augusta, Becc. Trunk becoming 50–100 ft. high in the wild, much lower in cult., slender, smooth: lvs. 6–10 ft. long; pinnae 1–2 ft., linear, acuminate, bright green; spadix much branched, 2½–3 ft. long: fr. elliptic-oblong, red; seed grooved on one side. Nicobar.

Siebertiana, Hort. Sts. slender: lvs. copper-colored when young, afterward rich green; petioles colored with small brownish scales; lfts. 10 in. long, ¾ in. broad, when young, afterward rich green; petioles colored as freely under cult. as either of these popular palms. This rare palm has been offered in Amer., but is not known to be cult. at present.

Sieberiana, Hort. Sts. slender: lvs. copper-colored when young, afterward rich green; petioles colored with small brownish scales; lfts. 10 in. long, ¾ in. broad, when young, afterward rich green; petioles colored as freely under cult. as either of these popular palms. This rare palm has been offered in Amer., but is not known to be cult. at present.

ANcient species resembling a kestia. N. TAYLOR.

PTYCHOSPERMA (Greek words, probably referring to the ruminate albumen of the seed). Palmaeae. A small and unimportant group of palms little known in America.

Trunks smooth, ringed, crowned at the summit by a dense cluster of pinnately divided lvs.: lfts. acuminate, either entire or jagged at the apex: spadix stipe or sometimes branched, appearing below the lvs.: fls. monoeccious in the same spadix: fr. an ovoid drupe. For cult., see Archontophrenix, to which belong many of the plants in the trade under Ptychosperma. For P. elegans, consult Seafordia.

Macartihus, H. Wendel. Described as dwarf, and most cult. specimens are so; in nature 20–30 ft.: lvs. pinnate, the lfts. arching, from 3–9 in. long, usually obliquely cut at the apex: infl. unknown. Austral. G. Z. 23, p. 205.

Root tuberous, very large: st. shrubby: branches fine. A hardy vine remarkable for the great rapidity of its growth, and most useful for covering arbors and verandas. It is also used as a forage plant. From a well-established root, vines will grow 40–60 ft. in a single season, producing a profusion of very large lvs. In the N. the plant dies to the ground in the winter, but in the S. the top becomes woody. The large fleshy root, assumes most curious shapes, the main branches often being 4–5 ft. long. Georgeson writes of the plant in Japan: “The roots are fleshy and yield starch of excellent quality; the tough fiber of the inner bark is manufactured into a sort of cloth which combines fineness with remarkable strength; and in certain situations the vine is unparalleled for ornament and shade.” The fls. are borne on the old or woody sts., but these sts. usually do not persist north of Philadelphia, and even rarely there. With age, the tops are more likely to survive the winter. Prop. by division of the roots, or by seeds when they can he had; also by cuttings.

Root tuberous, very large: st. shrubby: branches finely grayish pubescent: stipules minute, decussate, ovate-cordate: lts. membranous, roundish, 6–12 in. long, glabrous above, below densely covered with a whitish appressed pubescence: fls. in slender, dense, often pani- cate racemes 6–9 in. long; pedicels very short, densely fasedated; calyx ¾–½ in. long, densely silky; teeth rather obtuse, shorter than the tube; fr. not twice as long as the calyx; limb of standard orbicular, distinctly spurred: pod 2–3 in. long, membranous, flat, 4–5 seeded, clothed with long, gray, silky bristly hairs. India. Wright, Icones, 412. Intro. into U. S. in 1891. Suitable as an ornamental for the southern parts of the United States. The root contains a saccharine matter, an easily oxidizable resin; and a resin acid.

India. Wright, Icones, 412. Intro. into U. S. in 1891. Suitable as an ornamental for the southern parts of the United States. The root contains a saccharine matter, an easily oxidizable resin; and a resin acid. It is also said to be used as a food and in medicine in India. When cut, the root exudes a bitter, acrid, opalescent gum.
PULMONARIA (Latin, lung; the herb having been considered a remedy for diseases of the lungs). Boraginaceae. LUNGWORT. Perennial herbs with a creeping rootstock, used in flower-gardens and hardy borders. Leaves radical, often broad, cauleine few and alternate: fls. in terminal cymes, rather large, blue or purplish: stamens 5: filaments cylindrical: anthers broadly oval.-About 8-10 species in Eu. and 1 species said to extend into N. Asia. Mertensia, an allied genus, has a short open more deeply-lobed calyx, exerted, stamens, and slightly fleshy nectaries. 

Pulmonarias are of easy cultivation, preferring light soil, not very dry, in open or partially shaded positions. They are readily propagated by division. Divide the clumps every two or three years.

Pulmonaria angustifolia, Linn. Height 6-12 in.: st. setose-hairy, with articulate glands; radical lvs. linear-lanceolate, abruptly contracted to the middle only; corolla-tube straight, naked or ploose, limbs spreading, 5-lobed; stamens included in the tube: nuts smooth.-About 8-10 species in Eu. and 1 species said to extend into N. Asia. Mertensia, an allied genus, has a short open more deeply-lobed calyx, exerted, stamens, and slightly fleshy nectaries.

Pulmonarias are of easy cultivation, preferring light soil, not very dry, in open or partially shaded positions. They are readily propagated by division. Divide the clumps every two or three years.

A. Lvs. white-spotted.
B. Plant very glandular.

PULSATILLA: Anemone.

PULTEMÉA (probably named after Dr. Richard Pulteney, 1730-1801). Leguminosae. Shrubs suitable for the warmhouse, not commonly in cultivation, although many species have been occasionally grown. Leaves alternate: fls. in axillary or terminal clusters of 4-6 in the axils of the leaves: petals 5: stamens numerous: fruit a pod.-About 90 species in Austral. Pultenias grow best in a mixture of peat and silver sand in pots of 1-2 l. Lvs. linear-terete; stipules subulate-pointed: fls. pink, in terminal heads; calyx silky pubescent; pod acuminate. Austral. G.Z. 21:193.

PUMMELO (possibly confusion of Dutch pommele). A generic term including most of the varieties of Citrus grandis (see page 782, Vol. II), other names for forms of this species being grapefruit (page 1391, Vol. III) and shaddock (Vol. VI).

The grapefruits long grown in the West Indies and the United States are mostly a group of very juicy subglobose (not pear-shaped) thin-skinned varieties differing widely from the common pummelos of the East Indies which are usually more or less pear-shaped, thick-skinned, and have a firm pulp. These latter are called shaddocks in the West Indies and United States. These two extremes are well separated in the character of the fruit, and also show differences in the leaves and twigs, the pummelos having more or less hairy twigs, leaves downy on the upper surface and very broadly winged petioles, while the grapefruits have nearly smooth, slender twigs, leaves smooth on the upper surface, and narrower petioles.

In the Orient, however, there are a multitude of forms of pummelos, among which occur all the intermediates between the two extreme types noted above. Under these circumstances it seems advisable to retain the word pummelo in its usual East Indian sense, i.e., to include all varieties of Citrus grandis with the exception of the grapefruit group which is sufficiently distinct to merit a separate name. The attempt was made some years ago to apply the name pomelo to the grapefruit in this country but this name never attained any currency among growers, shippers, dealers, and consumers and was largely restricted to books and bulletins on descriptive horticulture. Pomelo is really a variant of pummelo, also written pummelew, pummele, pummelo, pomelo, and so on. In view of this confusing perplexity of similar names, it seems inadvisable to attempt to distinguish by the name pomelo the grapefruit of America from the pummelo of the East Indies.

As a result of a trip to Japan, China, and the Philippine Islands made by the writer in 1915, it was found that some varieties of pummelos were very resistant to citrus canker (caused by Pseudomonas citri), unlike the grapefruit which is very susceptible to this disease. Unless citrus canker can be wholly eradicated from the southeastern United States it will be necessary to hybridize the grapefruit with the most canker-resistant sorts of citrus fruits in the hope of securing new varieties combining the juiciness and high flavor of the grapefruit with the canker-resistance of the other parent.

In this work the canker-resistant varieties of the pummelo, some of them of excellent quality, promise to be of capital importance.

In view of this unforeseen importance of the pummelo, the following sketch of the more promising known varieties is given:

Malayan varieties.—Bandanavel, from Plo-ey, Banda Islands, Malaysia. Fruits very large, nearly round but bumpy, growing in clusters of five or six; peel an inch thick; pulp white, juicy and sweeter than the common pummelo, nearly or quite seedless; the fruits sometimes show an included navel, a smaller fruit the size of a peeled orange being formed near the top of the large fruit. Navel fruits are very rare in seedlings grown in Ambonaya from seed brought from Banda. This very interesting variety described by Rumphius about 200 years ago does not seem to have been noticed since.—Casomba. Rumphius describes this as a depressed globose variety as large as a man's head, and commonly grown on the island of Ambonaya. It has red vinous pulp as sweet as currants when ripe, often seedless.—Labuan, or Bali (?). A seedless pummelo of very superior quality is said to have been found by Sir Hugh Low from the island of Bali to Labuan Island off the coast of Borneo, from whence it was sent some fifteen years ago to the West Indies. The tree is said to be thornless.
Indian varieties.—Bombay Red. Fruit subglobose, 7 inches diameter; skin \( \frac{3}{4} \)-\( \frac{3}{2} \) inch thick; pulp very juicy, deep red (color of raw beef), pleasantly subacid, with a characteristic flavor. This is said by E. E. Bonavia to be "by far the finest variety of pummele" he had seen. He describes a number of other sorts varying in shape, size, color, and juiciness. The leaves and twigs of some varieties are smooth, of others downy or hairy. In 1904 a collection of thirteen sorts of Indian pummelos was received by the Department of Agriculture from the Botanic Garden at Calcutta. A number of these have fruited both in California and Florida. One of these Indian pummelos (shown in Fig. 3256) was grown at Gainsville, Florida, in 1915, and has pink flesh.

Siamese varieties.—The Siamese seedless pummelos, grown in the Nakon chaisri district, have long been famous and have recently been studied there by H. H. Boyle. (Phil. Ag. Rev. 7:65-9, pls. 3, 4, Feb., 1914. Journ. Heredity, 5:440-7, pls. 1-3, Oct., 1914.) Oval Nakon chaisri. The best variety is slightly oval, \( \frac{3}{4} \)-8 inches diameter, 4 inches high: skin pale yellow; flesh white, juicy, aromatic, not bitter; seeds few or none. Boyle considers this variety superior to any other pummele and to any grapefruit and says it is a good fruit for market purposes.—Flat Nakon chaisri. A very flat fruit, \( \frac{3}{4} \)-8 inches diameter, \( \frac{3}{4} \)-\( \frac{3}{2} \) inches high; skin bright yellow; flesh white, juicy, aromatic; seeds few or none. Boyle considers this an excellent fruit for market purposes. Two other seedless varieties, but of somewhat inferior quality, were found by Boyle.

Japanese varieties.—In Japan many varieties of pummelos, called Buntan, Uchimurasaki or Jabon are known, variously estimated from 75 to 200. The following are among some of the more promising studied by T. Tanaka in the course of a survey of the citrus fruits of Japan: Hirado. Large, depressed globose, about 4-5 inches in diameter and 3-4 inches high, with grapefruit-like smooth skin of lemon-yellow color; pulp juicy, red thin, segments regular, core rather small, very good flavor; seeds small but numerous. This variety originated at Hirado near Nagasaki, Japan, some seventy-five years ago as a seedling of a pummele brought from Java. The writer saw the bearing trees of this variety at the Nagasaki agricultural experiment station in 1915 and found the fruits to be juicy and of excellent quality and noted that the tree remained almost entirely exempt from citrus canker (caused by *Pseudomonas citri*) which was attacking seriously Washington navel orange trees grown only a few yards distant. On account of its superior quality and high degree of canker-resistance, hybrids were made in June, 1915, between it and American grapefruit by means of pollen shipped from Florida to Nagasaki in vacuum tubes (Science N.S. 42:375-377, Sept., 1915). It is hoped to secure in this way canker-resistant hybrids equal to the grapefruit in quality. Seedlings of the Hirado pummele are now being grown by the Department of Agriculture.—Ogami, vicinity of Kagoshima; rare; very large, very flat; rind smooth; thin, pinkish; core large, segments numerous, sometimes twenty-live, pulp pinkish, fine-grained, juicy, very good quality; seeds numerous.—Hata-jirushi, experiment farm of Count Tachibana, Fukuoka-ken; a very flat large pummele like the Ogami, very much like the latter in general characters but rind much thicker and pulp vesicles coarser, good-flavored; seeds numerous.—Yoko-jirushi, experiment farm of Count Tachibana, Yangawa, Fukuoka-ken. A large round variety with rough skin; oil glands remarkably large and prominent, not much rag, segments regular, pulp slightly pinkish, good quality, resembles living pear; seeds few.—Tanura. Shingum. Nakomichi, a round, smooth-skinned variety, with pale pink flesh, segments irregular, large, pulp coarse-grained and good quality; seeds very few.

Formosan varieties.—Mató, Matsao, Enashiko-chō, Formosa. Common; fruit small, conical; rough-skinned, rind very thin; core small, pulp similar to the Ogami, very high quality; practically seedless; very early ripening. Besides the Mató pummele, red (Te ya) and white (Pei ya) pummeles of fairly good quality are commonly grown in Formosa.

Chinese varieties. Canton varieties.—There are at least half a dozen varieties grown about Canton. The Sung-ma is one of the best for export. The sorts commonly exported are pear-shaped, with a fragrant thick peel and a very firm greenish yellow pulp of aromatic flavor. These pummeles are exported to all parts of the world where Cantonese Chinese live.—Amoy, a very large slightly pear-shaped pomelo with a thick skin and very firm white flesh, is produced near Amoy. In spite of its reputation it is of mediocre quality.

California seedlings.—There are many pummele trees in northern California grown from seeds planted years ago by the Cantonese Chinese immigrants. Until a few years ago Canton pummeles were regularly imported by Chinese merchants in San Francisco. G. P. Rixford has located two score or more seedling trees in California which show considerable variation in the size, color, shape, and quality of the fruit. Some are of fairly good quality. These seedlings are mostly old bearing trees and furnish excellent opportunity for crossing with grapefruit in the hope of securing canker-resistant hybrids.

Florida shaddocks.—In Florida, pummeles have been grown for a long time under the West Indian name shaddock. The grapefruit is so much better, however,
that the shaddocks have almost disappeared. H. H. Humé lists only two varieties, the *Mammoth*, oblate, 5-6 inches diameter, flesh firm, white, sweetish, bitter; and the *Pine*, oblate-pyramidal 3 x 6½ inches, flesh rough, pink, bitterish, subacid. Other forms are occasionally found but almost all are of very poor quality.

**Hybrids.**—Natural hybrids of the pummeo are common in Japan. They are mostly between the pumpelos and the *Cucurbita* species of orange. Some are of great promise, however, being large, juicy, and very good-flavored. The kamaza *Natsu mikan*, a very flat fruit 4-5 inches diameter, 2½-3 inches high, ripening very late in the season, is probably one of these hybrids. This group of hybrids is very similar to the *taigete*, obtained by crossing the grapefruit with oranges of the Mandarin type. In India there seem to be natural hybrids between pummeos and lemons or citrons; possibly the group of citrus fruits called Almehed by Bonavia is of this nature. After discovering that some varieties of pummeos are very resistant to citrus canker, the author inaugurated in 1915 in Japan a series of experiments in hybridizing the Florida grapefruit with different varieties of Japanese pummeos in the hope of securing canker-resistant grapefruit-like hybrids, as was noted above under Hirado pummeo.

**Sour pummeos.**—In India and other eastern countries very large, acid-fleshed pummeos occur which are said to yield up to a quart of juice. One such sour pummeo grown near Eustis, Florida, has been used in breeding new types of acid fruits by hybridizing.

WALTER T. SWINGLE.

**PUMPKIN AND SQUASH.** Fruits, and the plants that produce them, of species of *Cucurbita*, used for food when cooked and also for stock-feed. See *Cucurbita*.

In North America, the word pumpkin (colloquially but incorrectly pronounced *pumkin*) is applied to large late-maturing globular or oblong fruits of forms of *Cucurbita Pepo*, regarded as in the "field pumpkin" (Fig. 3257), from which pies are made and which is commonly fed to cattle and swine. The pumpkin is characterized by a five-angled stem which is not expanded where it joins the fruit (Fig. 1133, Vol. II), by rough vines and heritage, and by prominently lobed leaves. Sometimes the word is applied to some of the earlier forms of this species, as to the Sugar pumpkins that ripen late in summer or early in autumn and are used for pies. It is also applied to forms of *Cucurbita moschata*, which, in the form known as Canada Crookneck squash, is sometimes called "pie pumpkin."

The word squash is adapted from an American Indian word, and is applied in an indefinite way to various members of the genus *Cucurbita*. The application of the name does not conform to the specific lines of the plants. What are called summer squashes are mostly varieties of *Cucurbita Pepo*, of the Crookneck and Pattypan type. The winter squashes are either *C. maxima* or *C. moschata*, chiefly the former. If the name squash belongs to one species more than to another, this species is probably *C. maxima*. This species produces fruit with very firm or "solid" yellow flesh. The pictures on pages 909-911 in Vol. II, show some of the forms of these species. Fig. 3258 is the Winter or Canada Crookneck, one of the forms of *C. moschata*. Figs. 3259-3262 are forms of the multifarious *Cucurbita Pepo*. A further discussion of the application of the vernacular names will be found in Vol. II, page 909.

Culturally, the pumpkins and squashes comprise one group of warm-season frost-sensitive plants. They are very easy to grow, provided they are given a warm and quick soil. They are long-season plants (except the "pie squash"), and therefore in the North they are very likely to be caught by frosts before the full crop has matured, unless the plants are started early and make a rapid and continuous growth. In hard rough clay lands the plants do not get a foothold early enough to allow them to mature the crop. On such lands it is impossible, also, to plant the seeds early. As a consequence, nearly all squashes are grown on soils of a loose and relatively light character. Sandy loams or sandy loams are preferred in the northern limits, but an open clay loam is probably the best soil in general for these plants. On very rich bottom lands the plants often thrive remarkably well, but there is danger that they may run too much to vine, particularly when the soil has too much available fertilizer. In order that the plants shall start quickly, it is necessary that the soil be in excellent tilth. It is customary, with many large growers, to apply a little commercial fertilizer to the hills to give the plants a start. A fertilizer strong in nitrogen may answer this purpose very well; but care must be taken not to use nitrogen too late in the season, else the plants will continue to grow over-vigorously rather than to set fruit.

Pumpkins and squashes are of two general kinds, so far as culture is involved, the bush varieties and the long-running varieties. The bush types are usually early. The vines run very little, or not at all. The various summer squashes belong to this category, and most of them are varieties of *Cucurbita Pepo*. The hills of bush varieties are usually planted as close together as 4 by 4 feet. On high-priced land they are often planted 3 by 4 feet. The fruits are borne close to the center of the plant. The long-running varieties comprise the autumn and winter types; and to this category may also be referred, for cultural purposes, the common field pumpkins. There is much difference between the varieties as to length of vine. On strong soils, some varieties will run 15 to 20 feet, and sometimes even more, producing the fruit some feet from the hill or the root. These varieties are planted from 8 to 12 feet apart each way. Sometimes they are planted in corn-fields, and they are allowed to occupy the ground after tillage for the corn is completed, but with the introduction of corn-harvesting machinery this practice is falling away.

For general field conditions, the seeds of pumpkins and squashes are usually planted in hills where the plants are to stand. If the land is mellow and rich, these hills are nothing more than a bit of ground 12 to 18
inches across, that has been freshly hoed or spaded and leveled off. On this hill, from six to ten seeds are dropped, and they are covered an inch or less in depth. In order to provide the seeds with moisture, the earth is usually firmied with the hoe. When the very best results are desired, particularly for the home-garden, hills may be prepared by digging out a bushel of soil and filling the place with rich earth and fine manure.

3259. Summer Crookneck squash.—Cucurbita Pepo form.

It is expected that not more than three to five of the plants will finally be left to each hill; but there are many contingencies to be considered. The young plants may be taken off by cutworms or by other insects, or they may be caught by frost, and it is well not to remove the extra plants too soon.

If it is necessary to start the crop in advance of the season, the seeds may be planted in pots or boxes in a forcing-house or hotbed about three weeks before it is time to set them in the field. If the seeds are started much earlier than this, the plants are likely to get too large and to become stunted. When set in the field, the roots should fill the pot or box so that the earth is held in a compact ball, and the plant should be fresh, green, and stocky. Sometimes the seeds are planted on sections of inverted tough sod, and the entire piece is transferred directly to the field. Plants that become stunted and develop one or two flowers when they are in the box are usually of little use. Sometimes seeds are planted directly in the field in forcing hills, and when the plants are established and the season is settled the protecting box is removed and the plants stand in their permanent positions.

A good vine should produce two or three first-class fruits; if, however, one flower sets very early in the season, the vine may devote most of its energies to the perfection of that single fruit and not set many others, or may set them too late to allow them to mature. If it is desired, therefore, that the plants shall produce more than one fruit, it is advisable to pick off the first fruit, providing it sets long in advance of the appearance of other pistillate flowers. These remarks apply particularly to winter squashes in northern regions. With small varieties and under best conditions, as many as a half-dozen fruits may be secured from a single vine, and in some cases this number may be exceeded. Squash vines tend to root at the joints; but so far as general culture is concerned, this should be prevented, because it tends to prolong the growing season of the vine, although it may have to be encouraged if the borer is prevalent. It is usually well, therefore, to lift the joints occasionally when hoeing, although the vine should not be moved or disturbed. This precaution applies particularly in the short-season climates of the North, where every effort must be made to cause the plant to set its fruit early in the season and to complete its growth before cool weather.

Tillage is simple. It consists in light working of the surface until the plants begin to run strongly, after which the big weeds are pulled by hand. For early results with bush squashes, or when the land is of a cold or backward type, the plants may be grown in hills that are raised a few inches above the general level; this adds to the expense, and in most cases it is better to practise level culture.

The varieties of pumpkins and squashes are numerous, and it is difficult to keep them pure if various kinds are grown together. However, the true squashes (Cucurbita maxima) do not hybridize with the true pumpkin species (Cucurbita Pepo). There need be no fear, therefore, of mixing between the Crookneck or Scallop squashes on the one side and the varieties of Hubbard or Marrow types on the other. The summer or bush squashes are of three general classes: the Crooknecks, the Scallop or Pattypan varieties, and the Pineapple or oblong-conical varieties, all forms of C. Pepo. The autumn and winter varieties may be thrown into several groups: the true field pumpkin, of which the Connecticut Field (Fig. 3257) is the leading representative, being the one that is commonly used for stock and for pies; the Canada Crookneck or Cushaw types, which are varieties of C. moschata; the Marrow and Marblehead types, which are the leading winter squashes and are varieties of the C. maxima; the Turban squashes, which have a "squash within a squash" and are also varieties of C. maxima. The mammoth pumpkins or squashes which are sometimes grown for exhibition and which may weigh 200 or 300 pounds, are forms of C. maxima.

In Europe the vegetable marrow type is much prized. It is a form of Cucurbita Pepo. In this country it is little grown, although it thrives well, the various summer squashes of the Crookneck and Scallop types being more popular. The following English advice on this vegetable is from a contribution to Gardening Illustrated, from which Fig. 3263, representing Moore's vegetable marrow, is also reduced: "Vegetable marrows should be eaten young—say when about one-fourth or one-sixth their full size. Cut in this state, and boiled quickly until quite tender in plenty of water, carefully strained, and served with melted butter; they are second to no vegetable that comes to table, not even excepting green peas or asparagus. Early cutting, careful cooking, and serving are the chief points to which attention should be paid; but there are other points of the principal being rapid growth. Grow vegetable marrows quickly, and they are almost sure to be good; grow them slowly, and you will find them often tough and bitter. Hence the soil or place in which they are grown can hardly be too rich for them. Not but what they do fairly well in any
good garden soil, but the richer it is the better. On a
rush-hush-heap, for instance, vegetable marrows grow
with wonderful vigor, and fruit abundantly. For early
results, they are often started under glass in pots.
There are many kinds or varieties. The custard mar-
rows are fruits of the Scallop or Pattypan kind. The
summer Crookneck is little used abroad for food.
Insect enemies and diseases of pumpkins and squashes
are several. Perhaps the most serious is the striped
cucumber beetle, which destroys the tender young
plants. This insect is destroyed by the arsenicals
applied in flour, also with tobacco powder and some
other materials; but since it works on the under sides
of the leaves as well as on the upper, it is difficult
to make the application in such way as to afford a com-
plete protection. The insects also are likely to appear
in great numbers and to ruin the plants even whilst
they are getting their fill of arsenic. If the beetles are
abundant in the neighborhood, it is best to start a few
plants very early and to plant them about the field in
order to attract the early crop of beetles, thereby mak-
ing it possible to destroy them. From these early
plants the beetles may be hand-picked, or they may be
killed with very heavy applications of arsenicals —
applications so strong that they may even injure the
plants. Sometimes the hills of squashes are covered
with wire gauze or mosquito netting that is held above
the earth by means of hoops stuck into the ground.
This affords a good protection from insects that arrive
from the outside, providing the edges are thoroughly
covered with earth so that the insects cannot crawl
under; but if the insects should come through the ground
beneath the covers they will destroy the plants, not
being able to escape. The arsenicals should be applied
when the dew is on, or the plants may be sprayed with
bordeaux mixture to which the poison has been added.
The squash bug or stink-bug may be handled in the same
way as the striped cucumber beetle. This insect, how-
ever, remains throughout the season and, in many
cases, it is necessary to resort to hand-picking. The
insects crawl under chips or pieces of board at night,
and this fact may be utilized in catching them. The
young bugs can be killed by tobacco extract and soap,
and this fact may be utilized in catching them. The
insects crawl under chips or pieces of board at night,
and this fact may be utilized in catching them. The
young bugs can be killed by tobacco extract and soap,
and this fact may be utilized in catching them.

