terminal.

c. Bracts green, often pale-marginated, rotundate.

d. Lvs. grass-like, scarcely 3/16 in. broad: lip purple, yellow-spotted.

Officinale, Roscoe. Ginger. Fig. 4047. Sts. normally more than 3 ft. high from a tuberous rhizome: lvs. sessile, lanceolate or linear-lanceolate, attenuate-acuminate at base, up to 8 in. long and scarcely 3/16 in. broad: spikes elliptoidal, obtuse, dense, 2 in. long; bracts ovate, pale green, margins often yellow: calyx crenate; corolla yellowish green, lobes lanceolate, acute, lip oblong-ovate, purple, yellow-spotted, lateral lobes ovate, acute. Native of trop. Asia, but cult. throughout tropics and intro. into S. Fl. Gn. 26, p. 284.

dd. Lvs. lanceolate or oblong-lanceolate: lip yellow.

Zerumbet, Roscoe. Sts. 12-20 in. high, stout, from a tuberous rhizome: lvs. densely aggregated, oblong-lanceolate, acuminate, base acute, both surfaces glabrous or scattered pilose beneath, 31/2-6 x 2-21/2 in.: spike subglobose, dense, 2-31/2 in. long; bracts obtuse, pale green, margins pubescent (sometimes, at least when older, red); calyx spath-like, white; corolla-tube slender, lobes lanceolate, white, lip short, broadly suborbicular or subovate, pale yellow, tinged orange in the center (sometimes red-spotted), lateral lobes short, rotundate. India and Malaya. B.M. 2000.

cc. Bracts red or at the beginning reddish green, later becoming obscurely red or rose, commonly acute.

d. Spike elongated cylindrical, 3 in. or more long, apex obtuse.

spectabilis, Griff. Leafy sts. 6 ft. or more high, robust: lvs. subsessile, oblong-lanceolate, acuminate at base, obscurely green above, paler pubescent beneath, 8-12 x 31/2 in.: spike 8-12 in. long, a little over 2 in. diam., laxy cylindrical, apex rounded; bracts yellow, finally scarlet, apex obtuse: corolla yellowish white, dorsal lobe deep concave, broad, anterior narrower, linear-lanceolate, lip obovate, emarginate, 2-lobed, lemon-yellow, apex almost black, lateral lobes half as long as midlobe, ovate. Malay Penins. B.M. 7957.

dd. Spike 4 in. or less long, elongated, narrow-fusiform, apex acute.

Cylindricum, Moon. Leafy sts. 6 ft. or more high: lvs. sessile, oblong-lanceolate or lanceolate, attenuate-acuminate; base acute, glabrous above, puberulent beneath, up to 8 x 21/4 in.: spike 31/2 in. long, cylindrical, narrowed at both ends, dense, bracts lower obtuse, upper acute, pale or reddish; corolla-labes lanceolate, greenish, subequal, greenish, lip yellowish white, lateral lobes small, obtuse. Ceylon.

Z. cortinum, Hance. Leafy sts. differing from the flowering, about 3 ft. high: lvs. sessile, linear-lanceolate, glabrous above, pilose beneath, 12 x 21/4 in.: spike oblong, obtuse, 7 in. long, bracts ovate, scarlet: corolla-labes red, oblong, acuminate: lip oblong, lateral lobes inconspicuous. China.—Once offered in Fl.

P. Tracy Hubbard.
ZINNIA are hardy plants, growing a foot or more high and covered from July until the first hard frost with double flowers 2 inches or more across. Several well-marked colors are commonly seen in zinnias—white, sulfur, yellow, golden yellow, orange, scarlet-orange, scarlet, flesh-color, lilac, rose, magenta, crimson, violet, purple, and dark purple. There are also variegated forms, but the solid colors are most popular. The zinnia is rich in shades of purple and orange, but lacks the blue and pink of the China aster and is poor in reds compared with the dahlia. Three forms or classes of the common zinnia (Z. elegans) may be noted here:

I. Tall zinnias are ordinarily 20 to 30 inches high. This size and the next smaller size are the favorites for general purposes. The tall kinds are available in twelve and more colors. A robust race, which attains 28 to 40 inches under perfect conditions, is sometimes known to the trade as Z. elegans robusta grandiflora plenissima. It is also known as the Giant or Mammoth strain. This strain was developed after many years by Herr C. Lorenz and was introduced in 1886. A maximum diameter of 6 inches is recorded for flowers of this strain. In G.C. II. 26:461 is shown a flower measuring 4 by 4 inches, with about eighteen series of rays, the latter being so numerous and crowded that the flower is less regular than the common type. A specimen zinnia plant 3 feet high is attained in the North only by starting the seed early and giving perfect culture.

II. Medium-sized zinnias range from 12 to 20 inches in height. They are available in several colors. Here belong most of the forms known to trade catalogues as Z. pumila, Z. nana, and Z. compacta.

III. Dwarf zinnias range from 3 to 12 inches in height and are of two subtypes, the pompons and the Tom Thumbs. The pompons, or "Liliputians," are taller-growing and smaller-flowered, generally about 9 inches high, with a profusion of flowers about 2 inches across. The Tom Thumb type represents the largest possible flower on the smallest possible plant. Both types are available in several colors, not all of which are yet fixed in the seed.

Second in importance to Z. elegans is Z. Haageana. The single form was introduced to cultivation about 1861 and the double about 1871. It is dwarfer than most zinnias, and has smaller flowers, with a color-range restricted to shades of orange. It is distinct and pretty but less showy than the common zinnias. The first race of hybrids between Z. Haageana and Z. elegans appeared in 1876 under the name of Z. Darwinii. This group is said to resemble Z. elegans in size and color of flowers and to resemble Z. elegans in habit, being more branched and forming a broader and thicker bush.

Zinna are of the easiest culture, thriving in any deep good soil, whether loamy or sandy. The seeds may be sown about May 1, or whenever the soil is in fit condition for hardy annuals. Such treatment will give flowers from the first of July until frost. The young plants should be thinned so as to stand 1 to 2 feet apart, depending on whether they are of medium- or tall-growing habit. By midsummer the foliage should obscure the ground. For the very best results the seed may be started indoors about April 1, and the seedlings transplanted once or twice before being placed outdoors in permanent quarters. Dwarf varieties should be set 14 to 16 inches apart; taller kinds 2 feet each way. Zinnias are essentially coarse plants, but if the tall kinds are massed heavily in the borders or at some distance they produce striking and very acceptable effects. Their colors are strong, and the stoutness of stems and foliage add to the composition.

a. Plant annual.

b. Achenes of the disk-fls. short and broad, obovate, 2-2½ lines long.

c. Colors various: lvs. clasping, cordate-ovate or elliptic.

elegans, Jacq. Youth-and-Old-Age. Figs. 4049-4050. Erect annual, a foot or more high, but varying from 3 in.
3546 ZINNIA

to 3 ft.: lvs. ovate or elliptic, clasping, about 1 in. wide: rays becoming reflexed, originally purple or lilac, but now of nearly every color except blue and green; disk originally yellow or orange, but nearly or quite absent in the common double forms; fls. 2-5 in. across. July to Oct. Mex. Single forms are pictured in B.M. 527. P.M. 1:223, B.R. 1294 (the last two as Z. violacea). Double forms, F.S. 13:1394, R.H. 1861:251; 1864:331, G. 4:138. Pompons in Gn. 48, p. 464 (Liliput); 30:270 (deceptive as to size), R.B. 20, p. 152.—The common species from which most of the garden zinnias are derived.

c. Color of rays yellow; disk yellow.

**Haageana, Regel (Z. mezioida, Hort.)**. Fig. 4051. Distinguished from Z. elegans by the orange-colored fls., which are generally smaller; also the plant is dwarfer, as a rule, and the lvs. are merely sessile, not clasping. Trop. Amer. Single forms, Gn. 30, p. 270; 48, p. 494. Double, Gn. 30, p. 271; 48, p. 464, G. 2:73. F. 1871, p. 229, A.G. 13:218. Var. stellata, Hort. Florets twisted and acuminate, orange-yellow.—This is considered by Robinson & Greenman as a horticultural species not certainly distinguishable from Z. angustifolia, in spite of its broader lvs.

**pauciflora, Linn.** An erect annual: lvs. lanceolate to oblong-ovate, usually rough: heads yellow, about 1 in. across, with rather broad, spreading, red, purple or mostly yellow rays in cult. specimens: plant hisrute, with spreading hairs; somewhat corymbosely branched above: peduncles at maturity enlarged upward and hollow. Mex., Peruvian Andes.

d. Rays suberect or scarcely spreading; disk yellow.

**multiflora, Linn.** This and the next are included by most writers in Z. pauciflora, but Z. multiflora may be distinguished from Z. pauciflora by the pubescence of the st. being much finer, oppressed or rarely spreading, and the rays red or purple, mostly narrow and suberect or scarcely spreading. B.M. 149.

c. Color of rays red or purple.

d. Rays revolute; disk dark-colored.

**tenuiflora, Jacq.** Fig. 4052. Very distinct by reason of its linear rays which are cardinal-red in color, becoming revolute. It has a dainty fl. head about 1 in. across hardly comparable with the showy Z. elegans. This species has been cult. in Amer. but seems to be no longer advertised here. It is referred to Z. pauciflora by most writers, and to Z. multiflora by Robinson & Greenman. B.M. 555. A.G. 11:243.

AA. Plant perennial.

**grandiflora, Nutt.** Hardy, low-growing. Colo. perennial, with woody root, erect, stiff, and very rough st. having a shrubby base, linear lvs., and sulfur-yellow rays which are very broad, almost round in outline; lvs. less than 1 in. long and 3-nerved. Colo., New Mex., Ariz., Mex.

**ZIZANIA** (an old Greek name of some wild grain). Gramineae. Tall aquatic grasses with lush sts., long blades, and large terminal panicles of moncocious fls.; spikelets I-fl., the pistillate upper portion of the panicule narrow and appressed, the staminate lower portion spreading; pistillate spikelets long-awned.—Species 3, 2 in N. Amer. and 1 in N. Asia.

**palustris, Linn. (Z. aquatica, of Auth., not Linn.)**

**INDIAN RICE. WATER OATS. WATER RICE. WILD RICE.** Fig. 4053. Annual: culms tall, as much as 9 ft.: lvs. broad and flat.—Recommended for borders of lakes and ponds. The grain is excellent for fish and waterfowl. Wild rice lakes and ponds are favorite resorts of sportsmen in the fall. Before sowing, put the seed in coarse cotton bags and sink them in water for 24 hours. Sow in water from 6 in. to 5 ft. deep, with soft mud bottom, or on low marshy places which are covered with water the year round. In running water, sow as much out of the current as possible. Sportsmen are not generally aware that seed can be obtained in large quantities and at a reasonable price from seedsmen. Wild rice is very desirable for aquatic gardens, being one of
ZIZANIA

A. S. Hitchcock.

ZIZIA (named for I. B. Ziz, a Rhenish botanist). Umbellifera. Perennial herbs of little horticultural value, but offered by some dealers in native plants.

Leaves ternate or ternately compound or the basal undivided; fls. yellow, in compound umbels, the central fl. of each umbel sessile; involucres none; involucels of several small bracts; calyx-teeth prominent; fr. ovoid or oblong, glabrous or nearly so, ribs filiform, not winged.

Three species, N. Amer.

A. Rays of umbels 9-25, stout, ascending.

Z. aurea, Koch. GOLDEN ALFRED D. Height 1-2½ ft., glabrous and branched; basal and lower Ivs. 2-3-ternately compound; upper Ivs. ternate; fr. oblong, 2-1½ lines. April-June. Fields, meadows, and swamps, New Bruns., Sask. and S. D. to Fla. and Texas.—A weedy-looking plant.

Z. Bebbii, Brit. Distinguished from Z. aurea by the rays and by the fr., which is oval or broader, 1-1½ lines. May. Mountain woods, Va. and W. Va. to N. C. and Ga.

F. Tracy Hubbard.

ZIZYPHUS (from Zizouf, the Arabian name of Z. Lotus). Rhamnaceae. Jujube. Ornamental woody plants grown chiefly for their handsome foliage, and some species for their edible fruits.

Deciduous or evergreen shrubs or trees; Ivs. alternate, short-petioled, 3-5-nerved from the base, serrate or entire; the stipules mostly transformed into spines, often only one stipule spiny or one a straight and the other a hooked spine: fls. 5-merous; ovary 2-4, usually 2-loculed; style usually 2-parted: fr. subglobose to oblong, usually orange-red, ½-3¼ in. long, on a stalk nearly half its length. March-June. S. Asia, Afr., Austral. Gn. 13, p. 194. S.M. 3:447.—Variable in shape and color of the fr.; for figures of several varieties see Hooker Jour. Bot. 1 (1834):321. The jujube is somewhat planted in Fla. and Calif., although it yet has no commercial rating as a fr.-plant. The frs. or berries are ripe in Nov. and Dec., and the plant begins to bear at 3 years from planting. The jujube fr. is used in confectionery.

Z. sativa, Gaertn. (Z. vulgata, Lam.). COMMON JUJUBE. Shrub or small tree, attaining 30 ft., glabrous; prickly or unarmed; the longer prickle up to 1½ in. long; branchlets often fascièd, slender and having frequently the appearance of pinnate Ivs.: Ivs. ovate to ovate-lanceolate, acute or obtuse, oblique at the base, sometimes but it is tender north of Washington, D. C. Most kinds have handsome foliage and are well adapted for planting in shrubberies in the southern states and California. They seem to thrive in any well-drained soil. Propagation is by seeds, by greenwood cuttings under glass and by root-cuttings.

Jujuibe, Lam. Fig. 4054. Tree, 30-50 ft. high; branches usually prickly; young branchlets, petioles and inf. densely rusty tomentose: Ivs. broadly oval or ovate to oblong, obtuse, sometimes emarginate, serrate or entire, dark green and glabrous above, tawny or nearly white-tomentose beneath, 1-3 in. long: fls. in short-stalked many-fl. axillary cymes: fr. subglobose to oblong, usually orange-red, ½-3¼ in. long, on a stalk nearly half its length. March-June. S. Asia, Afr., Austral. Gn. 13, p. 194. S.M. 3:447.—Variable in shape and color of the fr.; for figures of several varieties see Hooker Jour. Bot. 1 (1834):321. The jujube is somewhat planted in Fla. and Calif., although it yet has no commercial rating as a fr.-plant. The frs. or berries are ripe in Nov. and Dec., and the plant begins to bear at 3 years from planting. The jujube fr. is used in confectionery.

Z. sativa, Gaertn. (Z. vulgata, Lam.). COMMON JUJUBE. Shrub or small tree, attaining 30 ft., glabrous: prickly or unarmed; the longer prickle up to 1½ in. long; branchlets often fascièd, slender and having frequently the appearance of pinnate Ivs.: Ivs. ovate to ovate-lanceolate, acute or obtuse, oblique at the base, sometimes

4053. Zizania palustris.
emarginate, serrulate, glabrous, ½-2 in. long; fls. yellowish, fascicled, in axillary cymes: fr. ovoid to oblong, dark blue black, 1½-2 in. long; fr. red, flat, short-toothed, May to December. The trees are regular bearers and the crop is never cut off by spring frosts, as they do not blossom until desired for consumption fresh is gathered when showing the characteristic reddish brown or mahogany color, but if to be dried it is left on the tree until it assumes a darker shade and the skin is wrinkled. In this condition, after a short exposure to the sun the fruit will keep a year or longer. For preserving in syrup or glazing, the unwrinkled fruit, being slightly more pitted, is preferred.

The jujube is well worth the attention of fruit-growers and when produced in sufficient quantities will find an active demand from citizens from the south of Europe, It will appeal to all when fresh from the tree when properly processed, and for its medicinal virtues when simply dried or made into pastes or tablets. 

G. P. RIXFORD.
CXX. Zinnia, Giant Yellow and Scarlet.

V. in a close spike-like panicle; spikelets closely appressed, 1-fl., awnless, the single glume coriaceous, acute, compressed, inclosing the lemma and palea. —Species 4. S. E. Asia and Australasia.

japonica, Steud. KOREAN LAWN-GRASS. PALM-BEACH GRASS. Somewhat coarser than Z. Matrella, the blades as much as ½ in. wide, the panicles about 1 in. long, often purplish. A native of Japan and China; intro. many years ago from Korea; now grown in Fla. and is hardy as far north as Conn. Recommended for use on sandy soil from N. C. to Fla. Dept. Agric., Div. Agrost. 20:29.

Matrella, Merr. (Z. pungens, Willd. *Osterdinium Matrella*, Kunze). MANILLA GRASS. Sts. creeping, throwing up numerous short leafy shoots and flowering sts.: lvs. crowded, firm, 1-3 in. long, ending in a sharp hard point; spikes 1-2 in. long; spikelets ½ in. long, smooth and hard. A native of S. E. Asia, E. Indies.—Grown in Fla. and along the Gulf Coast.

tenuifolia, Willd. MACARENE GRASS. VELVET-GRASS. Lvs. thread-like, finer than in the other species. Forms a beautiful turf resembling that of red fescue. Native of the Mascarene Isls. Intro. into the U. S. from Guam in 1912. Used in Calif. where it is called velvetgrass, and along the Gulf Coast.

The name velvet-grass describes it very aptly as it looks like dark green velvet. It grows so thickly that it will smother out any other plant, even Bermuda- or "devil"-grass. Even if frozen off it will come up from roots. It needs little water, no cutting, will run out all other plants, will not become a pest as it sets no seeds in California, and is lovely in appearance. It is so fine that it may be pulled into thousands of pieces to the square foot and every little piece will grow, so that a small quantity will plant a large area. (Ernest Braunton.)

A. S. Hitchcock.

**ZYGADENUS** (Greek, yoke and gland, some of the species having two glands in the base of the perianth). *Liliaceae*. Smooth and somewhat glaucous perennials with non-bulbous rhizomes or with tunicate bulbs; some of the species are grown as ornamentals in the open ground; interesting plants of secondary importance horticulturally.

Leaves radical or gathered at the base of the stem, linear, those of the st. small and few: raceme terminal, simple or paniculate-branched: fls. perfect or polyamous, white, yellowish or greenish; perianth withering persistent, spreading, the petal-like oblong or ovate segms. 1-2 glandular near the more or less narrow but not clawed base; stamens 6, free: caps. 3-celled in fr., the cells separate at the top or for their entire length.—About 25 species have been described, one of which is *Z. Kuntze*). Three feet or less, wide, green on both sides: racemes paniculate: fls. about ½ in. across, the segms. oblong and not clawed. N. Y. to Cal.

**AA.** Sts. from a more or less bulbous base.

**BB.** Locules dehiscing only above middle: stamens inserted on perianth-segms.: glands none: bulbous. (Antimium; preferably retained as distinct genus.)

**CC.** Glands very obscure: bulb somewhat fibrous, narrow.

**leimanthoides**, Gray (Oceanbrus leimanthoides, Small). Sts. slender and leafy, 4 ft. or less tall: lvs. ½ in. or less wide, green on both sides: racemes paniculate: fls. about ½ in. across, the segms. oblong and not clawed. N. Y. to Cal.

**DD.** Fls. polygamous, small.

venenosus, Wats. Slender, 2 ft. or less tall: lvs. very narrow (½ in. or less), sebaceous, not glaucous, the st., lvs. not sheathing, flowers long (½ in.), simple or branched raceme, the perianth free from the ovary, the segms. ½ in. or less long, elliptic-ovate to elliptic, short-clawed. Calif.—Bulb poisonous.

**ZYGOCÁCTUS** (cactus with zygomorphic flowers). *Epiphyllum* of horticulturists. *Cactaceae*. CHAB-CACTUS. This genus is confined to Brazil, so far as known, where the plants grow as epiphytes upon the trees, along with orchids, growing in large clusters on the branches: stts. flat and jointed, becoming rounded with age, and then areces only on the margins and more or less truncated ends, from which grow the new branches and the conspicuously zygomorphic fls. ovary devoid of bracts, and those of the tube comparatively large and colored as the petals. The genus is allied to *Epiphyllum* (Phyllocactus), with which it was at first united; but it is still more closely connected with Schlumbergera. In cult. many forms have been produced through hybridization between the different species and with *Epiphyllum* and the allies of Cereus, so that typical plants are rarely met with.
**ZYGOCACTUS**

Truncatus, Schum. (Epiphyllum truncatum, Haw.).

Clara Cactus, Christmas Cactus. Fig. 4055. Sts. much branched and hang in large bunches from the trees; joints obovate to oblong, with strongly truncate apex, 1½–2 in. long, by about ¾–1 in. broad, bright green, margins coarsely serrate, with 1–3 large, acute teeth on each side, the 2 upper ones forming more or less incurved horns on either side of the truncation; areoles bearing a few short yellowish or dark-colored bristles, or none: fls. horizontal, growing from the truncated end of the younger joints, strongly irregular, 2½–3½ in. long, in various shades of red, fr. petal-shaped, red, about 3 in. diam. Brazil.

B.M. 2562. G.C. III. 19:9.—Most of the forms in cult. are hybrids between this species and some other of the genus with allies of Cereus. A common basket- and ruffle-plant.

For Epiphyllum Buseellanum and E. Garthi, see Schlumbergera.

**J. N. Rose.**

**ZYGOPELALUM** (name referring to the united flower parts). Orchidaceae. Mostly epiphytic orchids of easy culture.

Plants with numerous distichous lvs. sheathing a short st. which usually becomes thickened into a pseudobulb; lvs. membranaceous, veiny or plicate; fls. solitary or in racemes, showy; sepalis and petals nearly alike in form and color, often united to each other at the base, the lateral sepalis forming a mentum with the foot of the column; labellum with the lateral lobes scarcely prominent, middle lobe broad and plane, spreading, or recurved at the apex, with a prominent fleshy crest on the disk; column incurved, wingless or with small wings; pollinia 4, not appendiculate.

The Z. Mackaii group grow well under pot culture. One or two species with creeping rhizomes, like Z. maxillare, thrive best on sections of tree fern, osmunda rhizome, or in baskets. A good compost consists of equal parts of chopped sod, peat-fiber and sphagnum moss, well mixed and interspersed with pieces of rough charcoal, about one-half of the pot space being devoted to clean drainage material. After distributing the roots, the compost should be worked in carefully but not too firmly about them, leaving the base of the plant even with, or just above, the rim of the pot. Repotting should be done when the plants show new root-action. The temperature should range about 60°F. by night and 65° to 70°F. by day in winter, and in summer as low as possible, with free ventilation during inclement weather. A cool, light location in the cattleya department is favorable. The compost should be kept in a moist condition at all times. The plants are propagated by cutting through the rhizome between the pseudobulbs at a good eye, potting up the parts and removing them to a rather higher temperature until they start into new growth. (Robt. M. Gray.)

**a. Anther long-rostrate.**

**a.a. Anther not rostrate.**

**b. Petals spotted or blotched.**

**c. Labellum glabrous.**

**Mackaii**, Hook. Fig. 4056. Pseudobulbs large, ovate: lvs. many, linear-lanceolate, 1 ft. long: scape 1½ in. long, bearing 5 or 6 large fls.: sepalis and petals dingy yellowish green, with blotches of purple on the inside, lanceolate, acute, erect, spreading, all united toward the base; labellum large, rounded, emarginate, white with radiating vein-like deep blue lines, glabrous. Brazil. B.M. 2748. B.R. 1433 (as Eupophia Mack- aiana). P.M. 3:97. L.B.C. 17:1664. J.H. III. 33:295. G.M. 53:1037.—This is distinguished from Z. intermedium and Z. crinitum by its smooth labellum and narrower lvs. Var. supérbus, grandiflorum, majus are also advertised. Var. Charlesworthii, Hort. Sepalas and petals emerald-green, without purple markings. G.C. III. 51:33.