The stem-borer attacks the vines later in the season,
boring into the main stalk near the root, and causing
the entire plant to lose vigor or to die. It is a soft white
larva. As a safeguard, it is well to cover the vines at the
joints with earth after they have begun to run, so that
roots will form at these places and sustain the plant
if the main stem is injured. The borers may also be cut
out with a thin-bladed knife. Tobacco dust is said to
keep the insect away. Infected

3262. The Negro squash. One of the

with the stem on, and much care should be exercised
to prevent any bruising or rough handling. In a rather
dry and somewhat dark cellar, with a temperature of
about 40°, such fruits may be kept all winter. Commer-
cial growers store them in above-ground houses built
for the purpose, placed only one layer deep on racks or
shelves. The house is well insulated to prevent fluctua-
tion, kept dry, and provided with a stove or other heat
for very cold weather, the temperature maintained at
about 40° to 45° F. The following advice on the storing
of squashes was written for the "Cyclopedia of American
Horticulture" by W. W. Rawson: "Cut the squashes
just before they are thoroughly ripe. Be careful not to
start the stem in the squash. Lay them on the ground
one deep and let them dry in the sun two or three
days before bringing to the building. Handle very care-
fully when putting in, and be sure that the wagon in
which they are carried has springs. Put them two deep
on shelves in a building. This should be done on a cool,
dry day. If the weather continues cool and dry, keep
them well aired by day; but, if damp weather comes,
build a small fire in the stove in order to dry out the
green stems. Keep the temperature above 50°, and air
well in dry weather. The squashes may need picking
over about Christmas if put in the building about
October 1; handle very carefully when picking over.
Fifty tons can be kept in a single building with a small
fire. Do not let them freeze, but if temperature goes
down to 40° at times it will do no harm; nor should it
be allowed to go as high as 70°. The Hubbard squash
keeps best and longest and does not shrink in weight as
much as other kinds; but any of them will shrink 20
per cent if kept until January 1."

L. H. B.

PUNICA (Punica, Carthaginian; hence Malum
puniceum, "apple of Carthage," an early name of the
pomegranate). Punicaceae. A small branched tree,
the branches rather terete and spiny. The common
pomegranate of cultivation.

Granatum, Linn. Pomegranate. A large deciduous
shrub or small tree, with oblong or obovate, obtuse,
entire, glabrous and more or less shining lvs.: fls.
orange-red, showy; calyx tubular, the short lobes per-
sistent on the top of the fr. (as on an apple); petals
inserted between the lobes; ovary imbedded in the
calyx-tube (or receptacle-tube), comprising several
locules or compartments in two series (one series above
the other), ripening into a large, juicy, many-seeded
pomegranate-like berry. Persia to N. W. India. G.W.19,
p. 610.—A handsome plant, with showy fls. 1 in. across

3263. Vegetable marrow.—Cucurbita Pepo.

PUMPKIN 3262. The Negro squash. One of the

3263. Vegetable marrow.—Cucurbita Pepo.
in summer. Hardy as far north as Washington and Baltimore. It is also grown as a conservatory plant, blooming in winter as well as summer. For ornament, the double-flowering kinds are the most popular (F.S. 13:1385, as *P. Granatum Lepidolea*). There are many varieties. The treatment of the fruit-bearing varieties is discussed under Pomegranate. Var. *sana*, Hort. (P. *sana*, Linn.). Seldom growing higher than a man, and usually treated as a pot-plant in the N. It is the best kind for greenhouse use. The double-flld. form is most common. B.M. 634. It is as hardy as the species, and is suitable for outdoor work where the climate is not too severe. On the Pacific Coast it is grown as a hedge-plant as far north as San Francisco. Both this and the species are easily grown by cuttings of dormant wood, as cuttings are, but the cuttings should be pushed indoors with some heat.

L. H. B.

**PURSHIA** (after F. T. Pursh, or Pusch, as is the original spelling of his name, 1774-1823; born at Groesbeckville, in Saxony; travelled in this country and wrote a flora of North America). Syn., *Kunzea Rosacea*. Low deciduous spreading shrub, allied to Cercocarpus, with alternate, mostly fasicled, small, cuneate and tridentate lvs.: fls. solitary, yellowish; calyx-tube tubular, lvs. bracteate, 5; stamens 5; disk almost sessile, 7-10-fid.; pedicels 1 or sometimes 2: fr. a pubescent leafy achene achieving the persistent calyx. Of little ornamental value with its sparse grayish or bluish green foliage and its rather inconspicuous fls. and frs., and but rarely cult. Probably hardy as far north as Mass., requiring sunny position and well-drained soil; an excess of moisture, especially during the winter, proves fatal to it. Prop. by seeds and probably by layers. The only species is *P. tridentata* (Kunzea *tridentata*, Spreng.). Dif- fusely branched shrub, attaining 5, rarely 10 ft.: lvs. cuneate-obovate, 3-lobed at the apex, whitish pubescent beneath, 5/ to 8-in. long: fls. solitary on short branchelets, almost sessile, yellowish, about 8-in. across: fr. ovate-oblong, acuminate. April-July. Ore. to Wyo., New Mex. and Calif. B.R. 1446. Var. *grandiflora*, Jones (P. *grandiflora*, Curran), is glabrous and has very small, almost glabrous lvs., sometimes pinnately 5-lobed.

ALFRED REHDER.

**PUSCHEKINIA** (named for Count M. Puschkin). *Lilium*. Hardy or half-hardy bulbous plants which may be used in the rock-garden or border.

Leaves radicale, few, the first often oblong, the others linear or lin, a simple leafless scape; fls. few, blue, boreel, racemose; perianth campanulate, of 6 subequal lobes; stamens 6; ovary sessile, 3-lobed: caps. membranaceous, dehiscent.—Two species, Asia Minor, the Caucasus and Afghanistan. These attractive spring-flowering bulbs have clusters of small 6-lobed white fls., each narrow lobe being pretty lined with blue. A good specimen may have as many as 10 fls., each 5/ in. across. The peculiar feature of the genus is the crown on which the stamens are borne. This is a white body of petal-like texture, having 6 lobes, each of which is variously colored. The genus is allied to *Seilla* and *Chionodoxa*. Height 2-12 in.: bulb globular, about %; in. thick: lvs. slender, erect; perianth usually bluish white; divisions elliptic-oblong, three times as long as the tube; crown one-third as long as divisions, eell to middle into truncate or retuse teeth. April, May. Var. *labiata*, Boiss. (P. *labiata*, Zucc.), differs from the type in having divisions of perianth 3/ in. long, and the teeth of the crown more acute and bifid. G.C. Ill. 32, p. 5; 54, p. 219. B.M. 2244. F.S. 21:2220 (as *P. sicula*).

F. TRACY HUBBARD.

**PUTRANJIVA** (Indian name). *Euphorbiiaceae*. Evergreen trees, cult. for ornament in the tropics: lvs. alternate, simple; fls. small, axillary, single or in small clusters, apetalous; calyx imbricate; stamens 1-10; disk absent; styles broad, spreading; ovary 2-3-celled, 2 ovules in each cell. fr. a 2-celled drupe.—Two or more species in Trop. Asia. Related to Drypetes.

**PÚYA** (Chilean name). *Bromeliaceae*. Large terrestrial serpentine South American bromeliads. Commonly sold to Puyrava (differing in having a fully superior rather than partially superior ovary).—Forty-four species, according to Mez (DC. Monogr. Phaner. 9). For culture, see also *Bilbergia*. Puya also includes the plants known in trade as Fourretia.

Puyas and puyaequines are generally found in collections of bromeliads and are usually grown in moist tropical houses. The native home of the puyas is on the steep rocky slopes of the Cordilleras at high altitudes with little other vegetation for company except other bromeliads. This would indicate that this plant would require the same conditions as do these puyas, and cooler conditions, or such as are given caleti and succulents, would suit them best, yet they thrive equally well in the tropical house. Indeed, the writer has found most of the family Bromeliaceae very accommodating not only to temperature and moisture conditions, but to soils and methods of growing them; for example many of the tiplantillas may be grown on blocks of wood as epiphytes, yet they do equally well grown in pots. But what perhaps is more remarkable is the fact that several of the stronger-growing bromeliads appear to grow equally well either in a strong loamy mixture, or a mixture of chopped fern root and charcoal. The writer has puyas growing in both mixtures with equal success. But the most irrational treatment is to give all the bromeliads conditions and soil similar to the environment in which they are found in their native habitat, yet according to the experience of the writer few plants possess such remarkable adaptability to changed conditions as do these plants. (E. J. Canning.)

**A. Fls. yellow.**

chilensis, Molina (*Pitcairnia caoctácea*, Pers., and *P. chilénsis*, Loddi.). Becoming 4-5 ft. or more high, sometimes branching; lvs. in tufts, 2-4 ft. long, very narrow, often recurved, the margins armed with strong recurved spines or thorns, glaucescent: blossoms in a branching, hoary, bracted inf. rising 3-5 ft. from the top of the caudex, the fls. large (2 in. across), sessile or nearly so, the 3 lanceolate sepals greenish and the obovate-oblong much-exserted petals yellow or greenish yellow, the 6 erect stamens shorter than the petals, the stigma 3-branched. Chile. B.M. 4715. F.S. 9:889, 870. J.F. 4:392. J.H. II. 52:533. G.C. III. 7:685; 48:390; 54:3.—A striking and mammouth bromeliad, making a yucca-like mass of foliage and projecting above it a very showy inflo.

**AA. Fls. white or rose-color.**

gigas, André. Still larger than the latter, sending its gigantic spikes 20-30 ft. into the air, from a rosette of hard and thick spiny-toothed agave-like lvs.: inf. simple, dense, club-shaped, terminating the tail, erect, bracted scape: fls. green above and white beneath, the spines black and hooked: fruit a 3-celled drupe. Colombia, 10,000 ft. R.H. 1881, p. 315, and Gn. 21, p. 300.—Can probably be handled like agaves.

**AAA. Fls. blue.**

cerifera, Lindli. (*Pitcairnia carioca*, Bentli. & Hook.). Foliage pineapple-like, with linear very acute
serrate: ffs many, crowded, in short spikes; branchward pyramidal habit; lvs. narrowly lanceolate, urticiferous, densely pubescent; spikes very dense, 2-3 in. long; more or less frequent in gardens in England. P. virgineum, Dur. & Jacks. A stout herb, 4-6 ft. high and loosely clustered much branched or panicled, with bracts more serrate than in P. coccinea: fls. very large and showy, with a flaring mouth, dull metallic blue. Chile. B.M. 5732. A plant that in bloom has the habit of a yucca. This and P. coccinea will probably stand considerable frost.

P. spathulata, Mees (Pitcairnia spathulata, Gleichen.). Lvs. up to 20 in. long and 1 in. broad, the spines incurved; panicled about 2 ft. long; sepals ovate, acuminate, pale rose; petals dull blue.Argentina. B.M. 7966.—P. robbins, Mees. Lvs. up to 20 in. long, linear, stiff, spiny in margin; petals 12-20 in. long; sepals green, lanceolate, 1-1½ in. long, acute; petals deep violet. Chile. B.M. 8194.

L. H. B. GEORGE V. NARB.†

**PYCNAZIUM** (Greek, dense, and Blossom; referring to compact flower-heads). *Labatiæ*. MOUNTAIN Mint. Baslä. Hardy aromatic perennial herbs suitable for the flower-garden.

Stems corymbose branched above: lvs. entire, glabrous or pubescent, nearly sessile; infl. dense, many-flowered; whorls, crowded with bracts and usually forming terminal heads or close cymes; fls. whitish or purplish, late summer and early autumn; calyx about 13-nerved, naked in the throat; corolla short, more or less 2-lipped; stamens 4, lower pair rather longer than the upper, which are sometimes abortive.—About 18 species, N. Amer. The oldest generic name of this is Koellia, which is used by many, but Pycnantheum is maintained in the list of "nomina conservanda" as accepted by the Vienna Congress. The genus differs from *Monarda* in having smaller and canescent fl-heads. Pycnanthems are mint-like plants of easy cult., in any good soil. The following grow 1-3 ft. high, and bear fl-heads ½ in. across or less.

A. *Lvs.* lanceolate or linear-lanceolate: calyx-teeth ovate-triangular.

*virginianum*, Dur. & J. (P. lanceolatum, Pursh.). St. rather stout: lvs. fragrant, firm, acuminate at apex, rounded or narrowed at base, 1-2 in. long, 2-5 lines wide. Dry fields, Canada to Ga., west to Minn. B.B. 3:112.

AA. *Lvs.* linear: calyx-teeth subulate, bristles-lipped.

P. *Monardella*, Michx. is properly Monarda ciliolata, Linna. A perennial herb with slender, usually simple at 1-3 ft. high; lvs. lanceolate to ovate, membranaceous, bright green, slender-petioled, 2-4 in. long; fl-heads solitary, terminal; corolla yellowish, 1 in. long or less. June-July. Florida, Ohio, Ga. B.R. 3:162.

F. W. BARCLAY.

F. TRACY HUBBARD.†

**PYCNOSTACHYS** (Greek, thick spike, referring to the heavy spikes of fls.). *Labatiæ*. Erect perennial herbs; lvs. opposite, broad or narrow, sessile or petiolate; whorls condensed into a dense terminal spike; fls. bright blue or violet; calyx slightly accrescent, 5-toothed; corolla-tube longer than the calyx, upper lip short, 4-toothed, longer lower, deeply concave; stamens 4: nutlets subglobose, smooth.—About 40 species, natives of Trop. and S. Afr., 1 in Madagascar. *P. urticijblum*, Hook. A much-branched perennial herb, 5-7 ft. high: lvs. ovate-acute, deeply cut, crenate, densely pubescent; spikes very dense, 2-3 in. long; corolla bright blue. Trop. and S. Afr. B.M. 3385. More or less frequent in gardens in England. *P. doweii*, N.E. Br. A stout herb, 4-6 ft. high and loosely branched pyramidal habit; lvs. narrowly lanceolate, acuminate, serrate: fls. many, crowded, in short spikes terminating all the branches, cobalt-blue; calyx-teeth needle-like. Trop. Afr. Intro. into England. B.M. 8450. *P. coccinea*, Hook., with 4-sided st., about 1 ft. high, bright blue fls. and sessile oblong or linear-lanceolate lvs., a native of Madagascar, has also been cult. in England.

**PYRACANTHA** (Greek, pyr, fire, and alantes, thorn; alluding to the bright red fruits). *Roserae*. Fire thorn. Ornamental shrubs, grown chiefly for their bright red berry-like fruits and also for their white flowers and firm foliage.

Thorny half-evergreen shrubs: lvs. alternate, short-petioled, narrow, crenulate or sometimes entire, stipitate; fls. in corymb; stamens short, 4-toothed, lower longer, deeply concave; sta­mens 20, with yellow anthers; carpels 5, free on their ventral side, on their dorsal side connate with the calyx-tube about half or less: fr. a small pome with persistent calyx, red or orange, with 5 stones.—Three species, from S. E. Eu. to Cent. China and the Himal­ayas. The genus is closely allied to *Cotoneaster* but is easily distin­guished by the ovate lvs. and the thorny branches, also by the more con­spicuous stipules. From *Crataegus* it is chiefly distin­guished by the structure of the ovary, which contains 2 equal ovules in each cell, while in *Cotoneaster* one cell contains only 1 fertile ovule and a second imperfect and smaller one. The pyracanthas are usually small shrubs with rather small and narrow leaves and with white flowers in small coryms followed by bright red or orange fruits. *P. coccineæ*, Roem. & Schult. is hardy as far north as Massachusetts in sheltered positions. It is a handsome low evergreen shrub, especially when loaded with its bright red fruits, these remaining on the branches all winter if not eaten by birds, which are fond of them; it is also pretty in spring with its numerous corymbs of white flowers. It is well adapted for planting on rocky slopes or sunny rockeries or for borders of shrubberies; it may also be used for low ornamental hedges or for covering walls, as it stands pruning well and is easily trained into any desired shape. It thrives in almost any kind of well­drained soil, including limestone, and prefers sunny positions. Propagation by seeds or by cuttings of ripened wood in fall under glass, kept during the winter in a temperate greenhouse; also by layers and sometimes by grafting on hawthorn or cotoneaster.

A. *Lvs.* beneath and calyx glabrous.

*coccineæ*, Roem. (Cotoneaster *Pyracanthæ*, Spach. *Crataegus Pyracanthæ* Berckh. *Melanocarpus Pyracanthæ*, Linn.). Fiery thorn. Fiery thorn. Everlasting thorn. Fig. 3264. Shrub, attaining 6 ft., rarely 20 ft., with numerous short spines; young branchlets and petals grayish pubescent; lvs. ovate-oblong to oblongate, acute, crenate, glabrous or slightly pubescent when young; ½-3/4 in. long; corymb pubescent, many-fl., about 1½ in. broad; fls. small, white; fr. numerous, bright red, about ½ in. across. May, June. Italy to W. Asia. Gr. 360. P. 464. Var. Latifoliis, Dipp. (Cotoneaster crenulatus, Hort., not Wenzig), is of more vigorous growth, with slender branches; lvs. less deeply crenate; corollas larger; fr. bright orange-red. Well suited for covering walls and said to be harder than

Pyrostepho (Greek, grain, thorn; the inner surface of the husk of the fruit is covered with many blunt prickle-like). Climbing shrubs with alternate, hairy, 3-5-nerved, entire, or toothed or lobed lvs. and fls. in spikes: fls. dienceous; perianth 4- or rarely 3-5-lobed; ovary superior, 1-celled, 2-ovuled: drupe compressed, with the mesocarp spinulose-verrucose within. About 15 species from Trop. and S. Afr. P. malefica, Engl. A succulent plant with a fleshy subglobose root, resembling a stone from a distance: branches short or long and scandent: lvs. kidney-shaped, irregularly 3-5-lobed, pilose: frs. small, in spikes: perianth 4-lobed. E. Afr. G. W. 10, p. 334.

Pyracantho (a name used from the time of Dioscorides, the derivation from the Greek, much fire, referring to the acrid roots). Composite. This name is still commonly derived from the garden, the "burning daisy," to a section of Chrysanthemum, almost every nursery catalogue offers P. roseum and its numerous varieties, which is referred to botanists to Chrysanthemum coccineum; also P. perthenioides var. aureum, the golden feather, and P. uliginosus. (See Vol. II, p. 753.) All three of these are rather common in gardens and they are known to be most loved by hardy perennials. More recent introductions under the name Pyrethrum are P. Tchihatchewii, also called "flying daisy," (see Chrysanthemum Tchihatchewii, Vol. II, p. 759), and P. leucopetala, Hausskn., a subalpine perennial with silvery white leaves and large yellow flower-heads. Aus. Minor. Suitable for the rockery. This last species is not mentioned under Chrysanthemum.

Pyrula (a diminutive of Pyrus, the pear tree, from some fancied resemblance in the foliage). Pyroleaceae. Wintergreen. Shin Leaf. Low and smooth perennials, with creeping subterranean shoots and stolons for the native garden though not commonly cultivated. Acanthaceous or caulescent, with a cluster of roundish or elliptical evergreen basal lvs. and a simple raceme of nodding white, greenish or purplish fls. on an upright more or less scaly-bracted scape: calyx 5-parted, persistent; petals 5, concave, deciduous; stamens 10: caps. depressed-globose, 5-lobed, 5-valved.—Ten to 15 species, Great Britain to N. Asia and N. Amer. south to Mex. Formerly referred to Ericaceae, but now placed in Pyrolaceae together with Chamaedaphne and Moneses. The name wintergreen is usually applied to Gaultheria.

Pyrola grows naturally in rather poor sandy uplands and in bogs. Like many members of the heath family, wintergreens are difficult to cultivate and will not succeed in garden soil. In removing them from the woods, care should be taken to secure a large ball of earth. They may then succeed in the shade of evergreens and upon rockeries in peaty soil. The species are scarcely in general cult.; they are offered by dealers in native plants. P. americana is probably more cultivated than the others.

P. floribunda white; style curved downward.

Pyrus, Schneid. (Coluteaster cinerata, Reg.) Shrubs with long and slender, spreading and often nearly prostrate branches; young branches yellowish tomentose: lvs. subcoriaceous, narrow-oblong, obtuse and mucronulate, recurved at the margin, entire or sparingly glandular-serrulate, glabrous, grayish green, bright green and glossy above, 1-2 in. long: fls. purple; anther-cells with beaked tips. Lab. to Pa., Rocky Mts., north to subarctic regions. June and July.

Pyrenacantho (Greek, grain, thorn; the inner surface of the husk of the fruit is covered with many blunt prickles). Leucocentra. Climbing shrubs with alternate, hairy, 3-5-nerved, entire, or toothed or lobed lvs. and fls. in spikes: fls. dienceous; perianth 4- or rarely 3-5-lobed; ovary superior, 1-celled, 2-ovuled: drupe compressed, with the mesocarp spinulose-verrucose within. About 15 species from Trop. and S. Afr. P. malefica, Engl. A succulent plant with a fleshy subglobose root, resembling a stone from a distance: branches short or long and scandent: lvs. kidney-shaped, irregularly 3-5-lobed, pilose: fls. small, in spikes: perianth 4-lobed. E. Afr. G. W. 10, p. 334.

Pyrus, Schneid. (Coluteaster cinerata, Reg.) Shrubs with long and slender, spreading and often nearly prostrate branches; young branches yellowish tomentose: lvs. subcoriaceous, narrow-oblong, obtuse and mucronulate, recurved at the margin, entire or sparingly glandular-serrulate, glabrous, grayish green, bright green and glossy above, 1-2 in. long: fls. purple; anther-cells with beaked tips. Lab. to Pa., Rocky Mts., north to subarctic regions. June and July.

Pyrostepho (Greek, grain, thorn; the inner surface of the husk of the fruit is covered with many blunt prickles). Leucocentra. Climbing shrubs with alternate, hairy, 3-5-nerved, entire, or toothed or lobed lvs. and fls. in spikes: fls. dienceous; perianth 4- or rarely 3-5-lobed; ovary superior, 1-celled, 2-ovuled: drupe compressed, with the mesocarp spinulose-verrucose within. About 15 species from Trop. and S. Afr. P. malefica, Engl. A succulent plant with a fleshy subglobose root, resembling a stone from a distance: branches short or long and scandent: lvs. kidney-shaped, irregularly 3-5-lobed, pilose: fls. small, in spikes: perianth 4-lobed. E. Afr. G. W. 10, p. 334.

Pyrostepho (Greek, grain, thorn; the inner surface of the husk of the fruit is covered with many blunt prickles). Leucocentra. Climbing shrubs with alternate, hairy, 3-5-nerved, entire, or toothed or lobed lvs. and fls. in spikes: fls. dienceous; perianth 4- or rarely 3-5-lobed; ovary superior, 1-celled, 2-ovuled: drupe compressed, with the mesocarp spinulose-verrucose within. About 15 species from Trop. and S. Afr. P. malefica, Engl. A succulent plant with a fleshy subglobose root, resembling a stone from a distance: branches short or long and scandent: lvs. kidney-shaped, irregularly 3-5-lobed, pilose: fls. small, in spikes: perianth 4-lobed. E. Afr. G. W. 10, p. 334.

Pyrus, Schneid. (Coluteaster cinerata, Reg.) Shrubs with long and slender, spreading and often nearly prostrate branches; young branches yellowish tomentose: lvs. subcoriaceous, narrow-oblong, obtuse and mucronulate, recurved at the margin, entire or sparingly glandular-serrulate, glabrous, grayish green, bright green and glossy above, 1-2 in. long: fls. purple; anther-cells with beaked tips. Lab. to Pa., Rocky Mts., north to subarctic regions. June and July.

Pyrostepho (Greek, grain, thorn; the inner surface of the husk of the fruit is covered with many blunt prickles). Leucocentra. Climbing shrubs with alternate, hairy, 3-5-nerved, entire, or toothed or lobed lvs. and fls. in spikes: fls. dienceous; perianth 4- or rarely 3-5-lobed; ovary superior, 1-celled, 2-ovuled: drupe compressed, with the mesocarp spinulose-verrucose within. About 15 species from Trop. and S. Afr. P. malefica, Engl. A succulent plant with a fleshy subglobose root, resembling a stone from a distance: branches short or long and scandent: lvs. kidney-shaped, irregularly 3-5-lobed, pilose: fls. small, in spikes: perianth 4-lobed. E. Afr. G. W. 10, p. 334.

Pyrus, Schneid. (Coluteaster cinerata, Reg.) Shrubs with long and slender, spreading and often nearly prostrate branches; young branches yellowish tomentose: lvs. subcoriaceous, narrow-oblong, obtuse and mucronulate, recurved at the margin, entire or sparingly glandular-serrulate, glabrous, grayish green, bright green and glossy above, 1-2 in. long: fls. purple; anther-cells with beaked tips. Lab. to Pa., Rocky Mts., north to subarctic regions. June and July.

Pyrostepho (Greek, grain, thorn; the inner surface of the husk of the fruit is covered with many blunt prickles). Leucocentra. Climbing shrubs with alternate, hairy, 3-5-nerved, entire, or toothed or lobed lvs. and fls. in spikes: fls. dienceous; perianth 4- or rarely 3-5-lobed; ovary superior, 1-celled, 2-ovuled: drupe compressed, with the mesocarp spinulose-verrucose within. About 15 species from Trop. and S. Afr. P. malefica, Engl. A succulent plant with a fleshy subglobose root, resembling a stone from a distance: branches short or long and scandent: lvs. kidney-shaped, irregularly 3-5-lobed, pilose: fls. small, in spikes: perianth 4-lobed. E. Afr. G. W. 10, p. 334.
PYRUS (Latin name of pear tree). Sometimes spelled Pyrus. Rosaceae. The Pome-Fruits, as all the kinds of pears, apples, and crab-apples; also many small trees and bushes grown for the very handsome early flowers and sometimes for the attractive habit, foliage, and little fruits.

Woody plants, bearing mostly on spurs, with simple but sometimes lobed alternate lvs. (pinnatifid sometimes in P. heterophylla) fls. usually perfect, but rarely polygonous, regular, in spring; torus urn-shaped and attached to the carpels and finally closing over them, and with them becoming fleshy in fr.; calyx-lobes 5 and persistent upon the top of the young fr., or in some cases falling away at maturity or before; petals 5, white or red, perigynous; stamens 15-20 or more; styles 2-5, crowning a 2-5-loculed inferior ovary in which the locules are usually 2-seeded. (Figs. 3266, 3267).

PYRUS was held to include not only the pears and apples, but the mountain-ashes or sorbuses, the medlar or quinces, the chokeberries and other groups (Bentham & Hooker, Genera Plantarum, 1867). As late as 1894, Focke (Engler & Prantl, Pflanzenfamilien) holds Pyrus intact except for the separation of Cydonia and Mespilus. While many botanists still hold most or all of these groups in Pyrus, the present tendency to segregate all groups for which separate definitions can be found results in the dismemberment of Pyrus. As the old rather gross assemblage, resulting from the effort to find agreements, can hardly be expected to hold, so the present disunion, resulting from the effort to find differences, may be expected to pass, and the practicable and convenient grouping may be found somewhere between the two extremes. There seems to be good justification for the separation of Cydonia and Mespilus, and perhaps also for Sorbus and Aronia, but it is yet to be determined whether the separation of Malus (the apples) will meet with continuing favor. See Malus, p. 1973, Vol. IV.

PYRUS (diminutive of Pyrus; alluding to the shape of the fr.). Santalaceae. Oil-Nut. Buffalo-Nut. A shrub in E. N. Amer. and 2 trees in the Himalayas with alternate, deciduous, entire lvs. and greenish fls. in spikes or racemes: fls. subdioecious, apetalous; sepals and stamens 4-5; filaments short; ovary inferior, 1-celled, with 2-3 ovules: fr. a 1-seeded drupe. The species in cult. is P. pahare, Michx. (P. oleifera, Gray). A straggling shrub, to 12 ft., puberulous while young; lvs. short-petioled, obovate-oblong, acuminate; fls. in clusters of showy white or blush fls. with the lvs. or in drooping panicles; calyx campanulate, 1-2 in. long; petals 5, obtuse, reflexing lobes. B.B. (ed. 2) 5:181. H.U. 5, p. 1.—One of the best rarer plants for warm greenhouses; blooms profusely in early winter.

ALFRED REHDER.

PYRUS, the pears and apples, once included a vast assemblage of nearly 200 species and subspecies in 6 sections: Pyrus, Malus, Mespilus, Cydonia, Sorbus, and Aronia. It was not until 1894 that the species in the section Pyrus were moved to separate genera by Hooker, for reasons stated above. The present classification, based on the work of many botanists, distinguishes about 80 species of Asia and North America, including some 30 species in the section Pyrus (Pyrus, Malus, Mespilus, Cydonia, Sorbus, and Aronia). The separation of these genera from Pyrus has been based on the presence or absence of certain characters, such as the number of petals, the length of the pedicels, and the shape of the fr. The species are mostly small trees, bearing clusters of showy white or blush fls. with the lvs. or in drooping panicles; calyx campanulate, 1-2 in. long; petals 5, obtuse, reflexing lobes. B.B. (ed. 2) 5:181. H.U. 5, p. 1.—One of the best rarer plants for warm greenhouses; blooms profusely in early winter.

ALFRED REHDER.

PYRULARIA (diminutive of Pyrus; alluding to the shape of the fr.). Santalaceae. Oil-Nut. Buffalo-Nut. A shrub in E. N. Amer. and 2 trees in the Himalayas with alternate, deciduous, entire lvs. and greenish fls. in spikes or racemes: fls. subdioecious, apetalous; sepals and stamens 4-5; filaments short; ovary inferior, 1-celled, with 2-3 ovules: fr. a 1-seeded drupe. The species in cult. is P. pahare, Michx. (P. oleifera, Gray). A straggling shrub, to 12 ft., puberulous while young; lvs. short-petioled, obovate-oblong, acuminate; fls. in clusters of showy white or blush fls. with the lvs. or in drooping panicles; calyx campanulate, 1-2 in. long; petals 5, obtuse, reflexing lobes. B.B. (ed. 2) 5:181. H.U. 5, p. 1.—One of the best rarer plants for warm greenhouses; blooms profusely in early winter.

ALFRED REHDER.
and the absence of fr-stalk (Fig. 3270) afford good structural characters, as well as the fl-bearing habit and other characters. Many of the species that have been named under Pyrus will be found in Sorbus.

The genus is held to comprise the pears and apples and no order (Pyrophorum and Malus), there are probably fifty or sixty species.

Under Pyrus, the names are P. arbutifolia, Linn., the red chokeberry; P. atropurpurea, Bailey, the purple chokeberry, sometimes regarded as a variety of the former; P. melanocarpa, Willd., the black chokeberry; P. floribunda, Lindl. (not Hort.), or barberry. The fruit of Pyrus is of the kind known to botanists as a pome. The morphology of the pome is still perhaps a subject of disagreement, although most botanists now consider it to be a hollow torus (receptacle), or hypanthium, or cupula, in which the ovary is imbedded. Fig. 3271 illustrates the theoretical structure. The ovary is at b, wholly enclosed in the fleshy torus a. Most of the edible part of the apple or pear, therefore, is considered to be torus, whereas the core is ovary. This ovary, in common apples and pears, is of five carpels or cells, as shown in the cross-section (Fig. 3272). It was formerly held that the edible part is largely calyx-tube, but various morphological considerations have inclined students to regard it as stem rather than calyx; the term calyx-tube is still retained, however, in descriptive writings.

One of these considerations is the fact that apples sometimes bear a rudimentary leaf (as in Fig. 3272), an organ which is commonly borne only by stem.

Apples sometimes take on most unusual and grotesque shapes, and two or more fruits may coalesce into one. The native American crabs, described in numbers 37 to 45 in this list, are yet little known to planters, but they comprise much promising material, and they should yield horticultural subjects for the entire area of the United States, outside the semi-tropical regions, and for good parts of Canada. As a class they bloom later than the Asiatic species. As yet, only P. iberica appears to have yielded a good double-flowered form. With the recent botanical discrimination in this interesting group, attention will probably be called to a closer study of the forms by collectors. They are easy of culture, and may be readily increased by grafting.

Hybridizing will probably play an important part in the horticultural development of the ornamental crabs, as they cross freely. It is probably due to this cause that the Asiatic forms are so difficult to distinguish botanically. The pears and apples appear not to intercross, although the curious P. auricularia is generally considered to be a hybrid between the pear and the crab-tree (Sorbus Aria).

The pear may be made to grow for a time when grafted on the apple, but it is usually impossible to graft the pear species permanently on the apple species with any degree of success; yet pears thrive on quinces and also on hawthorns, which are well-marked genera. In nursery practice when pear stocks are not at hand, long pear cions may be worked on apple pieces and roots may form from the cion and the pear become own-rooted on the failure of the apple stock. Apples appear not to be successful on pears.

3273. A pome bearing a rudimentary leaf (at A).
INDEX CONTINUED.

Plants of the genus Pyrus, including species, varieties, and hybrids are described in detail. The two groups are distinguished based on their characteristics.

THE TWO GROUPS.

1. Pears (Pyrophorum).—Fr. either with a conical base or possessing a cavity like an apple, the flesh bearing grit-cells (unless the flesh is smooth and without grit-cells); styles usually free or not united at the base: calyx-tube or hypanthium generally closed by a cushion-like formation, in figs. white. Species 1-18. Of these plants there are perhaps 15-20 species, native to S-Cent. Eu. and Asia, where it has been cultivated since the earliest times. There are no representatives indigenous, so far as known, in S. Amer. or Japan.

2. Apples (Malus).—Fr. usually with a distinct depression at either end, the flesh without grit-cells; styles more or less united below: calyx-tube or hypanthium open; figs. white, tinged red, sometimes clear white. Species 20-45. There are probably 40 good species of this subgenus, of wide distribution. The common apple, P. Malus, is probably indigenous in S. W. Asia. In

iberia, China, and Japan, several species are native, of which the best known are the smooth-growing crab trees with small frs. that yield their caloric value. In N. Amer. is another set, represented by the Oregon crab, P. ursina, the Prairie States crab, P. ursina, and the far western crab, P. Fusca. The American forms have recently been re-defined into several species, the actual limitations of which are yet to be determined. It has been difficult to find good characters to separate the small-fruited apples, particularly the Asiatic forms. The recent study of the Asiatic material, however, has resolved it into a number of well-marked species-forms.

I. PYROPHORUM, OR PYRUS PROPER. The Pears.

A. The occidental or Eurasian pears, being the common pomological pears of this country: lvs. appressed or crenate-serrate or entire (at least not exscisse-serrate), mostly abruptly pointed: calyx usually persistent at apex of fr. 

orgenus, Linn. Common Pear. Figs. 3275; also Figs. 2805 and others, p. 2505 and following. Strong upright tree, living to a great age and sometimes attaining a height of 75 ft. and a girth of 15 ft. and more, the lvs. on short spurs as well as on the main growths, the pedicles and sometimes the young growth pubescent, but all parts becoming glabrous; lvs. mostly obovate or ovate, with a prominent point, hard in texture and veiny, bright green, the serrations small and much appressed and obtuse, or sometimes the lvs. are almost entire; lvs. 4-12 in umbel-like clusters on slender (2-3-in.) pedicels, white, appearing with the lvs.; calyx persistent, or rarely deciduous; stamens 15-20; fr. very various under cult., usually tapering to the st., the flesh generally with gritty concretions. Native to S. Eu. and Asia, where it has been cultivated from the earliest times.—Probably indigenous as far east as Kashmir. In the Syrio-Persian region are several very distinct pyruses of the pear group, a number of which may be outlying forms of P. communis. In the wild in Eu., various thorny and small-fruited forms are known.

Var. Pyraster, Linn. Much like the type of P. communis, but the fr. globose: lvs. more rounded, strongly serrate, glabrous when young; usually thorny. Probably a wilding form.

Var. sativa, DC. The cult. pear, in many pomological forms, the tree large and free-growing and without thorns: lvs. large.

Var. cordata, Hook. f. (P. cordata, Desv.). A spiny shrub, wild in England and France: lvs. smaller than in the type (about 1 in. broad), ovate or nearly orbicu-
2868 PYRUS

was discovered about 1650 at Bollweiler, in Alsace; it bears very strongly, and apparently does not come true to seed to 50 ft., with buds and branchlets tomentose; lvs. 3-4 in. long, elliptic, unequal and rounded at base, short-acuminate, irregularly and coarsely sharp-serrate or double-serrate, lower surface pubescent or glabrous, 8 or more in tomentose clusters, on slender pedicels; calyx-tube and lobes tomentose; styles 2-3 in. diam., pyriform, red, silky-tomentose, the base mostly cup-shaped, the apex obtuse-acuminate or short-acuminate; fls. small, on densely tomentose pedicels; frs. globose to obovoid, slightly pubescent, the calyx persistent. Caucasus, S. Russia. The specific name was first written, by Pallas, elaegriofolia (not elaeagnuloida), because he considered elaegnus to be the proper spelling of the name of the oleaster genus, it having been spelled that way by Dodoens. Var. Kotzschiana, Boiss. (P. Kotzschiana, Boiss. P. ariolus var. Kotzschiana, Schneid., is usually spineless, the lvs. larger (about 1 in. long), the fr. globose and larger (about 1 diam.).

6. P. heterophylla, Regel & Schmalh. Small thorny glabrous tree, with very variable foliage, some plants having lvs. that are entire at the margin, others are all and almost of thread-like form, but the greater number with forms intermediate between these two extremes, usually ovate in outline, the lower surface pubescent, mostly pinnatifid and the segments unequal and rounded at base, short-acuminate, irregularly and coarsely sharp-serrate or double-serrate, lower surface pubescent or glabrous, 8 or more in tomentose clusters, on slender pedicels; calyx-tube and lobes tomentose; styles 2-3 in. diam., pyriform, red, silky-tomentose, the base mostly cup-shaped, the apex obtuse-acuminate or short-acuminate; fls. small, on densely tomentose pedicels; frs. globose to obovoid, slightly pubescent, the calyx persistent. Caucasus, S. Russia. The specific name was first written, by Pallas, elaegriofolia (not elaeagnuloida), because he considered elaegnus to be the proper spelling of the name of the oleaster genus, it having been spelled that way by Dodoens. Var. Kotzschiana, Boiss. (P. Kotzschiana, Boiss. P. ariolus var. Kotzschiana, Schneid., is usually spineless, the lvs. larger (about 1 in. long), the fr. globose and larger (about 1 diam.).

7. P. Korshinskyi, Litw. Tree, to 20 ft. or more, or a shrub, with branchlets and buds gray-tomentose; lvs. coriaceous, about 3 in. long, lanceolate or ovate-oblong, somewhat tomentose above and beneath, the margins with coarse crenate or double-crenate incurved gland-tipped serratures, the petiole long and tomentose; fr. nearly globose, stout-peduncled, nearly 1 in. diam., with persistent calyx. Kohkura, Turkestan.

8. P. salicifolia, Pall. Small tree, often splay, becoming 30 ft. tall, with gray-tomentose branchlets; lvs. willow-like, 2-3 in. long, (whence the name), linear-lanceolate or lanceolate, mostly tapering toward both ends, entire or very nearly so, hoary beneath; fls. white, in corymbs, short-peduncled; fr. round-pyramid, short stamened, yellow or greenish, about ½ in. diam., the calyx persistent. Caucasus, Armenia. G.C. III. 14: 115, G. 34: 365.—A showy spring-flowering small tree, Hardy in the northern states, and worthy of being better known. Var. pendula, Hort., has drooping branches. G. 32: 648. P. canescens, Spach, is perhaps a form or hybrid of P. salicifolia; lvs. lanceolate or narrow-elliptic, about 2½ in. long, at apex acute or mucronate, minutely crenulate, sometimes twisted, tomentose.

AA. The oriental or China-Japanese pears, grown in this country to some extent for ornament and fr., and producing hybrids with P. communis: lvs. mostly markedly acuminate and very sharp- or obtuse-serrate; calyx usually falling from the apex of the fr. in the cult. forms (not so in P. ussuriensis and P. ovoidea). (See Rehder, Synopsis of the Chinese Species of Pears, Proc. Amer. Acad. Arts and Sci. 50: 225-40; also Plantae Wilsonianae, 2: 263-6.)

9. serotina, Rehd. Fig. 3276. Tree, 20-50 ft., the branchlets glabrous or becoming so: fls. ovate-oblong or seldom ovate, 3-5 in. long, rounded at base and rarely subulate or cuneate, long-acuminate, strongly and sharply obtuse-serrate, with partially appressed serratures, when young villos or beneath cobwebby but becoming glabrous: inf. umbellate-racemose: fls. 5-6-fl.; glabrous or somewhat tomentose, the pedicels slender: fls. white; sepals or

2868 PYRUS

lar, subcordate: fls. smaller: fr. globose to slightly turbinate, about ½ in. diam.; calyx persistent.

There are garden forms of P. communis, differing in foliage, as var. trilobata, Hort., lvs. lobed; var. heterophylla, Hort., lvs. cut; var. variagata, Hort., lvs. variegated. In Algeria is var. longipes, Henry (P. longipes, Cos. & Dur.), a small tree with few spines: lvs. with long slender petiole, ovate, acuminate, subcordate, about 2 in. long and 1 in. broad; fr. globose, about ½ in. diam., the calyx deciduous. In Spain is var. mariana, Willk., a small tree, with ovate lvs. about 1 in. long, rounded at base, on very long slender petiole: fr. globose, about ½ in. diam., the calyx persistent.

2. nivalis, Jacq. Snow Pear. Tree, without thorns, the shoots grayish pubescent: lvs. 2-3 in. long, elliptic to oval to ovate-oval, obtuse or short-acute, cuneate at base, entire or toward apex minutely crenulate, gray-pubescent; fls. large, white, showy; fr. small, roundish pyriform, late-ripening, acid, becoming sweet when overripe. Austria, and wild in France and elsewhere, but probably as an escape.—The snow pear is a small tree, with thick shoots that are white-or gray-tomentose: fls. white; sepals or bracteoles orbiculate, about ½ in. diam., the calyx persistent.

Pyrus serotina. (X¼)

3276. Pyrus serotina. (X¼) 3277. Pyrus ussuriensis. (X¼)

Pyrus serotina, and by others to be a hybrid race of P. communis and P. anguinaulera; Schneider, however, places it as a good species with which he associates other names as synonyms and varieties, and according to his view P. salsifolia, DC. (sage-ivd., pear of the French), is P. nivalis X P. communis. It is not known to be in cult. in this country, but it is to be looked for in arboreta and other collections. Said to be called "snow pear" because the frs. are fit for eating after snow falls.

The following related species may be expected to appear now and then in trade-lists or in special collections:

3. P. anguinaulera, Vill. (P. portorica, Desf. P. canesilla, Guss. Prob. P. sincado, Diam.). Shrub or small tree (to 30 ft.), spiny, with light tomentose buds and young branchlets; lvs. thick and coriaceous, 1½-2 in. long, narrow-elliptic, oblong-lanceolate or oblong-acuminate; fr. globose, about ½ in. diam.; calyx-tube and lobes tomentose, fr. nearly globose, ½ in. diam., green and hard. France to Anacapa islands. Lvs. petiolaris, B. R. 1894 (as P. microcarpa, G. W. 14, p. 286.—The names P. Michauxia, Boiss., P. pteroceras, Pers., and P. salsifolia, Spach, probably represent hybrids of this species with P. nivalis.

XCIV. The bloom of Pyrus pulcherrima (P. floribunda).
calyx-lobes triangular-ovate and long-acuminate, 1/2 to about 3/4 in., long, glandulose-denticate; petals oval, short-clawed, nearly 3/4 in. long; stamens about 20; styles 4 or 5, glabrous; fr. subglobose, brown, slender-stalked, the calyx deciduous. Cent. and W. Chins. B.M. 8226 represents a form named by Rehd var. Staphiana, differing in pyriform fr., less appressed serratures on the lvs., and petals attenuate-clawed. P. serotina or its forms is recommended on the Pacific Coast as a more or less blight-resistant stock for the European types.

Var. culta, Rehd. (P. sinensis, Hort.), not Lindl. nor Poir. P. sinensis var. culta, Makino). Sand Pear. Fig. 2808, p. 2507, the details of if.-margins not showing. JAPANESE AND CHINESE PEAR of pomologists. Differs from the type of the species in its large pyriform or apple-form fr., larger and broader lvs. (which are often 6 in. long and 3-4 in. broad). JAPAN.—A very rapid-growing tree, with strong, thick shoots: fr. broadly ovate and long-pointed, very dark green, the margins thickly furnished with very sharp, sometimes almost bristle-like teeth: frs. large, appearing rather in advance of the foliage: fr. hard and usually roughish, commonly with a depression or “cavity” about the st., the flesh tough and gritty and poor in flavor, the calyx usually falling before maturity. R.H. 1879:170, 1880:110 (as P. Sieboldii).—Known in this country in a number of varieties, as Chinese Sand, Japanese Sand, California, Madame von Siebold (which pomological variety Rehd writes, “may be considered as representing the type” of var. culta), Mikado, Diasmo, Gold Dust. The frs. are often remarkably apple-like, especially in the russet varieties, but they are distinguished by the long st. and pear-like flesh. The Japanese pear is little prized for its fr. although the pears are useful for preserving and some of the varieties are showy and the frs. are good keepers, it is used for stocks upon which to work the common pear, and it has given good results in hybridizing. It is an excellent ornamental tree, being a clean grower of great vigor. Kieffer, Le Conte, and others are hybrids of P. communis and P. serotina var. culta (Figs. 2809-2810). This type has a stronger growth than the common pears, the lvs. are usually broader and darker green, with closely and mostly obtusely serrate edges, the fr. is more or less pyriform and the better flavor of than that of the oriental parent, and the calyx is either persistent or deciduous. Seedlings of Kieffer often produce the sharply toothed lvs. of P. serotina var. culta.

Other oriental pears are likely to appear in cult., and it is necessary to distinguish them briefly.

b. Lvs. coarsely and sharply serrate.

c. Fr. globose or subglobose, short-stalked: lvs. orbicular-ovate or ovate, these and if. glabrous from the first.

10. P. ussuriensis, Maxim. Fig. 3277. Differs from its allies, according to Rehd, chiefly in the short stalk of the fr. which is globose and has a persistent calyx, more abruptly orbicular strongly setose-serrate lvs., and in the lighter yellowish brown color of the branches; fr.-clusters rather dense and hemispherical, owing to the short stalks; petals obvate and rather gradually narrowed toward base; styles distinctly pilose near the base. Manchuria, Amoorland, Manchuria, Amoorland. R.H. 1872, p. 28 (as P. Simoni, Carr.).—Sometimes again, branches often yellow-gray.
PYRUS

17. P. Pashia, Buch-Ham. (P. saroldes, Wall.). Tree, mostly gny, when young with 3-lobed and doubly serrate lvs., like those of Crataegus, the young growths woolly: lvs. ovate or ovate-lanceolate, acuminate, crenate or serrate, becoming glabrous: 9s, 1 in. diam., mostly in woolly corymbose short-peduncled clusters; calyx-lobes acute, deciduous; stems about 30, Himalayas to W. China. Var. kumaon.”

18. P. Pashia, Buch-Ham. (P. saroldes, Wall.). Tree, mostly gny, when young with 3-lobed and doubly serrate lvs., like those of Crataegus, the young growths woolly: lvs. ovate or ovate-lanceolate, acuminate, crenate or serrate, becoming glabrous: 9s, 1 in. diam., mostly in woolly corymbose short-peduncled clusters; calyx-lobes acute, deciduous; stems about 30, Himalayas to W. China. Var. kumaon.”

19. Malus, Linn. (Malus communis, DC. Malus Malus, Brit.) Apple. Fig. 3283; also under 3283. Pyrus Malus, D.C. Mostly a wild or run-wild nearly or quite glabrous form, to which not many of the cult. pomological varieties can be referred. Young branchlets glabrous or soon becoming so: lvs. glabrous above, shining and only scattered-pubescent beneath, the petiole and pedicels only slightly pubescent; calyx-tube and outside of calyx-lobes glabrous but the latter pubescent inside. W. and Cent. Eu.

Var. pumila, Henry (Malus pumila, Mill. Pyrus pumila, Koch). The pubescent type, the source of nearly all the pomological apples, and kept specifically separate by some writers: small or large tree, or bush-like: young branches prominently tomentose, as well as the pedicels, calyx-tube, and both surfaces of the calyx-lobes: lvs. ovate or oval, dull and more or less tomentose beneath. Thought to be native only in S. E. Eu. and in Asia, although run wild elsewhere. A very dwarf form is the Paradise apple (P. Malus var. paradisiaca, Linn.), used as a stock on which to dwarf the pomological varities.

Var. astracanica, Loud. (Malus astracanica, Dum. Pyrus astracanica, DC.). Distinguished by large coarse serrate or doubly serrate lvs. which are tomen-

PYRUS

17. P. Pashia, Buch-Ham. (P. saroldes, Wall.). Tree, mostly gny, when young with 3-lobed and doubly serrate lvs., like those of Crataegus, the young growths woolly: lvs. ovate or ovate-lanceolate, acuminate, crenate or serrate, becoming glabrous: 9s, 1 in. diam., mostly in woolly corymbose short-peduncled clusters; calyx-lobes acute, deciduous; stems about 30, Himalayas to W. China. Var. kumaon.”

18. P. Pashia, Buch-Ham. (P. saroldes, Wall.). Tree, mostly gny, when young with 3-lobed and doubly serrate lvs., like those of Crataegus, the young growths woolly: lvs. ovate or ovate-lanceolate, acuminate, crenate or serrate, becoming glabrous: 9s, 1 in. diam., mostly in woolly corymbose short-peduncled clusters; calyx-lobes acute, deciduous; stems about 30, Himalayas to W. China. Var. kumaon.”