**Gaútheri**, Lem. Pseudobulbs oblong-sulcate, 4 in. high: scapes 2–3-ft.: fls. 3 in. across; sepalis and petals green blotched with brown; labellum broadly reniform, deep purple at the base, white in the middle, sometimes nearly all deep purple with a darker crest. Autumn. Brazil. I.H. 14:555. G.N. 49:118.—The lvs. are fasciculate, narrowly oblong, keeled, 12–16 in. long: infl. shorter than the lvs.
maxillare, Lodd. Pseudobulbs 2 in. long; lvs. lanceolate, 1 ft. long; scape 9 in. long, 6-8-fl.: fls. 1½ in. across; sepals and petals ovate-oblong, acute, green, with transverse brown blotches; labellum horizontal, purple, with a very large, glossy purple, notched horse-shoe-shaped crest, middle lobe roundish, waved, and obscurely lobed. Winter. Brazil. B.M.3886. L.B.C. 18:1776. J.H. III. 33:295. P.M.4:271.—Distinguished by its small fls. and very large crest.

cc. Labellum pubescent.

crinulum, Lodd. Habit of Z. intermedium: lvs. broadly linear-lanceolate; fls. on long, stout scapes; sepals and petals 2 in. long, oblong-lanceolate, green with rather few brown blotches; labellum 2 in. across, spreading, wavy, scarcely emarginate, white with purple veins radiating from the thick crest, disk hairy. Fls. at various times. Brazil. L.B.C.17:1687. B.M.3402 (as Z. Mackaaii var., crinulum).—This has fewer brown blotches on the sepals and petals than Z. intermedium. There are varieties with pink, blue, or almost colorless veins on the labellum. Var. caesileanum, Hort., has the veins deep blue. G.M. 46:153; 50:50. J.H. III. 46:197.

intermedium, Lodd. Lvs. ensiform, 1¾ ft. long, 1½ in. wide: scape longer than the lvs., bearing 5-6 fls. each nearly 3 in. across; sepals and petals oblong, acute, green with large, confluent blotches of brown; labellum rotund, narrowed at the base, deeply 2-lobed in front, pubescent, bluish white with radiating broken lines of purplish blue; column green and white. Fls. in winter. Brazil. R.H. 1873:190 (as Z. Rivieri).—Plants of Z. Mackaaii are often cult. under this name.

dd. Petals uniformly colored.

Sédentii Reichb. f. Plants strong, with the scape, about as long as the lvs. and bearing several fls.; sepals and petals deep purple-brown, bordered with green; labellum pale purple in front, becoming deep purple toward the base. F.M. 1880:417. Gr. 28:265.—A garden hybrid raised by Veitch.

HEINRICH HASSELBRING.

GEORGE V. NASH.

**ZYGOPHYLLUM** (yoke leaf, from the paired or opposite lfts. or lvs.). **Zygophyllaceae.** Small often spiny twiggy shrubs or subshrubs, with stiff branches, of about 60 species in Eu. and Asia but mostly in S. Afr. and Austral., apparently not in the American trade but likely to be planted for ornament now and then by amateurs in the warmer and drier parts of the country. Lvs. simple or 2-foliolate: fls. white or yellowish or red, on 1-fld. peduncles; calyx 4-5-parted; petals 4 or 5, clawed, twisted; stamens 8-10; disk fleshy and angled; ovary 4- or 5-celled, sessile: fr. an angled or winged caps. Prop. by seeds or cuttings. The species most likely to appear in collections are perhaps Z. Fabago, Linn., the Syrian bean-caper, with obovate lfts., copper-yellow fls., deep strong root and nearly or quite herbaceous top, S. W. Asia; Z. Morgana, Linn., with obvate obtuse lfts., long yellow petals, and shrubby habit, from S. Afr.; Z. spinifera, Linn., with linear lfts., yellowish or whitish nodding fls., a small bush only 1-2 ft. high, from S. Afr.
Supplement

Here are assembled certain lists and addenda that are supplementary to the body of the Cyclopedia, to provide the consultant with additional facilities for the use of the volumes. These appendices are as follows:

Collaborators in the making of the Cyclopedia .................................................. 3555
Cultivator’s guide to the articles ................................................................. 3562
Additional species ...................................................................................... 3565
New combinations in Latin names ............................................................... 3574
Finding-list of trade names ........................................................................ 3575
Index to the six volumes ............................................................................... 3611

Other articles of a similar character, providing keys and synopses, are printed in Vol. I, as follows:

Explanations, comprising a statement of the authorship of articles, nomenclature, pronunciation, spelling, the keys, abbreviations of botanical terms and expressions, books and periodicals to which reference is made, the authors of botanical names .......................................................... 31
Synopsis of the plant kingdom .................................................................... (with index) 1-78
Key to the families and genera ...................................................................... (with index) 79-147
Name-list, comprising the English equivalents of Latin names of species ..................... 148
Glossary of the usual botanical and horticultural technical words ................................. 160
A fuller discussion of nomenclature will be found under “Names and Nomenclature,” Vol. IV, 2095; also in the Finding-list ........................................................................................................ 3575

For five years the work of compiling the Standard Cyclopedia of Horticulture has been actively under way. The present office was opened in March, 1912, but the organizing of the work had been started before that time. Although founded on the Cyclopedia of American Horticulture, completed in 1902, the present Cyclopedia is newly organized and newly written. Whenever the articles in the former work have been used as a basis, they have been brought down to date. The preface to Vol. I states the scope and intention of the present work.

The List of Collaborators (pages 3555 to 3561) comprises upward of 400 names, and many other correspondents have aided in less formal ways. To all these helpers the reader will extend his gratitude for the satisfaction he may find in any of the pages. The publishers, printers, artists, writers, and others have cooperated in the freest spirit.

If the consultant desires to know the office methods in compiling a work of this character, he may read the introductory account in Vol. IV of the former Cyclopedia, for the general details do not differ greatly between the two. The Editor gathers his force, finds himself a table and a very few simple accessories, supplies himself with writing materials and books, and then goes to work and holds to it through all the letters from A to Etc. If the reader finds a misplaced letter or accent mark, he may consider that each page comprises about 10,000 pieces of type metal, or more than 36,000,000 pieces for the entire work; these pieces are of many technical devices; and human eyes are fallible. In the first year or two of the work, the Editor was engaged otherwise and could give only small fragments of his time to the Cyclopedia.

If the reader desires statistics of such work, the following figures may interest him:

I. The Number of Articles.
Total number of entries or articles, including cross-references (the sub-articles are the independent articles or parts in the main articles and in the symposia, indicated by black-face lower-case type):

Volume I ........................................ 693
Sub-articles .................................. 38
Volume II .................................... 1,101
Sub-articles .................................. 29
Volume III ................................... 756
Sub-articles .................................. 212
Volume IV ................................... 808
Sub-articles .................................. 94
Volume V ..................................... 650
Sub-articles .................................. 64
Volume VI ................................... 905
Sub-articles .................................. 19
Supplement (additional generic entries) ..................................................... 3

II. The Number of Plants.
The number of genera entered:

Volume I ..................................... 422
Volume II ..................................... 769
Volume III ................................... 442
Volume IV ................................... 550
Volume V ..................................... 449
Volume VI ................................... 639
Supplement .................................. 3

The number of main species described or entered, in black-face type:

Volume I ..................................... 1,801
Volume II ..................................... 2,741
Volume III ................................... 1,512
Volume IV ................................... 1,001
Volume V ..................................... 2,094
Volume VI ................................... 2,372
Supplement .................................. 102

(3553)
SUPPLEMENT

The number of minor species-entries in the main articles, in italic type:

<table>
<thead>
<tr>
<th>Volume</th>
<th>267</th>
</tr>
</thead>
<tbody>
<tr>
<td>Volume II</td>
<td>371</td>
</tr>
<tr>
<td>Volume III</td>
<td>270</td>
</tr>
<tr>
<td>Volume IV</td>
<td>436</td>
</tr>
<tr>
<td>Volume V</td>
<td>396</td>
</tr>
<tr>
<td>Volume VI</td>
<td>520</td>
</tr>
<tr>
<td>Total</td>
<td>2,060</td>
</tr>
</tbody>
</table>

The number of species in the supplementary lists, at the end of the various articles, in small italic type (including all but cross-references):

<table>
<thead>
<tr>
<th>Volume</th>
<th>985</th>
</tr>
</thead>
<tbody>
<tr>
<td>Volume II</td>
<td>1,424</td>
</tr>
<tr>
<td>Volume III</td>
<td>533</td>
</tr>
<tr>
<td>Volume IV</td>
<td>993</td>
</tr>
<tr>
<td>Volume V</td>
<td>1,198</td>
</tr>
<tr>
<td>Volume VI</td>
<td>916</td>
</tr>
<tr>
<td>Total</td>
<td>6,049</td>
</tr>
</tbody>
</table>

The number of Latin-named varieties (of species) of all grades in main articles:

<table>
<thead>
<tr>
<th>Volume</th>
<th>820</th>
</tr>
</thead>
<tbody>
<tr>
<td>Volume II</td>
<td>1,272</td>
</tr>
<tr>
<td>Volume III</td>
<td>705</td>
</tr>
<tr>
<td>Volume IV</td>
<td>1,031</td>
</tr>
<tr>
<td>Volume V</td>
<td>1,416</td>
</tr>
<tr>
<td>Volume VI</td>
<td>1,533</td>
</tr>
<tr>
<td>Supplement</td>
<td>29</td>
</tr>
<tr>
<td>Total</td>
<td>6,715</td>
</tr>
</tbody>
</table>

The number of synonyms:

<table>
<thead>
<tr>
<th>Volume</th>
<th>1,715</th>
</tr>
</thead>
<tbody>
<tr>
<td>Volume II</td>
<td>2,379</td>
</tr>
<tr>
<td>Volume III</td>
<td>1,558</td>
</tr>
<tr>
<td>Volume IV</td>
<td>1,727</td>
</tr>
<tr>
<td>Volume V</td>
<td>2,444</td>
</tr>
<tr>
<td>Volume VI</td>
<td>60</td>
</tr>
<tr>
<td>Supplement</td>
<td>60</td>
</tr>
<tr>
<td>Total</td>
<td>12,458</td>
</tr>
</tbody>
</table>

Total Latin names accounted for (aside from a few new entries in the finding-list in Supplement to Vol. VI):

<table>
<thead>
<tr>
<th>Volume</th>
<th>39,775</th>
</tr>
</thead>
<tbody>
<tr>
<td>Volume II</td>
<td>24,434</td>
</tr>
<tr>
<td>Volume III</td>
<td>6,688</td>
</tr>
<tr>
<td>Volume IV</td>
<td>6,311</td>
</tr>
<tr>
<td>Volume V</td>
<td>3,589</td>
</tr>
<tr>
<td>Volume VI</td>
<td>4,427</td>
</tr>
<tr>
<td>Supplement</td>
<td>524</td>
</tr>
<tr>
<td>Total</td>
<td>3,853</td>
</tr>
</tbody>
</table>

III. THE NUMBER OF SPECIES (IN BLACK-FACE TYPE), NATIVE TO NORTH AMERICA NORTH OF MEXICO:

<table>
<thead>
<tr>
<th>Volume</th>
<th>353</th>
</tr>
</thead>
<tbody>
<tr>
<td>Volume II</td>
<td>551</td>
</tr>
<tr>
<td>Volume III</td>
<td>359</td>
</tr>
<tr>
<td>Volume IV</td>
<td>427</td>
</tr>
<tr>
<td>Volume V</td>
<td>524</td>
</tr>
<tr>
<td>Volume VI</td>
<td>553</td>
</tr>
<tr>
<td>Supplement</td>
<td>7</td>
</tr>
<tr>
<td>Total</td>
<td>6,715</td>
</tr>
</tbody>
</table>

IV. THE DATES OF PUBLICATION:

<table>
<thead>
<tr>
<th>Volume</th>
<th>March 25, 1914</th>
</tr>
</thead>
<tbody>
<tr>
<td>Volume II</td>
<td>July 22, 1914</td>

</tr>
<tr>
<td>Volume V</td>
<td>October 4, 1916</td>
</tr>
<tr>
<td>Volume VI</td>
<td>March 28, 1917</td>
</tr>
</tbody>
</table>

Within the five years several horticulturists have passed away, whose biographies would have been proper subjects for entry in the Cyclopaedia. Among such losses are C. E. Bessey, who died February 25, 1915; H. E. Van Deman, April 28, 1915; G. B. Brackett, August 2, 1915; Edwin Lonsdale, September 1, 1915; W. Atlee Burpee, November 26, 1915; William Tricker, July 11, 1916; William S. Lyon, July 20, 1916; Jackson Dawson, August 3, 1916; Ernest Walker, December 5, 1916; W. C. Barry, December 12, 1916.

To spend five years in a review of the vegetable kingdom, with all its marvels and its unsolved problems, is in itself a great privilege. If in addition one may see the applications to the desires of man, may hold associations with several hundred enthusiastic and competent correspondents, may have relations with the commercial and financial questions involved, and may at the same time catch some glimpses of the reaches of evolution and feel a new contact with the earth, the making of a Cyclopaedia of this kind becomes not a task but an experience in life. The Editor hopes that the reader may share some of these prospects. The Editor is well aware of the shortcomings of the volumes and he would like to do the work all over again for the delight of it; but this reward must be left for other hands in the years that are to come.

Ithaca, New York,
February 1, 1917.

L. H. BAILEY.
COLLABORATORS

Comprising those persons who have aided in the making of the Standard Cyclopedia of Horticulture by the writing of articles, proof-reading, and the contributing of information.

*Means a contributor to the Cyclopedia of American Horticulture (1800–1902), whose name appears in the present work.

†Means contributor deceased since contribution was made for present Cyclopedia.

ETHEL ZOE BÁILEY, EDITOR'S ASSISTANT

ADAMS, GEORGE E., Prof. of Agronomy, Rhode Island State College, Kingston, R. I. (Rhode Island, Rhubarb.)

ALDERMAN, W. H., Prof. of Horticulture, College of Agriculture, Morgantown, W. Va. (Machinery, West Virginia.)

ALEXANDER, J. K., Dahlia Specialist, East Bridgewater, Mass. (Dahlia.)

AMIS, OAKES, Dir. Botanic Garden of Harvard University, Cambridge, Mass. (Many genera of orchids.)

ANTHONY, R. D., Assoc. Horticulturist of State Experiment Station, Geneva, N. Y. (Machinery.)

ARNOLO, GEO., Florist, Ensenore, N. Y. (China Aster.)

ATKINS, P. L. (Platycerium.)

BARKER, FRANK A., Asst. in Landscape Design, College of Agriculture, Urbana, Ill. (Herbs.)

BAILEY, HENRY TURNER, Teacher, Author, Editor "School Arts Magazine" and "Something-to-Do," North Scituate, Mass. (Bouquet.)

BARRON, LEONARD, Editor "The Garden Magazine," 322 E. 19th St., Brooklyn, N. Y. (Cut-Flower Industry, Florists' Plants, John Craig, Garden City, N. Y.)

BARRETT, O. W., Horticulturist of Canal Zone, Cristo­<>

BERCKMANS, L. A., Nurseryman, Augusta, Ga. (Herbs, Lawne, Magnolia, Planting lists, Pomegranate.)

BERCKMANS, P. J. (Arboreturm, Magnolia, Pinckneya.)

BESSET, C. E., Prof. of Botany, University of Nebraska, Lincoln, Neb. (Arboreculre, Evergreens.)

BETHUNE, C. J. S., Prof. of Entomology and Zoology, Ontario Agricultural College, Guelph, Ont. (Wm. Saunders.)

BIOLETTI, FREDERICK T., Prof. of Viticulture, College of Agriculture, University of California, Berkeley, Calif. (Grape, Olive.)

BLAIR, J. C., Head of Dept. of Horticulture, College of Agriculture, Urbana, Ill. (Greenhouse Glass, Illinois.)

BLAINE, M. A., Prof. of Horticulture and Horticulturist of Experiment Station, College of Agriculture, New Brunswick, N. J. (New Jersey, Patch.)

BOOTH, N. O., Prof. of Horticulture, Oklahoma Agricultural College, Stillwater, Okla. (Oklahoma.)

BRACKETT, G. B., Pomologist, U. S. Dept. of Agric., Washington, D. C. (Aid on biographies.)

BRAYNE, ELIZABETH, Ex-President Middlebury College, Botanist, Middlebury, Vt. (Vioa.)

BRANDERS, MRS. KATHERINE. (Leucadenregia, Picephy­ora.)

BRAUNTON, ERNEST, Landscape Designer and Consulting Horticulturist, 237 Franklin St., Los Angeles, Calif. (Many notes on California plants.)

BUTLER, ELIZABETH G. (MRS. N. L.), Botanist, New York Botanical Garden, Bronx, New York City. (Wild Flowers.)

BRODIE, F. W., Prof. of Horticulture and Forestry, Manhattan Agricultural College, Winnipeg, Man. (Manitoba.)

BROCKNER, NICHOL N. (Culture of many of the ferns.)

BUUS, C. T., Asst. Prof. of Economic Entomology, Harvard University, Bussey Institution, Forest Hills, Mass. (Arboriculture.)

BUUS, H. N., Florist, 3042 W. Madison St., Chicago, Ill. (Lily-of-the-Valley.)

BURLINGTON, FRANK, LANDSCAPE ARCHITECT, Northampton, Mass. For several years curator of the Smith College Botanic Gardens. (Notes on culture of many plants and phases of gardening.)

CANNING, EDWARD J., Practical Landscape Architect, Northampton, Mass. For several years curator of the Smith College Botanic Gardens. (Notes on culture of many plants and phases of gardening.)

CHASE, MRS. AGNES, Scientific Asst. in Systematic Agrostology, Bur. of Plant Ind., U. S. Dept. of Agric., Washington, D. C. (Much help on the grasses.)

CHEYNEY, E. G., Dir. of the College of Forestry, University of Minnesota, University Farm, St. Paul, Minn. (Minnesota, several biographies.)

CHURCH, J. E., JR., Meteorologist of Agricultural Experiment Station, University of Nevada, Reno, Nev. (Nevada.)

COVINGTON, ROBERT.

DURAND, J. N., Prof. of Pomology, Maryland State College of Agriculture, College Park, Md. (Mary.)

DURAND, E. B., Field Horticulturist, University of Idaho, Boise, Idaho. (Colorado.)

BENNERT, IDA D., Writer, Coldwater, Mich. (Home Flower-garden.)

225
*LANDRETH, BURNET. (David Landreth.)

LEONARD, M. D., Extension Asst. of Entomology, New York State College of Agriculture, Ithaca, N. Y. (Rose Insects, South.)

LEWIS, C. I., Prof. of Horticulture, State Agricultural College, Corvallis, Ore. (Apple, Loganberry, Oregon, Prune.)

LEWIS, F. H., Pecan Orchidist and Nurseryman, Pascalesburg, Miss. (Mississippi.)

LEWTON, FREDERICK L., Curator, Division of Textiles, New York State College of Agriculture, Ithaca, N. Y. (Cultural notes on many Florida plants.)

MACDOUGAL, D. T., Dir. of Botanical Research, Carnegie Institution of Washington, Desert Laboratory, Tucson, Ariz. (Sap, Transpiration.)

Macfarlane, J. M., Prof. of Botany, Dir. of the Botanical Garden, University of Pennsylvania, Philadelphia, Pa. (Darlingtonia, Dionaea, Drosera, Nepenthes, Sarracenia.)

MACK, W. T., Dominion Horticulturist, Central Experimental Farm, Ottawa, Canada. (Apple, British North America, currant, gooseberry, herbs, several biographies.)

MANNING, Warren H., Landscape Designer, Northboro, Mass. (Nut-culture.)

MARRATT, C. L., Chairman Federal Horticultural Board, Washington, D. C. (Inspection.)

*MASON, S. C. (Labels, Layering.)

Mathisen, Robert, Asst. Prof. of Economic Entomology, New York State College of Agriculture, Ithaca, N. Y. (Diseases and Insects.)

Mathews, C. W., Prof. of Horticulture, College of Agriculture, University of Kentucky, Lexington, Ky. (Kentucky.)

Mathews, E. SCHUYLER, Artist and Author, 17 Frost St., Cambridge, Mass. (Color, Standards of Color.)

*MATHWS, WM. (Culture of many orchids.)

MAYNARD, S. T., Horticultural Specialist and Landscape Gardener, Northboro, Mass. (Massachusetts.)

McClelland, T. B., Asst. Horticulturist, U. S. Experimental Station, Mayaguez, Porto Rico. (Cofea.)

McCUTCHEON, C. A., Prof. of Horticulture, Delaware College, Newark, Del. (Delaware.)

McFarland, J. HORACE, Printer, Author, Lecturer, Harrisburg, Pa. (Border, Garden Cities, Photography.)

McKelton, T. H., Prof. of Horticulture, State College of Agriculture, Athens, Ga. (Rueгр-phia, Georgia, Pear.)

*MEHER, JOSEPH. (Maluca.)

MEHNEH, W. E., Nurseryman, Germantown, Philadelphia, Pa. (Thea, Meheh.)

MENDENBETH, NATHAN, Asst. in Plant Introduction, Office of Foreign Seed and Plant Introduction, U. S. Dept. of Agric, Washington, D. C. (Sesquium.)

*MEREDITH, A. P. (Hameca.)

Michel, Eugene H., Supt. Dreer's Nurseries, Riverton, N. J. (Help on Name-List.)

Miller, Wilhem, Landscape Architect, 64 E. Van Buren St., Chicago, Ill. (Autumn-Gardening, Biennials, Chrysanthemum, Herbs, Landscape Extension, Planting articles, and many biographies and genera.)

Miner, Wm. W., Farmer and Fruit-Grower, Palmyra, N. Y. (A. M. Purdy.)

Mitchell, Arch, Nurseryman, Coaldale, Alberta, Alton. (David Landreth.)

Mitchell, Sydney B., University of California Library, Berkeley, Calif. (Culture of Gigantis, Iris, Iris.)

Montillon, Eugenie D., Instr. Landscape Art, New York State College of Agriculture, Ithaca, N. Y. (Topiary Work.)

Moon, Henry T., Nurseryman, Morrisville, Pa. (James Moon.)

Mooke, Albert Hamford, Botanist and Photographic Reproducer, 3 Divinity Ave., Cambridge, Mass. (Escallonia, Philadelphus, Spicantae.)

Murphy, O. M., Head of Horticultural Dept., State College, Pullman, Wash. (Washington.)

Muller, Route T., Surgeon, 616 Madison Ave., New York City. (Nut-culture.)

Morrison, B. Y., Landscape Architect, Takoma Park, D. C. (Arboreculture.)

Morrison, Wm. S., Prof. of History and Political Economy, Clemson College, S. C. (J. S. Newman.)

Morse, C. C. & Co., Seed-growers and Dealers, 730-759 Front St., San Francisco, Calif. (Seeds.)

* Munson, T. V., Nurseryman, Denison, Texas. (Grape, Texas.)

*Munson, W. M. (Vaccinium.)

Nash, George V., Head Gardener, New York Botanical Garden, Bronx Park, New York City. (Botany of most of the genera of orchids, aroids, and bremeliads.)

Nekeling, H., Horticulturist, Palm Cottage Gardens, Gotta, Fl. (Cultural notes on many Florida plants.)

Nelson, Aven., Prof. of Botany, University of Wyoming, and State Horticulturist, Laramie, Wyo. (Wyoming.)

*NEWBURY, H. E. (Polianthes.)

Newbury, W. R., Magnolia, N. C. (Polianthes.)

Newman, C. C., Prof. of Horticulture and Horticulturist of Experiment Station, Clemson College, S. C. (South Carolina.)

Norton, J. B. S., Prof. of Botany, Maryland Agricultural College, College Park, Md. (Botany of the Euphorbiaceae.)

O’Gara, P. J., Pathologist and Chief in Charge of Agricultural Investigations, American Smelting and Refining Co., Salt Lake City, Utah. (Frost.)

*O’MARA, PATRICK. (Potting.)

Oliver, G. W., Plant-Breeder, U. S. Dept. of Agric, Washington, D. C. (Many articles on palms, aroids, eucalyptus, and rare plants.)

Osman, John C., Landscape Architect, Brookline, Mass. (F. L. Oblate, Parks.)

Oswe, O. E., Plant Propagator, U. S. Plant Introduction Field Station, Chico, Calif. (Culture of many orchids, Border, Osmundine, etc.)