19. Malus, Linn. (Malus communis, DC. Malus Malus, Brit.) Apple. Fig. 3283; also under 3283. Pyrus Malus, D.C. Mostly a wild or run-wild nearly or quite glabrous form, to which not many of the cult. pomological varieties can be referred. Young branchlets glabrous or soon becoming so: lvs. glabrous above, shining and only scattered-pubescent beneath, the petiole and pedicels only slightly pubescent; calyx-tube and outside of calyx-lobes glabrous but the latter pubescent inside. W. and Cent. Eu.

Var. pumila, Henry (Malus pumila, Mill. Pyrus pumila, Koch). The pubescent type, the source of nearly all the pomological apples, and kept specifically separate by some writers: small or large tree, or bush-like: young branches prominently tomentose, as well as the pedicels, calyx-tube, and both surfaces of the calyx-lobes: lvs. ovate or oval, dull and more or less tomentose beneath. Thought to be native only in S. E. Eu. and in Asia, although run wild elsewhere. A very dwarf form is the Paradise apple (P. Malus var. paradisiaca, Linn.), used as a stock on which to dwarf the pomological varities.

Var. astracanica, Loud. (Malus astracanica, Dum. Pyrus astracanica, DC.). Distinguished by large coarse serrate or doubly serrate lvs. which are tomen-
PYRUS

tose beneath, and by the long pedicels. Probably Asian.

Var. apetala, Asch. & Graebn. (Pyrus apetala, Muenchh. P. dioica, Moench). Figs. 3284, 3285. Fls. with no colored petals, these organs being represented by very small green bract-like or sepal-like bodies, the sepals appearing, therefore, to be in 2 rows; stamens absent; styles 10-15; ovary 6- or 7-celled, perhaps more: fr. (apparently produced by pollination with other apples) much as in common apples except for a deep not closed cavity at the apex, there being one “core” above the other due probably to the crowding of the many cells as the pistil grows; as the apple grows, some or all the cores split open, and cause the hole in the top of the fr.; in Fig. 3285, b and c represent the persistent points of ruptured core-walls, and a marks a thickened petal or bract that stood in the fl. This monstrosity has been long known, and now and then recurs.

There are horticultural forms of *P. Malus* distinguished as: Var. aurea, Hort., with yellow-variegated lvs.; var. plena, Hort., with more or less double fls.; var. pendula, Hort., of weeping or drooping habit.

20. Soulardii, Bailey (Malus Soulardii, Brit.). SOULARD CRAB. Figs. 3286, 3287. Apparently natural hybrids of *P. Malus* and *P. soemosa*: a small tree, with much the look of an apple tree, and woody: lvs. large, round-ovate to elliptic-ovate or oblong-ovate, either rounded or tapering at the base, often very blunt or even rounded at the top, mostly bluntly or coarsely serrate or dentate when young, irregularly crenate-dentate at maturity, with a tendency to become lobed, on short pubescent petioles, thick and often rugose and woolly beneath: fls. bluish, in close woolly clusters like those of the apple: fr. often 2 in. or even more in diam., flattish lengthwise, yellow and often with a tinted cheek, the basin shallow, flesh fairly edible. Wild in the Mississippi Valley from Minn. to Texas, but always local and in different forms of fr.—Named for James G. Soulard, Galena, Ill., who intro. the first variety to cult. In some forms the lvs. become nearly smooth late in the season and there is little tendency toward an irregular notching or lobing of the margins. The tree is hardy and the fr. keeps well and is useful for culinary purposes. A few named varieties are grown in the upper Mississippi Valley, where trees of great hardiness are demanded. For accounts of the pomological offshoots of our native apples, see Bailey, “Evolution of Our Native Fruits,” and Craig & Hume, “Native Crab Apples and Their Cultivated Varieties,” Iowa Acad. Sci., 1899.

21. baccata, Linn. (Malus baccata, Borkh. Malus microcarpa var. baccata, Carr. M. baccata var. sibirica, Schneid.). SIBERIAN CRAB. Fig. 3288. Small round-headed tree, with a compact crown, smooth in all its parts as maturity; growth hard and wiry: lvs. ovate to ovato-lanceolate or ovate-acuminate, thin and glabrous, on slender petioles, finely and nearly evenly serrate, bright green: fls. appearing with the lvs. on long and very slender (2-3 in.) greenish pedicels, white, handsome: style mostly longer than the stamens, lightly hairy or glabrous: fr. from the size of a pea to ¼ in. diam., on long, hard sts., yellow or red and firm and often translucent in texture, never becoming mellow, the calyx falling away before maturity. Siberia to Manchuria and N. China. B.M. 6112. M.D.G. 1899:454. Gt. II:202. —Difficult to distinguish from *P. pulcherrima*: larger, becoming a distinct tree, sometimes as large as a large apple tree: lvs. with blunter teeth, and usually much longer, very slender, hard, glabrous petioles: fls. lighter colored, usually white; vernation convolute (lvs. rolled in the bud). It runs into many forms, particularly in fr. Var. mandshurica, Maxim. (Malus baccata var. mandshurica, Schneid.). Low densely branched tree when growing in the open but tall and wide-spreading in forests: lvs. broader, elliptic or round-elliptic, mostly entire, the petiole, rib, and nerves, as well as inf., more or less hairy: style scarcely as long as the stamens, mostly longer, very slender, hard, glabrous: fr. from the size of a pea to ¼ in. diam. Amur region, Korea, Cent. China, Japan. Var. himalaiica, Maxim. (Malus baccata var. himalaiica, Schneid.). Lvs. very broad-oval, coarsely serrate, more or less hairy underneath, particularly on midrib. W. Himalayas. A handsome form from Korea with pure white large lvs., large dark green lvs. and large dark red fr., is distinguished by Rehder as forma Jackie: var. mandshurica it differs in being glabrous.—The Siberian crab of pomologists belong to *P. baccata*, but to which of the several botanical forms (if to any of them) is not clearly determined; the species is also used in cold countries as a stock on which to graft the common apple. It is a species of great hardiness, withstanding the climate in the Canadian N.W. provinces. It is much subject to blight (pear-blight) and for this reason its usefulness is much limited. Hybrids with *P. Malus* promise a valuable type of apple for cold regions. See Fig. 648, Vol. I, and pp. 569.
and 570. The large-fruited pomological crab-apples of the Hyslop and Transcendent type are supposed to be hybrids between *P. baccata* and *P. Malus*, and to these forms the name *P. prunifolia* has been applied but probably erroneously. The *P. cerasifera*, Spach, is of the *P. baccata* group, and is probably a hybrid. It makes a large tree with spreading head, and bears very large pure white fls.: the fr. is variable in size, shape, and color, and either retains or drops the calyx.

22. *Halliana*, Voss (*Malus Halliana*, Koehne). Fig. 3289. Bush or small tree, 6-15 ft. tall, with a loose open crown: lvs. long-ovate, glabrous, leathery, crenate-serrate, the petioles short: fls. rose-colored, more or less polygamous, hanging on slender reddish pedicels, the calyx-lobes often more or less obtuse, the styles usually 4: fr. size of a pea or somewhat larger (3/4-1/2 in. diam.), abruptly contracted into a thickened pedicel, brownish red, ripening late in autumn and containing very large seeds. W. China; cult. in Japan. M.D.G. 1890: 457. One of the handsomest of the flowering apples. Var. *rosea*, Bailey, has rose-colored fls. and is very beautiful.

23. *theifera*, Bailey (*Malus theifera*, Rehd.). A small tree with stiff spreading branches, hardy at Boston, resembling a cherry tree when in bloom, the fls. white or light pink (there is a rose-colored form) with purple calyx and the unfolding lvs. purplish: distinguished from *P. Halliana*, its nearest ally, by larger and broader ovate or ovate-oblong or elliptic-ovate sharply glandular-serrate thinner lvs., longer pedicels and less slender pedicels, acute or acuminate calyx-lobes, mostly 3 styles, white or blush fls., and larger frs. China to Assam.—The fr. is globose, light greenish yellow with reddish cheek, ripening in Mass. in Oct.: fls. fragrant. Not yet grown outside botanical collections, but a handsome free-flowering species. Var. *rosea*, Bailey, has rose-colored fls. and is very beautiful.

24. *sikkimensis*, Hook. f. Small tree, with tomentose branches: lvs. ovate to ovate-oblong, 2-3 in. long, not lobed, the apex long-acuminate, abruptly narrowed at base, tomentose beneath, with fine and close sharp-pointed serratures, the petiole much shorter than the blade: fls. 1 in. across, 5-8 in a corymbose cluster, appearing with the lvs., white but pinkish outside, the buds rose-colored; pedicels very slender, 1/2-2 in. long; calyx-tube obovate, the lobes lanceolate and recurved; petals orbicular, claw very short, tomentose; stamens many; styles slender and glabrous, connate below: fr. turbinate, not depressed at base, 2/3 in. diam., dark red speckled white, the calyx wholly wanting. Himalaya. B.M. 7430.
PYRUS

cc. Calyx persistent on the fr.
l. Style glabrous at base; fr. punctate: lvs. sharply and mostly doubly serrate.

25. Pratti, Hemsl. (Malus Pratti, Schneid.). Young growths whitish hairy but becoming glabrescent: lvs. 3-4 in. long, the long petiole extra, ovate-lanceolate to ovate or elliptic, acuminate-acute, the base usually rounded, finely somewhat double-serrate with cally serrations: fls. medium size, in many-fl. terminal sub-sessile clusters, slender-pedicelled; calyx-lobes acuminate, white-silky inside; petals ½ in. long, short-clawed, rounded at apex, conspicuously veined; styles 5, glabrous: fr. about ½ in. long, oval, smooth, the calyx persistent.

China.

Style villous at base: fr. smooth and not punctate: lvs. simply serrate or crenato-serrate.

e. Lvs. membranaceous or thin in texture, dull above: calyx-lobes acuminate and longer than the tube.

20. rufifolia, Wild. (Malus rufifolia, Borkh. M. hybrida, Loisel.). For years considered to be a hybrid of P. baccata and P. Malus or other species, but a plant which he considers to be a variety of it (var. hindo) having been found wild in China leads Rehder to the conclusion that it is a good natural species; P. rufifolia itself is yet known only as a cult. plant: tree.

V. Rinki, Bailey (Malus pumila var. Rinki, Koidz. M. prunifolia var. Rinki, Rehd. M. prunifolia, Koidz. M. matsumurae, Koidz. M. rufifolia, Carr. Pyrus Rinko, Wenz. P. prunifolia, Miq.). Chinese Apple. Figs. 3290, 3291. Wide-spreading small tree, to 15 or 18 ft. high, more pubescent than the type (P. prunifolia) and representing a more southern range, the petioles shorter and the fls. pink or pinkish rather than white. China. B.M. 6265.—This tree yields an edible apple, sometimes as much as 1½ in. diam., of a greenish or yellowish color and with a bitter-sweet flavor; it was formerly grown in Japan for its fr., but its cult. has been discontinued since the intro. of the European apple, yet is now used as stocks for the imported kinds. In China it is still sparingly cult. In botanical characters the plant is much like P. Malus, but is distinguished by the much longer fr.-stalk, more sharply serrate and usually less tomentose lvs., the apex of the fr. not sunken but with a raised calyx which is thickened and fleshy at the base.

f. Lvs. paper-like in texture, shining above: calyx-lobes shorter than the tube or only equaling it.

27. spectabilis, Ait. (Malus spectabilis, Borkh. M. sinensis, D. M.). Chinese Flowering Apple. Fig. 3292. Small tree, with darker-colored fls. than those of the apple (the opening fl.-buds almost coral-red), and blooming earlier, making an erect vase-like head: lvs. narrower, oval to ovate-oblong, slender-stalked, nearly glabrous on both surfaces or becoming so, usually more closely serrate than those of the apple: pedicels and calyx-tube nearly or quite glabrous: fr. roundish or round-oval, without a cavity at the base, reddish yellow, sour. Probably China and Japan, although unknown wild and very little grown in those countries, although well known in cult. in Eu.; the plant called by this name in Japan is probably P. Halliana or P. micromalus. B.M. 267. L.B.C. 18:1729. Gn. 21, p. 46. Gmg. 3:273. G.F.1:272.—A very handsome early-blooming tree, of which the double-fl. and semi-double forms are most prized. P. Malus itself has been disseminated under the name of P. spectabilis. Harvy in the northern states. Var. Riversii, Booth, has very large half-double bright rose-red fls.

28. micromalus, Bailey (Malus micromalus, Makino- M. spectabilis var. micromalus, Koidz. Pyrus Kaida- Moull. Malus microcarpa var. Kaido, Carr. M. spec­ tabilis var. Kaido, Sieb.). Fig. 3293. Apparently a hybrid, P. spectabilis being undoubtedly one of the parents, and probably P. baccata or P. floribunda the other. From P. spectabilis it is distinguished by the narrower lvs. which are gradually narrowed at the base into a slender petiole, by tomentose pedicels and calyx, and the subglobose fr. which has a depression at base and apex, the calyx sometimes deciduous. Cult. in Japan, and said to have been intro. from China.
unknown in the wild. — A useful and showy plant, bearing profusely of bright red fls., with red calices and pedicels, and holding its many little fls. well into winter or even all winter.

**BB. Lvs. conduplicate (folded together lengthwise face to face in the bud), those on the strong shoots often lobed.**

**c. Calyx persistent.**

30. Tschonoskii, Maxim. (Malus Tschonoskii, Schneid.). Fig. 3294. Tree, 30-40 ft. with erect and open habit: lvs. ovate-acuminate, coarsely serrate, with sharp teeth, shining and pilose above although tomentose when young, somewhat tomentose beneath: fls. 2-5 together, white tinged rose, on whitish hairy pedicels about ½ in. long; calyx-tube whitish hairy, the lobes or sepals ovate-acute, spreading in ft.; petals about ½ in. long; fr. obovoid, about 1 in. diam.; calyx-lobes persistent, erect or nearly so, white-tomentose, 1 in. or less diam., yellow with a rosy check. Japan. B.M. 8179. G. F. 7:55 (reduced in Fig. 3294).

**cc. Calyx deciduous.**

31. Toringoides, Bailey. (Malus Toringoides, Rehd.). Distinguished from P. Tschonoskii by its smaller fls. in many-fl.d. clusters, much smaller frs. which are red and with reflexed calyx-lobes, and by the lvs. which are more distinctly lobed and sharply close-serrate: a handsome tree with spreading branches: lvs. simple, broadly ovate, with closely or finely toothed lobes; fr. small, ½ in. or less long, produced abundantly. China. G.M. 56:397.

**dd. Styles villous at base; fr. obvolute.**

32. kunsuensis, Batal. (Malus kunsuensis, Schneid. Eriobotryus kunsuensis, Schneid.). A distinct species, marked by the usually broad-ovate 3-5-lobed and sharp-serrate glabrous or glabrescent lvs. which are 3-nerved at base, and by the ovoid red fr. from which the calyx is deciduous: young twigs glabrous, red-brown; buds of the same elongate, acute; scales only finely ciliate: lvs. green dark above, somewhat glaucous on the nerves, somewhat paler beneath, glabrous or slightly hairy on the nerves, suborbund in outline, upper half palmately 3-lobed, lobes triangular, acute, margin serrate, the side lobes somewhat shorter; petiole 1½ in. or less long: infl. a false umbel; calyx acute, equaling the corolla; petals round, short-clawed, more or less hairy inside; stamens 20; styles 3, hairy and grown together at base: fr. purple, 3-celled, about ½ in. long. China.

**EE. Fls. white, the petals nearly orbicular and at base contracted into a claw.**

33. Sargentii, Bean (Malus Sargentii, Rehd.). A low bush, much branched, the branches rigid and often spinescent: lvs. ovate to elliptic-oblong or ovate-oblong, about 2-3 in. long, sharply and unequally serrate, slender-petioled, those on the vigorous branches mostly ovate and 5-lobed: fls. pure white, 1 in. across, in 5- or 6-fl.d. clusters, on glabrous pedicels about 1 in. long; calyx-tube and lobes glabrous outside and villous inside, the lobes ovate-lanceolate and acuminate; petals about twice as long as calyx-lobes, oval, short-clawed, glabrous; stamens 15-20; styles usually 4 (rarely 3 or 5), connate and villous below the middle: fr. subglobose, ½ in. or less diam., dark red with a slight bloom. Japan. S.T.S. 1:37. G.C. III. 57:291 (as P. Sargentii); 58:309 (fr.). G.M. 58:278.

**FF. Fls. reddish (carying to nearly white), the petals cuneate or rounded at base, obvolute or oblong.**

34. Sieboldii, Regel (Malus Sieboldii, Rehd. Pyrus Toringo, Sieb. M. Toringo, Sieb. P. Mengo, Sieb. M. microcarpa var. Toringo, Carr.) Fig. 3295. Shrub: lvs. ovate or oblong-ovate in outline, pubescent, becoming colored in autumn, strongly notched or lobed on either side at or below the middle, the middle lobe often notched again near the top, the remaining margins sharply dentate: fls. small, bluish, on slender sts.; styles 3-4, connate at base; sepals triangular-ovate or lanceolate, about equaling the tube: fr. the size of a pea, shedding its calyx, yellow or red. Japan. R.H. 1870:451; 1881, p. 296. Gn. 34, p. 206. M.D.G. 1899:456.—Grown mostly for ornament, but lately recommended as a hardy stock upon which to dwarf the apple. In Japan, the little frs. are gathered after frost and preserved. Upon the fr.-spurs, the lvs. are sometimes only toothed, but upon barren or strong shoots they are prominently lobed and suggest the lvs. of hawthorns. Var. arboreascens, Bailey (Malus Siebdlit var. arboreascens, Rehd.), which is widely distributed in Japan, differs from the type in its more tree-like habit (to 30 ft.), less pubescent, lvs. somewhat larger and usually less deeply divided and often lobed only on the ends of strong shoots, fls. often nearly white, frs. yellow or red. Var. calocephala, Bailey (M. Sieboldii var. calocephala, Rehd.), has large handsome bright red fr. and large fls.: lvs. on fruiting branches

**3294. Pyrus Tschonoskii (× 3¾). No. 29.**
mostly ovate-oblong and crenate-serrulate, those on the vigorous shoots mostly 3-lobed with the lateral lobes short and broad: distinguished from _P. Zabel_ by the 9-4 rather than 4-5 styles and by the lobed ivs.

35. _Zabel_, Mat. (M. _Zabel_, Rebh.). Low and much-branched tree, to 20 ft., with rounded head and twiggy growth, sometimes 40 ft. tall and with more ascending branches: lvs. long-petioled, oblong to ovate-oblong or elliptic-oblong, 1½—3 in. long, acute at apex, rounded or narrowed at base, entire or somewhat crenate-serrate, yellowish green above and light green beneath, soon glabrous, those on the ends of vigorous branches lanceolate and usually coarsely dentate: fls. white or slightly pinkish, borne in profusion, about 1 in. across, on loosely villous or glabrous pedicels about 1 in. long; calyx-lobes lanceolate, villous inside and less so outside; petals elliptic, obtuse, rounded at base but short-clawed, opening pink but becoming pure white; stamens about 25; styles 4 or 5, connate for one-third their length, densely villous: fr. 1½ in. or less diam., globose, red, the calyx deciduous. Mountains of Cent. Japan. S.T. S. 1:91.—Diffrers from both _P. Sargentii_ and _P. Sieboldii_ in the oblong lvs. which are not at all or only slightly lobed, and slender petioles; from _P. Sargentii_ also in longer petals rounded at base, glabrous lvs., longer petioles, and erect branches; from _P. Sieboldii_ also in differences in foliage, larger fls., larger broader petals rounded at base.

36. _pulcherrima_, Aschers. & Graebn. (P. _floribunda_, Kirchn., not Lindl. _M. floribunda_, Hort. _M. floribunda_, Sieb. _M. microcarpa_ var. _floribunda_, Carr.). _FLOWERING CRAB_. Unknown in the wild but long in cult., and perhaps a hybrid of _P. baccata_ and _P. Sieboldii_; intro. from Japan, where it seems not to be recognized, Rehder finding that what the Japanese botanists know under this name is _P. Halliana_: shrub or sometimes a small tree, often thorny: young growths glabrous or very soon becoming so: lvs. ovate and usually acuminate, the petals rather thick and redish and usually not much if any more than 1 in. long on the leading young shoots, the margins very sharply serrate or incised-serrate, not lobed, usually thick and shining above and glabrous (or soon becoming so) beneath: fls. rose or rose-red, appearing with the lvs., produced in great abundance and very showy; styles nearly always 4, very rarely 3 or 5, connate to the middle: fr. usually about the size of a pea, on long, slender stalks, red, not persisting till winter. China. R.H. 1866:311; 1871:391; 1881, p. 296. F.S. 15:1555. G.F. 1:152; 2:285. A.G. 13:437; 18:437. F.E. 9:573. G.M. 44:274; 53:1529 and p. 418. The name of this species is somewhat in confusion. It has been known as _P. floribunda_, but Lindley earlier gave this name to a very different plant, of the section or genus _Aronia_ (see p. 396, Vol. I), and the present species must take a new name. _P. pulcherrima_ is one of the best of all early spring-flowering bushes or small trees, and is now common in gardens. The semi-double forms improperly receive the names _Halliana_ and _Portenst._. It makes a broad round-headed great bush, with handsome rose-colored buds and whitish expanded fls. _P. aistrosanguinea_, Späth, is a handsome floriferous species of doubtful origin. It is probably _P. Halliana_ x _P. Sieboldii_ (Koehne supposes it to be _P. Halliana_ x _P. fusca_; resembles in general _P. pulcherrima_, but differs in its deep carmine fls. not fading to white, rather narrower petals, shorter ovate and somewhat obtuse calyx-lobes, more shining and finally glabrous lvs., those lvs. at the end of vigorous shoots sometimes slightly 3-lobed: fr. dark red. Gt. 47:1448.

Var. _Arnoldiana_, Bailey (M. _floribunda_ var. _Arnoldiana_, Rehb.). Originated at the Arnold Arboretum, Boston, as a seedling of _P. pulcherrima_ fls. more than one-half larger than in the type, pale rose: fr. much larger, yellow: of bushy habit.
Small tree, to 20 ft., with spreading unarmed branches, *E. angustijolia* villous pedicels. *Pyrula*, Bailey *tijolia*, form is sometimes described and figured as differs mostly in its pointed lvs., which are lightly obovate, slender-clawed; styles tomentose below: fro cuneate at base: fis. 1 in. across, fragrant, in few-lId. with rigid points and tomentose inside; petals narrow-pubescent outside, the lobes narrow-acuminate and so, thick and partially evergreen, rounded at apex, umbels, slender-pedicelled; calyx-tube glabrous or

Small tree, to 20 or 30 ft.: lvs. lance-oblong, crenate-serrate or almost entire, not lobed or only slightly virens, *Malus* *gustijOlia*, *virens*, *Dawsonidna*, *M. rivuldris* and *levipes*, *Malus* *gustijOlia*, *angustijolia*, Ait. *DD.* Apex of lvs. acute or acuminate. *BB.* Calyx persistent: eastern.

c. Foliate glabrous at maturity.

d. Apex of lvs. rounded and obtuse; margin crenate-serrate.

30. *platycarpa*, Bailey (Malus platycarpa, Rehd.), Small tree, to 20 ft., with spreading unarmed branches, young growths thin-tomentose but becoming glabrous: lvs. ovate to elliptic, rounded at base, the apex rounded but with short acute end, sharply and mostly doubly serrate, those on vigorous shoots broad-ovate and usually with several pairs of very broad triangular lobes: fis. 3–6 in race-me-like umbels, about sin. diam., on glabrous pedicels 1–1½ in. long; calyx-tube obovate and glabrous, the lobes or sepals lanceolate-acuminate and longer than the tube and densely tomentose within though glabrous without; petals orbicular-ovate, usually dentate; styles 5, villous below the middle and connate for one-third their length: fr. depressed-globose with deep depressions at both ends, broader than long (2 in. diam.), with persistent calyx, sometimes used for preserves. N. C. to Ga. in fertile bottoms. S.T.S. 2:189.—Mostly closely related to *P. coronaria*, but easily distinguished from this as well as from other species by the broad and large lvs. which are rounded and abruptly acuminate at apex, and never lobed, and by its very large fr.

Var. *Hoopesii*, Bailey (Malus coroneária var. *Hoopesii*, Rehd. *P. platycarpa* var. *Hoopesii*, Rehd.). Differs in calyx, oval to elliptic lvs. only slightly or not at all lobed, and by the larger fr. Known only in cult.