Padock, WENDELD, Prof. of Horticulture, Ohio State University, Columbus, Ohio. (Peach.)

Parsons, Samuel, Landscape Architect, Architects' Bldg., 101 Park Ave., New York City. (Lawns.)

*Peacock, Lawrence K. (Dahila.)

Pearl, A. S., Prof. of the Classics, University of Illinois, Urbana, Ill. (Help on Name-List.)

Peterson, Wm. A., Nurseryman, Chicago, Ill. (Preonia.)

Pfeiffer, W. R. Florist, Cromwell, Conn. (Rose.)
Pilat, C. F., Landscape Architect to the Park Board, 52 Broadway, New York City. (Planting.)

Pope, E. W., Agricultural Explorer, Bur. of Plant Ind., U. S. Dept. of Agric., Washington, D. C. (Culture and botany of many tropical fruits.)

Pate, H. L., Dean of Agricultural Dept., Virginia Agricultural College, Blacksburg, Va. (Virginiana.)

*Prince, L. B. (Wm. Prince.)

Phipp, G. H., Foreman, Exotic Orchid and Aquatic Dept., Missouri Botanical Garden, St. Louis, Mo. (Orchids, Aquatic plants.)

Purdy, C. R., Nurseryman, Specialist in hardy perennials, Ukiah, Calif. (California native plants, as Brodiaea, Caulochortus, etc.)

Raffaelle, C. T., Gardener, Royal Botanic Gardens, Kew, England. (Culture of Achimenes, Calathea, etc.)

Rankin, W. H., Ass't. Prof. Plant Pathology, New York State College of Agriculture, Ithaca, N. Y. (Arboriculture.)

*Rawson, Grove P. (Lantana.)

*Reasoner, E. N. (Banana and many other articles on semi-tropical plants.)

Rendle, Donald, Prof. of Plant Pathology, New York State College of Agriculture, Ithaca, N. Y. (Damping-off, Diseases.)

Reed, Wm. N., 122 W. 25th St., New York City. (Everlastings.)

Reed, J. L., Ph.D., Washington, D. C. (Musa, Nictiana, and several leguminous genera.)

Rixford, G. P., Physiologist, Bur. of Plant Ind., U. S. Dept. of Agric., 1813 Pierce St., San Francisco, Calif. (Ceratocephala, Platicarpa, Zygophyllum.)

Robbins, L. F., Prof. Emeritus of Agriculture, Cornell University: Residence, Berkeley, Calif. (Drainage, Fertility, Manure.)

Robinson, Albert E., Gardener to Louis Ettlinger, Pecksill, N. Y. (Lantana.)

Robinson, B. L., Prof. of Systematic Botany and Curator of the Gray Herbarium, Harvard University, Cambridge, Mass. (Acaparum, Eupatorium.)

Rooding, Geo. C., Nurseryman, Fresno, Calif. (P. C. Rooding, Peach.)

Rogers, Stanley S., Assoc. Prof. of Plant Pathology, College of Agriculture, University of California, Berkeley, Calif. (Ceratocephala, Platicarpa, Zygophyllum.)

Rolph, P. H., Dean, Florida Agricultural College, Dir. Agricultural Experiment Station; Dir. of Cooperative Agricultural Extension Work, Gainesville, Fla. (Ceratocephala, Platicarpa, Zygophyllum.)

Ross, N. J., 448 East 137th St., New York City. (Bromeliaceae.)

Ross, Theodore, Sec. for Agriculture, Charlotte-town, P. E. I. (Prince Edward Island.)

*Roth, F. (Raphus.)

Rover, Richard, Nurseryman, Glenside, Pa. (Notes on culture of many hardy garden herbs.)

Rowlee, W. W., Prof. of Botany, Cornell University, Ithaca, N. Y. (Liatris, Saizia.)

Saull, R. F., Banker, Washington, D. C. (John Saul.)

Schinder, John, & Co., Inc. Flower Bulb Specialists, 2 Stone St., New York City. (Help on Tulips.)

Schmitz, X. E. E., Head Gardener, Horticultural Hall, Fairmount Park, Philadelphia, Pa. (Ferns.)

*Scott, William. (Many cultural articles.)

Sears, F. C., Prof. of Pomology, Massachusetts Agricultural College, Amherst, Mass. (C. R. Prescott.)

*Seavet, Frances Copley. (Railroad-Gardening.)

*Sixton, Joseph. (Pomos-Grass.)

*Shaw, George W., Land Expert, 71 New Montgomery St., San Francisco, Calif. (Bean.)

Shaw, Percy J., Horticulturist, Agricultural College, Truro, N. S. (Nova Scotia.)

Shinn, Charles H., Writer, Northfield, Calif. (Fig., John Rock, James Shinn, Calif., Sequoia.)

*Skore, Robert. (Bedding, Begonia, Marguerite.)

Shull, Geo. H., Prof. of Botany and Genetics, Princeton University, Princeton, N. J. (Xenia.)

*Siegbrecht, H. A., Florist and Nurseryman, New Rochelle, N. Y. (Billbergia, Ficus, Gardens, etc.)

Simons, O. C., Landscape Gardener, 1101 Buena Ave., Chicago, Ill. (Adolph Strauch, Landscape Cemeteries, Shrubbery.)

Simpson, Chas. T., Collaborator, U. S. Dept of Agric., Little River, Fla. (Many notes on Florida plants, P. F. Reasoner.)

*Slingerland, M. V. (Diseases and Insects.)

Smith, Cora A., Teacher of Biology, Erie, Pa. (Birds.)

Smith, Elmer, Florist, Adrian, Mich. (Chrysanthemum.)

Smith, Irving C., Market-Gardener and Fruit-Grower, Ashland, Wis. (Onions.)

*Smith, Jared G. (Many genera of palms.)

*Steele, E. S. (Perugynium-Gardening.)

*Deverts, H. T., Asst. Prof. of Landscape Gardening, College of Agriculture, University of California, Berkeley, Calif. (Fig., Planting lists.)

Stewart, Geo. F., Gardener on the Gen. S. C. Lawrence Estate, Medford, Mass. (Articles on the culture of many greenhouse plants.)

Stewart, John P., Experimenter in Pomology, Experiment Station, State College, Pa. (Pennsylvania.)

Steward, W. M., Editor "Horticulture," Boston, Mass. (Exhibitions.)

Stony, G. E., Prof. of Botany, Vegetable Physiology and Pathology, Massachusetts Agricultural College, Amherst, Mass. (Ectro-Horticulture, Light.)

*Spartey, E. M., State Specialist in Vegetable-Gardening, College of Agriculture, Durham, N. H.; formerly of Canada. (Quebec.)

Stechenhaug, A. V., Prof. of Pomology, College of Agriculture, University of California, Berkeley, Calif. (Storage, Tulips, etc.)

Stonie, C. C., Botanical Assistant, Office of Foreign Seed and Plant Introduction, Washington, D. C. (Carica, Euphorbe.)

*Sturtivant, Edmund D. (Nympheas.)

Collaborators 3559

TANIMURA, ISSA, Dir. of Japan Forage Experiment Station, and Pres. of "Soyobo," Tokyo, Japan. (Dwarfing, Japanese Gardening.)

*TAHAN, W. H. (Many genera of palms.)

TAYLOR, A. D., Landscape Architect, 1900 Euclid Ave., Cleveland, Ohio. (Drainage for Landscape Work.)

TAYLOR, NORMAN, Curator of Brooklyn Botanic Garden, Brooklyn, N. Y. (Many Composite, Palmaceae, and Araliae. Alpine Plants, Boy-Gardening; and many other articles.)

THOMSON, C. H., Asst. Prof. of Horticulture, Massachusetts Agricultural College, Amherst, Mass. (Bryophyllum, Sarcocenta.)

THOMPSON, H. C., Horticulturist, Bur. of Plant Ind., U. S. Dept. of Agric., Washington, D. C. (Strawberry in the South.)

THOMPSON, J. B., Asst. Agronomist of U. S. Experiment Station, Honolulu, Hawaii. (Guam.)

TRELLES, WILLIAM, Prof. of Botany, University of Illinois, Urbana, Ill. (Lilaceous genera as Agave, Aloe, Furcarea, Yucca, etc.; Henry Shaw; Oxalis.)

*TRUCKER, WILLIAM, Specialist in Aquatics, American Museum of Natural History, New York City. (Aquarium, Aquatics, Nymphma, Water-Gardening.)

TUCKER, GILBERT M. (Date, Opunlia, Root-Galls.)

TUCKER, E. S., formerly Assoc. Entomologist, Experiment Station, Baton Rouge, La. (Fertilizers, Lime.)

TUCKER, S. M., Agronomist, Bur. of Plant Ind., U. S. Dept. of Agric., Washington, D. C. (Many vegetables, Landscape Gardening, Village Improvement, Plum.)

TULLINGHER, ROBERT W., Specialist in Rural Engineering, U. S. Dept. of Agric., Washington, D. C. (Machinery.)

TUCKER, E. S., formerly Assoc. Entomologist, Experiment Station, Baton Rouge, La. (Orange.)

*WALKER, ERNEST, formerly Prof. of Horticulture, Alabama Polytechnic Institute, State Horticulturist, Auburn. Late of Bolling Farms, Bolling, Ala. (Arkansas, Watering.)

*WARD, C. W., (Pelargoniums.)

*WARD, R. H. (J. A. Warder.)

WARD, G. F., Prof. of Farm Management, New York State College of Agriculture, Ithaca, N. Y. (Cost-Accounting.)

WATROUS, C. L., Nurseryman, Des Moines, Iowa. (Arboriculture, Iowa.)

WATSON, B. M., Late Instr. in Horticulture, Harvard University (Retired), Plymouth, Mass. (Cocleicum, Cutting, Forcing, House Plants, Winter Protection, Rose, Rhododendrom.)

WATTS, RALPH L., Dean and Director of the School of Agriculture and Experiment Station, State College, Pa. (Celerzy, G. C. Bu, Gabriel Heiser, Tomato.)

WATSON, F. A., Head of Division of Horticulture and Prof. of Landscape Gardening, Massachusetts Agricultural College, Amherst, Mass. (Many vegetables, Landscape Gardening, Village Improvement, Plum.)

WEBBER, H. J., Dir. Citrus Experiment Station, University of California, Riverside, Calif. (Breeding, Castimiroa.)

WEBER, H. J., Manager Agricultural Service Bureau of the American Agricultural Chemical Co., Boston, Mass. (Fertilizers, Lime.)

WHEELER, WILFRID, Sec. Massachusetts Board of Agriculture, Boston, Mass. (Strawberry.)

WHEIR, H. H., Prof. of Plant Pathology, New York State College of Agriculture, Ithaca, N. Y. (Diseases, Fungi, Root-Galli.)

WHIPPLE, O. B., Prof. of Horticulture, State College of Agriculture, Boxeman, Mont. (Apple.)

WHITE, E. A., Prof. of Floriculture, New York State College of Agriculture, Ithaca, N. Y. (Design, Floriculture, Mignonette, Primula.)

WHITE, ELIZABETH C., Grower of Cranberries and Blueberries, New Lisbon, N. Y. (Cranberry.)

*WHITNEY, MILTON. (Irrigation, Soils.)

WHITNEY, W. C., Prof. of Horticulture and Horticulturist to the Experiment Station, University of Missouri, Columbia, Mo. (Extension Teaching, Missouri, several biographies.)

WICKSON, E. J., Prof. of Horticulture, Emeritus, College of Agriculture and Experiment Station, State College, New Mexico. (Nut-Culture in New Mexico.)

WILSON, K. L., Nurseryman, Des Moines, Iowa. (Arboriculture, Iowa.)

WILKINSON, C. S., State Commissioner of Agriculture, Albany, N. Y. (Aricot, Cover-Crops, Spraying, Exhibitions.)

WILSON, WILFORD M., Prof. of Meteorology, New York State College of Agriculture, Ithaca, N. Y. (Prost.)
WINSLOW, R. M., Provincial Horticulturist and Inspector of Fruit Pests, Dept. of Agriculture, Victoria, B. C. (British Columbia.)

WOODBURY, C. G., Prof. of Horticulture, Purdue University, LaFayette, Ind. (W. H. Bagan.)

WOODS, ALBERT F., Dean Colleges of Agriculture and Forestry and Dir. of Experiment Stations, University of Minnesota, University Farm, St. Paul, Minn. (Variation.)

WOOLVERTON, LINUS, Fruit-Grower, Grimsby, Ont. (Many biographical sketches.)

WORK, PAUL, Instr. in Vegetable-Gardening, New York State College of Agriculture, Ithaca, N. Y. (Irrigation, Kitchen-Garden, Vegetable-Gardening.)

WRIGHT, J. HARRISON, Fruit-Grower, Riverside, Calif. (Help on palms.)

WYMAN, A. PHELPS. (Many genera of trees and shrubs.)

ZVOLANEK, ANT. C., Seed-grower, Lompoc, Cali. (Sweet Pea in California.)
CULTIVATOR'S GUIDE TO THE ARTICLES

The numerals refer to pages when the articles are not in the regular alphabetic sequence.

The articles in the Cyclopaedia are of four general classes: (1) cultural directions for the gardener, fruit-grower, vegetable-gardener, florist, and home planter; (2) identification, comprising the botanical accounts of genera, species and varieties; (3) general information about plants, comprising much of the introductory material in Vol. I and articles in the alphabetic text as Autumn Colors, Bull Horn, Color, Standards of Color, Cuttings, Evergreens, Insects, Ivy, Japanese gardens, Landscape gardening, Lawns, Perennials, Pests of fruits, Planting, Rose, Rusts, Shrubs, Roses, Spraying, Trees, and Vines; (4) geographical articles, comprising British North America, Island Dependencies, North American States. The identificational and informational articles appear, for the most part, in regular alphabetic order. The cultural directions, however, are in part contained in class articles of many kinds, inasmuch as they have only indefinite alphabetic designation. With each important generic entry, cultural directions will be found, as under Wisteria, Rhamnus, Ardisia, Pyrola, treatment, With list of lead- Vines: see under Planting, 2684.

The cultural directions, however, are in part contained in class articles of many kinds, inasmuch as they have only indefinite alphabetic designation. With each important generic entry, cultural directions will be found, as under Wisteria, Rhamnus, Ardisia, Pyrola, treatment, With list of lead- Vines: see under Planting, 2684.

The cultural directions, however, are in part contained in class articles of many kinds, inasmuch as they have only indefinite alphabetic designation. With each important generic entry, cultural directions will be found, as under Wisteria, Rhamnus, Ardisia, Pyrola, treatment, With list of lead- Vines: see under Planting, 2684.

1. Leading or important class articles of a cultural or plant-handling character.

Some of the leading class articles, dealing with the cultivation and handling of plants and products and with arrangement of plant materials, are as follows:

- Alpine plants.
- Annuals.
- Ants.
- Aquatics.
- Arboriculture.
- Arboriculture (Symposium), comprising contributed parts on uses, insects and diseases, culture, transplanting, lists.
- Autumn-gardening.
- Bamboo.
- Banks.
- Basket plants.
- Bedding, or bedding-out.
- Bees.
- Birds.
- Bog-gardening; also page 2666.
- Border.
- Botanic garden.
- Bouquet.
- Breeding of plants.
- Bulbs.
- Conifer; also page 258.
- Conservatory.
- Culinary herbs.
- Cut-flower industry.
- Cutting.
- Design, floral.
- Diseases and insects (Symposium), comprising extensive lists, also fungicides, insecticides, sprays.
- Drainage.
- Dwelling.
- Electro-horticulture.
- Elision.
- Everbearing fruit.
- Evergreens.
- Everlastings.
- Exhibitions (Symposium).
- Ferns (Symposium), with lists and culture.
- Fertility.
- Fertilizers.
- Floral designs: see Designs, floral.
- Floriculture.
- Foliage-garden: see Kitchen-garden and flower-garden.
- Forage.
- Forestry.
- Formal-gardening; see under Landscape gardening, 1705.
- Frost.
- Fruit-growing.
- Fumigation: see under Diseases and insects, 1044.
- Fungi.
- Grafting.
- Grasses.
- Greenhouse and management (Symposium).
- Herbals.
- Herbs (Symposium), with lists.
- Horticulture.
- Hotbeds and coldframes.
- House plants.
- Insects: see under Diseases and insects.
- Inspections of horticultural merchandise.
- Irrigation, including sub-irrigation.
- Japanese gardens; see under Landscape gardening, 1709.
- Kitchen-garden and flower-garden (Symposium).
- Labels.
- Landscape gardening (Symposium), including formal gardens, cemeteries, parks, lawn-making, and other.
- Lawns; see under Landscape gardening, 1840.
- Lawn planting; see under Landscape gardening, Herbs, Planting, Arboriculture (see List No, 9, page 3564).
- Layers.
- Light for greenhouses.
- Lists of trees (including Arboriculture), herbs (Herbs), shrubs (Planting); also under Ferns, Orchids, Palms, Machinery and implements (Symposium).
- Mastic.
- Market-gardening.
- Misting.
- Mush-chund-gardening.
- Mushrooms.
- Planting.
- Nut-culture.
- Nuts.
- Orchids (Symposium), comprising different parts; see also to the culture under the alphabetic orchid entries.
- Orchard; see Fruit-growing.
- Packages.
- Parks (Symposium), comprising different phases of botany and treatment, with list of leading palms and their culture.
- Park; see under Landscape gardening, 1801; also 2694.
- Pest control.
- Perennials.
- Perforating-gardening.
- Perforations.
- Planting (Symposium), comprising more than twenty articles on special phases of the work, with lists of shrubs.
- Pollen, Pollination.
- Potting.
- Rooting.
- Railroad-gardening.
- Rock-gardening.
- Rustic work: see under Planting, 2677.
- Scenic; see under Planting, 2681.
- Seaside planting; see under Planting, 2695; 2700; under Fruits, flowers, vegetables, also Arboriculture, 1467, 1472, 1473, 1475.
- Shade-loving plants; see under Planting, 2695; 2700; under Herbs, 1467, 1472, 1473, 1475.
- Shade trees; see under Arboriculture.
- Soil management; fertilizing; cover-crops.
- Solls.
- Tillage machinery, 1942.
- Drainage.
- Mulching.
- Irrigation.
- Manure.
- Fertilizers.
- Lime, in horticulture.
- Compost.
- Pest.
- 3. Insects, diseases, birds, weeds; frost; means of control.
- Ants, 1034.
- Bees.
- Insect injury to trees, 364.
- Milk, 1041.
- Nematodes, 1011.
- Sowbugs.
- Rose insects, 3018.
- Diseases.
- Disease of trees, 368
- Rose diseases, 3018.
- Fungi.
- Fungicide-off.
- Mildew.
- Moths.
- Shrubbery; see under Planting.
- Small-fruits: see the separate articles, as Blackberry, Blueberry, Buffalo berry, Current, Dewberry, Gooseberry, Raspberry, also Fruit-growing, 2672.
- Sprouting-gardening.
- Storage.
- Sub-tropical gardening; see under planting, 2666.
- Succulents; see under Planting, 2672.
- Sun-loving plants; see under Planting, 2695; also Bog-gardening, 2695, 2697-2700, 2703.
- Wall-gardening; see under Plantings, 2658.
- Walks, paths and driveways.
- Water-gardening, see under Planting, 2684, also Bog-gardening, 2695, 2697.
- Aquatic; Aquatics, Nym- phaours, Victoria, and others.
- Watering.
- Wild-gardening; see under Planting, 2658.
- Windbreaks.
- Window-gardening and window-boxes.
- Winter-gardening; see under Planting, 2677.
- Winter protection; see under Planting, 2684.
- Woods; see under Planting, 2692; also Landscape gardening.
- Also articles on the different fruits, flowers, vegetables, trees, shrubs, ornamental plants, in regular alphabetic order.
4. Propagation; breeding.

Seeds and seedage.

Cuttings.

Grafting.

Budding, 1364.

Layering, propagation by, 1831.

Pieces, grafting.

Roses, prop., 3064.

3. Marketing; transportation; inspection; exhibitions.

Marketing of horticultural produce.

Package.

Storage.

Cold-storage.

Transportation.

6. Gardening; greenhouse; floriculture; florists' plants; flower-growing. (See List No. 9, on Landscape Gardening, etc.)

Autumn-gardening.

Basket plants.

Bedding.

Bog-gardening; also 2665.

Border.

Bower.

Flower-garden, 1747.

House plants.

Perfumery-gardening.

Railroad-gardening.

Rock-gardening.

Sea-side-gardening, 2670.

Spring-gardening.

Stove plants.

Subtropical-gardening, 2669.

Vegetables, culture of, 2972.

Wall-gardening, 2850.

Water-gardening, 2658.

Wild-gardening, 2663.

Window-gardening.

Machinery and implements, 1669.

Fence, 1781.

Trellising, 3375.

Potting soils, 3178.

Pots and potting, 2777, 2778.

Osmundine.

Cut-flower industry.

Light, for greenhouses. 1855.

Labels, 1761.

Pruning.

Border.

Piceas, grafting.

Wall-gardening. 2680.

Winter protection, 2684.

Pruning.

Transplanting.

Greenhouse.

Light, for greenhouses, 1855.

Sub-irrigation in greenhouse, 1864.

Conservatory.

Hardy plants, forcing of, 1265.

Floriculture.

Florist's plants.

Cut-flower industry.

Cultural plants.

Forcing.

Alpine plants.

Annuals.

Bulbous.

Biennials.

Bignoniaceae, 602, 651.

Bromeliads, 588.

Bulbs.

Cacti; also Succulents, 2672.

Evergreen.

Ferns.

Fuchsias, treasured.

Hedges.

Orchids.

Palm.

Water-gardening, 2668.

Aquarium.

Aquatics.

7. Vegetable-gardening and vegetables; sweet herbs, and the like.

Vegetable-gardening.

Market-gardening.

Nursery-gardening.

Kitchen-garden.

Vegetable-growing tools and implements, 1953.

Irrigation for vegetable-growers. Vegetables, forcing-houses, 1409.

Vegetables, forcing of, 1264.

Tomatoes, forcing of, 1269.

Artichoke.

Artichokes, Jerusalem.

Asparagus.

Asparagus, fertilizer for, 1227.

Beans.

Bean, fertilizer for, 1228.

Beet.

Beet, fertilizer for, 1225.

Sugar beets, fertilizer for, 1225.

Bushel sprouts.

Cabbage.

Cabbage and cole crops, fertilizer for, 1226.

Carrot.

Carrot, fertilizer for, 1226.

Cauliflower.

Celery.

Celery, fertilizer for, 1227.

Chard.

Chayote (Chich. tall. 3124.

Chard, fertilizer for, 1225.

Chervil.

Chicory.

Chicory, fertilizer for, 1226.

Chives.

Chress, fertilizer for, 1226.

Collards.

Corn.

Corn-salad.

Cucumber.

Cucumber, fertilizer for, 1227.

Cucumber, forcing, 1257.

Eggplant.

Endive.

Endive, fertilizer for, 1226.

Garlic.

Greens.

Horseradish.

Kale.

Kohlrabi, Lape, 1833.

Lettuce, fertilizer for, 1226.

Lettuce, forcing, 1255.

Leek, 1833.

Kohlrabi.

Potato.

Potato, fertilizer for, 1225.

Potato, fertilizer for, 1226.

Potato, fertilizer for, 1227.

Tomato, fertilizer for, 1227.

Tomato, forcing, 1259.

Tomato, fertilizer for, 1226.

Tomato, fertilizers for, 1225.

Tomato, fertilizers for, 1226.

Tomato, fertilizers for, 1227.

Tomato, fertilizers for, 1228.

Tomato, fertilizers for, 1229.

Tomato, fertilizers for, 1226.

Tomato, fertilizers for, 1227.

Tomato, fertilizers for, 1228.

Tomato, fertilizers for, 1229.

Tomato, fertilizers for, 1230.

Tomato, fertilizers for, 1225.

Tomato, fertilizers for, 1226.

Tomato, fertilizers for, 1227.

Tomato, fertilizers for, 1228.

Tomato, fertilizers for, 1229.

Tomato, fertilizers for, 1230.

Tomato, fertilizers for, 1226.

Tomato, fertilizers for, 1227.

Tomato, fertilizers for, 1228.

Tomato, fertilizers for, 1229.

Tomato, fertilizers for, 1230.

Tomato, fertilizers for, 1226.

Tomato, fertilizers for, 1227.

Tomato, fertilizers for, 1228.

Tomato, fertilizers for, 1229.

Tomato, fertilizers for, 1230.

Tomato, fertilizers for, 1226.

Tomato, fertilizers for, 1227.

Tomato, fertilizers for, 1228.

Tomato, fertilizers for, 1229.

Tomato, fertilizers for, 1230.

Tomato, fertilizers for, 1226.

Tomato, fertilizers for, 1227.

Tomato, fertilizers for, 1228.

Tomato, fertilizers for, 1229.

Tomato, fertilizers for, 1230.

Tomato, fertilizers for, 1226.

Tomato, fertilizers for, 1227.

Tomato, fertilizers for, 1228.

Tomato, fertilizers for, 1229.

Tomato, fertilizers for, 1230.

Tomato, fertilizers for, 1226.

Tomato, fertilizers for, 1227.

Tomato, fertilizers for, 1228.

Tomato, fertilizers for, 1229.

Tomato, fertilizers for, 1230.

Tomato, fertilizers for, 1226.

Tomato, fertilizers for, 1227.

Tomato, fertilizers for, 1228.

Tomato, fertilizers for, 1229.

Tomato, fertilizers for, 1230.

Tomato, fertilizers for, 1226.

Tomato, fertilizers for, 1227.

Tomato, fertilizers for, 1228.

Tomato, fertilizers for, 1229.

Tomato, fertilizers for, 1230.

Tomato, fertilizers for, 1226.
Pineapple, fertilizer for, 1225.
Pistacia.
Pot-fruit, forcing of, 1224.
Prune.
Pummelo.
Quince.
Quince, fertilizer for, 1225.
Raspberry.

9. Landscape gardening; lawns and planting; herbs, shrubs, trees.

Landscape gardening.
Landscape extension, 1813.
Design, relation of planting to, 2657.
Designing landscapes, 1783.
Garden cities.
Civic art, horticultural phases of, 1811.

Shrubs and woody plants, lists of, 2660 for Northeast; 2693 for Middle West; 2695 for Midcontinental Region; 2696 for South; 2700 for California.
Shrubbery, 2690.

Vines for California, 2705.
Trumpet-vines, 631.
Vitis.
Hedges.
Osage orange for hedges, 1961.
Privet for hedges, 1950.
Aralia (Rhododendron), 2335.
Lilac (Syringa), 3297.
Evergreens.
Arboretum.
Arboriculture.
Conifers, 358.
Oak (Quercus), 2380.
Pine.
Spruces, ornamental, 2615.

And many other entries under the generic names of trees and shrubs.
ADDITIONAL SPECIES

The first volume of this Cyclopaedia was published in March, 1914. The lists of plants on which it was founded were brought down to the close of 1912, and it was with this date, as stated on page xi, that the Cyclopaedia undertook to cover its task, although subsequent introductions have been inserted up to the closing of the pages so far as possible and as the information has come to hand. Undoubtedly some names were overlooked. Four years and more have passed since the original lists were prepared, and cross-referenced back and forth throughout the letters of the alphabet. Within this time, species have been introduced to cultivation within the United States and Canada, and which may now be described. The present list is not complete for the subtropical parts, and probably not all the introductions have been discovered for the other parts. The commerce in plants is incessant, and the situation is never at rest.

The consultant will probably be disappointed in not finding some of the well-advertised binomials in either the body of the Cyclopaedia or this Supplement. The Editor has a long list of such names, but, without the plants themselves before him, he cannot know what the names mean. They are such as have no botanical standing, and the descriptions in the catalogues do not identify them. Probably some of these binomials represent generic and varietal names, with the species-name omitted. This is a prevalent but very faulty practice, as it obscures all relationships and plunges the subject into confusion. So long as this practice prevails, it is impossible to make clear identification of cultivated plants.

Only in one group does there appear to have been any marked extension of species, and this is in the willows (Salix). Some of the very attractive Chinese and other willows are very recently offered, and the account of that genus is therefore much extended. The additions in the willows are made by Alfred Rehder, as are also the additions and modifications in all the articles originally prepared by him.

††ÅBIES. Page 172.

Delavayi, Franch. (Ketéch Friri, Mast.). (After No. 11 in the treatment of Åbies.) Tall tree, to 200 ft.; young branches yellowish or reddish brown, lustrous, usually glabrous: winter buds obtuse, resinous: Ivs. spreading, crowded, usually blunt and emarginate, strongly recurved at the margins, silvery white below, ½-1 in. long: cones oblong-ovate to oblong-cylindric, usually truncate, deep violet, about 2½ in. long; bracts usually slightly exerted. Ch. China. G.C. III. 39:212 (as A. Fargesii on p. 218).

Faxoniana, Rehd. & Wilson. (After No. 11.) Tall tree, to 120 ft.: young branches yellowish or reddish brown, lustrous, usually glabrous: winter buds obtuse, very resinous: Ivs. crowded, distichously spreading, linear, short-pointed or obtuse to emarginate, ½-1 in. long, silvery white beneath: cones ovoid or ovoid-oblong, usually truncate violet-purple, about 2¼ in. long; bracts exerted. W. China.

recurvata, Mast. (After No. 11.) Tall tree, to 120 ft.: young branches pale yellowish gray, lustrous, glabrous: winter bud slightly pointed, very resinous: Ivs. crowded, spreading or recurved, sometimes falcate, pointed, bright green or glaucous, of about the same color on both sides, about ½ in. on fruiting branches, about 1 in. long and more pointed on young plants: cones oblong-ovoid, usually flattened at the apex, violet-purple before maturity, later gray-brown, about 3 in. long; bracts not exerted. W. China.

squamata, Mast. (After No. 11.) Tall tree, to 120 ft.; bark purplish brown, exfoliating in thin flakes like the river birch: young branches brown, glabrous; winter buds obtuse, very resinous: Ivs. very crowded, ascending, mucronate or obtuse, often falcate, glaucous yellow while young, becoming nearly green, ½-1 in. long: cones oblong-ovoid, obtuse, violet, 2-3 in. long; bracts slightly exerted. W. China. G.C. III. 39:290.

—Very remarkable for its bright purplish brown bark, scaling off in thin flakes. It has violet-purple resinous cones, and short relatively broad leaves.

ALEURITÉS. Page 245.

montana, Wilson. (After No. 11.) Tall tree, to 120 ft.; bark purplish brown, exfoliating in thin flakes like the river birch: young branches brown, glabrous; winter buds obtuse, very resinous: Ivs. very crowded, ascending, mucronate or obtuse, often falcate, glaucous yellow while young, becoming nearly green, ½-1 in. long: cones oblong-ovoid, obtuse, violet, 2-3 in. long; bracts slightly exerted. W. China. G.C. III. 39:290.

AMPELOPSIS. Page 278.

Watsoniana, Wilson (Vitis leceodae, Veitch, not Planch.). (After No. 10.) Tall climbing shrub, with slender forked tendrils, glabrous: Ivs. simply pinnate; lfts. 5, stalked, ovate to ovate-oblong, acuminate, rounded at the base, remotely serrate, bright green above, glaucious beneath, 3-4½ in. long: fls. and frs. not known, but probably not much different from those of A. leceoides to which this species is closely related, but easily distinguished by the always simply pinnate lvs. with fewer and larger lfts. Cent. China. J.H.S. 28:235, figs. 95, 96, erroneously cited under A. lanoides on p. 278 of this work.

ANGOPHORA. Page 288.

intermedia, DC. (Metrosideros floribunda, Smith, not Hort.). Tree, described by Bentham as having rough persistent fibrous bark, the parts nearly or quite glabrous: Ivs. lanceolate to ovate-lanceolate, distinctly stalked, 2-4 in. or more long, sharply acuminate: fls. rather small, in loose corymbs or trichotomous panicles; calyx about 2 lines long or longer, with 5 prominent ribs, the teeth short-subulate. Austral.—In Calif. said to be a very fine drought-resisting shade and avenue tree.

lanceolata, Cav. Described in Calif. as a mediumsized white-fld. tree; by Bentham said to be "a tree of considerable size," with bark deciduous in large smooth flakes, the parts glabrous or essentially so: Ivs. lanceolate, acuminate, 3-5 in. long, distinctly petiolate, with numerous parallel pinate veins: fls. in rather dense terminal clusters, larger and denser than in A. intermedia; calyx about 3 lines long, the teeth shorter and thicker than in A. intermedia. Austral.

AQUILÉGIA. Page 339.

akitenisis, Huth. St. erect, branched above: radical and lower cauline lvs. twice ternate, uppermost cauline lvs. simple, narrowly lanceolate: sepal. oval, longer than the limb of the petals, pale purple when dry; petals with a rather straight spur, limb subtruncate, pale yellow. Japan; intro. as an alpine species, with blue-and-yellow fls.; the author of species does not state its relationships.
ARGYREA

splendens, Sweet. (Convulvulus splendens, Hornem. Lettsomia splendens, Roxbg. Iponma splendens, Sims.) Described by Clarke as "a large climber!" Lvs. elliptic and acuminate, never coriaceous but the base rhomboid or rounded, blade about 7 in. long and petiole 3 in., glabrous above and silky beneath; fls. rose-colored or pale red, in few- or many-flld. pedunculate corymb; corolla tubular-canopanulate, 1 1/2 in. long, the plait hairy outside; sepals tomentose, ovate and obtuse, 1/2 in. long; caps. scarlet, papery. India. B.M. 2925.—Doubtful whether known in this country. The plant in cult. as Convulvulus splendens may be a form of the common morning-glory, Ipomoea purpurea.

BÉBERIS. Page 487.

R-regeliana. No. 2. Fig. 539, represents B. amurensis rather than B. Regeliana, which is probably better considered a variety of B. amurensis, and to be called B. amurenensis var. japonica, Rehd.

lævis, No. 24. The species described under this name is B. atrocarpa, Schneid. (B. lævis, Hort., not Franchet). The true B. lævis is not in cult.; it has more closely serrate dark brownish pubescent leaves and the middle one. W. China. Var. szechuannica, Schneid. (var. mandschurica, Schneid., not Winkler). Tree with widespread branches; lvs. rounded or broadly cuneate at the base, glabrous or nearly so, dull or bluish green above; lateral lobes of scales spreading, half as long as the lanceolate middle one. W. China.

BUDDLEIA. Page 585.

Färquharii, L. Barron (B. asiatica × B. officinalis), (After No. 5.) Intermediate between the parents. Lvs. lanceolate, 4-6 in. long, white or yellowish white beneath; fls. pale mauve, fragrant, in slender spikes forming large terminal panicles to 1 ft. long; the spikes are composed of stalked, 5-7-fld. clusters. Raised by R. & F. Farquhar & Co., Boston, in 1913. Gn.M. 21:155.

CALLISTEMON. Page 630.

Other names, than those described in Vol. II are listed in California, but their botanical standing is in doubt. The best that can be done at present is to make the following statements:

coccineus, Muell. Similar to C. lanceolatus but lvs. smaller, 1-1/2 in. long, pungent and acute; midrib and nerve-like margins prominent but lateral veins inconspicuous: stamens 1/2-1 in. long, red, with yellow anthers: fr. strongly contracted at summit. Austral.

Cunninghamii, Koch. Listed in Calif.: "Lvs. extremely narrow. Growth low and compact." Botanically described as follows: Lvs. elliptical, wide-spreading, pale green, pellucid or sometimes roughish, marginal nerves and veins rather prominent; young lvs. reddish, somewhat silky: stamens scarcely 3 times longer than the petals. Austral.

floribundus pendulus. A trade name used in Calif. for an unknown form recently intro. from European gardens. Described as of compact growth with short slender drooping branches well covered with short broad and rather blunt lvs. Probably a form of C. lanceolatus.

hybrida, DC. Described only from lvs. which are rigid, linear, almost pungent, and with marginal nerves. Not recognized by recent authors. The plant offered in Calif. under this name is probably a garden hybrid from Eu.

C. robustus, and C. splendens are trade names used in Calif. for forms recently intro. from Eu. Their botanical status is unknown.

CELSIA. Page 709.

Arcturus, Jacq. Probably perennial, but sometimes perhaps annual or biennial, differing from C. cretica, among other things, in its long-pedicilled rather than
subsessile fls.: more or less woolly, especially below: lvs. all alternate, canescent beneath, short-petioled, lyrate, the terminal segm.; large and obovate-oblong with cre­nate margins, the later segms. smaller and ovate; caul­ine lvs. few, obovate and slightly clasping; fls. verben­cum-like, yellow, the five spreading lobes oblong, pur¬ple-hairy stamens deflexed and ascending. Crete. B.M. 1962.

CENTAURÉA. Page 712.

orientalis, Linn. (After No. 9.) Perennial, 3 ft., erect and branching, the branches sparingly cobwebby: lvs. coriaceous, glabrous or roughish, pinnatisect into lanceolate or linear divisions: heads yellow-flld. (said to be a red-flld. form); large, ovoid, bracts of involucre pale or colored at tip, the intermediate or outer ones ovate and prominently pinnate. Caucasus region.—A hand­some species, with long-stalked heads. Centaurea is a large genus, with many ornamental species, and other kinds than those described in the Cyclopaedia are likely to come into the trade from time to time as flower-gar­den and border subjects.

CHÆNOMÈLES. Page 727.

japónica. It has been shown recently that Thun­berg, when describing his Pirus japonica, had the spe­cies now called C. Maulei in mind; therefore the name C. japonica, Lindl., must replace the name C. Maulei, and the species called here C. japonica must bear the name C. lagénaria, Koidzumi (Cydonia lagénaria Lois.).; and C. cathayensis should be a variety of it: Var. cathayensis, Rehd. (C. cathayensis, Schneid.). Lvs. narrower, lanceolate, pubescent beneath while young. Cent. China. H.T. 27:2657, 2658. Another variety is: Var. Wilsonii, Rehd. Lvs. covered beneath with a persistent fulvous woolly tomentum. W. China.

C. Maulei, Schneid., becomes C. japonica, Lindl.

CLÉMATIS. Page 787.

No. 14, C. nutans. Var. thyrsoides is now considered a distinct species and has been named:

C. Rehdériana, Crab. (C. nutans var. thyrsoides, Rehd. & Wilson.)

No. 28, C. montana, add: forma platyspála, Rehd. & Wilson. A form of C. montana var. Wilsoni with broadly obovate, rounded or truncate sepals: the fls. are very round in shape and appear at the same time as the lvs.

CÓCOS. Page 812.

schizóphila, Mart. Trunk; 6-9 ft. high: lvs. 6-9 ft. long; segms. 30-40, linear, acuminate, 12-16 in. long: spadix up to 3 ft. long: drupe orange-red. Brazil.—Described as a strong-growing species, useful for plant­ing out in Flá. and Calif.

CÓRNUA. Page 851.

Wáteri, Wang. (After No. 13.) Tree, to 40 ft.; branchlets nearly glabrous: lvs. elliptic, acuminate, broadly cuneate at the base, sometimes nearly rounded, usually crisped at the margin, dark green above, pale green and slightly canescent beneath, with 4 pairs of veins, 2-4 in. long: panicle corymbose, about 3 in. across; style club-shaped: fr. black, about 24 in. across. Cent. China.—This plant has been confused with C. Wilsoniana which is apparently not in cult. and is clearly distinguished by the whitish under side of the lvs. and the cylindric style.

Hémislesi, Schneid. & Wang. (After No. 14.) Shrub, to 20 ft.; branchlets appressed-pubescent at first, becoming glabrous and reddish brown or purple: lvs. ovate to ovate-elliptic, short-acuminate, rounded at the base, with 6-7 pairs of veins, whitish and appressed pubescent beneath, often with brownish hairs along the midrib and veins, 2-3 in. long: corymb umbel-like, 2-3 in. broad, slightly pubescent or with brownish woolly hairs; style cylindric: fr. 2j5 in. across, bluish black. W. China.

CRATÁGUS. Page 878.

coloradensis, A. Nels. (After No. 35.) Low tree, to 12 ft., with glossy brown, sparingly spiny branches: lvs. broadly oval to orbicular, acute, rounded or some­what cuneate at the base, incised and coarsely toothed, sparingly pubescent above, nearly glabrous beneath except pubescent on the midrib and veins, about 2 in. long; pétioles rather short: corymbs many-flld.; pedi­cels and calyx-tube hisrate; stamens 10; styles usually 3: fr. subglobose, about 34 in. across, dark scarlet, with juicy pulp. Colo.

C. Wilsoniana, A. Nels. (After No. 35.) Small tree, to 15 ft.; branchlets glabrous, purple-bush, spiny: lvs. elliptic-ovate or obovate, acute, abruptly narrowed at the base, incised and slightly lobed above the middle, lustrous and sparingly pubescent above, particularly on the veins, glabrous beneath, 1½-2½ in. long: corymb gla­brous; stamens 5-8, with purple anthers: fr. subglobose, 2½ in. across, brown. Colo.

saligina, Greene. (After No. 37.) Tree, to 20 ft., with spreading or drooping branches, spiny; branchlets bright red, glabrous: lvs. oblong-elliptic to rhombo­lanceolate, acute or sometimes rounded at the apex, cuneate at the base, slightly hairy and dark green above, paler green and glabrous beneath, 1½-2 in. long; corymbs glabrous: frs. 2½ in. across; stamens 20, anthers yellow: fr. globose, blue-black, 3½ in. across, with 3-5 nutlets. Colo. S.M. 491. B.B. 482.

CÝPERUS. Page 939.

nervosus, Benth. Plant hairy-pubescent, to 3 ft., perennial: lvs. many, nearly sessile, elliptic or oblong-acute, those on the st. 4 in. long and not prominently nerved, the radical ones narrow-ob lanceolate and with several pairs of strong nerves: fls. deep cobalt-blue, about 1½ in. across, in many lax axillary and terminal racemes which are 3-6 in. long; corolla broadly cam­panulate with a short tube. Himalayan region. B.M. 7513, where it is said to be “the largest-flowered Himalayan Cynoglossum, and a very handsome plant.”

CYPÈRUS. Page 940.

adenophorus, Schrad. About 2 ft. high: culm gla­brous: lvs. shorter than the culm, linear, caninate: umbel 9-14-rayed; umbelules 6-9-rayed; rays 10-20­spiked; spikelets linear-lanceolate, many-flled, 3 lines long, the ind. whitish green: fr. obovate, 3-angled punctate-seabrous. Brazil.—Useful for pots.
DEMÓNOROPS. Page 951.

fissus, Blume. Lf.-segms. many and graceful, 6-8 in. long, lanceolate, subulate-acuminate, pilate, apex penicillate, obtuse; spadix erect, contracted: fr. ovoid-globose, about the size of a small cherry. Borneo.—Foliage described as bronzy green.

DECKÉNIA (after Karl von der Decken, German explorer of East Africa, killed in 1884 by the Somalis). Sometimes misspelled Deckeria: but there is a genus name Deckeria which, however, is regarded as a synonym of Eriactea. Palmae. One species, by some referred to Acanthopus, from the Seychelles, now intro. as a warhouse palm. D. mabillis, Wendl., is a tall palm, reaching 100 ft. and more, and 1 ft. or more in diam.: lvs. pinnate, 10-12 ft. or more long, the sheath 3-6 ft. long and usually spiny; petiole about 1 ft. long, pale green and smooth; pinus narrow, hairy beneath, bily when young; midrib yellow: fls. monocious, in 3's, the middle one female, the male with 9 stamens and minute perianth, the female with imbricate perianth: spadix with slender pendulous branches which are spiny at the base; spathes 2, spiny, seldom exceeding 1 ft.; fr. much compressed, ovoid-deltoid, 3'/2 in. long and 3'/4 in. thick, black turning to straw-colored.

DELFHINIUM. Page 975.

speciosum. The trade name may apply to a showy garden form of undetermined origin. D. speciosum, Bieb., to which the botanical name applies, is a tall gray-tomentose perennial of the Caucasus: st. angled, paniculate above: lvs. palmately parted, the upper ones alternate: fis. crowded in the uppermost axils, sessile; calyx tubular-funnel-shaped, the lobes 5, triangular with a connate at base into a cylindric spike 1 ft. or more long; stipules membranaceous, 4-6 in. long, 1'/2-2 in. broad, obtuse, entire, undulately lobed or coarsely toothed, sometimes deeply and narrowly lobed, acuminate, base rounded, 3-4 in. long; stipules membranaceous, 4-6 in. long, 1'/2-2 in. broad, obtuse, yellowish with brown spots: fr. solitary or clustered, almost globose, pubescent. Natal and Zululand.—Used for the manufacture of native cloth and rough cordage.

DIÁNHTHUS. Page 997.

marginalis. The trade name may represent a marginate or edged form of one of the common annual garden pinks; if D. marginalis, Poiret., it is a perennial of Europe, with linear marginate lvs. and solitary white fls.; calyce scales or bracts acute and shorter than the calyx.

ÉLYMUS. Page 1111.

giganteus, Vahl. Giant Siberian Rye-Grass. A tall species resembling E. condensatus: spike 1 ft. or more long; glumes narrow below, subulate above, longer than the several florets; lemma pubescent, awnless. Siberia.—Sometimes cult. as an ornamental.

ERÉMURUS. Page 1128.

turkestánicus, Regel. Plant about 4 ft. high, with very long and dense terminal raceme of reddish brown fls. with long-exserted stamens and white-margined perianth-segms.: lvs. broadly linear, acuminate. Turkestan.

EUCAÝLPTUS. Page 1152.

álba, Reinw. (E. platypodióla, F. v. M.). Related to E. popúlifólia, but lvs. much more variable, from lanceolate to broadly ovate or almost orbicular, acute to cordate at base, mostly 3 in. long; umbels in the axils, unifl., 1-7-fld.; pedicels short or almost none, angular: cap hemispherical, low: valves slightly protruding. Austral. Maiden, Crit. Rev. Eucal. 105, 106, 107.—Growing at Las Angeles.

EUßATÓRIUM. Page 1166, after No. 22 (but lvs. stalked).

serécinum, Michx. An attractive species, 4-8 ft. high, with grayish white numerous fls. in a broad, cymose infl.: branching, pubescent at least above: lvs. ovate-lanceolate, long-acuminate, 3-7-10 in.; stipules membranaceous, 3-7-10 in. long: fr. 7-15 in the campanulate involucre, of which the bracts are obtuse or truncate. Minn., south and southeast.

ÉVÓDIA. Page 1155.

hypéhénzis, Dode. (After E. Henryi.) Tree, to 60 ft.: lfts. 7-9, short-stalked, elliptic-ovate to elliptic-lanceolate, long-acuminate, rounded or rarely narrowed at the base, glaucescent or pale green beneath and glau­eous or nearly so except villous in the axis of the veins, 3-6 in. long: infl. slightly pubescent, 4-5 in. broad: fr. beaked, yellowish grey, slightly hairy. Cent. China.

FÍCUS. Page 1229.

ulmifólia, Lam. (F. sinuósa, Miq.). Shrub, 9-15 ft. high: lvs. alternate, variable, very harsh, oblong, sub­entire, undulate lobed or coarsely toothed, sometimes deeply and narrowly lobed, acuminate, base rounded, 3-4 in. long; stipules membranaceous, 4-6 in. long, 1'/2-2 in. broad; fr. axil­lary, solitary or in pairs, orange-red to purplish, ovoid to ellipsoid, about 3'/4 in. long. Philippines.

útillus, Sim. Large tree: lvs. elliptic-cordate, 6-10 in. long; 4-5 in. broad, obtuse, leathery; petiole thick, 2-4 in. long; stipules membranaceous, 4-6 in. long, 1'/2-2 in. broad, obtuse, yellowish with brown spots: fr. solitary or clustered, almost globose, pubescent. Natal and Zululand.—Used for the manufacture of native cloth and rough cordage.