40. *lancifolia*, Bailey (Malus lancifolia, Rehd.). Fig. 3296. Small tree, to 25 ft., with spreading spiny branches, the branchlets slightly pubescent or nearly glabrous: lvs. ovate-lanceolate to oblange-lanceolate, 1½–3 in. long, at the apex acute or short-acuminate, at the base rounded or broad-cuneate, either finely or coarsely serrate and frequently doubly serrate with the short teeth pointing forward, those on vigorous shoots ovate or oblange-ovate and often slightly lobed: fis. 3–6, in umbel-like racemes, white or rose, something over 1 in. across, on slender glabrous pedicels 1 in. or more long; calyx-tube obovate and on the outside glabrous, the lobes or sepals oblange-lanceolate and exceeding the tube and villous-tomentose within but glabrous without; petals oval, long-clawed; styles 5, densely villous below the middle: fr. subglobose, about 1 in. diam., on slender drooping pedicels, green and waxy, Pa. and Va. to Mo. S.T.S. 2:188 (a sprig of which is reduced in Fig. 3296).—Distinguished from *P. coronaria* by the shape of the lvs., which are acuminate and less coriaceous, by the narrower and longer calyx-lobes, styles villous to middle, and by the different fr.

EE. Lvs. distinctly lobed, particularly on the strong shoots and sometimes on the flowering branchlets.

41. *glaucescens*, Bailey (Malus glaucescens, Rehd.). Fig. 3297–3299. Small tree or large shrub, with twiggy spiny head, the branchlets glabrous or at first slightly pubescent: lvs. triangular-oval or oval, 2–3½ in. long, at the apex acute or short-acuminate or even rounded, at base truncate villous-tomentose when young but becoming glabrous, glaucescent beneath, more or less triangular-lobed, coarsely serrate with abruptly acuminate teeth, the lowest pair of veins arising some distance above the base of the blade; petioles slender, soon becoming glabrous: fis. white or pink, 5–7 in umbel-like racemes, appear when lvs. are nearly full-grown, on slender glabrous pedicels 1 in. or so long; calyx-tube thinly villous outside, the lobes obleng-
lanceolate-acuminate and densely tomentose within; petals oval, rounded at top, more or less gradually narrowed into a claw; styles slightly shorter than the stamens: fr. flattened and concave at both ends, broader than long, not angled, yellow and waxy at maturity, fragrant. N. Y., and southward in the Appalachian region to N. C.; early-flowering. S.T.S. 2:187. This species is often confused with the following, but is easily distinguished by its distinctly lobed cratagus-like lvs. whitish on their under side.

42. coronaria, Linn. (Malus frangrans, Rehd. Malus coronaria, Mill.). Closely related to P. glaucescens, but differing in less deeply lobed more elongated lvs. which are green and not glaucous beneath at maturity, glabrous calyx-tube, and the fr. being strongly ribbed at the deeply sunken apex. N. Y. to Ala. B.M. 2009. B.R. 651. S.S. 4:167 (all as P. coronaria). R.H. 1884, p. 104 (as P. microcarpa coronaria), On. 29, p. 395; 34, p. 206. — The fr., which is produced in abundance, was often buried by the early settlers for use in the spring, when its acerbity was largely extracted; and it was sometimes used for cider. It is also useful for jellies and preserves. The species was probably never intro. into cult. for its frs., although it is native from Minn. and Wis. to Neb., Kans., and Mo. B.M. 8488. S.S. 4:168 (frs. too flat). — Frs. appraised by the settlers, but the species is probably not in cult. for its frs., although a late-blooming double-flowered variety has been lately intro., —Beechey's crab, sometimes referred to P. angustifolia. G.C. III. 25:397. R.B. 38:165. R.H. 1910:90. P. ioensis is a variable species, in some of its forms difficult to separate from P. coronaria, P. angustifolia, and other species. Var. Palmeri, Bailey (M. ioensis var. Palmeri, Rehd.). Small and slender tree, to 18 ft., differing from the type chiefly in the smaller oblong more thinly pubescent lvs. which are rounded at apex, and those on the flowering shoots not lobed and crenate-serrate. Mo. Var. spinoda, Bailey (M. ioensis var. spinosa, Rehd.). Dense bushy shrub, 6-8 ft., with slender spiny branches: differs from var. Palmeri in a shrubby habit, smaller lvs. and frs., and glabrescent calyx: from P. coro­naria (P. angustifolia) in the pubescence of the lvs., serrate or serrulate fl.-margins and lobed ovate lvs. of the strong shoots. Mo. Var. Búshii, Bailey (M. ioensis var. Búshii, Rehd.). Differ in bearing less deeply lobed lvs. than the type, which are glabrous: from var. Pal­meri it differs in having oblong-lanceolate acute glabrescent lvs. Mo. Var. creniserrata, Bailey (M. ioen­sis var. creniserrata, Rehd.), is a slender spineless tree with branches villous when young, and crenate-serrate or entire elliptic-ovate to oblong-ovate lvs., or those on the vigorous shoots somewhat doubly serrate: calyx

44. ioensis, Bailey (P. coronaria var. ioensis, Wood. Malus ioensis, Brit. Malus coronaria var. ioensis, Schneid. P. ioensis, Carruth?). Prairie or

3290. Pyrus glaucescens. (X ¼)
2878 PYRUS
tomentose. La. Var. texana, Bailey (M. ioeensis var. texana, Rehd.). Small much-branched tree, to 18 ft., or sometimes a shrub forming thickets, with densely tomentose branchlets which become glabrescent the first or second year, differing from the type in having smaller and much broader lvs. that are not at all or only slightly lobed and densely villous at maturity. Texas, representing the southwestern extension of the species.

45. bracteata, Bailey (Malus bracteata, Rehd.). Tree, to 30 ft. or more tall, forming a broad head: a glabrescent form: lvs. elliptic-ovate to oblong-ovate, serrate or incisely serrate and less deeply so than in P. ioensis and with less deep lobing, sometimes slightly lobed near the base, those on the vigorous shoots usually ovate and with recurved very short lobes on either side and the margins commonly only slightly serrate, the foliage glabrous or glabrescent except the slightly pubescent lvs. at the end of strong shoots; racemes 3-5-fld., the pedicels about ½-in. long, glabrous or nearly so and bearing subulate bractlets 1/4-½-in. long which persist during flowering. Mo.

PYXIDANTHERA (Greek, a small box and anther; the anthers opening transversely like the lid of a box). Diapensiaceae. PYXIE. FLOWERING Moss. PINE-BARREN BEAUTY. An evergreen creeping plant found in cushion-like masses in the sandy pine lands of N. J. to N. C. When it flowers in early April to early May, its white starry blossoms dot the light green or brownish green fl. and st. cushions. It grows best in moist sandy soil in the full sunlight and sometimes on gravel slopes of slight inclination. When growing among fallen lvs., its st. become longer and the whole plant more open in character. The plant is rarely cult., although adapted to rock-gardens in sandy or gravelly pockets. Related to Diapensia, an alpine plant, and slightly to Galax. The only species is P. barbuláta, Michx. An evergreen herb with depressed prostrate nearly glabrous stl., much branched at the base and creeping: lvs. numerous, blades leathery, linear-oblancoceolate, or linear-elliptic, imbricated, small, ± long: calyx campanulate, lobes 5, oblong, obtuse; corolla white, tube oblong-campanulate, petals 5, spatulate to obovate, spreading; anthers of 5 stamens yellow, opening transversely; ovary 3-celled: caps. 3-valved, few-seeded. B.M. 4592. Mn. 8:33. B.B. 2:583. Gn. 27, p. 209. G. 36:649. J.F. 2:150.

JOHN W. HARSHBERGER.

3300. Prairie States crab.—Pyrus icenasis (X 1/2). No. 44.
QUAMASIA (quasak, the Indian name). Liliaceae. A name given by Rafinesque in 1818 to the plants that Lindley, in 1832, called Camassia. On the principle of fifty years of accepted usage, the name Camassia is retained in the "nomina conservanda" of the International Botanical Congress (Vienna), and under that name the plants are treated in Vol. II. One species, variously known as Camassia esculenta, Quamassia esculenta and Quamassia hyacinthina, is native in the eastern United States, but the most showy species are from the Pacific side of the continent.

QUAMOCIT (Greek, a dwarf kidney bean). Including Caloba and Mina. Convolvulaceae. Annual, or in tropical regions some perennial twining vines; most of them of easy culture, of rapid growth, and with a profusion of small flowers.

The genus differs from all other Convolvulaceae by its axillary often 2-forked clusters of fls., the thickened pedicels of some species, the slender corolla-tube not expanding at the base, the limb of the corolla salverform or cup-shaped, stamens and style extended, and often decinate.—About 10 species. Q. pinanata is the best-known species, often used to advantage upon arbors, verandas, walls, or on screens in the conservatory.

A. Sepals without awns; pedicels thickened: lvs. pinnately divided.

pinnata, Bojer (Ipomoea Quamocit, Linn. Q. vulgaris, Choisy. Q. Quadracit, Brit.). CYPRRESS-VINE. INDIAN PINK. Fig. 3301. St. smooth, slender, twining to a height of 10-20 ft.: lvs. short-petioled or sessile: pedicels few-fl., commonly much longer than the pedioles: corolla 1-1½ in. long, scarlet, the tube narrowly funnelform, inflated above; the limb nearly flat, 5-lobed. July-Oct. Naturalized from Trop. Amer., Va. to Fla., west to Kans. and Texas; sparingly escaped from cult. farther north. B.M. 188 (as Convolvula Nid); 244. Gn. 39, p. 33.—Beautiful in fl. and foliage but usually does not succeed well in the N. unless started early in the hot-house and transplanted. Var. albata, Hort., has white fls.

AA. Sepals awned: lvs. entire or lobed.

b. Corolla-limb expanding abruptly from a slender tube, cup-shaped, ½-3 in. broad or broader.

ccines, Moench (Ipomoea coccinea, Linn.). STAR IPOMEA. Fig. 3302. St. freely twining for 10 ft.: lvs. slender-petioled, entire or angulate, acuminate: pedicel 2-6 in. long, to 7-fl.; corolla ½-2½ in. wide, salverform; limb obscurely lobed, scarlet with yellow throat. Aug.-Oct. Apparently naturalized from Trop. Amer., on river banks in the Middle and South Atlantic states; probably indigenous to N. Mex. and Ariz. B.M. 221.—Fls. are produced in abundance, but are very small.

Var. hederifolia, House (Ipomoea hederifolia, Linn. Ipomoea coccinea var. hederifolia, Gray. Mina sandwicensis, Hort.). Fig. 3303. This Plains form of the species has angulate, 3-lobed or even 3-5-parted lvs., and fls. usually larger. B.R. 9. B.M. 1769. I.H. 41, p. 159.—It is superior to the type for ornamental purposes.

Var. luteola, House (Ipomoea luteola, Jacq. Ipomoea coccinea var. lutea, Hort.). Fls. yellow, an inch long. Varies to orange in color.

nn. Corolla-limb expanding funnel form from a slender bent tube: lvs. 3-lobed.

c. Tube of corolla nearly 2 in. long, the limb 5-angled, scarlet.

grandiflora, Don (Ipomoea Puntia, Cham. & Schlecht.). A perennial vine with cordate-hastate, 3-lobed lvs., finely pubescent: pedicels elongated, bearing 3-9 scarlet fls.; corolla about 2 in. long, slender, bent, expanding into a 5-angled limb less than an inch broad. S. Mex.

cc. Tube of corolla scarcely 1 in. long, yellowish, with a purplish, deeply 5-lobed limb.

vitifolia, Don (Caloba vititofia, Cav.). A perennial twining glandous vine: lvs. entire or 3-lobed. the middle lobe constricted below: pedicels elongated, several-fl.: corolla about 1 in. long, the yellowish tube expanding above into a scarlet, deeply 5-lobed limb, the exerted stamens elongated and decinate. S. Mex.

bbb. Corolla-limb cylindrical and bent, longer than the limb, yellow tinged with red.

QUAMOCLIT

3303. Quamoclit coccinea var. hederifolia. (X ½)

QUERCUS

3304. Annual-fruited oak—Quercus alba. The mature acorn is borne on the wood of the season. (X 10)

—Distinguished from all other ipomoeas by its bag-shaped corolla and scorpioid infl. It is a very free bloomer, and deservedly popular. H. D. HOUSE.

QUÁSSIA (from an aboriginal name). Simaroubaceae. Trees, sometimes cultivated in the greenhouse.

Leaves alternate, pinnate; lfts. alternate, entire, orioraceous: panicles axillary and terminal, elongated, branched; lfts. suberymose-diclinous; calyx small, 5-lobed; petals 5; stamens 10 in the male, rudimentary in the female lfts.; ovary sunken in the disk, deeply 5-parted: fr. 1-5 spreading sessile drupes.—About 3 species. Trop. Amer. and Trop. Afr.

amara, Linn. Shrubby tree; lfts. opposite, odd-pinnate, dark green with bright pink veins; lfts. 5, elliptical-oblong, pointed, entire, tapering toward the base, subsessile at the petiolar structures; petiole articulate, winged; lfts. crimson, in racemes; corolla never fully expanded, the petals having a spiral twist and curling round one another: drupes biglandular ovoid, black with a pale spot at the base. Trop. Amer. B.M. 497.—It furnishes the bitter quassia wood and its medicinal extract is used as a tonic. Now cult. in the tropics of both hemispheres. F. TRACY HUBBARD.

QUEKÁTIA (in honor of E. J. Queckett). Orchidaceae. Small epiphytic plants: lfts. terete, fleshy: scape filiform, branched: lfts. small, in sepals and petals similar, linear; lpp. erect from foot of column, about as long as sepals, entire, hollowed at base; column erect, with 2 recurved appendages at apex; anther terminal, incumbent; pollinia 2, waxy, ovoid, upon linear stalks.—About 6 species known, all Brazilian. Related to Ada; little known horticulturally. GEORGE V. NASH.

QUÉRÚC (ancient Latin name). Fagaceae. Oak. Ornamental trees, rarely shrubs, grown chiefly for their handsome foliage and interesting habit; many species are important timber trees. See Oak.

Deciduous or evergreen trees, rarely shrubby: winter buds with usually many imbricate scales: lvs. alternate, short-petioled, with deciduous stipules, pendulous catkins with 4-7-parted calyx and 4-12, usually 6, stamens; pistillate in 1- to many-fld. spikes in the axil of the young lvs., each fl. consisting of an incompletely 3-, or rarely 4-5-seeded ovary, surrounded by imbricate bracts; style short or elongated, dilated above and stigmatic on the inner face; fr. a 1-seeded subglobulous to oblong nut, surrounded at the base or sometime almost inclosed by a cup-like involucre.—More than 200 species are known, distributed through the colder and temperate regions of the northern hemisphere and in the mountains of the tropics. The numerous species are usually divided into 3 subgenera. The species of the subgenus Cyclobalanopsis which has the scales of the cup connate into concentric rings are all Asiatic. The American species belong to Lepidobalanus (balanus is Greek for acorn) and to Erythrodalbanus. In the former, comprising the white oak tribe, the acorns mature the first year (Fig. 3304). In the latter, comprising the black oaks, the acorns mature the second year (Fig. 3305). Besides the 200 species, about 40 hybrids have been recorded. Pasania, often included under Quercus, is now usually considered a distinct genus, which see. The latest monograph of the whole genus is by A. DeCandolle in "Prodromus," vol. 16, 2, pp. 1-108 (1864-1865). Important illustrated works on American oaks are A. Michaux, "Histoire des Chênes de l'Amérique" (1801), with 36 plates; Kellogg and Greene, "Illustrations of West American Oaks" (1889), with 37 plates; Sargent, "Silva of North America," vol. 8 (1895), with 82 plates, and Liebmann, "Chênes de l'Amérique Tropicale" (1869), with 47 plates. Most of the European and west Asian oaks are figured in Kotschy "Eichen Europas und des Orients" (1862), with 40 colored plates. For comparative illustrations of lvs. see M.D. 1889, p. 32; A. B. 27, p. 61; G.W., 7, pp. 570, 571, 573; for those of frs. see M.D. 1900, p. 40; R.B. 27, p. 106.

The oaks are mostly trees, often tall with massive trunk and stout spreading limbs, with medium-sized, short-petioled leaves, usually more or less lobed, dentate or serrate, rarely entire, with inconspicuous flowers, the staminate ones in slender pendulous catkins and with fruits or "acorns" consisting of a globular to oblong nut inclosed at the base only, rarely wholly or nearly wholly, by a cup-like involucre. The oaks comprise some of the most important forest trees of the northern hemisphere. The wood of most species is strong, tough, hard, durable, and highly valued for many purposes, especially ship-building, construction, for furniture, and in the manufacture of wagons, tools and many other articles. The bark of some species, in America that of Q. velutina and Q. Prinus, is used for tanning leather. Cork is obtained from the bark of Q. Suber and Q. occidentalis in southern Europe. The bark of a few species has also been employed in medicine. The acorns of several species are edible, in America especially those of Q. Prinus, Q. Emoryi and Q. lobata; in Europe those of Q. Itez var. Ballota and Q. Aegilops; in Japan those of Q. glauca; in many European countries the acorns of all species are an important food for hogs. In eastern Asia a silkworm feeds on the leaves of different species. A parasitic insect living on Q. coccifera in...
southern Europe and northern Africa yields a scarlet dye. Galls caused by the puncture of certain insects are used for tanning and dying and are now chiefly obtained from Q. ilex var. infectoria in western Asia. Some of the above-mentioned species are described only in the supplementary list, page 292.

The deciduous species are mostly hardy North, while of the evergreen ones none seems to be hardy farther north than Washington, D.C.; some half-evergreen, as Q. alba, Q. elaeagnus, and Q. coccifera, form symmetrical broad pyramids. A very few hardy species are shrubs, generally called scrub oaks, as Q. prinoides and Q. ilicifolia. Oaks rank among our most valuable park and avenue trees, and are as beautiful when grown as single trees as they are when grouped together and forming groves and woods. As avenue trees, Q. palustris, Q. rubra, Q. coccinea, Q. imbricaria and Q. Phellos are among the best, the last-named when medium-sized trees are desired; in the southern states, Q. laurifolia, Q. nigra, and the evergreen Q. virginiana are preferred. The shrubby species, like Q. prinoides and Q. ilicifolia, may be used for covering rocky hillsides and dry ridges.

Oak leaves are always beautiful. They have many shades of green; especially attractive are some with leaves of contrasting colors, the under side being silvery white, the upper one dark green, as in Q. Muhlenbergii, Q. macrocarpa, Q. Prinus, and some foreign evergreen species. In many oaks the leaves show a handsome pink or crimson color when unfolding, and some species assume brilliant autumnal tints. Especially beautiful in autumn are Q. occidentalis and Q. palustris, with the foliage turning brilliant scarlet; Q. rubra, Q. imbricaria, and Q. Prinus, which turn bright or dark red; Q. alba, violet or vinous purple; Q. lyrata, scarlet or orange; Q. Phellos, pale yellow; Q. montana, orange or orange-brown; Q. falcata and Q. ilicifolia, orange-brown or yellow; Q. stellata and Q. nigra, brown or dull orange. Some of the foreign species, like Q. sessiliflora and also Q. Robur, Q. Carris, Q. lasiusina, Q. glandulifera, and others, retain the green color until late in fall. Besides our native evergreen species, Q. ilex, Q. myrtifolia, and Q. glauca are among the best evergreen oaks for cultivation in the South; the European Q. ilex and Q. Suber are also handsome evergreen trees.

Generally the oak grows best in a moderately moist, rich soil, including heavy clay; some, as Q. bicolor, Q. nigra, Q. alba, Q. Phellos, Q. falcata, and Q. virginiana, prefer moister situations and grow naturally in low and often even in swampy ground; while others, especially the red oaks, like Q. rubra, Q. coccinea, Q. imbricaria, Q. miliariflora, Q. montana, and Q. stellata, grow well in drier, rocky or sandy soil, and the scrub oaks on dry and barren soil. The black and red oaks, especially the pin oak, are usually easily transplanted and large trees are moved successfully while the white oaks are more particular and only younger nursery-grown trees can be safely transplanted.

Oaks are propagated usually by seeds sown immediately after gathering in fall; this is especially necessary with Q. alba, Q. New York, and some other white oaks which sprout as soon as they are ripe; but only the root is produced in fall, while the stem does not appear until the following spring. The seeds of red and black oaks, and also of Q. Robur, if not sown soon, should be stratified and sown early in spring. Acorns should be packed in earthen, moss, or sawdust when shipped for a great distance. Varieties are usually grafted on potted stock in the greenhouse in early spring or sometimes in August. As a stock Q. Robur is preferred, but Q. rubra, Q. velutina, and Q. montana are also employed. It is probably safer to graft various white of and red oak each on stock of the same group. The evergreen species are sometimes increased by layers and also by cuttings.

ALBA; 3, Q. velutina; 4, Q. rubra; 5, Q. MARIANTA; 6, Q. macro-

Cups deeper and somewhat turbinate; acorn usually

round head, the foliage turning dark red in fall. Hybrids are known with the following species, with Q. velutina, Q. FACATA, Q. Phellos and Q. imbricaria. Var. ambiguus, Fern. (Q. ambiguus, Michx. 1, not H.B.K. Q. boREALIS, Michx. f. Q. coccinea var. ambiguus, Gray.) Cups deeper and somewhat turbinated; acorn usually smaller. The northern form. See also note under No. 8.
one-half by the turbinate or deeply saucer-shaped cup gradually narrowed at the base, with closely appressed, brown-pubescent scales. S. Mich. to Man. and Iowa. S.S. 14:771.

6. Kelloggi, Newb. (Q. californica, Coop.). CALIFORNIA BLACK OAK. Fig. 3311. Tree, occasionally to 100 ft., with stout spreading branches forming an open, round-topped head; lvs. divided about to the middle by wide sinuses into usually 7 oblong, toothed lobes, pubescent when young, at length glabrous and glossy above, yellowish green and glabrous or floccose beneath, 3-6 in. long: fr. short-stalked; acorn ovoid or oblong, mostly rounded at the top, 1-1½ in. long, embraced about one-third or one-half by the deep hemispherical glabrous cup. Ore. to Calif. S.S. 8:416. G.F. 9:145.

7. velutina, Lam. (Q. tinctoria, Bartram). BLACK OAK. Fig. 3305, 3306, 3309. Tree, to 80, sometimes to 150 ft., with rather slender branches, spreading gradually into a narrow, open head: bark very dark brown, inner bark orange: lvs. pinnatifid, with 7-9 broad toothed lobes; dark and dull green above, brownish pubescent beneath at first, glabrous at length, except in the axils of the veins, 4-10 in. long: fr. short-stalked; acorn ovoid, ½-1 in. long, embraced about one-half by the hemispherical densely pubescent cup. Maine to Va., west to Ohio and Ky. S.S. 8:420. Em. 1:170. G.F. 5:55. 

—This species hybridizes with Q. coccinea, Q. rubra, Q. imbricaria and Q. Phellos (Q. heterophylla, Michx.).

8. falcata, Michx. (Q. digitata, Sudw. Q. cumulta, Auth., not Wang.). SPANISH OAK. Tree, to 70, rarely to 100 ft., with stout spreading branches forming an open, round-topped head: lvs. deeply pinnatifid, with 5-7 entire, acute and often falcate lobes gradually narrowed from a broad base and spreading at nearly right angles, separated by broad sinuses, drooping, dark green and glabrous above, tawny or grayish pubescent beneath, 3-8 in. long: fr. short-stalked; acorn subglobose, ½ in. high, embraced about one-half by the turbinate cup. N. J. to Fla., west to Mo. and Texas. S.S. 8:420. G.F. 8:104. P.E. 20:943. —Handsome, with peculiarly distinct foliage, but not quite hardy N. It appears that the original description of Q. rubra, Linn., applies to the Spanish oak (see Sargent in Rhodora 17:39); therefore, under a strict application of the rule of priority, Q. falcata, Michx. ought to be called Q. rubra and the tree heretofore known as Q. rubra ought to be known as Q. borealis, if var. ambiguus is not considered specifically distinct; otherwise it ought to receive a new name. The name Q. borealis applies more strictly to the northern form (Q. rubra var. ambiguus), while the more southern form becomes Q. borealis var. maxima, Sarg.

9. pagodefolia, Ashe (Q. falcata var. pagodefolia, Ell.). SWAMP SPANISH OAK. Tall tree, sometimes 120 ft. high, with wide-spread branches forming a broad open head, but narrow in the forest; branchlets tomentose: lvs. deeply pinnatifid, with 5-11 entire, acute, spreading leaves narrowed from a broad base and often falcate, dark green and lustrous above, white-tomentose beneath, 5-8 in. long: fr. short-stalked or nearly sessile; acorn ovate to subglobose, little over ½ in. across, inclined about one-half by the turbinate cup; scales loosely imbricate, pubescent except on the margin. Va. to Fla., west to S. Ill. and Ark. S.S. 14:772. —Handsome and valuable timber tree; about as hardy as the preceding species.

10. ilicifolia, Wang. (Q. Båntiæri, Michx. Q. rana, Sarg.). BEAR or SCRUB OAK. Intricately branched, spreading shrub to 10 ft. high, rarely small tree to 20 ft.: lvs. pinnately lobed, with usually 2 broad triangular lobes on each side, dark green and glabrous above, white-tomentose beneath, 3-8 in. long: fr. short-stalked or nearly sessile; acorn ovate, with the prickles set well back from the central peck, ½ in. long, embraced about one-third by the turbinate cup; scales loosely imbricate, pubescent except on the margin. Va. to Fla., west to S. Ill. and Ark. S.S. 14:777. —Handsome and valuable timber tree; about as hardy as the preceding species.