GALÉGA. Page 1311.

bicolor, Hausskn. Perhaps a form of G. officinalis: lfts. oblong-linear rather than oblong-lanceolate, often retuse: raceme more lax or open: calyx-teeth mostly shorter than the tube rather than longer: standard deep blue, the wings and keel whislh blue. Mesopotamia.

GENTIÁNA. Page 1323.

tibética, King. A Himalayan species of which no close relatives from that region are described in this Cyclopædia, and which now appears as a name in the trade. Described by King as follows: st. very stout, erect, 18 in. high, simple: st.-lvs. 6 in. long, lanceolate, connate at base into a cylindrical sheath, the uppermost sessile and whorled and forming an involucre to the infl. fls. crowded in the uppermost axils, sessile: calyx tubular, membranaceous, truncate, split on one side, the mouth minutely 5-toothed; corolla nearly 1 in. long, tubular-funnel-shaped, the lobes 5, triangular with a triangular fold in each sinus: caps. included; seeds elliptical.

HELICHRÝSUM. Page 1450, after H. arenarium.

angustifólium, DC. Subshrub, the many virgate stts. oppressed-canescent: lvs. linear, odorous, margins revolute: fl.-heads in a compound lax terminal corymb, small, oblong-cylindric, the pale involucre with few imbricate scarious obtuse scales. S. Eu.—said to be a good plant for edgings, with white foliage.

HITEBS. Page 1483.

The names H. cruéntus and H. Lambertianus in lists are probably forms of H. Rose-sinensis; however, the botanical species bearing these names may be described, as surely:

cruéntus, Bertol. St. erect, unarmed: lvs. petiolo, palmately 3-6-fld, base cuneate, lobes oblong, lanceolate, obtuse, obtusely crenate: fls. racemose, red, 2-3 or solitary; outer calyx half shorter than the inner, many-parted, the segms. lanceolate-linear, acuminate, inner deeply 5-fld, much larger, about 1 in. long: caps. ovate. Guatemala.
HIBISCUS

LamBERTIÀNUS, H.B.K. Herb: st. simple, 6 ft. high, aculeate, minutely pilose: lvs. petioled, ovate-lanceolate, acuminate, base rounded, serrate, hispulate and green above, below canescent-tritomentose, 5 in. or more long; stipules linear-subulate: fls. axillary, solitary, pedunculate, large; calyx double, outer 11-parted, divisions linear, inner campanulate, 5-parted; corolla 5-parted, unequally oblong, apex rotundate, base cuneate. Venezuela.

ÍNULA. Page 1555, after J. hirta.

montana, Linn. Perennial, with erect mostly 1-headed villous st.: lvs.-lanceolate, entire, villous, the radical ones narrowed into petiole: outer involucre scales oblong-lanceolate and somewhat obsolescent, the inner ones acute: achenes hairy: plant about 1-1½ ft. high, the heads bearing many narrow yellow rays. S. Eu.

IRIS. Section Evansia, species 1-5, page 1669.

gracilipes, Gray. Rootstock slender and branched: lvs. 3-4, radical, linear and grass-like, becoming 1 ft. long: peduncle filiform, about the length of the lvs., 1-3-headed: fl. solitary and sessile in the scarious I-1vld. spathe, lilac; tube exceeding the 3-angled ovary, the segments oblong-lanceolate, the outer 2 long glabrous; crest yellow; stigma 2-fid, cut. N. Japan.—Small plant, about 8 in. high, flowering freely in May.

JUNIPERUS. Page 1728.

chinensis var. procumbens, No. 11. Under this name apparently three different forms have been confused; these are:

chinensis var. japonica, Vilm. (J. japonica, Carr.). A dwarf shrub with foliage mostly of the juvenile type; of this two forms are in cult.: Var. japonica aürea, Bean (J. chinensis var. procumbens aürea, Beiss.). Of more spreading habit with a few long branches, the young growth yellow golden. Var. japonica aüreo-variegata, Bean (J. chinensis var. procumbens aüreo-variegata, Beiss.). Of more compact and upright habit, the young growth variegated with golden yellow.

chinensis var. Sargentii, Henry. A prostrate form with long spreading stems, the lateral branchlets ascending, forming dense mats; lvs. on young plants almost all acicular and grass-green, on fruiting plants all or nearly all scale-like and bluish green. Japan.—As a ground-cover this juniper is one of the most valuable. Intro. in 1892 to the Arnold Arboretum by Sargent and subsequently distributed as J. chinensis var. procumbens.

procumbens, Sieb. (J. chinensis var. procumbens, Endl.). Low prostrate shrub with the branches ascending at the ends: lvs. bluish green or glaucous, all acicular, in 3's, lanceolate, pungent, with a broad white band above divided near the apex by the green midrib: fr. not known. Japan.—Closely related to J. squarrosa. Winter.
NEPHROLEPIS

a. *Nephrolepis exaltata* and its varieties.

*b. Forms with once-pinnate foliage.*

- *exaltata*: with species, tropics generally.
- *bostoniensis*.
- *Childsii*.
- *Davallii*.
- *Dwarf Boston*.
- *Emontoniensis* (English) *falcata*. (There is also an *English falcata*).
- *Grettni*.
- *Grunatri*.

**BBB. Forms with twice-pinnate foliage.**

- *Anna Foster*.
- *Goodly Pierson (parentage uncertain)*.
- *Barrowsi*.
- *Clarkii*.
- *Dumplex Barrosei*.
- *Elmsfordi*.
- *Fosteriana (same as Anna Foster)*.

**BBBB. Forms with thrice-pinnate foliage (sometimes producing 2-pinnate forms).**

- *Clarkii*.
- *elegantissima*.
- *elegantissima "improved."
- *elegantissima compacta*
- *elegantissima cristata* (English).
- *exaltata cristata* (Eng.).
- *Galvestoni*.
- *Icyporoides* (English).
- *muscosa*.
- *Piersonii compacta (elegantissima compacta)*.

**BBBBB. Forms with 4-pinnate foliage.**

- *Amerophili*.
- *dissecta* (English).
- *Glandii*.
- "gracillima" (not certainly the original gracillima of Barrows).
- *magnifica*.

**BBB. Forms with 5-pinnate foliage.**

- *Craigi*.

**AAP. Nephrolepis varieties and species other than exaltata.**

- *acuminata*.
- *acuta*.
- *Barteri*.
- *Bausei*.
- *bisserrata*.
- *bisserrata (davallioideus) furcans*.
- *bisserrata furcans minor (davallioideus furcans minor)*.
- *bisserrata var. (Undetermined form)*.
- *concinna* (English).
- *cordata compacta: cordifolia compacta*.
- *cordifolia compacta*.
- *cordifolia gigantea*.
- *cordifolia elegans*.
- *cordifolia tessellata*.
- *crispata congesta*.
- *davallioideus: bisserrata*.
- *davallioideus furcans: bisserrata furcans*.
- *Duffii*.
- *enfolia* (English).
- *enfolia (= *enfolia*).
- "exaltata furcans" = bisserrata furcans.
- "exaltata grandiceps" = bisserrata furcans minor.

**PELARGONIUM.**

Page 2532.

- *acerifolium*, L'Her. One of the Pelargonium section, allied to No. 20, inserted here because *Geranium citriodorum* is a name in the trade and the G. citriodorum, Cav., is considered to be referable to *P. acerifolium*: the species *P. acerifolium* is shrubby or subshrubby, 6-8 ft. tall, glaucous-green, differing from *P. angulosum* (of which Harvey makes it a variety) in having the lvs. more cuneate at base, more deeply lobed, and more scabrous. S. Afr.—Knuth, in his recent Monograph, keeps the species distinct.

**ALFRED B. BENEDICT.**

**NYMPHAEA.** Page 2310.

- *ovalifolia*. (After No. 4.) The plant called *Nymphaea ovalifolia*, as intro. into gardens in 1916, is from newly imported African seed, and was first raised by E. T. Harvey, of Cincinnati. It is not the true *N. ovalifolia*, Conard. The new plant has more oval lvs. than *N. cerulea*, and larger and paler fls. It is to be regarded as a form of *N. cerulea*, deserving a personal name rather than a Latin name. In 1908 Gilg of Berlin described 6 new species of African water-lilies, all allied to *N. cerulea*. The new form here mentioned falls between *N. magenta* and *N. spectabilis* of Gilg, having certain characteristics of both species. The plant is "a prodigious grower, the fl.-stalks extending 10 or more ft." The fl. is "a rich cream color tipped with blue at the end of the petals." (Quotations from letters from Mr. Harvey.) Petals 20; stamens 92; carpels 21; sepals thickly marked outside with black lines and dots. Fl. 6-8 in. across. (Data from specimens furnished by Mr. Harvey.)

**PASANIA.** Page 2479.

- *P. acerifolium*: apparently not in cult. Lvs. narrowly elliptic, with large irregular brown blotches above but plain green beneath: fls. deep blue, closed in dull weather.

- H. S. CONARD.

**PÁSÁNIA.** Page 2470.

- *P. acerifolium*: apparently not in cult. Lvs. narrowly elliptic, with large irregular brown blotches above but plain green beneath: fls. deep blue, closed in dull weather.
RHODODENDRON. Page 2938.

In the Suppl. List under R. Culverwellii, strike out var. wollense, which has turned out to be nothing but R. divaricatum (see Kew Bull. 1914:382).

SALIX. Pages 3052.

To No. 6, after var. decipiens, W. D. Koch (S. decipiens, Hoffm.) add: Var. bullata, Spaeth (S. bullata, Hort.). Forms a compact subshrub bush.

Between Nos. 6 and 7 insert:

To No. 7, add the following variety: Var. calva. C. F. W. May. (S. alba var. calva, Smith.). Of pyramidal habit: lvs. larger, at maturity glabrescent, more bluish green above and more glaucous below.

After No. 7 insert:

hexandra, Ehrh. (S. alba × S. pentandra). Low tree; mature branchlets glabrous: lvs. lanceolate, green on both sides, silky at first, becoming glabrous: cymes like those of S. alba; stamens 4-5. In Eu., with the parents.

After Salix No. 17 invert several species and hybrids, as follows:

latifolia, Forbes (S. Câpea × S. myrsinifolia). Shrub: branchlets pubescent: lvs. oval or oblong to oblong-obovate, usually acute, irregularly serrate, dark green and finally glabrous above, glaucous and silky below at first, finally glabrescent; ovary thinly silky or partly glabrous. Occurs with the parents.

Erdinger, Kern. (S. Câpea × S. daphnoides). Tall, arborecent shrub: young branchlets short-pubescent, older branchlets glabrous: lvs. obovate-oblong to oblong, acuminate, usually narrowed at base, entire or slightly serrate, pubescent while young, nearly glabrous at maturity: ovary usually glabrous or thinly silky. Occurs with the parents. Var. cremenesis, Rehd. (S. cremenesis, Kern.). Closer to S. Caprea: lvs. broader, more densely pubescent beneath: ovary silky.

Winterianâ, Gren. &. Godr. (S. Câpea × S. purpurea). Shrub with upright branches: young branchlets sparingly short-pubescent, later glabrous, brown: lvs. obovate or oblong to oblong-lanceolate, acuminate, usually narrowed at base, irregularly serrate, thinly silky-pubescent while young, later glabrous, dark green and lustrous above, glaucous below: stamens connate at base; ovary grayish pubescent. Occurs with the parents.

cinerea, Linn. Large shrub or small tree, to 25 ft.: 1- and 2-year-old branchlets tomentose: stipules often persistent: lvs. obovate or elliptic, acute or rounded, narrowed or rounded at the base, irregularly serrate, pubescent on both sides, 1½-2½ in. long: catkins sessile, before the lvs.; staminate ovoid; filaments pilose, free; pistillate cylindrical; ovary pubescent; style very short or wanting. April. Eu., N. Af., W. and N. Asir. Var. eelifolia, Rechb. (var. angustifolia, Doll.). Lvs. elliptic-lanceolate.

Lestadiâna, Hartm. (S. cinerea × S. lapponum. S. canescens, Fries). Low or medium-sized shrub: young branchlets pubescent, older glabrous: lvs. obovate to oblong, acute or short-rounded, narrowed at the base, irregularly serrate or entire, pubescent above, tomentose beneath: lvs. before the lvs.; stamens sparingly hairy at the base; ovary pubescent; style to one-third as long as ovary. N. Eu. with the parents.
A very variable glabrous, style slender. Eu., W. Asia to Kamchatka.

aula, Linn. Shrub, 3–8 ft.: branches spreading, unifoliate, glabrous: lvs. elliptic to lanceolate, acute, cuneate or rarely obtuse at the base, irregularly serrate, pubescent when young, later glabrous above, glabrescent and glaucous beneath: catkins on short, often leafy stalks; stamens usually connate one-half; ovary pubescent with short style. Eu. with the parents.

ambigua, Ehrh. (S. aulsa × S. répens). Shrub, about 3 ft., ovary peeping st.: branches glabrous: lvs. elliptic to lanceolate, obtuse, pubescent, later glabrescent above, about 1 in. long: catkins a little before the lvs.; ovary pubescent; style rather long. In Eu. with the parents.

ludiciana, White. (S. aulsa × S. phylicifolia). Shrub: branches glabrous at maturity: stamens usually persistent: lvs. elliptic to narrowly oblong-obovate, crenulate, glabrous at maturity, glaucous beneath: catkins rather small, on leafy stalks, cylindric; ovary pubescent. N. Eu., with the parents.

sesquifolia, White. (S. aulsa × S. phylicifolia × S. purpurea). Intermediate in general appearance between S. aulsa and S. phylicifolia: lvs. in shape like the former but with the nervation of the latter and nearly glabrous at maturity: stamens quite connate; ovary pubescent with slender style. Observed in England with the parents.

grandifolia, Scop. (S. appendiculata, Vill.). Shrub, to 10 ft., with spreading branches: branches tomentose while young; stamens often conspicuous, semi-cordate: lvs. oval to obovate-lanceolate, acute, cuneate or rounded at the base, crenately serrate, glabrous at maturity except the pubescent midrib beneath, dark green above, light green or glaucous and reticulate beneath, 4–6 in. long: catkins before or with the lvs. on short stalks with small bract-like lvs.; stamens hairy below; ovary long-stalked, pubescent; style short. Higher mountains of Cent. and S. Eu.

nerifolia, Schleich. (S. grandifolia × S. purpurea. S. Pontederina, Schleich., not Willd. S. austriaca, Kerner). Shrub, to 6 ft., with upright slender branches: young branchlets pubescent, later glabrous, greenish or brown: stamens rather narrow: lvs. obvoate-lanceolate to lanceolate, acute, serrulate, glabrous at maturity, glaucous and reticulate beneath, 2–3 in. long: catkins shortly before the lvs.; filaments more or less connate; ovary pubescent; with very short style. Cent. Eu. with the parents.

mysirifolia, Salisb. (S. nigricans, Smith. × S. vadanca, Cháix.). Shrub, to 12 ft.: branchlets hairy or glabrescent, dull: stamens often rather large, subcordate: lvs. varying from elliptic, or rarely suborbicular to oblong-obovate or broadly lanceolate, usually acute, rounded at the base, crenate to nearly entire, glabrous or glabrescent above, more or less pubescent beneath, 1–3 in. long, usually blackish when dried: catkins with or a little before the lvs., short-stalked, bracted or leafy at the base; staminate rarely exceeding the style; ovary glabrous, style slender. Eu., W. Asia to Kamchatka.

tetraglia, Smith (S. myricifólia × S. phylicifólia). Intermediate between the closely related parents. It can best be recognized by the combination in various degrees of the characters of the two species which are chiefly the duller and more pubescent branches and lvs. and the larger stamens of S. myricifólia and the more shining and glabrous branches and lvs. and the smaller stamens of S. phylicifólia. Occurs in Eu. between the parents.

phylicifolia, Linn. (S. major, Ehrh.). Upright shrub, to 3 or rarely 8 ft., with stiff and rather short branches: branches glabrous, polished: stamens small, caducous, or wanting: lvs. short-petioled, elliptic or elliptic-oblong, acute, rounded at base, nearly entire or minutely crenate-serrate, glabrous at maturity, yellowish green and glossy above, glaucous beneath, 1–3 in. long, not black when dried: catkins before or with the lvs., on short leafy stalks; ovary pubescent or sometimes glabrous, stalked; style rather long. N. and Cent. Eu., N. Asia.

After Salix, No. 24, insert three:

stipularis, Smith (S. cinerea × S. viminála. S. holoóvrea, Willd.). Shrub or small tree: branches long and stout, persistently pubescent: lvs. lanceolate to oblong-obovate, acute or acuminate, irregularly serrulate or crenulate, hairy on both sides, more densely beneath, 3–7 in. long: catkins before the lvs., short-stalked or nearly sessile; stamens very long; ovary stalked, pubescent, with short style and slender stigmas. Eu., N. Asia, with the parents.

daphnoides, Vill. Tall shrub, to 30 ft., rarely tree: branches yellowish or brownish, bloomy, glabrous; stamens cordate: lvs. short-stalked, lanceolate, acuminate, glandular-serrulate, glabrous, glaucous beneath, 1½–3 in. long: catkins sessile, before the lvs.; staminate nearly 2 in. long, filaments sometimes united at the base; pistillate rather shorter; ovary short-stalked, glabrous, with long style. N. and Cent. Eu., N. and Cent. Asia.

After Salix, No. 27, insert three:

Piperi, Bebb. Shrub, to 20 ft.: branchlets glabrous, dark brown: lvs. elliptic-oblong, obovate or ob lanceolate, acute, undulate crenate or nearly entire, glabrous, glaucous beneath, 4–6 in. long: catkins sessile or short-peduncled; stamens united or free at base; ovary smooth; style rather long. Wash.

hastata, Linn. Shrub, to 6 ft., young branchlets pubescent, older glabrous, brown: stamens often very large, obliquely ovate: lvs. elliptic or ovate, acute, glabrous, irregularly serrulate, 1½–2½ in. long: catkins with the lvs., in leafy stalks; filaments glabrous; ovary glabrous, style rather long. Eu., N. and Cent. Asia.

glabra, Scop. Low shrub, to 4 ft., with short, stout branches: young branchlets glabrous, brown: lvs. broadly oval or ovate to oblong, acute, rarely obtuse at the ends, minutely crenulate, glabrous, glaucous beneath, 1½–3 in. long: catkins with the lvs., on leafy stalks: filaments pubescent at the base; ovary stalked, glabrous, style rather long. Cent. Eu.

After Salix, No. 29, insert two:

Reuteri, Mortizii (S. daphnoides × S. inéna, S. Wimmer, Kerner). Tall shrub: young branchlets densely pubescent, older brown, glabrous, often bloomy: stamens small, lanceolate; lvs. lanceolate or narrowly...
lanceolate, acute at both ends, serrulate, silky pubescent while young, glabrescent at maturity, dark green above, glaucescent beneath, 1½–3 in. long; catkins before the lvs., nearly sessile, cylindric; staminate 1–1½ in. long; ovary short-stalked, glabrous, with short style. Cent. Eu., with the parents.

**gracilista**, Miq. (S. Thunbergiana, Blume). Shrub: young branchlets tomentose, older reddish brown: stipules cordate: lvs. oblong-obovate to oblong-lanceolate, acute at both ends, serrulate, pubescent when young, later glabrous above, thinly pubescent and glaucescent below with prominent veins, 2–4 in. long: catkins cylindric, before the lvs., sessile; staminate 1–1½ in. long, stamens 2, with connate filaments; pistillate longer; ovary pubescent with long and slender style. Japan.

To *Salix*, No. 30, add the following varieties:

**Var. Lambertiana**, W. D. Koch. Lvs. broader, generally obovate-lanceolate, more abruptly acuminate, usually more rounded at the base, up to 4 in. long and ¾ in. broad. **Var. sericea**, W. D. Koch. Lvs. silky when young, becoming glabrous. Here belongs the "Kecks Willow" (var. *Kecksi*, Hort.). **Var. amplexicaulis**, Boiss. Lvs. sessile or subsessile, cordate or rounded at the base, acuminate, oblong to oblong-lanceolate, glabrous.

After *Salix* No. 30 insert two:

**rubra**, Huds. (S. purpurea × S. viminalis, S. Forbyana, Smith). Small shrub: young branchlets short-pubescent, older glabrous: lvs. linear to lanceolate-oblong, acute or acuminate, denticulate, pubescent while young, later glabrescent: catkins subsessile, stamens 2, with more or less connate filaments and red anthers; ovary short-stalked, pubescent, with distinct style. Eu., W. to N. E. Asia, with the parents.

**Sieboldiana**, Blume. Upright shrub: young branchlets tomentose, older glabrous: lvs. ovate to oblong, acute, rounded at the base, obtusely serrate, dark green and glabrous above, glaucescent and glabrous below, pubescent only when young, 2–3 in. long: catkins cylindric, short-stalked, with small lvs. at the base; stamens 2, distinct or connate, or only 1; ovary stalked, pubescent, style half as long as ov. ½ or shorter, with short oval stigmas. Japan.

**SOLANUM**. Page 3185.

**giganteum**, Jacq. (next to No. 34). An erect shrub-like plant growing to a height of 10–25 ft.: sts. somewhat woody, thickly set with short, stout prickles and white-woolly with stellate pubescence: lvs. oblong or oblong-elliptical, narrowed at both ends, about 8 in. long by 3 in. broad, smooth above, and white-tomentose beneath: fls. cymose, pale violet or blue; calyx small, hoary, unequally 5-cleft; corolla about ½ in. diam., rather deeply lobed; ovary puberulous: fr. red at maturity and about ¼ in. diam. India and Ceylon.—A tender species flowering under cult. when about 4 ft. in height. It is doubtful whether this species is in the American trade, although probably it is as ornamental as other species more or less grown. The *S. giganteum* of lists may be merely a trade name applied to one of the tall-growing species otherwise described under *Solanum*. W. F. Wight.
NEW COMBINATIONS IN LATIN NAMES

When a species is transferred to another genus, and when a variety is transferred to another species or associated with another species-name or reduced from specific to varietal rank, the names follow them and a "new combination" results. Thus, if an author desires to place the almond in Prunus rather than in Amygdalus, in which Linnaeus originally described it as Amygdalus communis, the new combination Prunus communis results. If Rubus leibostis of Koehne is considered by Zabel to be only a form of R. auratum, the new combination R. auratum var. leibostis, Zabel, results.

To enable botanists and bibliographers to record and trace the different dispositions and properly to understand the standing of various names of relationships, all such new combinations are entered whenever complete synonyms are made.

In the Cyclopedia, it has been the desire to avoid the making of new combinations, as explained on page xi of Vol. I; although, under the exigencies of the work, a very small number has arisen. In Vols. V and VI, many combinations were inevitable, and those were duly published in Rhodora, XVIII, 152–160 (July, 1918); these were largely in the genera Polycarpa, Pyrus, Prunus, Passiflora, Prunus, Stachys, Limonium, Saxifraga, Tropeolum.

A list of several incidental scattered new combinations made in the Cyclopedia itself is here given, so far as desired, without histories, for the easy reference of the bibliographer. These are such combinations as the authors designed to make. Undoubtedly other combinations are mostly of horticultural varieties and of those who have occasion to work over special groups; but these may not be considered here. The new combinations are mostly of horticultural varieties and of species-forms of minor importance. Numberless associations of varietal names cannot be traced to one definite source, as they are found in trade catalogues, periodicals, and other non-botanical publications, or may be customarily employed by horticulturists; these are therefore given the designation "Hort." (hortorum, "of the gardens;" page xvii, Vol. I). In those cases in which no authority is given for varietal rank, the names follow them and a specific to varietal rank, the names follow them and a

Organized as a Joint Committee in 1915, with J. Horace McFarland as Chairman and Harlan P. Kelsey as Secretary. The organizations participating, with list of committees, are as follows:

American Association of Park Superintendents.—Hermin W. Merkel, Forester Zoological Park, New York City; John Dunbar, Assistant Superintendent of Parks, Rochester, New York; Theodore Wirth, Superintendent of Parks, Mnnneapolis, Minnesota.

American Society of Landscape Architects.—Frederick Law Olmsted, Brookline, Massachusetts; Sid. J. Hare, Kansas City, Missouri; William Pitkin, Jr., Rochester, New York; Warren H. Manning, Boston, Massachusetts.