3308. Leaves of Quercus coccinea (X1g). No. 3.

3309. Acorns of Quercus coccinea (on left) and Quercus velutina. (Natural size.) Nos. 3 and 7.

3310. Quercus Schneckii. No. 4.
**Quercus lobata** (Michx.) Round-topped or often irregular head: lvs. short-petioled, oblong or subglobose, about one-half from the saucer-shaped cup. Figs. 3306, 3307. Tree, to 80 ft.: lvs. slender-petioled, oblong to oblong-lanceolate, acuminate, crenately serrate, with bristle-like teeth, dark green and glabrous above, whitish tomentulose below, 3½-6 in. long; fr. almost sessile; acorn subglobose, not much exceeding the large cup; scales thick, lanceolate, recurved. N. China. S.L.F. 1:28. Handsome tree with distinct foliage almost like that of *Castanea crenata*; has proved hardy in Mass. and W. N. Y.

**Quercus virgiliana** (Michx.) Michx. Handsome tree with large glossy foliage; hardy N. Tree, to 50 ft., with broad, round-topped head: lvs. short-petioled, obovate, sinuously toothed, with 3-6 rounded broad teeth on each side, dark green and usually glabrous above at length, light green and pubescent beneath, firm and leathery, to 12 in. long; fr. almost sessile; acorn ovate, ½-3½ in. long, embraced one-half by the large cup; scales lanceolate, thin, spreading and recurved. Japan, W. China. S.I.F. 1:27. F.E. 14:542 (pl. 29).—Remarkable for its large lvs., on young plants to 1 ft. long and 8 in. broad; hardy N. Var. pinnatifida, Matsum. (Q. pinnatifida, Franch. & Sav.). Lvs. divided almost to the midrib into linear lobes with crisp irregular margins, interesting form.

**Quercus sitchensis** (Bong.) Engelm. has obovate-lanceolate lvs. entire or coarsely toothed, with bristly teeth, soon glabrous, 4-6 in. long; cup turbinate.

**Subgenus Lepidobalanus. White Oaks.**

16. *variabilis*, Blume (Q. chinensis, Bunge, not Abel. Q. Bungeana, Forbes. Q. serrata, Carruth., not Thunb.). Tree, to 80 ft.: lvs. slender-petioled, oblong-lanceolate, acuminate, crenately serrate, with bristle-like teeth, dark green and glabrous above, whitish tomentulose below, 3¼-6 in. long; fr. almost sessile; acorn subglobose, not much exceeding the large cup; scales thick, lanceolate, recurved. N. China, Japan. S.I.F. 1:28.—Handsome tree with distinct foliage almost like that of *Castanea crenata*; has proved hardy in Mass. and W. N. Y.

17. *dentata*, Thunb. (Q. Dalmio, Hort. Q. oboead, Bunge). Tree, to 80 ft., with broad, round-topped head: lvs. short-petioled, obovate, sinuously toothed, with 3-6 rounded broad teeth on each side, dark green and usually glabrous above at length, light green and pubescent beneath, firm and leathery, to 12 in. long; fr. almost sessile; acorn ovate, ½-3½ in. long, embraced one-half by the large cup; scales lanceolate, thin, spreading and recurved. Japan, W. China. S.I.F. 1:27. F.E. 14:542 (pl. 29).—Remarkable for its large lvs., on young plants to 1 ft. long and 8 in. broad; hardy N. Var. pinnatifida, Matsum. (Q. pinnatifida, Franch. & Sav.). Lvs. divided almost to the midrib into linear lobes with crisp irregular margins, interesting form.

**Quercus sessiliflora**, Fisch. Tree, to 100 ft.: branches glabrous: lvs. on very short petioles less than ¾ in. long, obovate to obovate-oblong, obtuse at the apex, narrowed toward the rounded or auriculate base, coarsely toothed or sinuously lobed, with short and broad usually obtuse or obtusate teeth, dark green above and glabrous, paler green and glabrous beneath or pilose on the veins only, 4-8 in. long; fr. several or solitary on a short stalk or nearly sessile; acorn ovoid or ellipsoid, about ¾ in. long, embraced about one-third by the cup which is grayish tomentulose with thickened tuberculate scales, thinner and acuminate at the slightly fringed margin. E. Siberia, N. China, Korea, N. Japan. Var. grosseserrata, Rehd. & Wilson (Q. grosseserrata, Blume. Q. crispula, Blume). Lvs. somewhat usually acutish at the apex with acute or acutish sometimes dentate teeth: cup with thin closely appressed scales, not fringed at the margin. Japan. Som. Japanese botanists distinguish *Q. crispula* as a species by the hemispherical cup inclosing the acorn about one-half from *Q. grosseserrata* which has a saucer-shaped cup inclosing the acorn one-fourth or one-third, but many specimens are intermediate in this character, and, as the lvs. of the two forms are exactly alike, it seems hardly possible to distinguish these two

**Quercus kelloggi**, Regel. & Wilson. (X7ii) Round-topped or often irregular head: lvs. short-petioled, oblong or subglobose, about one-fourth to one-third by the saucer-shaped cup. N. Y. to Fla., west to Mo. and Del. to Fla., west to Neb. and Tex. S.S. 8:426, 427. There are hybrids with *Q. ilicifolia* and *Q. Phellos*, and *Q. imbricaria*. Handsome tree, with large glossy foliage; hardy N. Better known as *Q. nigra*, but this name really belongs to the preceding species.

18. *Phellos*, Linn. Willow Oak. Figs. 3306, 3307. Tree, to 30 ft., sometimes becoming to 50 ft., with slender branches forming a conical, round-topped head, lvs. short-petioled, linear-oblong, bright green above, pubescent below when young, glabrous and light green at length, 2-4 in. long: frs. almost sessile, acorn subglobose, ½-¾ in. high, embraced about one-fourth by the saucer-shaped cup. F.E. 18:592 (pl. 62).—Handsome medium-sized tree with handsome foliage turning pale yellow in fall; prefers moist or almost swampy soil.

19. *laurifolia*, Michx. Laurel Oak. Tree, to 60, occasionally to 100 ft., with comparatively slender branches forming a dense, round-topped head; lvs. oblong or oblong-obovate, sometimes slightly lobed, acute or rarely obtusish, dark green and shining above, light green and puberulous at first, glabrous at length, 2-6 in. long; fr. short-stalked; acorn ovoid or subglobose, about ¼ in. long, embraced one-fourth by the saucer-shaped cup. Var. pinnatifida, Matsum. (Q. pinnatifida, Franch. & Sav.). Lvs. divided almost to the midrib into linear lobes with crisp irregular margins, interesting form.

20. *mongolica*, Fisch. Tree, to 100 ft.: branches glabrous: lvs. on very short petioles less than ¾ in. long, obovate to obovate-oblong, obtuse at the apex, narrowed toward the rounded or auriculate base, coarsely toothed or sinuously lobed, with short and broad usually obtuse or obtusate teeth, dark green above and glabrous, paler green and glabrous beneath or pilose on the veins only, 4-8 in. long; fr. several or solitary on a short stalk or nearly sessile; acorn ovoid or ellipsoid, about ¾ in. long, embraced about one-third by the cup which is grayish tomentulose with thickened tuberculate scales, thinner and acuminate at the slightly fringed margin. E. Siberia, N. China, Korea, N. Japan. Var. grosseserrata, Rehd. & Wilson (Q. grosseserrata, Blume. Q. crispula, Blume). Lvs. somewhat usually acutish at the apex with acute or acutish sometimes dentate teeth: cup with thin closely appressed scales, not fringed at the margin. Japan. Som. Japanese botanists distinguish *Q. crispula* as a species by the hemispherical cup inclosing the acorn about one-half from *Q. grosseserrata* which has a saucer-shaped cup inclosing the acorn one-fourth or one-third, but many specimens are intermediate in this character, and, as the lvs. of the two forms are exactly alike, it seems hardly possible to distinguish these two...
forms as varieties. Var. grosseserrata has proved perfectly hardy at the Arnold Arboretum and forms handsome trees of vigorous growth.

19. *glandulifera*, Blume. Tree, to 40 ft., rarely to 70 ft., shrub in cult.; lvs. cuneate or rounded at the base, oblong-ovate to oblong-elliptic, acute with 7-12 glandular-tipped, acute teeth on each side, light green above, glabrous, whitish or grayish green beneath, pressed silky at first, almost half-evergreen, 2½-5 in. long; fr. peduncled, usually several; acorn ovate, about ½ in. high, embraced one-third to one-half by the cup. Maine to Ala., west to Minn. and Texas. S.S. 8:378. Em. 1:158.—Pretty shrub for covering dry and rocky ridges. In trade sometimes under the misleading name of *Q. humilis*, for which see suppl. list.

23. *Prinus*, Linn. (Q. *Prinus var. palustris*, Michx. *Q. Micahouri, Nutt.*). BASKET OAK. Cow Oak. Tree, to 100 ft., with round-topped, rather dense head; bark light gray, scaly; lvs. oblong or ovate-oblong, acute, deeply crenulate-toothed, with obtuse, mucronulate teeth, bright green and shining above, grayish tomentulose beneath, 4-7 in. long; fr. short-peduncled; acorn ovoid, 1-1½ in. high, embraced about one-third by the tomentose cup. Del. to Fla., west to Ind. and Texas. S.S. 8:382, 383.—The *Q. Prinus* of most recent authors is the following species. One of the most beautiful of the chestnut oaks; prefers moist soil.

24. *montana*, Wild. (Q. *Prinus var. monticola*, Michx. *Q. Prinus, Engelm., not Linn.*). CHESTNUT OAK. Rock CHESTNUT OAK. Fig. 3306. Tree, to 70, or occasionally to 100 ft., with broad, irregular head and dark brown, ridged bark; lvs. slender-stalked, oblong to oblong-lanceolate, coarsely crenulate-toothed, bright or yellowish green above, paler beneath, tomentulose when young, often almost glabrous at length, 5-8 in. long; fr. solitary or in pairs, on peduncles about 1 in. long; acorn ovoid, 1-1½ in. high, embraced about one-third by the cup. Maine and Ont. to Ala. S.S. 8:375, 376. Em. 1:155 (as *Q. Castanea*) and 156. G.C. III. 14:617. G.F. 1:510.—Handsome oak, growing well in rather dry soil. A hybrid of this...
oblong, 1-1 1/2 in. high, embraced one-third by the cup. Que. to Ga., west to Mich. and Ark. S.S. 8:380, 381. Em. 1:153. G.F. 4:296.-It is less desirable as an ornamental tree than many other species, but the wood is valuable. By the light gray bark separating in large thin scales and the numerous small branches which appear on the larger limbs and often on the trunk, it is easily distinguished from allied species.

36. macrocarpa, Michx. BUR OAK. MOSBY CUP OAK. Fig. 3306. Tree, to 80, sometimes 160 ft., with large spreading branches, forming a broad, round head; bark light brown, deeply furrowed; younger branches sometimes with corky wings; leaves obovate or oblong-obovate, lyrate-pinnatifid, with 4-10 pairs of lobes, the lower ones smaller, separated by wide and deep sinuses, the upper ones much narrower, sinuately dentate above the middle, bright green and shining above, grayish or whitish tomentose beneath, 4-8 in. long; fr. sessile or short-stalked; acorn broadly ovate or ovate, ¾-1 ½ in. high, embraced about one-half by the large 5/4-three-in.-wide cup, with the upper scales awned and forming a fringe-like border. Nova Scotia to Pa., west to Man. and Texas. S.S. 8:371, 372. Em. 1:149. G.F. 2:900:2: 907. Mn. 2:153. G.F. 4:242.

Var. olivariiformis, Gray (Q. olivariformis, Michx.). Leaves deeply pinnatifid, lobes almost as narrow and separated by wide sinuses: cup usually elongated, much higher than broad. S.S. 8:373. M.D.G. 1901:167.—The bur oak is of vigorous growth and becomes a stately tree and is of picturesque appearance in winter with its corky branches. The crown is often fan-shaped until tree is mature.

27. lyrata, Wall. OBERCUP OAK. SWAMP, or SWAMP POST OAK. Tree, to 100 ft., with rather small, often pendulous branches forming a symmetrical, round-topped head; leaves obovate to oblong-obovate, deeply lyrate-pinnatifid, with 3-5 pairs of oblong or lanceolate lobes, the lower ones much smaller, separated by a wide sinus from the upper ones, dark green and shining above, whitish tomentulose beneath or sometimes light green and pubescent: fr. short-stalked; acorn globose, ½-1 in. high, almost entirely inclosed by the large saucer-shaped cup; lower scales tuberculate, upper one subulate. Calif. S.S. 8:382. G.F. 3:611; 10:55, 202, 205. C.L.A. 1:83.—Graceful wide-spreading tree; has not been cult. successfully outside of Calif.

31. albita, Nees (Q. Hindel, Bentham). VALLEY or WEEPING OAK (WHITE OAK of the Pacific States). Tree, to 100 ft., with stout spreading branches forming a broad, open head; bark light gray; leaves obovate or oblong-obovate, narrowed at the base, with 3-8 pairs of rather narrow obtuse and sometimes toothed lobes, pubescent when young, soon glabrous, bright green above, glaucous beneath: fr. short- or long-stalked; acorn oblong-ovate, 1 in. high, embraced about one-third by the cup; scales closely pubescent. Maine to Fla., west to Minn. and Texas. S.S. 8:356, 357. Em. 1:145. G.F. 3:91:4:6, 7; 5:259, 450. F.E. 20:650 (pl. 110); 32:489.—The white oak is one of the noblest trees of the northern states and a beautiful park tree, where space can be allowed for its full development; the foliage assumes a beautiful deep vinous red or violet-purple color in fall. Var. repanda, Michx., is a form in which the leaves have rather shallow sinuses and the frs. are usually short-stalked. Var. pinnatifida, Michx., has the leaves deeply pinnatifid with narrow often deeply toothed lobes and the frs. usually

Fig. 3312. Tree, to 100 ft., with great, wide-spreading limbs and slender drooping branches; leaves oblong or oblong-obovate, narrowed at the base, with 3-8 pairs of rather narrow obtuse and sometimes toothed lobes, pubescent when young, soon glabrous, bright green above, glaucous beneath: fr. short- or long-stalked; acorn oblong-ovate, 1 in. high, embraced about one-third by the cup; scales closely pubescent. Maine to Fla., west to Minn. and Texas. S.S. 8:356, 357. Em. 1:145. G.F. 3:91; 4:6, 7; 5:259, 450. F.E. 20:650 (pl. 110); 32:489.—The white oak is one of the noblest trees of the northern states and a beautiful park tree, where space can be allowed for its full development; the foliage assumes a beautiful deep vinous red or violet-purple color in fall. Var. repanda, Michx., is a form in which the leaves have rather shallow sinuses and the frs. are usually short-stalked. Var. pinnatifida, Michx., has the leaves deeply pinnatifid with narrow often deeply toothed lobes and the frs. usually
slender-stalked. S.S. 8:358. Hybrids of this species with *Quercus macrocarpa*, *Q. montana*, and *Q. stellata* are known. S.S. 8:359-61. The hybrid with *Q. montana* was found in the nursery of John Saul, near Washington, D.C., and has been distributed as Saul's oak (*Q. Sauliti*, Schneid.).

34. lanuginosa, Thuill. (Q. *pubescens*, Willd.). Tree, to 40 ft., but sometimes remaining shrubby; branches tomentose when young; lvs. pinnately lobed or pinnatifid, with 4-8 pairs of obtuse or acute lobes, glabrous above, pubescent or tomentose and grayish green beneath, 2-4 in. long; fr. almost sessile; acorn ovoid, ½-1 in. long, inelosed about one-half by the tomentose cup; scales closely appressed. Cent. and S. Eu., W. Asia. H.W. 2:22, pp. 69-71. A very variable species, often shrubby, growing mostly on dry, rocky, and often on limestone soil; the more southern forms are tender. Var. *Hartwissiana*, Dipp. *Q. Hartwissiana*, Hort.). Lvs. small, rather acutely lobed, yellowish tomentose beneath. Var. *pinatifida*, Schneid. (*Q. pubescens* var. *pinatifida*, A. Braun). Lvs. deeply lobed. Var. *cristata*, Beck, is similar but margin more crisp and under side more tomentose. Var. *pendula*, Jacq. (*Q. Zeliana*, var. *pendula* and *Q. pseudoliriontis pendula*, Hort.), with pendulous branches

3318. Variation in the leaves of live oak.—*Quercus virginiana* (Nearly natural size). No. 40.
and densely tomentose lvs., resembles the following species and is supposed by some authors to be a hybrid between the two.

35. T. záta, Bose (Q. pyrenáica, Willd. Q. camáta and Q. crínita, Hort.). Tree, to 40 ft., with slender branches; branchlets yellowish tomentose; lvs. pinnatifid half-way to the middle or more, with rather narrow and acute lobes, pubescent above, yellowish or grayish tomentose beneath, 3-5 in. long; fr. short- or long-peduncled; acorn oblong, embraced one-third to one-half by the tomentose cup; scales loosely appressed, nut large. Spain, S. France. Var. pendulá, Dipp., with pendulous branches.—Somewhat tender N.

36. conferta, Kit. (Q. pannonáica, Hort. Q. húngárica, Hubény). Tree, to 120 ft., with gradually spreading branches forming a round-topped, open head; bark rather light brown; lvs. very short-petioled, acuminate at the base, obovate, deeply pinnatifid, with 5-7 pairs of often toothed lobes, dark green and almost glabrous at length, pale and tomentose beneath, 4-7 in. long; fr. short-peduncled; acorn ovoid-oblong, embraced about one-third by the cup; scales rather large, loosely appressed. Italy, S. E. Eu. Q.C. Ill. 5:85. F.E. 19-236 (pl. 99). H.W. 2:24, pp. 72, 73.—Handsome oak with dark green foliage; hardy in Mass., but seems not reliable farther north.

37. Cérris, Linn. Terrýy Oak. Tree, to 120 ft., with rather short spreading branches forming a broad pyramidal, at length often irregular open head; lvs. oblong or obovate-oblong, pinnatifid, with 3-8 pairs of entire or few-toothed lobes, dark green and somewhat rough above, grayish pubescent or almost glabrous beneath at length: fr. short-stalked, ripening the second year; acorn oblong-ovate, to 1½ in. long, embraced about one-half by the large mossy cup. S.E. Eu. W. Asia. Mn. 3:166. Gm. 27, pp. 476, 477. H.W. 2:25, pp. 74-6. G.W. 8, p. 181. F.E. 14:1264 (pl. 41).—Handsome oak with dark green foliage and of pyramidal habit when young, but not quite hardy N. Easily recognized even in winter by the slender subulate scales surrounding and exceeding the winter buds.

3320. Quercus chrysolepis. (×3) 

úta, Loud. Lvs. deeply pinnatifid, often almost to the midrib divided into narrow oblong acute lobes. Var. ambryóyána, Aschers & Graebn. (Q. ambryóyána, Simonka). Lvs. half-evergreen, smaller, subcoriaceous, glabrous above, with bristly teeth; stipules smaller, caducous. Hungary.—There are hybrids with Q. Suber, for which see Q. Lucombeana, in suppl. list. Var. laciníata, Loud., Lvs. long-petiolate, less deeply lobed, or almost sinuately dentate with short, acute entire lobes. For Q. australiaca sempervirens, see Q. Pseudotaurinera in suppl. list. Var. laciníata, Loud., Lvs. deeply pinnatifid, often almost to the midrib divided into narrow oblong acute lobes. Var. ambryóyána, Aschers & Graebn. (Q. ambryóyána, Simonka). Lvs. half-evergreen, smaller, subcoriaceous, glabrous above, with bristly teeth; stipules smaller, caducous. Hungary.—There are hybrids with Q. Suber, for which see Q. Lucombeana, in suppl. list.

38. Sûber, Linn. Córk Oak. Evergreen tree, to 50 ft., with broad round-topped head and thick, deeply furrowed, spongy, elastic bark; lvs. oblong to oblong-rounded or subcordate at the base, remotely serrate glabrous above, whitish tomentose or sometimes glabrescent beneath, 1-3 in. long; fr. short-stalked; acorn ovate or oblong-ovate, ½-1½ in. high, embraced about one-third by the cup; scales thick, usually with short and often recurred tips. S. Eu. N. Afr. H.W. 2, pp. 80, 81. G.W. 8, p. 182.—From this species cork is obtained; it is much cult. for this purpose in E. India and recently also in Calif., where it seems to thrive well. Q. ocrédens, Gay, differs chiefly in the fr. ripening the second year, in the less persistent lvs., the old one mostly falling in spring, in the shorter scales of the cup and in its greater hardness; its bark is not distinguished commercially from that of the true cork oak.

39. Íls, Linn. Holly or Holm Oak. Evergreen tree, to 60 ft., with large, round-topped head; bark not corky; lvs. very variable, ovate to lanceolate, remotely serrate or almost entire and with revolute margin, dark green above, yellowish or whitish tomentose or sometimes glabrescent beneath, 1-3 in. long; fr. 1-3, usually peduncled; acorn ovate, embraced about one-half by the cup; scales thin, appressed, rarely slightly spreading. S. Eu. M. D.G. 1898:275. H.W. 2:25, pp. 77-79. G.M. 54:805. Gm. 65, p. 320. Var. Ballota, DC. (Q. Ballota, Dips.). Lvs. smaller, orbicular or broadly ovate; the sweet acorn is often gathered for food. Var. Fordii, Nichols. (Q. Fordii, Carr.). Of pyramidal habit with narrower and smaller lvs. R.H. 1861, pp. 114, 115; 1885, pp. 352, 353. Not to be confused with Q. Fordiana, Hemsl., a Chinese species with chestnut-like lvs.

40. virginiana, Mill. (Q. virginiana, Ait.). Live Oak. Figs. 3317-3319. Evergreen tree, to 50 or rarely to 70 ft., with almost horizontal limbs, forming a widespread head; sometimes shrubby; lvs. elliptic or oblong, usually entire, with revolute margin, rarely with a few spiny teeth above the middle, dark green and glossy above, whitish tomentulose beneath, 1-3 in. long; fr. peduncled; acorn ovate, about 1 in. long, embraced about one-third by the cup; scales thin, appressed. Va. to Fla., west to Mex. S.S. 8:394, 395. G.F. 1:476; 5:486, 487; 6:7; 8:235. F.R. 1:643. G.E. 8:1. G.W. 9, p. 505.—One of the most beautiful of the American oaks and much planted as a shade and avenue tree in the southern states; easily transplanted and of rapid growth; also very beautiful as a timber tree.

41. chrysolepis, Liebm. Calóríñía Live Oak. Maui Oak. Fig. 3320. Evergreen tree, to 50, rarely to 100 ft., with wide-spread head and often pendulous branches; lvs. short-petioled, oval to oblong-ovate, acute and spiny-toothed or entire, bluish or yellowish above, glaucous beneath; covered with fulvous tomentum when young, 1-4 in. long; fr. short-stalked, ripening the second year; acorn ovoid, ½-1½ in. high, embraced about one-fourth by the shallow cup which is often very thick and densely fulvous-tomentose. Ore. to Calif. S.S. 8:368, 369. G.F. 8:127.—The most beautiful of the Californian oaks.

42. agrífolia, Née. Figs. 3321, 3322 (adapted from Pacific R. R. Report). Similar in habit to the former, sometimes shrubby; lvs. broadly ovate to oblong, sinuately spiny-toothed, usually convex, dull green above, light green below, pubescent at first, 1½-3 in. long; fr. usually sessile; acorn conic-ovate, often elongated, to 1½ in. long, embraced one-fourth to one-third by the cup; scales thin, slightly puberulous. Calif. S.S. 8:403. F.S. 7, p. 138.

Subgenus Cyclobalanopsis.

43. glauca, Thunb. (Cyclobalânóspis glauca, Oerst.). Evergreen tree, to 45 ft.; branchlets glabrous or nearly
so: lvs. on slender petioles 1½-1 in. long, elliptic-oblong to ovate-oblong, acuminate, broadly cuneate or nearly rounded at the base, dentate along the margin, lustrous above, glaucous beneath and silky, at least while young, 3½-5½ in. long: fr. short-stalked, 1½ in. cup subcircular-shaped, silky-pubescent outside, with 5-7 concentric rings; nut elliptoid, 2½ in. long. Japan. S.F. 150. 8:

44. myrsinefolia, Blume (Q. Vibriagyana, Franch. & Sav. Q. bimisiaeformis, Fort., not Hance). Cyclobalanopsis vibragyna, Schott.) Everett ree, to 50 ft.: lvs. lanceolate or oblong-lanceolate, acuminate, cuneate at the base, glabrous or pubescent from the beginning, shining green above, 3½-5 in. long, ½-1½ in. wide: fr. in short spines; nut oblong-ovoid, 1½-2½ in. long, emarginate about one-third by the glabrous cup, consisting of about 6 concentric rings. Japan. 150. 8:

19. p. 285; 79, p. 388.—Handsome tree, rare in cult. The species in the following list are not hardy North except when planted in the South or the Southern states. In the American trade confused with Q. acuta and in European gardens with Q. glauca.

45. acuta, Thunb. (Q. Buergeri, Blume. Cyclobalanopsis acuta, Oerst.) Everett small tree: lvs. oblong-ovate to ovate-lanceolate, acuminate, rounded at the base, cuneate or truncate on the margins at the base: pubescent on the margin: glossy green above, yellowish green beneath, glabrous, only when unfolding covered with a brownish quickly disappearing film, 3½-5½ in. long: fr. in nearly sessile clusters: lvs. oblong-elliptic, about ½ in. long, emarginate about one-fourth by the pubescent cup, consisting of about 6 concentric rings. Japan. Korea. S.F. 1:32. G.L. 19, p. 388.—Handsome tree, rare in cult.

Var. Acuta, Michx. BLUE LEAFED.-Q. acuta, var. aurea, Torrey=Q. Acuta aurea, Torrey. Lvs. on slender petioles; ½ in. long, elliptic-oblong, usually glabrous, at least when young, 2½-3½ in. long: fr. almost sessile. Garden origin. Q. acuta, var. aurea, Torrey. Lvs. on slender petioles; ½ in. long, elliptic-oblong, usually glabrous, at least when young, 2½-3½ in. long: fr. almost sessile. Garden origin.

Var. Atkinsoniana, var. aurea, Torrey=Q. Atkinsoniana aurea, Torrey. Lvs. oblong-elliptic, with 5-7 ribs, faintly pubescent outside, with 5-7 concentric rings; nut ovoid-elliptic, about ½ in. long, embraced about one-half by the cup. Japan. S.I.F. 1:32. G.L. 19, p. 388.—Handsome tree, rare in cult.
Iv. eliptica—oblong to lanceolate, acuminate, serrate above the middle, thinly and bordering by a broad, irregular, creamy white margin.

4 or 5 wavy concentric long and divided near the base, serrate, glaucous, 4-5 in. long; fr. in short spikes; acorns ovate, about 5 in., cup with concentric crenate rings, gray tomentulose. Cent. Chile, A. var. Fargesii, Rehd. & Wilson. Lvs. smaller; rings of cup entire.

Q. mongolica, Hort., not Q. mongolica, Willd. Evergreen small tree, to 30 ft., with spreading, often contorted branches; allied to Q. undulata. Lvs. ovate-oblong, acute, serrate, veins prominent, close and meeting in the midrib, wide, armed with stout upturned spines; spike dense, up to 8 in. long, many-flowered, the bracts rounded at apex, usually entire; frs. up to 2 in. long; sepals webby below; petals blue above; stamens much shorter than petals. Brazil. B.H. 1882:48 (as Q. refa). F.S. 10:1028. Gt. 1875:324.

GEORGE V. NASH.

QUILLALA (from Quillata, the Chilean name, which comes from guilltun, to wash: the bark of the tree contains saponin, an antimony compound, which when cleaned or washed makes it useful as soap). Rosaceae. Glabrous evergreen trees, whose bark is sometimes saponaceous, occasionally grown in the greenhouse and hardy outdoors in the southern United States.

Leaves sparse, petioled, simple, thick-coriaceous, rather entire; stipules small, deciduous; peduncles axillary and terminal, 3-5-flowered; fls. polygamous-dioecious, rather large, tomentose, the lateral male, the central female; petals, calyx, leaves, persistent, lobes 5, broadly ovate, valvate; petals 5, small, sessile, spathulate; disk thick, fleshy, 5-lobed; stamens 10; carpels 5; follicles 5, oblong, obtuse, leathery, cohering at their base, many-seeded. About 3 or 4 species, natives of S. Brazil, Chile, and Peru.

Saponaria, Molina. Soap-bark Tree. A large tree; lvs. 1½-2 in. long, ovate, shining, dentate, short-petioled; fls. white, about 5 in. across, usually terminal, solitary, or in clusters of 3 or 5 on the same peduncle. Chile. B.M. 1765-66. Cult. in S. Calif. F. TRACY HUBBARD.
farm. In a few cases, when its merits are recognized, it is given drier richer ground and cultivated with judicious care. Naturally, the quince is adapted to deep rich warm soils. The fertility of the soil should be strongly emphasized, as the root, instead of penetrating deeply, spreads out extensively and consequently is near the surface. It is slow-growing on any soil but responds very quickly to good fertility. On cold damp soils the fruit is inclined to be woody and it may possibly be for this reason that the quince is not more popular for preserving purposes. On the richer drier soils the quality is much improved. The idea is very prevalent that the tree is adapted to low ground. The lower grounds, generally speaking, are richer, but in this respect only may the trees be said to be adapted to it. Excessive moisture is harmful to the quince as to other fruits. Cultivation must be judicious. In many respects it should resemble that given the dwarf pear. The roots being near the surface, cultivation and especially plowing must be shallow. It is common practice to ridge well up to the trees not only to protect the roots but to permit easy drainage; also the tree being very subject to fire blight, it does not permit of thorough cultivation with the consequent succulent wood-growth. Moderate cultivation in spring and early summer followed at once by a cover-crop or a good sod-mulch is considered good practice.

The quince tree is small, twisted and dwarf in its habit. It seldom reaches a height of more than 12 or 15 feet, although some grow higher. The larger number are much lower. Being dwarf in its habit, the quince tree can be planted as close as 13 to 15 feet in an orchard, the latter distance being the more popular. Planted too close, it is forced upright, like other trees. The fruiting habit is distinct and peculiar, resembling no other orchard fruit, but is similar to the hickory and the walnut. The blossoms are produced on the current season's growth (Fig. 3323). A short growth starts from the terminal winter bud and on the end of this the flower and fruit are produced (Figs. 3324, 3325). There is no proper stem or peduncle to the fruit, but the quince sits close or sessile on a short leafy branch. The wood-growth is continued by an axillary bud of the previous season. This peculiar habit of growth gives the tree its crooked bunchy appearance. (Fig. 3326.)

Pruning should receive careful attention, otherwise the quince tree will soon become too thick and also more or less unshapely. When set in orchard, the young tree may be pruned to a short whip, as shown in Fig. 3327. The trunk is kept very short; some growers prefer to start the top as low as shown in Fig. 3328, but the former and probably still the prevailing practice is to grow a trunk like those seen in Fig. 3329. These longer trunks are convenient if one is to use the curculio catcher, as shown in Fig. 3330. The pruning consists in keeping the top open and well spread (Fig. 3328). To cause the top to spread and to keep it low and within bounds, more or less heading-in may be practised; but as the fruit-shoots spring from the ends of the branches, clipping-in of all the tree would remove practically all the fruit.

The questions of cultivation and fertilizers are largely inter-related. Thorough tillage makes available a large amount of plant-food, and consequently less fertilizer is necessary. However, too thorough cultivation and consequent succulent growth increases blight. The question of fertilizers comes down to one of producing moderate growth of a hardy resistant nature. This means that in cultivated orchards, heavy applications of nitrates or nitrogenous manures must be withheld. Phosphate and potash on the other hand can be applied in quantity, especially on the lighter soils. The cover-crops will probably supply the necessary nitrogen. If growth is very slow, a light application of farmyard manure may be made. Lime and land-plaster can also be applied in quantity. The fruit is sold in eleven-quart baskets, bushels, and barrels, and ranges from 75 cents to $1.25 a bushel, depending on the market and the demand. In Ontario the demand is very limited and there are scarcely any orchards on a commercial basis. In the eastern states and especially New York State, there are some orchards of considerable size (Fig. 3329). The fruit, though apparently hard and long-keeping, is comparatively easily bruised or marked and must be handled with care.
The trees begin to bear a few fruits the second and third years after planting but can not generally be said to bear a profitable crop until ten to twelve years of age. The fruit is very subject to limb-rub and disease, and must be carefully grown to look well. The ordinary practice is to spray the tree with dormant-strength lime-sulfur at the same time that the apples and peaches are sprayed and then again just after the fruit is nicely set with bordeaux mixture, to each forty gallons of which has been added three pounds of lead arsenate. Summer-strength lime-sulfur with the above amount of poison would give the same results for the summer spray. Judicious pruning also tends to thin the fruit and improve the quality. Seedling stocks—Quince of Angers—are largely imported from Europe for roots. These roots are used also for dwarfing the pear. The trees are grown much the same as other nursery trees. The seedlings are set in the nursery row in early spring and budded in August. By a year from the following spring, that is two years from the setting of the seeding, the trees are ready for the planter. The quince can also be propagated by cuttings, mound-layering and root-grafting, but the above-named method is the common one in practice. Trees received from the nursery should be given the same care as other nursery trees. Heel them in carefully if the soil is not ready for planting. Plant about 2 inches deeper than the bud. Head at 15 to 20 inches. If budded trees are used and planted the proper depth, there is little or no danger from suckering. The most damaging diseases are fire-blight, affecting the wood and especially the new growth; leaf-blight, affecting branches, fruit and foliage; and black-rot and bitter-rot, affecting the fruit. For the fire-blight, the worst disease, there is no direct remedy, but trees should not be allowed to over-grow, wild hawthorns and wild apples and pears near the plantation should be destroyed, and all affected parts should be removed promptly. The most serious insect attacking the quince is the quince curculio (Conotrachelus crategi). This may be controlled by spraying with six to eight pounds of lead arsenate to one hundred gallons of water, or in the place of water bordeaux mixture at the proper season. This must be done when the beetles first make their appearance and again about ten days later. This insect is found on the quince in Ontario. The same insects as attack the apple generally attack the quince and the treatments are similar. Sometimes the jarring method is employed, as shown in Fig. 3330, as for the plum, the beetles being knocked off by hitting the tree with a padded mallet. Orange (Fig. 3325) and Champion are the leading varieties of quince. The former is the variety most largely grown in Ontario and previous to 1870 was the only variety. It is large in size, skin golden yellow with greemish or russet color around stem. The flesh is tender and the flavor good. The season is late September and October. Its origin was southern Europe. The latter variety, of American origin, is large, pear-shaped and on the tree has a distinctly greenish yellow color. The tree is larger and taller-growing than Orange. The fruit is very late ripening. Other commonly grown varieties are Bentley, Fuller, Rea, Meech, and Van Deman. F. M. CLEMENT.

QUISQUALIS (Latin, who, what kind). Combretaceae. Rambling subscandent large shrubs, including the rangoon creeper which is hardy in the extreme south of the United States and is also sometimes grown in the warmhouse. Leaves opposite, oblong or obovate, acuminate, entire; fls. in short spikes, axillary and terminal, white or red; calyx-tube prolonged, long and slender above the ovary, deciduous; petals 5; stamens 10; short; ovary 1-celled: fr. dry, coriaceous, 5-angled or 5-winged,
1-seeded.—About 4 species, chiefly Indian, 1 in Trop. and S. Afr. The name *quisqualis* means literally *who? what?* and is said to have been given by Rumphius in astonishment at the plant’s behavior, for it is said to grow erect and shrub-like to a height of 3 ft., when it throws out from the base a new growth that climbs up the neighboring trees, after which the original shrub perishes. Many other interesting statements about this plant are made in B.M. 2033.

*Quisqualis indica* is cultivated in northern hothouses. For best results it should be planted in beds of soil composed of fibrous loam, peat, and sand. The flowers appear from June to September, and last well when cut. After flowering the plant should be cut back severely and water applied less frequently until the wood is ripened. New growth starts the following spring. If the plant is kept in a very hot and humid atmosphere, it makes a rampant growth. It is remarkably free from insect pests and fungous diseases. Propagation is by softwood cuttings inserted in sand with bottom heat. (Emil Mische.)

*indica*, Linn. (*Celtis nütans*, Hort. Reasoner, not Roxbg.). RANGOON CREEPER. Lvs. 4 in. long, nearly glabrous; calyx-tube extremely long (2–3 in.), slender, green; calyx-teeth triangular, acute, not acuminate; petals rose or scarlet; fr. with very sharp angles but hardly winged. Malaya. Widely cult. in tropics. B.M. 2033. B.R. 492. R.H. 1898:50 (as *Q. pubescens*).

F. Tracy Hubbard.†
RADERMÀCHIA (after J. C. M. Radermacher, 1757-83, a Dutch resident of Java, published a list of Javanese plants). Also spelled Radermachera. Bignoniaceae. Ornamental trees. Plants with large opposite, pinnate or bipinnate lvs. and large fls. in terminal panicles: calyx campanulate, truncate or dentate; corolla campanulate, with 4 or 5 incised sepals: caps. linear, loculicidal; septum thick spongy with the seeds in shallow impressions.—Only two species seem to be in cult.; they can be grown in warm temperate regions only, and are prop. by seeds, also by air-layering and by cuttings.—Species 8, in S. E. Asia.

R. sinica seems to revel in the light sandy soil of the Florida gardens. Its abundant, large, fern-like, crimped bipinnate foliage and its luxuriant symmetrical growth combine to make it an object of great beauty. It grows to a height of 10 to 12 ft. in one season, and if not cut down by a severe freeze it attains a height of 20 ft. in two years, provided the soil is made rich by a good fertilizer. Planted out in a conservatory in the North it soon reaches stately dimensions. It is easily raised from cuttings placed in sand. (R. Nehrling.)

pentandra, Hemsl. (Orozamia flavum, Rehd.). Evergreen tree, to 20 ft., glabrous: lvs. bipinnate, with the stout petiole 2-3 ft. long; lfts. oblong to oblong-lanceolate, entire, 3-7 in. long; panicule about 1 ft. long; calyx with 5 short toothed: fls. white and yellow; tube 2 in. long; limb spreading, about 3 in. across; stamens 5: caps. linear-cylindric, to 3 ft. long. S. E. China. Typical Chinese only. I. 1928. S. T. S. 1: 92.—Handsome tree with bold foliage and showy yellow fls. exhaling a heavy rather disagreeable odor; intro. by the Arnold Arboretum, and flowered in the greenhouse in 1903.

sativa, Hemsl. (Stereospermum sinicum, Haner). Evergreen tree: lvs. bipinnate; pinnae 8, each with about 7 stalked, ovate-lanceolate entire lfts. obtusely acuminate, glabrous, about 2 in. long; panicule large, terminal; calyx campanulate, with 5 short triangular teeth; corolla pale sulfur-yellow, with funneliform tube about 3 in. long and spreading roundish lobes about 1 in. long with crisped margin: caps. subterete, 16 in. long and rather showy. Numerous, the style short: pods seldom seen, globular, on ascending pedicels. Eu.; escaped in N. Amer. in moist places and along water-courses.—The long tough roots furnish the horse-radish of gardens. See Horse-Radish.

RÁDICA (litter radish or root). Syn., Roripa, Nasturtium. Cruciferae. Herbs, not cultivated except water-cress, horse-radish, and one or two others.

Plants mostly small, perennial, biennial, and annual, with small white or yellow fls. mostly in racemes: lvs. (or at least the lowermost) usually pinnate or pinnatifid, commonly glabrous: fr. a silicle or short siliquid, globaral to cylindrical, with strongly convex nerveless valves; seeds usually many, small and numerous, in most species in a double row in each locale, the cotyledons accumbent.—Species more than 50, widely spread in eastern and western hemispheres, inhabiting low grounds, swamps, and pools or streams, mostly weedy in character. These plants formerly appeared under the name Nasturtium, which, however, dates only from 1756 whereas Radicula dates from 1757. These plants probably should bear the name Roripa, which ec. The nasturtiums of gardens and are prop. by seeds, also more than 50, widely spread in eastern and western hemispheres, inhabiting low grounds, swamps, and pools or streams, mostly weedy in character. These plants formerly appeared under the name Nasturtium, which, however, dates only from 1756 whereas Radicula dates from 1757. These plants probably should bear the name Roripa, which ec.
much used for garnishing and for salads. See Cress. In the tropics Nasturtium indicum, DC. (see Koripa), is a desirable cress. This is an erect annual, with yellow, flat, and deeply pinnatifid (rarely entire) radial lvs. It is said to have been cult. in Europe, but it is probably useless or at least unnecessary outside the tropics.

L. H. B.

RADISH (Latin, radix, a root). A name applied to certain forms or species of Raphanus (of the family Cruciferae), particularly to the kinds that produce thickened edible roots; these roots are eaten raw, except some persons cook the large summer and winter kinds. See Raphanus.

The radish is variable in size, shape, color, and consistency of root and in season of maturity. Varieties may be classified as spring, summer, and winter radishes; or as globular, half-long, and long radishes; or as red, white, gray, and black radishes. Figs. 3331-3333 show some of the forms.

The origin and nativity of the radish are questions of dispute. For geographical reasons, it is supposed that the radish is wild in temperate Asia, probably in the oriental part, although truly indigenous radishes are doubtfully known. Not infrequently the radish runs wild about gardens, and in that case the root soon deteriorates into a small slender woody and more or less fibrous member. It has been thought by some that the radish is only a modified form of the wild charlock, or Raphanus Raphanistrum. In fact, experiments were made on the charlock by Carriere, who was able in a few years to produce edible radishes from the wild plant (cf. Cyclo. Amer. Hort. IV:1467). While these investigations seem to be conclusive that the radish can be produced from the charlock, they nevertheless do not prove that such was the actual origin of the garden radish. DeCandolle, whilst accepting Carriere's experiments, was unable to understand how the radishes of India, China, and Japan could have originated from the charlock, since that plant is unknown in those countries and the radish has been grown there for centuries. It is possible that the radishes of the Orient are a different species from those in Europe, although they are generally regarded as the same species. Recent experiments in France (Yvonne Trouard-Riolle, "Recherches morphologiques et biologiques sur les radis cultivés," Nancy, 1915) indicate that the cultivated radish has not been derived from R. Raphanistrum by cultivation, but that R. sativus is specifically distinct although little known as a wild plant. It is supposed that the Japanese radish is derived from one aboriginal form of R. sativus which is native of China and Japan, and that the European radishes have come from another aboriginal form.

The summer and winter radishes are not popular in this country unless among those of recent foreign origin. The winter radishes in particular are little grown. These are late-maturing kinds, requiring more of the season for growth and of such large size and firm flesh that they keep well, as turnips are kept. The summer and winter radishes require no special treatment, except that plans must be made to allow them a longer period. In eastern Asia are singular kinds of radish that are little known here. In North America, the small spring radishes comprise practically the range of general cultivation.

The rat-tail radish, Fig. 3346, is grown for its much-developed soft pods, which may be used as are radishes and in the making of pickles. It is rarely grown in American gardens, although it is well worth raising as a curiosity. It is annual, and its cultivation presents no difficulties. There is also a fleshy podded radish of parts of India, with the edible pods short and soft.

The radish is one of the most popular of garden vegetables. It is of quick growth, and the product is secured at the time of the year when fresh vegetables are in demand. In order that radishes may be of the best quality, they should have made rapid growth. The soil should be rich, light and loose,—one that drains readily and does not bake with heavy rains. Radishes fit for the table may be had in three to six weeks from the sowing, depending on the variety and season of maturity. Varieties may be classified as spring, summer, and winter radishes, depending on the time they mature. The radishes are divided into three classes, namely: (1) The small spring radishes comprise practically the radish that are little known here. In North America, the small spring radishes comprise practically the range of general cultivation.

Aside from the root-maggot, the radish is relatively free from insects and diseases. When the root-maggot appears in any place, it is usually best to discontinue the growing of radishes in that area for two or three years, until the insects have been starved out. The maggots may be killed by an injection of bisulfide of carbon into the earth about the plants; but this is usually more expensive than the product is worth. Carbolic acid emulsion may also be used. Early radishes may be grown in hotbeds or coldframes with the greatest ease, and in these places they are usually less subject to the attacks of the cabbage maggot, since the crop is matured in advance of the maggot season.

Radishes are readily forced in the winter months. It is necessary that the house be light. The soil should be a sandy loam, free from silt and clay. It is best to grow radishes in solid beds rather than on benches. They thrive best in a low temperature. The temperature during the day should not exceed 65° to 75° in the shade, and at night it may drop to 45° to 50°. If the temperature is too high, and particularly if the beds are given bottom heat, the plants tend to run to top rather than to root. The seed is usually sown in rows from 5 to 8 inches apart, and they are thinned in the row until they stand 2 or 3 inches apart. In order that the crop shall be uniform and mature simultaneously, it is advisable either to sift the seed or to transplant the young radishes. Galloway has found, by experiment, that radish seeds of inch in diameter are too small to give a satisfactory and uniform crop. He therefore advises that seeds be run through sieves with a mesh of that diameter in order to separate the small specimens. In a certain experiment, he secured from two pounds of commercial seed nineteen and one-half ounces of large

3332. Half-Long Scarlet radish. (x1/2)
seed, ten and two-third ounces small seed, the remainder being bits of gravel; sticks and other impurities. The chief value of this sorting lies in the greater uniformity of the crop. Almost every plant can then be relied upon to reach maturity. It is the practice in some houses to transplant the young radishes. The seed may be sown in flats or in beds at one end of the house, and when the radishes have made two or three leaves, they are transplanted into permanent quarters. In this operation, all the small and weak plants are discarded and the crop is therefore more uniform. It is supposed by some growers, also, that the breaking of the tap-root in the process of transplanting tends to make the tuber shorter and thicker and to induce an earlier maturity. By means of transplanting, the use of the house may be economized. Whilst one crop is growing, another may be started in a seed-bed or in flats. As soon as the first crop is removed, the ground may be thoroughly raked, fertilized, and the new plants put in. In some cases the new crop is transplanted between the rows of the old crop a few days before the latter is removed. But, unless the soil is rich and in good condition, it is better to wait until the crop is removed in order that the land may be thoroughly fitted for the new plants. Radishes are often grown in conjunction with lettuce. If they are grown in the same temperature, the varieties most used for forcing, as also for the early spring crop in the garden, are the globular or half-long kinds. With these varieties, a depth of soil of 4 inches is sufficient for good results.

L. H. B.

Another view of the cultivation of the radish.

There are few garden roots in which fresh crispness is more essential to palatability than in the radish, or which can be more easily held in prime condition for so long after gathering, and usually one is able to secure roots of excellent quality from the market. On the other hand, an abundant family supply can be grown on a small area and the radishes can be quickly gathered and fitted for the table, so that every country garden or even town yard may be easily made to furnish a family supply. Radishes are cool-weather plants, and although when young or quickly grown, they may be killed by severe or long-continued freezing, they will endure a moderate frost without injury; the plants do not thrive in the cooler weather of autumn. These require more stability-manure is very likely to result in ill-shaped coarse-grained strong-flavored roots, and the uniformity and symmetry of the root is very dependent upon the soil, the quality and friability of the soil. The seed should lie some ten to twenty grains to the foot, in drills about 1 inch deep, and covered with about an inch of soil. It has been found advantageous, just before the starting plants begin to push through the soil, to cover the row with a liberal sprinkling of either tobacco dust, or of land plaster and kerosene, as a repellant to black beetle and other insects.

Forcing varieties.

A group of varieties of radishes has been developed in which the roots reach usable size very quickly,—in some stocks by the time the cotyledons are full sized and before more than three or four leaves have developed,—so that under favorable conditions a culture may be started, grown to maturity, marketed and the roots become tough and unpalatable if grown slow and continue in prime edible condition much longer. In garden cultures, the first sowing should be made as soon as the ground can be worked and ordinarily it will furnish usable roots in twenty-five to thirty days and remain in edible condition from five to twenty days. To secure a succession, two to five sowings should be made at intervals of ten to twenty days, but it is useless to attempt to grow radishes in the hot weather of midsummer, as they would not only make a poor growth but the roots would be tough, strong-flavored and unpalatable.

Radishes require for their best, or even for a good development, a rich friable soil which has been made so by heavy manuring and judicious culture in previous years rather than by heavy manuring, while the use of fresh stable-manure is very likely to result in ill-shaped coarse-grained strong-flavored roots, and the uniformity and symmetry of the root is very dependent upon the soil, the quality and friability of the soil. The seed should lie some ten to twenty grains to the foot, in drills about 1 inch deep, and covered with about an inch of soil. It has been found advantageous, just before the starting plants begin to push through the soil, to cover the row with a liberal sprinkling of either tobacco dust, or of land plaster and kerosene, as a repellant to black beetle and other insects.

Seedsmen offer a wide range of varietal forms, ranging from the quick-maturing red or white Olive-Shaped, the Half-Long or the Long Scarlet, to the later-maturing longer-seasoned Chartier, or White Vienna, and the still later larger Strasbourg or Stuttgart, which might be classed as summer varieties, although when planted so as to mature in the heat of midsummer they are likely to be strong-flavored and unpalatable.

Fall and winter radishes.

There are varieties which develop to usable size more slowly than the preceding and which remain crisp and tender much longer. They should not be planted until midsummer or later so that they may come to maturity in the cooler weather of autumn. These require more room for their best development than the spring varie-

RING, ranging in shape from those distinctly flat, through flattened, thickened or long-turnip-shaped, and globular, to tankard or half-long, and in color from white through various shades of red and yellow to dark purple. In some varieties the color is of uniform shade over the whole root, in other much or less of the lower part is white, while in others the generally white surface is marked with dots and splashes of red. In the forcing of radishes, uniformity as to rapidity of maturing and in attraciveness of color are the most important qualities. The success of any culture is very dependent upon the varietal character of the seed used, and varieties are continually offering under new names stocks that are in reality but superior strains of the older varieties.

Spring radishes.

These are slower in coming into usable size than the forcing sorts, but the plants are larger, harder both to cold and heat, and the roots are larger and continue in prime edible condition much longer. In garden cultures, the first sowing should be made as soon as the ground can be worked and ordinarily it will furnish usable roots in twenty-five to thirty days and remain in edible condition from five to twenty days. To secure a succession, two to five sowings should be made at intervals of ten to twenty days, but it is useless to attempt to grow radishes in the hot weather of midsummer, as they would not only make a poor growth but the roots would be tough, strong-flavored and unpalatable.