American Pharmaceutical Association.—Dr. H. H. Rusby, Columbia University, New York City; Oliver A. Farwell, Detroit, Michigan; Dr. Lyman F. Kebler, Washington, District of Columbia.

The primary or first-given entries under the genus in every case are the trade names or those used commonly in journals and elsewhere; when these names differ from the Cyclopedia name they are in Ital type; when the same as the Cyclopedia name, they are in black-face type.

A name in parenthesis is one that is used in the trade or in periodicals: thus, "Acanthophenix rubra (Areca)" means that the plant may appear in catalogues under the name Areca. Such entries are cross-references.

The stars (*) denote the names recommended by the American Joint Committee on Horticultural Nomenclature for the use of nurserymen. These markings are made wholly on the responsibility of the Committee, the List being lent for this purpose, and they are not supervised or recommended by the Editor.

While it is desirable that the names used by botanists and horticulturists shall be the same, yet the dealer is confronted with trade conditions which may modify his practice in some cases. The Editor naturally prefers to stand for the accepted botanical names.

To save space, the abbreviation var. (variety) is omitted; but the Editor does not thereby commit himself to the use of trinomials.

STATEMENT OF THE AMERICAN JOINT COMMITTEE ON HORTICULTURAL NOMENCLATURE

At a meeting August 1, 1916, in which the representatives of the American Association of Park Superintendents, and the American Society of Landscape Architects also participated, the same officers were continued and the American Joint Committee on Horticultural Nomenclature was adopted. The representatives of the American Pharmaceutical Association were added to the committee a few weeks later.

Scope of work.

So far as practicable, it is proposed to secure the standardizing of a single botanical name, together with a single vernacular or "common" name for every tree, shrub, and herbaceous plant in the American horticultural trade.

It is probable also that the Joint Committee will undertake later to recommend a list of "plant-name abbreviations," as an aid to those who use plant names daily and continually, such as nurserymen, seedsmen, florists, landscape architects, pharmacists, park officials, and others.

The subjoined starred list of Latin binomials should be considered only as a preliminary report. The magnitude and manifest difficulties of the problem, and lack of time occasioned by the early publication of the last volume of this Cyclopedia, have made it necessary for the Joint Committee to confine its recommendations almost wholly to the "botanical" names of woody plants as given in this "Finding-List." The even more important work of endeavoring to standardize popular or "common" names must follow later.

Practical importance of stability in nomenclature.

The confusion of names in the horticultural plant world is at present so great as to clog popular plant knowledge and actually to limit to no small degree the use of certain trees, shrubs and flowers in our American plantings. The
A striking case of this sort is that of the tree so widely disseminated for street planting under the common name “Carolina Poplar.” Experts on the poplar state that this is probably Populus Eugenia, a hybrid originated in Europe, and that the native Carolina Poplar practically never passes in the trade under that name. In this extreme case the transferred name is so universally accepted by the trade that an attempt to correct the original mistake would be inadvisable at present.

Other causes than mistaken identification of plants have contributed to the existing confusion. These involve differences of opinion and of practice among botanists in regard to plants names when there is no question at all about the identity of the plants. For one thing, in doubtful cases they are not yet wholly agreed upon the rules or “code” which shall apply, to decide which of two or more names shall stand; but these differences are comparatively few. Much more important are differences of personal judgment among botanists as to what constitutes in any given case a sufficient difference between two groups of related plants to place them in different genera, for example, whether the known difference between apples and pears is enough to separate them into two genera, Malus and Pyrus, or is so slight that they should be consolidated into a single genus. The same sort of difference in judgment arises as to what constitutes a sufficient difference to call for separation into distinct species, and as to what are “varieties.” These differences are inevitable and are independent of rules or other arbitrary decisions.

For example, Azaleas is now classed under Rhododendron by some botanists, yet for trade reasons it seems inexpedient to catalogue the Azaleas as Rhododendrons.
in descriptive, euphonious, and short, in distinct contrast to many Latin names. Common names are usually easier to remember by those who are not botanists, and they serve a most useful purpose in linking up the plant with its correct, or accepted scientific name. The Joint Committee expects in the near future to publish in connection with the scientific names a list of common names, with recommendations for horticultural use, believing that such a list will serve purposes of plant knowledge and identification even more effectively than the present starred list of botanical names.

Identification.

As has been stated, a leading cause of plant-name confusion lies in the careless dissemination of plants under a wrong name. In doubtful cases when means are not at hand for positively identifying plants and labeling them properly, it is earnestly urged that adequate specimens (including flowers, fruit, leaves, and roots, where possible) be sent to a competent authority for correct identification and naming, such as Dr. L. H. Bailey, Ithaca, New York; the United States Department of Agriculture, Washington; any well-equipped botanical garden; or the Arnold Arboretum, Jamaica Plain, Massachusetts. Specimens should be pressed and dried smooth, and sent flat between cardboards.

Acknowledgment.

The Joint Committee wishes to acknowledge its gratitude to Dr. Bailey for the opportunity afforded of presenting to the American horticultural public its first efforts toward standardizing plant names through the medium of the "Standard Cyclopedia of Horticulture." Moreover, the Committee has enjoyed the earnest cooperation and advice of Dr. Bailey, and thus the work has been made far more complete and helpful than it could possibly have been otherwise.

Recommendations of the Joint Committee on the use of the Finding-List.

1. The stars (*) denote the names recommended for uniform use by the American horticultural trade, for such period of time as shall elapse until a new list is agreed upon.

2. In cases in which the starred name differs from the Standard Cyclopedia name and the cataloguer or writer for any reason does not wish to use it, the Joint Committee urges the use of the Cyclopedia name rather than the use of a third alternative.

3. When no star appears in the list, as in the case of nearly all the herbaceous plants, the Joint Committee has not yet specifically passed on the names.

4. In cataloguing, the Finding-List will enable one to place other names in parentheses with the name recommended by the Joint Committee, and to use them also as cross-references. Customers seeking a plant will thus be enabled to locate it readily under any of its well-known names if cross-reference is freely used. The Joint Committee believes that there is no better method known of educating the tradesman and public alike to a correct knowledge of plant names and to the consequent adoption of the recommended or standardized name.

Examples: If he were cataloguing certain plants formerly known to systematists as Andromeda, a good treatment would be as follows:

Andromeda floribunda. See Pieris.

And under Pieris the entry would be:

PIERIS (Andromeda) FLORIBUNDA.

(Note: The genus Andromeda is not entirely obsolete, but now includes in America only two species, A. polifolia and A. glaucophylla.)

In some cases, it is only the species that is involved, the genus remaining the same. Thus, the name Magnolia stellata is now used in place of M. Halliana. Perhaps the best entry would be:

Magnolia Halliana. See M. STELLATA.

And again in its proper place carrying description, sizes, and prices—

MAGNOLIA STELLATA (M. Halliana).

Other examples are—

AZALEA NUDIFLORA (Rhododendron nudiflorum).

FRAXINUS NIGRA (F. sambucifolia).

HALESIA TETRAPTERA (H. carolina, Mohrodendron carolinum).

CORNUS STOLONIFERA var. FLAVIRAMEA (var. aurea).

ACER PALMATUM (A. polymorphum) var. ATROPURPUREUM.

These examples will suggest how to make up proper entries. It is further recommended that synonyms introduced in cross-reference or in parentheses always be printed in italics or in smaller type than the accepted standardized name.

5. In cataloguing, labeling, etc., the abbreviation "var." (variety) following a species name may be omitted for the sake of brevity.

The name of a variety or horticultural form is often further abbreviated by omitting the species-name (for example: Acer purpurascens for A. pseudoplatanus var. purpurascens); but this practice is liable to cause confusion, as when specific and varietal names in a given genus are similar or alike, and therefore when a varietal name is so contrasted the abbreviation "v." or "var." should be retained (for example: Acer var. purpurascens for Acer pseudoplatanus var. purpurascens).

6. It is suggested that all tradesmen publishing catalogues or lists print in a conspicuous place a notice similar to the following: "The names of trees and shrubs in this catalogue are based on the recommendations of the American Joint Committee on Horticultural Nomenclature as they appear in Bailey's Standard Cyclopedia of Horticulture, pages 3575 to 3591."

The Joint Committee takes this opportunity to urge all members of the organizations represented in it and all others interested in standardizing plant names to offer criticisms and suggestions for the help and instruction of the Committee in its future work. It is only by persistent effort and cooperation that we may hope to bring reasonable order and understanding out of the existing chaos in plant nomenclature.

Note: This table provides a list of binomials, which are scientific names used in botany. Each entry consists of the genus and species names, separated by a space. The table includes various plant species, each with its common name in parentheses where applicable. The list covers a wide range of plant species, from flowering to coniferous types, and includes both common and scientific names. The table is designed to provide a quick reference for identifying and listing binomials, useful for educational or research purposes.
ARUNDINARIA (Bambusa). *A. auricoma.
- *Falcata.
- *Falcata i.
- folis variegatis; probably *A. Fortunei.

DESMODIUM. D. bicolor: *Lespedeza bicolor.

--- ^japonicum: L. japonica.

--- ^penduliflorum: L. formosa.

--- Koehne (L. Sieboldii not tenable under the rules).

DEUTZIA. D. candidissima; *D. scabra candidissima. 
--- corymbiflora: *D. setchuenensis
corymbiflora.
--- crenata: *D. scabra crenata.
--- *discolor.
--- Fortuni: *D. scabra Fortuni.
--- *gracilis.
--- *Lemoinei.
--- *myriandha.
--- *parviflora.
--- *scabra.
--- *Schneideriana.
--- *Vulgarina.
--- *Watereri: *D. scabra Watereri.

DIANTHUS. D. albus: *Dianthus albus plenus, mirabilis, densis.
--- *myriantha.
--- *Lemoinei.
--- *penduliflorum; 

DEUTZIA. D. albiflora: *D. albiflora.
--- *formosa.

DODONAEA. *D. cuneata. 

DOLICHOS. *D. biflorus.
--- *Bismpetetus: a form of D. Lablab.
--- *japonicus: Pueraria hirtuta: *P. Thunbergiana.
--- *Lablab.
--- *lignosus.
--- *sequispedalis: *Vigna sequispedalis.

DORONICUM. D. australis.

--- caucasicus.
--- *Clusi.
--- *excelsum: D. plantagineum excelsum.
--- *magnificum.
--- *plantagineum.

DRAKE. *D. androsaceae: D. fladnizensis.

DRAZEDA. *D. amabilis: Cordyline amabilis, a form of C. terminalis.

--- australis: C. australis.
--- Baptista: C. Baptista, a form of C. terminalis.
--- demersum.
--- Draco.
--- *fragrans.
--- Godseffiana.
--- *Goldiesiana.
--- *imperialis: C. imperialis, a form of C. terminalis.
--- *indica: C. indica; but often applied to C. australis.
--- Kernerii, a form of D. fragrans.
--- Liddeni: D. fragrans Lindeni.
--- Massangeana: D. fragrans Massangeana.

DROBA. *D. andreanae: D. fladnizensis.

DROBA. *D. andreanae: D. fladnizensis.

DROBA. *D. andreanae: D. fladnizensis.

DROBA. *D. andreanae: D. fladnizensis.

DROBA. *D. andreanae: D. fladnizensis.

DROBA. *D. andreanae: D. fladnizensis.

DROBA. *D. andreanae: D. fladnizensis.

DROBA. *D. andreanae: D. fladnizensis.

DROBA. *D. andreanae: D. fladnizensis.

DROBA. *D. andreanae: D. fladnizensis.

DROBA. *D. andreanae: D. fladnizensis.

DROBA. *D. andreanae: D. fladnizensis.

DROBA. *D. andreanae: D. fladnizensis.

DROBA. *D. andreanae: D. fladnizensis.

DROBA. *D. andreanae: D. fladnizensis.
ECHEVERIA (see *Cotyledon). E. agavoides: Cotyledon agavoides (out equally correct as E. agavoides).
- metallica: E. gibbiflora metallica.
- secunda (Cotyledon).
ECHINACEA (Brauneria). E. angustifolia.
- parviflora: E. purpurea serotina.
- purpurea.
ECHINOCACTUS: *E. viridiflorus:
- Echinocereus viridiflorus.
ECHINOCEREUS: E. viridiflorus.
ECHINOCYSTIS. *E. lobata.
ELEODENDRON. *E. orientale
- Pungens:
- .nacrophylla.
- refiexa:
- *langipes:
- multiflora. *E. longipes.
ELLEAGNUS. *E. angustifolia.
- papyrifera:
- Chrysantha.
ECHENTIALIA. E. cristata.
ELEOPEA. E. canadensis (Anacharis).
ELLEOPEA. E. angustifolia.
ECHIUM. E. fastuosum.
- exaltatus.
- humilis.
ECHINOPS. E. bannaticus.
ECHINOCEREUS viridiflorus.
ECHINOCYSTIS. E. lobata.
ECHINOCYSTIS. E. viridiflorus.
ECHOCACTUS. E. secunda (Cotyledon).
ECHINACEA (see *Cotyledon).
ECHINOCERUS. E. cristata.
ELCHAMIS. E. angustifolia.
- argentea.
- aurea:
- ciliaris.
- cinerea.
- Macrophylla.
- multiforma. *E. longipes.
- Pungens.
- reflexa. E. pungens reflexa.
- Simonii: E. pungens Simonii.
- umbellata.
ELHIS. E. gymnospermus.
ELHIS. E. orientale (Aralia Chabrieri).
ELUSINE. E. barbata nomencl:
- tristachya.
- coracana.
- indic.";
ELODEA. E. canadensis (Anacharis).
ELHIS. E. orientale.
ELIS. E. cristata.
- Stauononii.
ELMUS. E. arenarius.
- Giganteus (page 3568).
- glaucus.
ELMILL. E. spicata: E. flammea (Cacalia).
EMENAMETH. E. penduliflora.
ENKIANTHUS: *E. campanulatus.
- japonicus: *E. perulatus.
EOMECON. E. chionanthus.
EPHECRA. *E. alutissima.
EPIC. *E. repens.
EPILIBRA. E. angustifolium.
- fairtanum.
EPILIBRA. E. angustifolium (out)
- hirsutum.
EPIMEDIUM. E. alpinum.
- colchicum: E. pinnaeolus colchicum.
- diphyllum: Aceranthus diphylla.
- macranthum.
- Muschinenhum.
- nivum: E. macranthum niveum.
- violaceum: E. macranthum violaceum.
EPIPACTIS. E. pubescens: Goodyera pubescens.
EPHYLLUM. E. Makoyanum: Schlumbergera Russeliana.
- truncatum: Zygocactus truncatus.
ERAGROSTIS. E. abyssinica.
- amabilis (Posa).
- elegans: E. interrupta.
- geniculata (Briza).
- maxima.
- minus.
- obtusa.
ERANTHIS. *E. byemalis.
EREMURUS: E. himalacicus.
- robustus.
- turkestanicus (page 3568).
ERIANTHUS. E. Ravenneae.
ERICA. *E. carnea.
- ciliaris.
- cinerea.
- Maackii: supposed to be a hybrid of E. ciliaris X E. Tetralix.
- Mediterranean.
- melanthera.
- persulcata.
- stricta.
- Tetralix.
- vagans.
- vulgaris:
- Calluna vulgaris.
- Wilmoreana: *E. Wilmorei.
ERGERON. E. alpinus.
- aurantiacus.
- bellidifolius: E. pulchellus.
- glabellus.
- glaucus.
- grandiflorus:
- E. speciosus grandiflorus, not E. grandiflorus of botanists.
- intermedius: not identified.
- macronatus (Vittadinia).
- multiradiatus.
- speciosus (Stenactis).
- umbellatus: not identified.
ERNIS. E. alpinus.
ERIOTRYA. *E. japonica (Loquat. Platina).
ERIANGAEA. E. tomentosa.
ERODIUM. E. cicutarium.
- E. maritimum.
- hybridum.
- meridimum.
- Olivenarian.
- planum.
- yuccifolium: E. aquatricum.
ERYNGIUM. E. alpinum.
- Manescavii.
- polyanthemos.
- sideroxylon.
- stuartiana.
- Berteriana.
- jacobeus.
- polyanthemos.
- resinifera.
- robusta.
- rostrata.
- rudis.
- sideroxylen.
- Stuartiana.
- tetricornis.
-と言is.
- virgata.
EUCHARIDUM. E. grandiflorum.
ERYTHRONIUM. A. albidad.
- americanum.
- Californicum.
- citrinum.
- giganteum: E. grandiflorum.
- grandiflorum.
- Hartwegii.
- Hendersonii.
- purpurascens.
- revolutum.
ESCALLONIA. E. Beteriana: *E. pulvulenta.
- *Jeucantha.
- Mgoalsdevia.
- Philippiana: E. virgata.
- rosea: not known botanically.
- rubra: *E. rubra glabriuscula, not E. rubra of botanists.
- *virgata.
ESCHSHOLTZIA. E. alba: a white form of E. Californica.
- aurantica: a form of E. californica.
- californica.
- crocea: E. californica crocea.
- Douglasii: E. californica Douglassi.
- maritima: the cultivated plant is a form of E. californica, not E. maritima of botanists.
- tenuifolia.
- Thorbirnii: a form of E. californica.
EUCALYPTUS. *E. alpina.
- angustifolia.
- incraseata angulosa.
- bicolor.
- Botaniol.
- botryooides.
- cajaputea: E. odorata.
- calophylla.
- citroidora: E. maculate citroidora.
- cornuta.
- corynocalyx.
- crebra.
- diversicolor.
- fibifolia.
- globulus.
- Gunnii.
- hemiphloia.
- incraseata.
- Lehmannii.
- leucoxylen.
- macrophylla.
- maculate.
- mellelora.
- Muelleriana.
- obliqua.
- occidentalis.
- pasciflora: E. coriacea.
- odor.
- Piperita.
- polyanthemos.
- resinifera.
- robusta.
- rostrata.
- rudis.
- sideroxylen.
- Stuartiana.
- tetricornis.
- speakis.
GALLARDIA, continued.
— *maxima: G. aristata.
— *vita: G. pulchella pita.

GALANTHUS. G. nivalis.

GALAX. *G. aphylla.

GALEGA. G. biicolor; probably a form of G. officinalis (page 3568).
— *Hartlandii: G. officinalis Hartlandii.
— *officinalis.

GALEORCHIS. See Orchis.

GALIUM. G. boreale.

GALONIA. G. candidans (Hyacinthus).

GAMOLES. G. Tagetes.

GALEGA. *C. multiflorus.
— *Spartium junceum.

GLADIC. G. puniceus.

GLADIC. G. canariensis.
— *C. scoparius racemosus.
— *C. scoparius fragrans.
— *C. scoparius ciliaris.
— *C. scoparius ciliaris variegata.

GAPPING. *G. eliptica.

GAUTHIERA. *G. procumbens.
— *G. divergens.
— *G. grandiflora.
— *G. officinalis Hartlandii.

GARLANDIA. *G. biloba.

GARDENIA. *G. jasminoides.
— *G. floribunda.
— *G. chiloense miniatum.

GARDENIA. *G. jasminoides Hartlandii.
— *G. floribunda.
— *G. grandiflora.
— *G. flavum.

GARKILIA. G. Lindheimeri.

GAYLUSSA. *G. frondosa.
— *G. armenum.
— *G. officinalis.
— *G. grandiflorum.

GLECHOMA. *G. ciliaris.

GEOXINFO. G. Rothchildiana.

GEOXINFO. G. argenteum.
— *G. lanatum.
— *G. virgineum.
— *G. fruticosus.

GEOXINFO. G. argenteum.
— *G. lanatum.
— *G. virgineum.
— *G. fruticosus.

GEOXINFO. G. argenteum.
— *G. lanatum.
— *G. virgineum.
— *G. fruticosus.

GEOXINFO. G. argenteum.
— *G. lanatum.
— *G. virgineum.
— *G. fruticosus.

GEOXINFO. G. argenteum.
— *G. lanatum.
— *G. virgineum.
— *G. fruticosus.

GEUM. G. atrosanguineum.
— G. acaulis.
— G. officinalis.
— G. tricolor.
— G. arguta.
— G. maritima.
— G. chinens.
— G. fruticosus.
— G. coccineum.
— G. chiloense.
— G. chiloense miniatum.
— G. officinalis Hartlandii.

GEOXINFO. G. argenteum.
— *G. lanatum.
— *G. virgineum.
— *G. fruticosus.

GEOXINFO. G. argenteum.
— *G. lanatum.
— *G. virgineum.
— *G. fruticosus.

GEOXINFO. G. argenteum.
— *G. lanatum.
— *G. virgineum.
— *G. fruticosus.

GEOXINFO. G. argenteum.
— *G. lanatum.
— *G. virgineum.
— *G. fruticosus.

GEOXINFO. G. argenteum.
— *G. lanatum.
— *G. virgineum.
— *G. fruticosus.

GEOXINFO. G. argenteum.
— *G. lanatum.
— *G. virgineum.
— *G. fruticosus.

GEOXINFO. G. argenteum.
— *G. lanatum.
— *G. virgineum.
— *G. fruticosus.
HELIANTHEMUM. *H. alpestre.  
— roseum (Acroclinium).  
— roseum album (Acroclinium).  
—*porcina (Acroclinium).

HELICHRYSUM. *H. angustifolium.  
—*elegans.  
—*paniculata.  
—*radiata.  
—*serrata.  
—*syriacus.  
—*villosum.  
—*squalida.

| Kaempferti (Parfibugion, Senecio) 
| Wilsoniana (see Senecio, page 3153) |
| Ligustrum                   | L. acuminatum                    |
| Amurensis                   |                                |
| Chinense                     | L. sinense                       |
| Corniculum                  | L. corinae                       |
| Ibota                        |                                |
| *Ibota                       |                                |
| *Japonicum                   |                                |
| *Lucidum                     |                                |
| Macracarpum                 | L. acuminatum macrocarpum        |
| Macrophyllum                 | L. lucidum                       |
| Marginitatum                | Probably L. vulgare argenteo-marginatum or auro-marginatum |
| medium                        | *L. acuminatum                   |
| Nepalense                    |                                |
| *Ovaliformes                 |                                |
| *Ouboui                      |                                |
| Regelianum                  | L. Ibota Regelianum              |
| *Sinense                     |                                |
| *Spicatum                     | The cultivated plant is probably L. Masseolangeanum, L. japonicum, L. lucidum or L. nepalense |
| *Vulgare                      |                                |
| Lilium                       | L. auratum                       |
| Batemarie                    |                                |
| Bloomeramia                  | L. Humboldtii                    |
| Bolanderi                    |                                |
LONICERA, continued.
- *fugrantiissima; sometimes also used for L. Standishii.
- *fuchsioideae: *L. Brownii fuchsioidei, not L. fuchsioidei of botanists.
- *gigantea: either L. etrusca pubescens or L. etrusca superba.
- *glaucus: *L. dioica.
- *grandiflora: *L. tatarica grandiflora.
- *Halliana: *L. japonica Halliana.
- *Heckrottii.
- *Henri.
- *involutus.
- *japonica.
- *Ledebouri.
- *Maackii (Chamaecerasus).
- *Morrowii.
- *muendeniensis.
- *muscaviensis.
- *pulchella.
- *oblongifolia.
- *Periclymenum.
- *pileata.
- *pfennigeri.
- *pynenaica.
- *Ruprechtiana.
- *segreziensis.
- *sinensia: *L. Standishii.
- *spinosa (Chamaecerasus). Name sometimes applied to *L. spinosa Albertii.
- *Standishii.
- *Sulivani: *L. prolifera.
- *tatarica.
- *thibetica.
- *trichosantha.
- *virginalis: *L. tatarica virginalis.
- *Xylosteum.

LOPHOSPERMUM. *L. scandes (Maurandia Lophospermum).

LOTUS. *L. Bertholetii.
- *corniculatus.
- *Jacobeus.
- *pelargonchus: *L. Bertholetii.

LUCUMA. *L. mammosa.
- *nervosa.

LUFFA. *L. acutangula (Cucumis).
- *cylindrica.

LUNARIA. *L. biennis: *L. annua.

LUPINUS. *L. affinis.
- *cardinalis: *L. fulgens.
- *Erinus.
- *gracilis: applies to *L. gracilis or L. Erinus gracilis.
- *heterophylla; or the stock may be L. Erinus.
- *pumila: L. Erinus pumila, not L. pumila of botanists.
- *ramosa: L. tenior.
- *scandens: *L. Erinus speciosa, not *L. speciosa of botanists.
- *syphilitica.
- *tenior.
- *Tupa.

LUMARIA. *L. ciliata: Blechnum Moorei.

LONICERA. *L. Albertii: *L. spinosa Albertii (Chamaecerasus).
- *albida: *L. bella albida.
- *aurica: *L. Periclymenum aurea, not L. aurea of botanists.
- *bicolor: *L. Periclymenum bicolor.
- *bella.
- *brachyphylla: a form of *L. japonica.
- *Browallii.
- *canadensis.
- *Caprifolium; but the plant cultivated is perhaps sometimes *L. americanana.
- *chinensis: *L. japonica chinensis.
- *chrysanthana.
- *dioica.
- *falcata.
- *flexuosa: *L. japonica flexuosa.
LYCHNIS, continued.
- grandiflora: L. coronata.
- Haageana.
- plenissima: L. Flos-cuculi plenissima.
- Sieboldii: L. coronata Sieboldii.
- splendens: L. Viscaria splendens.
- Vesperina: L. alba.
- Viscaria (Viscarias).

LYCIUM. *L. barbarum: the plants cultivated as L. barbarum and L. europaeum are usually L. halimifolium or L. chinense; the true species (L. barbarum and L. europaeum) are probably not grown in this country.
- chinense.
- europaeum.
- halimifolium.

LYCOPERSICUM. L. esculentum (Tomato).
- pimpinelliformium.

LYCOPODIUM. L. clavatum.
- complanatum.
- dendroideum: L. obscurum.
- lucidulum.

LYCORIS. L. squamigera (Amaryllis).

LYGODIUM. L. japonicum.
- japonicum: L. japonicum.
- halimifolium.
- europaeum.
- chinense.

LYONIA. L. barystachys.
- ligustrina.

LYRIS. L. barystachys.
- ligustrina.

LYSICHITUS. L. coronatus.
- purpurea.
- Sieboldii.
- Watsonii.

LYTHRUM. L. alatum.
- roseum: L. Salicaria roseum.
- Salicaria.
- virgatum.

MAACKIA. M. amurensis (Chinese).

MAEDELIA. M. ternifolia.

MAIURIA. M. aurantiaca: M. garnetii.
- pomifera: Toxylon pomiferum.

MAGNOLIA. M. grandiflora: M. grandiflora angustifolia.
- grandiflora: M. grandiflora eburneum.
- Nobertiana: *M. Soulangeana Nobertiana.
- *obovata: M. liliflora.
- parviflora.
- purpurea: M. liliflora: M. obovata.
- rustic: *M. Soulangeana rustic.
- salicifolia; sometimes missapplied to M. grandiflora angustifolia.
- Soulangeana.
- speciosa: *M. Soulangeana speciosa.
- stellata.
- stricta: *M. grandiflora exoniensis.
- Thompsoniana.
- tripetala.
- Watsonii.
- Yulan: M. denudata: *M. conspicua.

MAHONIA (Odostemon under American Code). M. Aquifolium.
- Barclaiana.
- Emeryana:
- hypericifolia.
- Hypericum.
- Lophospermum (Lophospermum).

MAHONIA. M. Aquifolium.
- Barclaiana.
- Hypericum.
- Lophospermum (Lophospermum).

MELALEUCA. M. Alternifolia.
- Emeryana:
- hypericifolia.
- Hypericum.
- Lophospermum (Lophospermum).

MELASTOMA. M. alternifolia.
- Emeryana:
- hypericifolia.
- Hypericum.
- Lophospermum (Lophospermum).

MELIA. M. azedarach: M. azedarach umbraculiformis.

MALVA. M. Alcea.
- crispa.
- miniata: Spherical cispalina.
- moschata.

MALVAVISCUS. M. arboreus (Achosan).

MAMMEEA. M. americana.

MANGIFERA. M. indica.

MANETTIA. M. bicolor: some of the stock is probably M. australis.

MANIFERA. M. indica.

MANIHOT. M. utilissima (Cassava).

MARRUBIUM. M. vulgar (Horhound).

MARTHEALLA. M. trinervia.

MARTinezia. M. Caryotafoila.

MARTYRIA. M. Craniolaria: Craniolaria ananassa.
- formosa: M. fragrans.
- lutea.
- proboscidea: M. Louisiana.

MATRICARIA. M. cana: M. Chamomilla parthenoides.
- grandiflora: M. inodoroplentisima not M. grandiflora of botanistes.
- parthenoides.

MATTEUCCIA. M. Struthiopteris (Onoclea).

MATTHIOILA. M. bicornis.
- incana.

MAURANDIA. M. antirrhiniflora: Antirrhinum maurusioides.
- Barclaiana.
- Emeryna: a color form of M. Barclaiana.
- Lophospermum (Lophospermum).

MAYTENUS. M. Boaria.

MECONOPSIS. M. integrifolia.

MEDICAGO. M. arbores.
- sativa (Alfalfa).
- scutellata.

MEDINILLA. M. ambilis: M. Teysmanniana.
- magnifica.

MELALBUSCA. M. alba: *M. armillaris.
- *decussata.
- *ereticifolia.
- *hypericifolia.
- *Vincana.
- *Leucadendron.
- *oppositifolia: *M. hypericifolia.
- *Wilsonii.

MELIA. M. Azedarach.
- umbraculiformis: *M. Azedarach umbraculiformis.
MELIANTHUS. M. major.
MELICOCCA. M. bijuga (Genip).
MELILOTUS. M. alba.
MELISSA. M. officinalis (Balm).
MELOTHRIA. M. punctata (Piloryce).
— scabra.
MENISPERMUM. *M. canadense.
— dauricum.
MENTHA. M. piperita.
— rotundifolia.
— viridis: M. spicata.
MENZELIA. M. aurea. Baill. (M. Lindleyi not tenable under the rules). (Bartonia).
MENYANTHES. M. trifoliata.
MENZIESIA. *M. pilosa.
MERATIA. *M. precox (Chimonanthus).
MERTENSIA. M. ciliata.
MESMBRYANTHEMUM. M. cordifolium.
— crystallinum.
— roseum.
— tricolor: M. luteus alpinus.
— *Callistemon lanceolatus.
MEXICANUS. M. jalapa.
— M. cupreus.
— M. luteus alpinus.
— M. major.
— M. mollis.
— M. Pottsii.
— M. Pottsii.
— M. rosea.
— M. Tiatorinus.
— M. semperflorens.
MIRABILIS. M. Jalapa.
— *M. semperflorens.
MOLINIA. M. crerulea (Aira).
MOLUCCELLA. M. lathyrsoides.
MIMUS. M. fistulosa mollis.
— T. Jonquilla.
— T. incomparabilis.
— T. orientalis.
— T. orientalis.

FINDING-LIST OF BINOMIALS

ODONTOSORIA. O. chinensis (Davallia).

GENOTHERA. Ge. acaulis.
- biennis.
- historta.
- brachycarpa.
- caespitosa.
- Drummondii.
- Fraseri: Ge. glauca Fraseri.
- fruticosa.
- glauca.
- Lamarkiana.
- macrocarpa: Ge. missouriensis.
- Pilgrimii.
- rosea.
- serratula.
- speciosa.
- tetraptera.
- Whitneyi: Godetia grandiflora.
- Youngii: Ge. fruticosa Youngii.

OLEA. *O. europa (Olive).
- fragrans: *Osmanthus fragrans.

OMPHALODES. O. linifolia (Cycno-

OINOCLEA. O. sensibilis.
- Struthiopteris: Matteuccia Struthiopteris.

ONOPORDON. O. tauricum.

ONYCHIUM. O. japonicum.

OPIOGLOSSUM. O. vulgatum.

- platorus: *P. glabratus.
- intermediate: *P. intermedius.
- monogynus: *P. monogynus.
- opulifolius: *P. opulifolius.
- pubescens: *P. malvaceus.
- Ramaleyi: P. bracteatus or P. intermedius.

OPUNTIA. O. chilensis.

ORLEAUS. O. rubra: but O. enneaphylla rosea Is probably N. flavo-virens.
- Zalus, Z. selaginoides.

OROBUS. O. salmonensis.

ORNITHOGALUM. O. arabicum.
- Ficus-indica.
- vulgaris.
- polyantha.

ORIGANUM. O. Majorana (Sweet
Marjoram).

ORCHIS. O. spectabilis: Galeorchis spectabilis (doubtfully separable from the genus Orchis; under that genus it is O. spectabilis).

OREDOXOA. O. regia (Roystonea regia).

ORIGANUM. O. Majorana (Sweet
Marjoram).

ORNITHOGALUM. O. arabicum.
- pyramidal: O. narbonense pyramidal.
- umbellatum.

OROBUS. O. lathyroides: Vicia orbo-
boidea.
- niger: Lathyrus niger.
- verus: Lathyrus vernus.

ORONTIUM. O. aquaticum.

ORYZA. O. sativa (Rice).

OSMANTHUS. *O. Aquifolium.
- *Delavayi.
- *fragrans (Olea).

OSMUNDA. O. cinnamomea.
- Claytoniana.
- gracilis; probably a form of O. regalis.
- palustris: O. regalis.
- regalis.

OSTREA. O. virginica: *O. virginiana.

OTHONNA. O. crassifolia.

OUVIRANDA. O. fenestralis: Aponogeton fenestralis.

OXALIS. O. Acetosella.
- alba: a white form of either O. lasiandra or O. variabilis.
- albiflora: O. variabilis.
- Bowiei.
- cernua.
- Deppei.
- lasiandra.
- rosea; but O. enneaphyta rosea Is perhaps sometimes meant.
- tropoletteta: O. corniculata atro-purpurea.
- validiensis.
- violacea.

OXYDENDRUM. *O. arboreum (Andromeda).

PACHYSTIMA. *P. Canbyi.

PACHYSANDRA. *P. terminalis.

PÆONIA. P. alba: probably P. decora alba.
- albiflora.
- anemonalis: P. officinalis albiflora.
- albo-plena.
- arborea: P. suffruticosa.
- chinensis: P. albo-plena.
- edulis: P. alboflora.
- festiva: either P. albiflora festiva or P. officinalis festiva.
- Humei: P. suffruticosa Humei.
- jutea.
- Moutan: P. suffruticosa.
- officinalis.
- rosea: Probably P. suffruticosa rosea, but possibly P. officinalis albo-plena.
- suffruticosa.
- tenuifolia.

There are many Latin names in the garden forms of Peonv, as P. amabilis, atorubra, bicolour, candidissima, chrysanthemum, Delachii, delicatissima, elegantissima, formosa, fragrantissima, gigantea, grandiflora, nigricans, papaveriflora, Pottata, prolifer, pulcherrima, purpurea, rosea, Thorbeckii, triplum, umbellata, and others.

PALAFOXIA. P. Hookeriana: Polyple-
teris Hookeriana.

PALIURUS. *P. Spinna-Christi.

PANAX. P. ginseng: Dizygotea Veitchii gracilis.
- ornatum: Polyscias Guifoyei monstrosa.
PASSIFLORA, continued.
- mississippi (Tasmania).
- Porrifolii: P. alato-caruca.
- princeps: P. racemosa.
- quadrangularis.
- Van Volzemii.
- violaceum.
PASTINACA. P. sativa (Parasip).
PAULINIA. P. thalictrifolia.
PAULOWNIA. P. imperialis: *P. montemotosa.

PAVIA. *E. flavus: *E. scoulaycha: *E. parvi flora.
- nana: *E. Pavia humilis.
- rubra: *E. Pavia.
PAVONIA. P. hastata. (page 3570).
PHELLEPHERON. P. acerifolium
- nana: *E. Pavia: *E. aculeata.
PAPAVER. P. alpinum.
PARKINSONIA. *P. acuminatus.
PAPAVER. P. alpinum.
PARKINSONIA. *P. acuminatus.
PAPAVER. P. alpinum.
PARKINSONIA. *P. acuminatus.
PAPAVER. P. alpinum.
PARKINSONIA. *P. acuminatus.
PAPAVER. P. alpinum.

PAPAVER. P. acerifolium
- nana: *E. Pavia: *E. aculeata.
PAPAVER. P. alpinum.
PARKINSONIA. *P. acuminatus.
PAPAVER. P. alpinum.
PARKINSONIA. *P. acuminatus.
PAPAVER. P. alpinum.

PAPAVER. P. acerifolium
- nana: *E. Pavia: *E. aculeata.
PAPAVER. P. alpinum.
PHILADELPHUS, continued.
— pubescens; sometimes perhaps means P. laxus.
—sericatus.
—spectabilis: *P. coronarius
—speciosissimus.
—speciosus: *P. laxus.
—Zeyheri.

PHILLYREA. *P. angustifolia (Filariap).—*decora (Filaria).
—*latifolia.

PHILLODENDRON. P. giganteum.
—spectabile.

PHLEBODIUM. P. aureum (Polyodium).

PHILLYREA. *P. angustifolia (Filariap).
—*Zeyheri.
—*speciosus:
—*speciosissimus:

PHLOX. P. amena.
—*decora (Filaria).
—*spectabile.

PHLOMIS. P. tuberosa.

PHLOX. continued.
—*Zeyheri.
—*speciosus:
—*speciosissimus:

PHOSPHATURIA. P. densiflorum.
—bracteatum: *O. bracteatum.
—intermedius: *O. intermedius.
—*monogynus: *O. monogynus.
—*opulifolius (Spira): *O. opulifolius.
—*malvaceus: *O. malvaceus: *O. pubescens.

PHYSOSTEGIA. P. gregilis.

PHYSOSTEGIA. *P. angustifolia (Filariap).
—*speciosa:
—*punctata.
—*maculata.
—*paniculata.

PHYSOSTEGIA. *P. angustifolia (Filariap).
—*punctata:
—*maculata.
—*paniculata.

PHYSOSTEGIA. *P. angustifolia (Filariap).
—*punctata:
—*maculata.
—*paniculata.

PHYSOSTEGIA. *P. angustifolia (Filariap).
—*punctata:
—*maculata.
—*paniculata.

PHYSOSTEGIA. *P. angustifolia (Filariap).
—*punctata:
—*maculata.
—*paniculata.

PHYSOSTEGIA. *P. angustifolia (Filariap).
—*punctata:
—*maculata.
—*paniculata.

PHYSOSTEGIA. *P. angustifolia (Filariap).
—*punctata:
—*maculata.
—*paniculata.

PHYSOSTEGIA. *P. angustifolia (Filariap).
—*punctata:
—*maculata.
—*paniculata.

PHYSOSTEGIA. *P. angustifolia (Filariap).
—*punctata:
—*maculata.
—*paniculata.

PHYSOSTEGIA. *P. angustifolia (Filariap).
—*punctata:
—*maculata.
—*paniculata.

PHYSOSTEGIA. *P. angustifolia (Filariap).
—*punctata:
—*maculata.
—*paniculata.

PHYSOSTEGIA. *P. angustifolia (Filariap).
—*punctata:
—*maculata.
—*paniculata.

PHYSOSTEGIA. *P. angustifolia (Filariap).
—*punctata:
—*maculata.
—*paniculata.

PHYSOSTEGIA. *P. angustifolia (Filariap).
—*punctata:
—*maculata.
—*paniculata.
PLATANUS. *P. acerifolia (this is the tree usually planted as P. orientalis).
— occidentalis.
— orientalis.
— Sieboldii.
PLATYCYRUM. P. alpicerne.
— Stenaria: P. æthiopicum.
— Willinkii.
PLATYCODON. P. album: P. grandiflorum album.
— grandiflorum (Campanula).
— japonicum: P. grandiflorum japonicum.
— Mariesii: P. grandiflorum Mariesii.
PLATYSTEEMON. P. californicus.
PLUMBAGO. *P. capensis.
— Dalmaisiana.
— reptans.
— suaveolens; but the plant in culture is *P. amplexicaule.
— suaveolens.
— Falcatum.
— oleracea (cultivated form).
— Senega.
— Sieboldii.
— sericeum.
POLYGALA. *P. brachypoda.
— monilifera.
— pyramidalis; perhaps a group of hybrids in need of further study.
— deltoides.
— Eugenei (Carolina P., in part)
— fastigiata: *P. nigra italica.
— fortissima.
— Fremontii.
— greja: P. grandidentata; perhaps sometimes P. tremuloides.
— grandidentata.
— italica: *P. nigra italica.
— Maximowiczii.
— monilifera: P. deltoides monilifera.
— nigra.
— pyramidalis: usually means *P. nigra italica (Lombardy Poplar), but name likely to be used for other pyramidal forms, as P. alba pyramidalis and P. tremula pyramidalis.
— Sargentii.
— Simonii.
— 'tremula'.
— tremuloides.
— suaveolens; but the plant in cultivation is *P. Maximowiczii.
PORTERANTHUS (name under American Code). P. stipulacoas: Gilliesia stipulata.
PORTULACA. P. albi flora: P. grandiflora albiflora.
— aurea: P. oleracea.
— grandiflora.
— oleracea (cultivated form).
— Thelassoni: P. grandiflora Thelassoni.
— Thorburnii: P. grandiflora Thorburnii.
POLYPODIUM. P. aureum: Phelebodium aureum.
— falcatum.
— glaucum: Phymatodes glaucum.
— subauriculatum (Goniophlebium).
— vulgare.
PRUNUS, continued.

- *Lusitanica*: *Laurocerasus lusitanica.*
- *Lyonii.*
- *Mallevie.*
- *Marilyma.*
- *melanocarpa*: *P. demissa melanocarpa.*
- *Mume.*
- *Munsoniana.*
- *Myrobalana*: *P. cerasifera.*
- *Nana* (Russian Dwarf Almond): *Amygdalus nana.*
- *nigra.*
- *Padus* (Bird Cherry).
- *pendula*: applied to weeping forms of several species, but oftenest to *P. subhirtella pendula,* one of the Japanese flowering cherries.
- *pennsylvaniaica.*
- *Persica* (Peach): *A. Persica.*
- *Pissardi*: *P. cerasifera Pissardi.*
- *platyrrhynchos*: *P. Persica platyrrhynchos* (Flat Peach): *A. Persica platyrrhynchos.*
- *Pseudo-Cerasus*: *P. serrulata,* also incorrectly used as a general name for other Japanese flowering cherries, as *P. Lannesiana,* probably *P. glandulosa.*
- *Pterocarya.*
- *Pyrus.*
- *Quadripli.*
- *Quadrumagne.*
- *Quercus.*
- *Rhexii*: *P. eretica Rhexii.*
- *Rhus*: *P. Cerasus Rhus.*
- *sachalinensis*: *P. serrulata sachseninensis.*
- *Sargentii*: *P. serrulata sargentii.*
- *semperflorens*: *P. Cerasus semperflorens.*
- *serotina.*
- *serrulata.*
- *sibérica*: *P. Armeniaca sibirica.*
- *Sieboldii* (Japanese Flowering Cherry).
- *Simpsonii.*
- *sitka*: probably *P. glauclosa* and *P. japonica* (Cherry-Almond).
- *spinosa.*
- *subhirtella* (Japanese Flowering Cherry).
- *tomentosa.*
- *triflora*: *P. cerasifera.*
- *triophora*: *P. cerasifera.*
- *virginiana* (Choke-Cherry).
- Watsonii: *P. angustifolia Watsonii* (Sand Plum).

FSIDUM. *P. Cattleyanum.*
- *Friedrichsthalianum.*
- *Gujava.*

PETLEA. *P. aurea*: *P. trifoliata aurea.*
- *trifoliata.*

PTERIDION (doubtfully separable from Pteris). *P. aquilinum* (Pteris).

PTERIS. *P. adiantoides*: not known botanically.
- *aquilinum*: Pteridion aquilinum.
- *argyraea*: P. quadiuira argyraea.
- *Childii*: a form of *P. cretica.*
- *cretica.*
- *hastata*: *Pellina virdis.*
- *intermedia*: Pt. heterophylla intermediata.
- *Mayii*: Pt. cretica Mayii.
- *nobilis*: Pt. cretica nobilis.
- *Ouwardii*: Pt. cerasifera Ouwardii.
- *Rivertoniana*: a form of Pt. cretica serrulata.
- *Sieboldii*: a form of Pt. cretica.
- *tremula.*
- *Wilsonii*: Pt. cretica Wilsonii.
- *P. fraxinifolia.*
- *stenopectera.*

PETROSTYRAK. *P. corymbosa.*
- *hisipida.*

PYCHAGRAPHIS. *P. singaporensis.*

PYCHOSPERMA. *P. Alexandrre: Archontophexicus Alexandrre.*
- Cunninghamam: A. Cunninghamam.
- *elegans*: A. Alexandrre and A. Cunninghamam; the palm cultivated in California under this name is recently named Loroma amethystina (see Seefordth, page 1323).
- *singaporensis*: Pychag aphris singaporensis (page 3571).

PUERARIA. *P. Thunbergiana: P. hirsuta* (Dolichos).

PULMONARIA. *P. angustifolia.*
- *azuera*: *P. angustifolia azurea.*
- *maculata*: *P. officinalis.*
- *saccharata.*

PUNICA. *P. Granatum.*
- *Logei*: a form of *P. Granatum.*
- *nana*: *P. Granatum nana.*

PYRACANTHA. *P. angustifolia* (Cotoneaster).
- *coccinea.*
- *crenulata* (Cotoneaster).
- *Lalandii*: *P. coccinea Lalandii.*

PYRTHRUM. *P. argens: P. argens aureum.*
- *aureum*: C. Parthenium aureum.
- *corymbosum*: C. corymbosum.
- *hybrida*: C. coccineum.
- *parthenifolium*: C. Parthenium.
- *roseum*: C. coccineum.
- *scleroides*: C. Parthenium scleroides.
- *uliginosum*: C. uliginosum.

PYROSTEGIA. *P. venusta*: *Bigonia venusta.*

PYRUS. *P. americana*: *Sorbus americana.*
- *angustifolia*: *Malus angustifolia.*
- *arbifolia*: *Aronia arbifolia.*
- *Arnoldiana*: P. pulcherrima Arnoldiana.
- *Atrosanguinea*: *Malus atrosanguinea.*
- *Aucuparia*: *Sorbus Aucuparia.*
- *baccata*: *Malus baccata.*
- *cerasifera*: *M. cerasifera.*
- *communis* (Pear).
- *coronaria*: *M. coronaria.*
- *florentina*: *P. eretica florentina.*
- *floribunda*: *P. pulcherrima.*
- *fusa*: *M. fusa.*
- *Halliana*: *M. Halliana.*
- *ioensis*: *M. ioensis.*
- *Niedzwetzkyana*: *M. Niedzwetzkyana.*
- *nigra*: *Aronia melanocarpa.*
- *Parkmanii*: P. Halliana Parkmanii.
- *prunifolia*: *M. prunifolia.*
- *pulcherrima*: *M. floribunda.*
- *quercifolia*: Sorbus hybrid: *S. quercifolia.*
- *Ringo*: *P. prunifolia Rinki.*
- *Sargentii*: *M. Sargentii.*
- *Scheideckeri*: P. pulcherrima Scheideckeri.
- *Scheideckeri*: *M. Scheideckeri.*
- *serotina* (Japan Pearl).
- *Sieboldii*: *Malus Toringo.*
- *Sorbus*: *Sorbus domestica.*
- *Soulardii*: *Malus Soulardii.*
- *spectabilis*: *Malus spectabilis.*
- *Zumi*: *M. Zumi.*

QUAMOCLIT. *C. coccinea* (Ipomoea Minia).
- *Ipomea* (Ipomoea).

QUERCUS. *Q. acuta.*
- *afrigola.*
- *alba.*
- *aquatica*: *Q. nigra.*
- *Bartii*: *Q. ilicifolia.*
- *bicolor.*
- *Cerris.*
- *coccinea.*
- *Concordia*: *Q. Robur Concordia.*
- *cuspidata*: *C. cuspidata* (see Vd. V, page 2891).
- *dentata*: but sometimes applied to *Q. glandulifera.*
- *Douglasii.*
- *Duvaucellier*: *Q. Robur Duvaucellier.*
- *falcata.*
- *ferruginea*: *Q. marilandica.*
- *Garryana.*
- *glauca.*
- *Flex.*
- *ilicifolia.*
- *limicola.*
- *Koellogi.*
- *Laurelia.*
- *lobata.*
- *lyrata.*
- *macrocarpa.*
FINDING-LIST OF BINOMIALS 3603

QUERCUS, continued.

—*marilandica.

—*Michauxii (Basket Oak): Q. Prinus.

—montana (see Q. Prinus, below).

—*nigra.

—obtusiloba: *Q. stellata.

—*palustris.

—panonica: *Q. conferta.

—pectinata: *Q. Robur pectinata.

—pedunculata: *Q. Robur.

—*Phellos.

—platanoides: *Q. bicolor.

—Prinus (Basket Oak): applied in the trade to the *Chestnut Oak only, which is Q. montana of the Cyclopedia but for which others retain the name Q. Prinus and apply Q. Michauxii to the Basket Oak: *Q. Michauxii.

—*Prinus (*Chestnut Oak): Q. montana.

—pyramidalis: *Q. Robur fastigiata.

—Prinus: *Q. rubra.

—* sempervirens: *Q. virginiana.

—*Sunder.

—*tincctoria: *Q. velutina.

—*velutina.

—*virginiana.

RADICULA. R. Armoracia (Horseradish). Preferably Roripa Armoracia.

—Nasturtium-aquaticum (Watercress. Preferably Roripa Nasturtium).

RAJANIA. R. pleioneura.

RANUNCULUS. R. acutifolius.

—acris.

—amplexicaulis.

—asiaticus.

—bulbosus.

—gramineus.

—repens.

—spectosus: R. bulbosus.

—*bulbosus.

—*acris.

—asiaticus.

—bulbosus.

—*virginiana.

RANUNCULUS. *R. bulbosus.

—*acris.

—asiaticus.

—bulbosus.

—*virginiana.

RADICULA. R. Armoracia (Horseradish). Preferably Roripa Armoracia.

—Nasturtium-aquaticum (Watercress. Preferably Roripa Nasturtium).

RAJANIA. R. pleioneura.

RANUNCULUS. R. acutifolius.

—acris.

—amplexicaulis.

—asiaticus.

—bulbosus.

—gramineus.

—repens.

—spectosus: R. bulbosus.

—*bulbosus.

—*acris.

—asiaticus.

—bulbosus.

—*virginiana.

RANUNCULUS. *R. bulbosus.

—*acris.

—asiaticus.

—bulbosus.

—*virginiana.

RHODANTHE. R. palmatum.

RHODANTHE. R. maculata: Helipterum Manglessi maculatum.

—Manglessi: R. Manglessi.

RHODOCITON. R. volubile.

RHODODENDRON. R. arboreum.

—*azalea arboreum.

—*arbutilum.

—*calendulaceum: *A. lutea.

—canadense: *Rhodora canadensis.

—canescens: *A. canescens.

—*caroliniana.

—*cataviense.

—*cerrisum.

—*indicum: *A. indica.

—*japonicum: *A. japonica.

—*kaempferi: *A. Kaempferi.

—*ledifolium: *A. ledifolia.

—*luteum: *A. pontica.

—*maximum.

—*morteri: *A. gandavensis.

—*myrtifolium, but also R. Kotschyi.

—*nudiflorum: *A. nudiflora.

—*obtusum amoenum: *A. amena.

—*obtusum Hinodigiri: *A. Hinodigiri.

—*occidentale: *A. occidentale.

—*ponticum.

—*poukhane yodogawa: *A. yodogawa.

—*precox.

—*pubidatum: R. minus.

—*racemosum.

—*rosemum: R. maximum roseum.

—*sinense: *A. mollis.

—*Smirnovii.

—*Vaseyi: *A. Vaseyi.

—*viscosum: *A. viscosum.

—*Wilsonianum: R. leutevirens (page 2571).

RHODORA. R. canadensis: Rhododendron canadense.

—*filicoides: *G. obtusa filicoides.

—*lepidodendron: probably the trade plant is C. thyoides andoleian-sis.

—*obtusa: *C. obtusa.

—*prinsepia: *C. prinsepia.

—*plumosa: *C. prinsepia plumosa.

—*purpureum: *C. prinsepia squarrosa; probably applied also to Thujia orientalis decussata.

—*Veitchii: *C. prinsepia squarrosa.

RHAMNUS. *R. Alaternus.

—*alpina; trade plant is probably R. fallax.

—*californica.

—*catenaria; name sometimes miss-applied to R. dahurica.

—*dahurica; sometimes cultivated as R. cata viense.

—*frangula.

—*ineretina.

—*purshiana.

—*rubra.

RHAPIS. R. flabelliformis.

—*humilis.

RHEUM. R. Collinianum.

—*palustre.

—Rhaponticum (Rhubarb).

RHEXIGA. R. virginica.

 RHODANTHE. R. maculata: Helipterum Manglessi maculatum.

—Manglessi: R. Manglessi.

RHODOCITON. R. volubile.

RHODODENDRON. R. arboreum.

—*azalea arboreum.

—*arbutilum.

—*calendulaceum: *A. lutea.

—canadense: *Rhodora canadensis.

—canescens: *A. canescens.

—*caroliniana.

—*cataviense.

—*cerrisum.

—*indicum: *A. indica.

—*japonicum: *A. japonica.

—*kaempferi: *A. Kaempferi.

—*ledifolium: *A. ledifolia.

—*luteum: *A. pontica.

—*maximum.

—*morteri: *A. gandavensis.

—*myrtifolium, but also R. Kotschyi.

—*nudiflorum: *A. nudiflora.

—*obtusum amoenum: *A. amena.

—*obtusum Hinodigiri: *A. Hinodigiri.

—*occidentale: *A. occidentale.

—*ponticum.

—*poukhane yodogawa: *A. yodogawa.

—*precox.

—*pubidatum: R. minus.

—*racemosum.

—*rosemum: R. maximum roseum.

—*sinense: *A. mollis.

—*Smirnovii.

—*Vaseyi: *A. Vaseyi.

—*viscosum: *A. viscosum.

—*Wilsonianum: R. leutevirens (page 2571).

RHODORA. R. canadensis: Rhododendron canadense.

—*filicoides: *G. obtusa filicoides.

—*lepidodendron: probably the trade plant is C. thyoides andoleyan-sis.

—*obtusa: *C. obtusa.

—*prinsepia: *C. prinsepia.

—*plumosa: *C. prinsepia plumosa.

—*purpureum: *C. prinsepia squarrosa; probably applied also to Thujia orientalis decussata.

—*Veitchii: *C. prinsepia squarrosa.

RHAMNUS. *R. Alaternus.

—*alpina; trade plant is probably R. fallax.

—*californica.

—*catenaria; name sometimes mis-
ROBINIA, continued.
- *inermis: probably *R. pseudacacia inermis or *R. pseudacacia umbraculifera, but sometimes possibly used to designate *R. hispida macrophylla.
- *Kelseyi.
- *neo-mexicana.
- *Pseudacacia.
- *semperflorens: *R. pseudacacia semperflorens.
- *viscosa.

ROCHEA. *R. coccinea (Crasula).

RODGERSIA. *P. podophylla.
- *tabularis.

ROMNEYA. *R. Coulteri.
- *tabularis.

RODGERSIA. *P. podophylla.
- *viscosa.

ROCHEA. *R. coccinea (Crassula).

ROSA. *R. arkansana; the material cultivated under this name may be R. palustris.
- *rubrifolia.
- *rubiginosa.
- *palustris: *R. carolina.
- *polyantha: *R. nutkana.
- *multiflora.
- *macrophylla.
- *revigata (Cherokee nose).
- *gymnocarpa.
- *alba; also applied to forms of Salix chinensis, possibly a form of *S. alba calva.
- *americana: *S. alba calva.
- *Capea.
- *cineria.
- *cordata.
- *sibirica.
- *color.
- *dolorosa: *S. blanda.
- *Elegans: *S. incana.
- *elegantissima (Thurlow's Weeping Willow); probably also applied otherwise.
- *Erinosa.
- *fragilis (Brittle Willow).
- *glabra.
- *glomerata: *S. nigra.
- *globosa: *S. nigra.
- *globosa: *S. nigra.
- *lutescens: probably a form of *S. nigra.
- *pallida.
- *pedunculata.
- *sororia.
- *amarilis.
- *glabra.
- *glabra.
- *sibirica.
- *sibirica.

SALVIA. S. argentea.
- azurea.
- bicolor; trade plant possibly S. splendens bicolor or S. coccinea bicolor.
- cocinea; possibly sometimes applied in the trade to S. splendens.
- færtacea.
- globosa.
- *Greggi.
- Horinum.
- involucrata.
- leucantha.
- officinalis (Sage).
- patens.
- Picheri: S. azurea grandiflora.
- pratensis.
- rubicunda: S. pratensis rubicunda.
- *S. azurea grandiflora.
- bicolor; trade plant possibly S. gJobosa.
- *farinacea.
- *Greggii.
- Leucanthemum.
- involucrata.
- patens.
- pratensis.
- Pitcheri:
- rubicunda:
- Sclarea.
- splendens.
- spelmina:
- uliginosa.
- Verbenaca.
- virgata; but may apply also to S. Sanguinaria. S. can!ldensis.
- incana:
- SANTOLINA. S. Chamrecyparissus.
- SANSUVERIA. S. zeylanica.
- SANGUISORBA. S. canadensis.
- maritima:
- SANVITALIA. S. procumbens.
- SAPONARIA. S. calabrica.
- officinalis.
- *Officinalis.
- *Vaccaria.
- SARRACENIA. S. Catesbiei.
- Drummondii.
- S. Drummondii rubra.
- *Sanvitalia rubicunda.
- SARRACENIA. S. Catesbiei.
- Drummondii.
- S. Drummondii rubra.
- *Sanvitalia rubicunda.
- SARRACENIA. S. Catesbiei.
- Drummondii.
- S. Drummondii rubra.
- *Sanvitalia rubicunda.
- SARRACENIA. S. Catesbiei.
- Drummondii.
- S. Drummondii rubra.
- *Sanvitalia rubicunda.
- SARRACENIA. S. Catesbiei.
- Drummondii.
- S. Drummondii rubra.
- *Sanvitalia rubicunda.
- SARRACENIA. S. Catesbiei.
- Drummondii.
- S. Drummondii rubra.
- *Sanvitalia rubicunda.
- SARRACENIA. S. Catesbiei.
- Drummondii.
- S. Drummondii rubra.
- *Sanvitalia rubicunda.
- SARRACENIA. S. Catesbiei.
- Drummondii.
- S. Drummondii rubra.
- *Sanvitalia rubicunda.
- SARRACENIA. S. Catesbiei.
- Drummondii.
- S. Drummondii rubra.
- *Sanvitalia rubicunda.
- SARRACENIA. S. Catesbiei.
- Drummondii.
- S. Drummondii rubra.
- *Sanvitalia rubicunda.
- SARRACENIA. S. Catesbiei.
- Drummondii.
- S. Drummondii rubra.
- *Sanvitalia rubicunda.
- SARRACENIA. S. Catesbiei.
- Drummondii.
- S. Drummondii rubra.
- *Sanvitalia rubicunda.
- SARRACENIA. S. Catesbiei.
- Drummondii.
- S. Drummondii rubra.
- *Sanvitalia rubicunda.
SEMPE RIVUM, continued.
— pyrenaicum; but perhaps S. tectorum pyrenaicum.
— soboliferum; this name is com monly used for S. globiferum.
— tectorum.
— violaceum: probably S. tectorum violaceum.

SENECIO. S. Cinerea.
— eliotorum: Ligularia clivorum.
— cruen tus (Cineraria).
— elegans (Jacobaea).
— Koempferi: L. Koempferi.
— mikanoides (German Ivy).
— pulcher.
— sandens; some of the stock is perhaps S. mikanoides.
— tanguitica.
— Wilsoniana: L. Wilsoniana.

SEQUOIA (Wellingtonia). *S. gigantea (Bitter-Sweet).
— pendula.
— Schafta.
— Sarifraga.
— pennsylvanica.

SILPHIUM. S.laciniatum.

SINAPIS. See Brassica.

SILENE. S. acaulis.

SIDALCEA. S. candida.

SHEPHERDIA. (Lepargyrea in American Code). *S. argentea.

SHORTIA. *S. arguta.
— alba; an American plant usually catalogued as S. salicifolia, which is Asiatic.
— tenuous.
— Wilsoniana: S. Wilsoniana.

SHORTIA. S. californica:
— Aitchisonii.

SHORTIA. S. aruentea:
— Warendi.

SHEPHERDIA. (Lepargyrea in American Code). *S. argentea.

SHEPHERDIA. (Lepargyrea in American Code). *S. argentea.

SHORTIA. S. californica:
— Aitchisonii.

SHOREA. S. meliantha.

SHOREA. S. succina.

SHOREA. S. succina.

SHOREA. S. succina.

SHOREA. S. succina.

SHOREA. S. succina.

SHOREA. S. succina.

SHOREA. S. succina.

SHOREA. S. succina.

SHOREA. S. succina.

SHOREA. S. succina.

SHEPHERDIA. (Lepargyrea in American Code). *S. argentea.

— coccineus: T. Serpyllum coccineus.
— Serpyllum. vulgaris.

THYRSACANTHUS. T. rutelana: Odontomena Schomburgkianum.

TIARELLA. T. cordifolia.
— purpurea: T. cordifolia purpurea.

TIBOUCHINA. T. semidecandra (Liandriandra macrantha).

TIGRIDA. T. canarium: T. Pa-vonia canariensis.
— conchiflora: T. Pavonia conchi-flora.
— grandiflora: T. Pavonia grandi-flora.
— immaculata: T. Pavonia alba im-maculata or lutea immaculata.
— lilaee: T. Pavonia lilaeae.
— Pavonia.
— rosea: T. Pavonia rosea.

TILLIA. T. alba: a confused name applying to forms of T. tomen-tosa, T. petiolaris, and T. neglecta.
—*americana.
— argentea: *T. tomentosa.
— aspleniifolia: *T. platyphyllos lacinata.
—*cordata.
—*dasyphylla: *T. eukhloira.
—*eucnboa: T. Pavonia grandiflora.
—*europea: T. vulgaris; sometimes misapplied to T. platyphyllos and T. cordata.
—*heterophylla.
— macrophylla: *T. americana mac- rophylla.
— mississippiensis: *T. americana macrophylla.
—*petiolaris.
—*platyphyllos.
—*tomentosa.
—*ulmifolia: *T. cordata.
—*vulgaria.

TILLANDSIA. T. usneoides (Span-sarella: *T. platyphylla.
— aspleniifolia: T. Pavonia lilaeae.
— argentea: T. uvaria argentea.
— grandiflora: T. uvaria grandiflora.
— Quartiliana: T. foliosa.
— Saundersi: T. uvaria Saundersii.
— sulphurea: T. sulphurea.
— tricolor: T. tricolor.
— Uvaria: T. uvaria.

TRISTANIA. T. conferta.

TRITICUM. T. restivum (Wheat).

TRITONIA (Montbretia). T. auran-tiaca.

TRITOMA. T. corallina.

TRISTANIA. T. conferta.
VALERIANA. V. alba: probably a white form of Centranthus ruber, but perhaps V. officinalis alba.
- cocinea: unknown botanically.
- officinalis.
- rubra: Centranthus ruber.

VALERIANELLA. V. olitoria (Corn Salad).

VALLISNERIA. V. spiralis.

VALLOTTA. V. purpurea.

VEREDIVUM. V. calendulaceum: V. decursus calendulaceum.

VERATRUM. V. viride.

VERBASCUM. V. nigrum.

VALVULA. V. purpurea.

VERATRUM. V. viride.

VENIDUM.

VALLISNERIA. V. spiralis.

VERBENA. V. citriodora:
- pannosum:
- montana:
- erinoides.
- teucrioides.
- venosa.
- noveboracens.
- alpina.
- amethystina: *V. gentianoides.
- elliptica.
- ineana.
- repens.
- tosea:
- speciosn.
- rupeslris;
- spicata.
- subsessilis.
- Traversii.
- Teucrium.
- verbenaeea:
- longifolia.

VIBURNUM. *V. acerifolium.

VERSCBAFFELTIA. V. splendida.

VIOLA. continued.
- Papilio: V. cornuta Papilio.
- pedata.
- pedunculata.
- Priceana.
- pubescens.
- rotundifolia.
- septentrionalis.
- tricolor.

VIRGILIA: V. lutea: *Cladastis lutes.

VISCARIA. V. elegans: Lycmis Viscaria elegans.
- oculata: L. Costi-roses oculata.

VITEX. *V. Agnus-castus.
- incisa: *V. Negundo incisa.
- *Negundo.

VITIS (see Ampelopsis, Cissus, Parthenocissus). V. aconitifolia:
- *Ampelopsis aconitifolia.
- *amurensis.
- *Berlandieri.
- *bicolor.
- *Bourquiniana.
- brevpedunculata: *A. heterophylla amurensis.
- *californica.
- *candicans.
- capensis: *Cissus capensis (page 3482).
- *Champinii.
- *Cinerea.
- *Colgeiideae.
- cordata: *A. cordata.
- *cordifolia.
- *discolor: *C. discolor.
- *Doaniana.
- *Giriana.

HENRYANA: Parthenocissus

VIGNA. V. Catjang.

VICTORIA. V. regis.

Trickeri: V. Cruziana.

Vicia. V. Faba (Broad or Windsor Bean).
- Gerardii: V. cracca Gerardii.
- oroboides (Orobus lathyroides).
- sativa (Spring Vetch).
- villosa (Hairy Vetch).

VICTORIA.

VIGNA. V. regis.

Trickeri: V. Cruziana.

Vicia. V. Faba (Broad or Windsor Bean).
- Gerardii: V. cracca Gerardii.
- oroboides (Orobus lathyroides).
- sativa (Spring Vetch).
- villosa (Hairy Vetch).

VAMBOUS. V. alba:
- *molle; often misapplied to V. aegopodium.

VERNONIA. V. arkansana: V. crinita.
- noveboracensis.

VERONICA. V. Allionii.
- *alpina.
- *ameetephyta: *V. spuria.
- *Andersoni.
- *carnes; but may apply to a form of V. spuria.
- *dentata: *V. elliptica.
- *elliptica.
- *gentianoides.
- *imperialis.
- *incana.
- *longifolia.
- *maritima: *V. longifolia.
- *punctata.
- *repsens.
- *rosea: V. longifolia rosea, V. spicata rosea or V. pectinata rosea.
- *rupedra: a form of V. Teucrium.
- *spectosa.
- *speciosa.
- *spicata.
- *spuria.
- *subessetia: *V. longifolia subessetia.
- *Teucrium.
- *Traversi.
- *Vernoniana: unknown botanically.
- *virginica.

VERSCHAFFELTIA. V. splendidia.

VIBURNUM. *V. acerifolium.
- *alnifolium.
- *americanum (American High-bush Cranberry).
- *Carlesii.
- *cassinoides.
- *dentatum.
- *filatrum.
- *ellipticum.
- *lapponicum.

VIBURNUM, continued.
- *Lantana.
- *lantanoideae: *V. alnifolium.
- *Lentago.
- *macrocephalum.
- *macrophyllum: *V. japonicum.
- *mollis; often misapplied to V. venosum and V. venosum Canbyi.
- *nudum.
- *odoratissimum.
- *Opulus (European High-bush Cranberry).
- *Oxycoccus: *V. americanum, but sometimes misapplied to V. Opulus.
- *plicatum: V. tomentosum plenum: *V. tomentosum plicatum.
- *prunifolium.
- *pubescent.
- *pyriforme: *V. prunifolium.
- *rhodophyllum.
- *rubrum.
- *Sandankwa: *V. suspensum.
- *Sieboldii.
- *Sterile may be V. macrocephalum sterile or V. Opulus sterile.
- *suspensum.
- *Tinus.
- *Tomentosum.
- *utile.
- *venosum.
- *Wrightii.

VICIA. V. Faba (Broad or Windsor Bean).
- Gerardii: V. cracca Gerardii.
- oroboides (Orobus lathyroides).
- sativa (Spring Vetch).
- villosa (Hairy Vetch).

VIBURNUM. continued.

- *sanguinea.
WASHINGTONIA, continued.
- gracilis.
- robusta: W. filifera robusta (Brahea).
- Sirens.

WATSONIA. W. Aridemi: W. viridifolia O'Brienii.

WEIGELA (if the American and East Asian species are considered to be con-generic, the name becomes Diervilla, and this is the usual disposition; the name Weigela, however, is well established in horticultural practice).
- *amabilis: Diervilla florids, or perhaps sometimes D. coroensis.
- *arborea: D. coroensis arborea.
- *candida: D. hybrida candida.
- *Debosi: D. hybrida Debosi.
- *floribunda: D. floribunda.
- *hirtensis: D. japonica hirtensis.
- *Hybrida: D. hybrida.
- *japonica: D. japonica.
- *nana: D. hybrida nana variegata.
- *rosa: D. florida.
- *sessillolia: *D. sessillolia.
- *Steltneri: D. hybrida Steltneri.
- *venosa: D. hybrida venosa.
- *Verschaffelii: D. hybrida Verschaffelii.

WELLINGTONIA. W. gigantea: *Sequoia gigantea.

WHITLAVIA. W. glxinoioides: Phacelia Whitlavia glxinoioides.
- grandiflora: P. Whitlavia.

WIGANDIA. W. caracasana.
- imperialis.
- *macrophylla: W. caracasana macropylla.

Viageri.

WISTERIA. W. brachybotrys: *W. floribunda.
- brachybotrys alba: *W. venusta.
- rhinensis: *W. sinensis.
- floribunda.
- *frutescens.
- *magnifica: *W. frutescens magnaica.
- *multijuga: W. floribunda macrobotrys.
- *sinensis: but often it is W. floribunda.
- *speciosa: *W. frutescens.
- *venusta.

WOODSIA. W. ilvensis.
- obtusa.

WOODWARDIA. W. angustifolia: W. areolata. virginica.

XANTHISMA. X. texanum (Centaureum).

XANTHOCERAS. X. sorbifolia.

XANTHORRHIZA. X. apifolia: *Zanthorrhiza apifolia.

XANTHOSOMA. X. Lindenii (Phylotrenium).

XANTHYLOXYLUM. See Zanthoxyllum.

XERANTHEMUM. X. annuum.

XOLISMA. X. ligustrina: *Lyonia ligustrina.

YUCCA. *Y. aloifolia.
- angustifolia: *Y. glauca.
- *baccata.
- *filamentosa.
- *filicida.
- *glaucza.
- *gloriosa.
- *Treculeana.

ZALUZIANSKYA. Z. capensis (Nycterinia).

ZANTEDESCHIA (Richardia. Florists' Calla). Z. aethiopica.
- albo-maculata.
- Elliottiana.

ZANTHORYLZMA. *Z. apifolia (Xanthorrhiza).

ZANTHOCYXYLUM. *Z. americanum.
- *piperitum.

ZEA. Z. japonica: Z. Mays japonica.
- Mays (Maize. Indian Corn).

ZEBRINA. Z. pendula (Tradescantia).

ZELKOVA. Z. acuminata: *Z. serrata.

ZENOBIA. *Z. pulverulenta (Andromeda).

ZEPHYRANTHES. Z. alba.
- Atamasco (Amaryllis).
- cardidu: rosen.

ZINGIBER: Z. officinale (Ginger).

ZINNIA. Z. elegans.
- Haageana.

ZIZANIA. Z. aquatica: Z. palustris.
- Mays (Maize. Indian Corn).

ZIZYPHUS. *Z. Jujuba.

ZYGOCACTUS. Z. huncatus (Epiphyllum).