Radishes require for their best, or even for a good development, a rich friable soil which has been made so by heavy manuring and judicious culture in previous years rather than by heavy manuring, while the use of fresh stable-manure is very likely to result in ill-shaped coarse-grained strong-flavored roots, and the uniformity and symmetry of the root is very dependent upon the soil, the quality and friability of the soil. The seed should lie some ten to twenty grains to the foot, in drills about 1 inch deep, and covered with about an inch of soil. It has been found advantageous, just before the starting plants begin to push through the soil, to cover the row with a liberal sprinkling of either tobacco dust, or of land plaster and kerosene, as a repellant to black beetle and other insects.

Seedsmen offer a wide range of varietal forms, ranging from the quick-maturing red or white Olive-Shaped, the Half-Long or the Long Scarlet, to the later-maturing longer-seasoned Chartier, or White Vienna, and the still later larger Strasbourg or Stuttgart, which might be classed as summer varieties, although when planted so as to mature in the heat of midsummer they are likely to be strong-flavored and unpalatable.

Fall and winter radishes.

There are varieties which develop to usable size more slowly than the preceding and which remain crisp and tender much longer. They should not be planted until midsummer or later so that they may come to maturity in the cooler weather of autumn. These require more room for their best development than the spring varie
ties but are even more responsive to fertile well-prepared soil and frequent cultivation. They may be used as they reach desirable size and will stand considerable frost without injury, but should be pulled and stored much as one would carrots or parsnips so as to avoid severe freezing. The Long Black Spanish, the White Russian, the Chinese Scarlet Winter and Deep Scarlet Panier, the latter one of the most symmetrical and beautifully colored roots in cultivation, belong to this class which is well worthy of more general cultivation.

Chinese and Japanese radishes.

These are possibly the oldest of cultivated kinds. The large many-leaved plants are 2 feet or more across and form immense roots which not infrequently weigh forty to fifty pounds. The flesh is less agreeable in texture and flavor than that of the sorts more commonly grown, and though they have been loudly espoused by seedsmen, they have never come into very general cultivation in this country, except by the Chinese and Japanese who use them as a cooked vegetable more than as a salad.

Seed-growing.

There are few garden vegetables in which uniformity of varietal character is more important to satisfactory results than the radish. This is particularly true of the quickly maturing forcing varieties, the seed of which is largely grown in Europe. As grown there, carefully bred stock-seed is sown thickly in narrow rows and when the most mature roots reach usable size, the crop is pulled, all immature or off-character roots are rejected, and those which are of satisfactory form, size, and color are promptly reset about 10 inches apart in rows about 3 feet apart and soon start into fresh growth and mature a crop of seed.

In this country, seed of both the forcing and larger-rooted sorts are commonly planted ten to twenty to the yard in drills, 3 feet apart, and when the plants are mature enough to indicate their varietal quality, the plantings are carefully gone over, the inferior and superfluous roots pulled and destroyed, and superior ones to furnish the desired quantity of stock-seed are pulled and set out by themselves, where there will be little danger of the flowers being fertilized by pollen from other plants.

The yield and quality of seed is very dependent upon uniformly favorable weather conditions inducing a quick, even growth, fertilization of the flowers by insects, and freedom from storms or exceptionally high temperatures. A hive or two of bees in the field will often materially increase the yield of seed. When the later and the most immature pods begin to ripen, the plants may be cut and laid in windrows or piles not over 3 to 4 feet deep on the threshing-floors and allowed to remain from ten to fifty days (depending upon weather conditions), until the stems are fully cured and dry. The seed may then be threshed out either with flails or machine and sacked, but must be watched, and if necessary, winnowed out, to prevent heart-burn. It is a better practice, particularly with the later sorts, to leave the harvested plants under shelter until midwinter or early spring before threshing. Again, in case of some of the later harder-fleshed sorts, better yields are secured by not planting until autumn, and before severe weather, pulling, topping, and storing the small roots until spring, much as is done with seed-crops of beets or turnips.

W. W. TRACY.

RAFFIA is the Malagasy name of a palm which furnishes a staple article of commerce called raffia fiber. It is indigenous to Madagascar, where it grows without cultivation or attention of any kind. One palm leaf, or frond, produces eighty to one hundred long green divisions 2 to 5 feet in length, like the leaves of the sugar-cane, but of a dark lustrous green color and thicker and stiffer. The under part of this green leaf is of a pale greenish yellow color, and from that side the inner skin is peeled off in the same manner as the skin on the outside of a pea pod, except that it peels off straight to the tip without breaking. It is then of the palest green, and after being dried in the sun assumes a light straw-color. This is the raffia fiber of commerce. Raffia fiber is extensively used by the natives for making cloths called silk lambas and rebannas, which bring fancy prices in Europe and America, where it is used in the manufacture of various kinds of hats, and the like. A large trade is also had in raffia fiber in Europe for use in the manufacture of fancy baskets, but in America, while raffia fiber has been used to a limited extent in the manufacture of hats, its principal use is for tying vines, flowers, asparagus and celery bunches and the like. Raffia is not affected by moisture or change in temperature so as to risk cutting or winding the most delicate tissues, and it does not break or ravel when folded or knotted. These qualities bring it into general use in Europe, especially in the vineyards of France, where it is extensively used, and consequently maintains its price. It is virtually inexhaustible in Madagascar, the supply being limited only by the scarcity of labor. For export, the fiber is collected in large skeins, twisted or plaited, and then packed in compressed bales of about 100 kilograms (220 pounds) each. About 20,000 bales are exported annually.

CHAS. W. JACOB & ALLISON.

RAFFLESIA (named for Sir Thomas Stamford Raffles). Rafflesiaceae. Fleshy parasites, with a solitary large sallow fl. with a cadaverous odor rising from a superficial rhizome, leaves, fl. parts, and tube, fleshy, with a tube-hemispherical at the base, solid in the male fls., and adnate to the ovary in the female fls., broad-canapulate above the ovary, limb 5-parted, the segms. imbricated in 1 row; ovary inferior, with numerous ovules. About 5 species, Malaya. R. Arnoldi. R. Br. Fls. flesh-colored, 3 ft. across, mottled with a thick fleshy rim or corona lining the upper part of the tube. In the male fls. there is a thick fleshy column within the corona and adnate to the perianth-tube and having at the top a wide flat plate, the overhanging margin of which is revolute and on which is placed a ring of sessile anthers. The female fls. are similar, but lack the anthers and possess an ovary adherent to the base of the perianth-tube and having a single cell. Sumatra. G: 7:547. J.H. III. 54:373.

RAILROAD-GARDENING. That phase or application of landscape gardening (or landscape architecture) which aims to improve the appearance of railway rights-of-way and station grounds; and, as an art of design, which lays out the approaches and makes the subdivisions of the grounds as best to serve convenience and beauty.

In this article, in a cyclopedia of horticulture, it is not intended to discuss the theory of design for railway properties, but rather to consider the plant-growing features; yet the layout must be taken into consideration. The subdivision of the property and the general theory of arrangement are necessarily controlled by the nature of the property itself, the extent of trackage, the need for passenger and freight access, the size of settlement to be served. Probably nowhere are the main elements more rigidly fixed by the necessities of the case, for the engineering requirements must be met; and yet there are large civic relations that should receive careful consideration.

In a small suburban railway station property, the planting feature may well be very prominent or even, to the general observer, dominant. Large trees are in place, and flanking lines of shrubbery and many good
XCV. Radish, in several varieties.
growing features. In small cities, of say 10,000 inhabitants more or less, the station buildings become relatively more dominant and the planting falls into a subordinate place, and the gardening may take on the features of ornament; the approaches and the general layout begin to assume a civic character. In large cities, the architecture, arrangement, and formal approaches necessarily dominate, the plant materials are reduced to a very minor feature or disappear altogether, and the landscape architect approaches the work as a problem in city-planning and design. There remains the small country station in the farming country, which usually has been wholly neglected in respect to its landscape features and which has little-expense beyond the mere right-of-way; this is a problem quite by itself and which has not yet been studied to any extent. This application of the landscape art to real rural conditions will develop when the whole subject of country-planning begins to appeal to the public mind.

**Historical sketch.**

The railroad-gardening movement is best understood by a consideration of its historical development, and this is here attempted, although the treatment is not complete nor does it pretend to bring the subject down to date.

**The movement in England.**—Planting has been practised on the station grounds of some English railways for many years, but it is almost exclusively limited to purely ornamental gardening. The corporations do little beyond offering prizes to station-masters and their assistants. This system was put in operation about forty years ago on the Great Eastern, in about 1885 on the Midland, and at a more recent time on the Great Western Railway. The prizes range from 5s. to £5, and in 1900 aggregated £300 on the Midland Railway. The little planting that is done by the railway companies themselves is confined to a few trees of low growth near stations, to a background of shrubs for some of the so-called “platform gardens,” and to sowing broom and gorse on certain slopes of the permanent way between stations. The “allotment gardens” that attract attention on English roads are small tracts near the block signal stations where railway employees use vegetable- and fruit-gardens for their own use, and sometimes care for a few flowering plants.

**Sweden.**—Ornamental planting has been universal on government railways, as well as on most private railways in Sweden, since 1862. According to the Royal Administration of the Swedish State Railways, the following distinctions are made: (1) decorative and fire protective plantings on station grounds; (2) mixed plantings (decorative and economic) on “habitation grounds”; (3) plantings along the railway lines as hedges or for protection against snow. Station planting consists of trees selected to suit the climate of various parts of the country, of shrubs, and of perennials and annuals (flowering as well as bedding plants). At the largest stations (only about seventy-five) annuals are exclusively used for “modern or elegant combinations.” The planting at habitation grounds consists of fruit-trees, small-fruits, a few ornamental shrubs, some flowering plants, and a small kitchen-garden. The state railways yearly plant out about 40,000 hardwooded plants (trees and shrubs), and 400,000 softwooded plants (perennials and annuals), which are nearly all grown at five greenhouses, hotbeds, and nurseries situated in different parts of the country. On private railways the same plan is followed on a smaller scale.

**In various other countries** there are scattered examples of ornamental, economic, and protective planting on railways, including the cultivation of fruits along the rights of way of certain railways of Germany and of France.

The Canadian Pacific Railway Company has planted a considerable part of its right of way to tamarack and other suitable trees to supply the tie material of the future.

The director of the association called Het National Belang, at Utrecht, says that the association has contracts with the State Railway Company and the Holland Railway to plant the dykes of their roads. Different kinds of willows, low apple and pear trees (half-stem appel en peeren-bloemen) and wild prune trees are used, the fruit of the last being “used for jams.”
The common quince is used to a limited extent in Uruguay for binding earth on embankments, and the paradise tree for shading station platforms. "The Ombu is the national tree of Uruguay,—useless as fuel or timber, useless as food, but as Jerome as Jonah, guarded at midday at certain seasons."

The Royal Railway Department of Siam reports through M. Kloke, acting Director General of Railways, that efforts have formerly been made to establish the prickly pear in Ceylon and other islands of the Korat section, which were destroyed by cattle; Eucalyptus trees grown from seed received from Australia have developed quickly into "stately trees"; and good success has also resulted from the introduction of a tree from Manilla which is said strongly to resemble the cherry tree, and is well suited for making "shady alleys;" and that India-rubber trees are used at smaller stations.

Remarkable work has been accomplished in Algiers. The director of the P. L. M. Railroad Company wrote some years ago that about 825,000 trees had been planted between 1869 and 1875, of which 495,000 were forest trees and 30,000 fruit-trees. The prevailing forest trees are eucalyptus and locusts; others are mulberry, plane, pine, cypress, willow, poplar, oak, sycamore, and mimosa. About one-fifth of the forest trees were planted about stations and watch-towers for ornamental purposes, and the remaining four-fifths were used in protective plantings. The fruit-trees include mandarin, apricot, and almond.

In Mexico some companies, notably the Mexican Central, maintain flower-gardens and parks at larger stations.

United States.—The first traceable indications of the movement in this country are about 1870. It was not until several years later that infrequent allusions to the work crept into print. From the year 1880, however, the movement gained in favor so rapidly that by 1884 several new and exceptionally artistic stations had been built for the Boston & Albany Railroad Company after designs by the late eminent architect, H. H. Richardson, and the latter date marks the adoption of a consistent scheme of permanent planting, aiming at nature-like effects instead of the purely ornamental, i. e., formal gardening, previously used. This happy result was due to the influence of Charles S. Sargent, of the Arnold Arboretum, a director of the road, and to Wm. Bliss, its president. Designs for the improvement of the grounds around these stations were made by F. L. Olmsted, the veteran landscape architect, and since 1884 the development of these plans, as well as all of the horticultural interests of the road, have been in charge of a competent landscape gardener, E. A. Richardson, who says: "The plan followed is to conform the treatment and development of the station grounds to the adjacent ground; a natural style being followed amid natural surroundings, and a more cultivated style in highly cultivated regions; to utilize all natural advantages of ground surface, rocks, water, and native growths; to make large use of trees, shrubs, vines, and plants indigenous to the locality where improvements are being made; to supply beds for shrubs with from eighteen to twenty-four inches of good loam; and to plant so closely in the beginning that as the plants grow they can be thinned to supply other grounds as needed." It goes without saying that these methods are not only the most practical but that they insure the most artistic results.

Among the first railway companies to improve their station grounds by planting were the Central of New Jersey (1886), the Baltimore & Ohio (date uncertain), the Boston & Albany (1880), the New York Central & Hudson River (1880), the Erie (1881), the Southern Pacific (1885), the Pennsylvania (1886), and the Austin & Northwestern of Texas (1887). Other roads appreciate the value of the work and encourage it; and railroad-gardening has now become a recognized form of landscape improvement, although yet at its merest beginnings.

The methods.

In the public mind, railroad-gardening usually means the formal use of flower-beds about stations. Such work is ornamental gardening, not landscape gardening. Most of the so-called landscape gardening at railroad

3335. One method of treating a railway ground,—temporary formal ornament and no durable flank-planting.

and sodding. This so encouraged the baggage-master that he solicited the townspeople for money to buy seeds and plants, and with such success that he maintained for three years a flower-garden that favorably impressed the higher officials of the road, and led to the establishment of similar gardens at other points, and eventually to the adoption of a system of planting which, under intelligent artistic supervision, has been radically changed in style till it now stands as the nearest approach to a comprehensive and consistent example of railroad-gardening. (Fig. 3334.) In 1882 and 1884 several new and exceptionally artistic stations had been built for the Boston & Albany Railroad Company after designs by the late eminent architect, H. H. Richardson, and the latter date marks the adoption of a consistent scheme of permanent planting, aiming at nature-like effects instead of the purely ornamental, i. e., formal gardening, previously used. This happy result was due to the influence of Charles S. Sargent, of

the Arnold Arboretum, a director of the road, and to Wm. Bliss, its president. Designs for the improvement of the grounds around these stations were made by F. L. Olmsted, the veteran landscape architect, and since 1884 the development of these plans, as well as all of the horticultural interests of the road, have been in charge of a competent landscape gardener, E. A. Richardson, who says: "The plan followed is to conform the treatment and development of the station grounds to the adjacent ground; a natural style being followed amid natural surroundings, and a more cultivated style in highly cultivated regions; to utilize all natural advantages of ground surface, rocks, water, and native growths; to make large use of trees, shrubs, vines, and plants indigenous to the locality where improvements are being made; to supply beds for shrubs with from eighteen to twenty-four inches of good loam; and to plant so closely in the beginning that as the plants grow they can be thinned to supply other grounds as needed." It goes without saying that these methods are not only the most practical but that they insure the most artistic results.

Among the first railway companies to improve their station grounds by planting were the Central of New Jersey (1886), the Baltimore & Ohio (date uncertain), the Boston & Albany (1880), the New York Central & Hudson River (1880), the Erie (1881), the Southern Pacific (1885), the Pennsylvania (1886), and the Austin & Northwestern of Texas (1887). Other roads appreciate the value of the work and encourage it; and railroad-gardening has now become a recognized form of landscape improvement, although yet at its merest beginnings.

The methods.

In the public mind, railroad-gardening usually means the formal use of flower-beds about stations. Such work is ornamental gardening, not landscape gardening. Most of the so-called landscape gardening at railroad

the Arnold Arboretum, a director of the road, and to Wm. Bliss, its president. Designs for the improvement of the grounds around these stations were made by F. L. Olmsted, the veteran landscape architect, and since 1884 the development of these plans, as well as all of the horticultural interests of the road, have been in charge of a competent landscape gardener, E. A. Richardson, who says: "The plan followed is to conform the treatment and development of the station grounds to the adjacent ground; a natural style being followed amid natural surroundings, and a more cultivated style in highly cultivated regions; to utilize all natural advantages of ground surface, rocks, water, and native growths; to make large use of trees, shrubs, vines, and plants indigenous to the locality where improvements are being made; to supply beds for shrubs with from eighteen to twenty-four inches of good loam; and to plant so closely in the beginning that as the plants grow they can be thinned to supply other grounds as needed." It goes without saying that these methods are not only the most practical but that they insure the most artistic results.

Among the first railway companies to improve their station grounds by planting were the Central of New Jersey (1886), the Baltimore & Ohio (date uncertain), the Boston & Albany (1880), the New York Central & Hudson River (1880), the Erie (1881), the Southern Pacific (1885), the Pennsylvania (1886), and the Austin & Northwestern of Texas (1887). Other roads appreciate the value of the work and encourage it; and railroad-gardening has now become a recognized form of landscape improvement, although yet at its merest beginnings.

The methods.

In the public mind, railroad-gardening usually means the formal use of flower-beds about stations. Such work is ornamental gardening, not landscape gardening. Most of the so-called landscape gardening at railroad
stations is really merely decorative. Carpet-beds are relatively costly as compared with hardy shrubbery. They last but a few months and then leave bareness, while the best hardy trees and shrubs skilfully arranged are interesting all the year round. (Figs. 3333, 3334.) This making of nature-like pictures with relatively simple, inexpensive, and permanent materials is a much higher art than that involved in creating and maintaining flower-beds and a few summer-blooming plants. However, both have their places. Many a tired traveler is cheered by the bright colors of a neatly kept railroad station. Such displays are suitable at the stations if anywhere along the line. They are always preferable to dirt, ugliness, and a general air of indifference. But railroad-gardening never becomes worthy our best attention until it rises to the plane and importance of planning. (Fig. 3337.)

Some of the underlying considerations in the landscape improvement were stated in an editorial in "Garden and Forest," 1889, by the late W. A. Stiles, from which we quote: 'Up to the present time, with few exceptions, railroad-gardening has failed to accomplish what the public has a right to expect of it from an artistic point of view. Instead of using their opportunities for increasing the taste and knowledge of the communities they serve, railroad managers have generally been satisfied to reproduce all that was glaringly bad in the prevailing horticultural fashion of the time. Perhaps this is inevitable, and it will continue so as long as they feel that they need not call for the advice of an expert of a higher class than the ordinary jobbing gardener. It is the old story—a man employs an architect to build his house, but thinks he needs no advice in laying out the park that surrounds it.'

'No railroad-gardening is ever to become a potent and permanent means of public education, it must be organized upon a more economical basis, and with more regard to the laws of good taste and good business. This subject has already occupied the attention of a few thoughtful men, and we are confident that some progress has at last been made.' Mr. Stiles commends the plans of the then new station grounds of the Boston & Albany Railway for "convenience, neatness, and simplicity. No beds, no brilliant flowers, no startling effects. They rely for attractiveness on convenient, well-kept roads, neat turf, a few good trees, and masses of well-selected and well-planted shrubs, among which herbaceous and bulbous plants are allowed to grow. The plan is simple, and when thoroughly carried out in the beginning it is easy to maintain."

On the treatment of the right-of-way between stations, Mr. Stiles says: "What is needed is a ground-covering that will be more permanent than turf and will not need its constant cutting and attention, which can be secured without the enormous first expenditure for accurate grading and the deep soil that makes a grass slope presentable," and adds: "Such low plants as wild roses, dwarf willows and sumacs, sweet fern, bayberry, etc., when once established will prevent surface soil from washing, will not grow tall enough to interfere with operating the road, and if destroyed by fire would soon grow again from the root and re-cover the ground."

The proof of these deductions is seen yearly on many roads, where thousands of miles of railroad rights-of-way which, in the spring and early summer, are like ribbons of flowered brocades linking the towns together but later in the season become blackened wastes from accidental or intentional fires. Year by year this mournful program is repeated.

Railway officials offer no practical objections to the use of small trees and of shrubs between stations which are cut every two years, yet the expenditure for accurate grading and the deep soil that makes a grass slope presentable, and for the outer boundaries of rights of way that are 100 or more feet wide, on straight stretches, or on long tangents, and not on short curves or near grade crossings. The tracks should never be menaced by the danger of trees falling on them in wind-storms, nor should the telephone lines and poles be interfered with, nor the view of the line obstructed. The danger to planting from fire can never be entirely eliminated until some non-spark-producing fuel is substituted for coal.

Planting for protection, as practised so far, includes: (1) covering banks with vegetation to prevent erosion, and (2) planting for protection from wind and snow, and from landslides. All this has been successfully done in various parts of the world. Snow-hedges are comparatively common at home and abroad. A notable example of confidence in the advantage of belts of trees for this purpose is seen in the groves planted some years ago by the Northern Pacific Railway Company. About 60,000 trees were set out in 1890, and the chief engineer of the road says: 'This experiment has been undertaken to determine the possibility of substituting groves for snow-fences. It is necessary to protect all railway cuts in these prairie regions in some manner as the strong winds across the treeless prairies cause the snow to drift badly. A strip 100 feet wide, is cultivated to keep down weeds and overcome danger from fire, and through the middle of it runs a grove 60 feet wide, the inner edge being 125 feet from the track, and parallel with the tracks through cuts. The trees are
planted in parallel rows spaced 6 feet apart at right angles with and 3 feet apart parallel with the track. The two outer rows on each side are golden Russian and laurel-leaved willows; the third row from the outer margins, box-elder and ash; and the five central rows, cottonwood. This arrangement is expected to produce a dense grove, increasing in height from both sides to the center, which will furnish an effective windbreak."

The feasibility of planting for protection against the encroachments of shifting sand on the seacoast, along rivers, and on so-called desert lands, has been demonstrated by the researches and experiments of the United States Department of Agriculture. The advantages of such plantings are sure to be eventually recognized and utilized by railway companies whose lines are exposed to this danger. The disagreeable features and their suppression constitute an important phase of landscape improvement about railway properties. There are two important classes of disfigurement: defacement by signs, and defacement by abused and neglected grounds adjoining railway rights-of-way. The more noticeable of these is the display of hideous sign-boards that disfigure railway rights of way and, indeed, seem to have the right of way on highways of every description. These amount to a public nuisance that should be legally controlled, but as they are placed on adjacent land or buildings instead of on railway property, their direct suppression by railway officials is out of the question. These eyecores, however, furnish an added and cogent reason for massing plantations of small trees, shrubs, and vines at certain points along rights-of-way where the topography of adjacent land invites such disfigurement. These gaudy signs not only blot out or mar most fine landscape views (being adroitly placed to mar most fine landscape views (being adroitly placed to direct end), but are allowed to distort otherwise unobjectionable farm buildings, while the approach to villages and towns is announced in screaming colors by the crowding together of these frightful adjuncts of civilization. While railway companies are not strictly responsible for these conditions, it is certain that they might sway public opinion and effect a much-needed reform by continuous, systematic work in the way of "planting out" the disfigurements, and by establishing attractive plantations wherever possible. This policy is likely to result in a reformation in the direction of the second source of unpleasant views from trains; viz., the unkempt, sordid, and often wretchedly squalid appearance of grounds adjoining rights-of-way through villages, towns, and small cities. If a park is maintained on the station grounds, nearby residents are likely to catch the good spirit and improve the looks of neighboring back yards. To this end, a rule against dumping on railway ground should be strictly enforced. The objectionable features that obtain in large cities must probably be endured until mitigated by the efforts of municipal art and social-service leagues.

Protection of natural scenery is a prime consideration. Notwithstanding the prominence given in railway advertising to fine natural scenery, little credit seems due to railway companies in general for protecting such scenery. That they might wield a mighty influence for their own and the public good is proved by a few examples. It is learned that the unofficial work of representatives of the New York Central and the Michigan Central roads did much to create the public sentiment that led to the formation of government parks on each side of Niagara Falls, and that the same roads should be credited with comprehensive and extended efforts to secure legislation looking to the prevention of further defacement of the palisades of the Hudson. Many of the movements for protecting natural views and worthy objects have close relation with the improvement of railway properties.

Planting for economic purposes is among the possibilities along rights of way, for the purpose of producing timber for furnishing cross-ties, poles, and posts. It is asserted that, under competent supervision, this branch can be made not only to pay the entire expenses of the department but to become a source of revenue. This branch of the work appeals to practical railway men as perhaps no other phase can be expected to, and to what extent the fortunes of various groves of locust, catalpa, and tamarack influence the point of view of chief engineers it would be difficult to learn, but that numbers of them are turning otherwise unoccupied railways lands to this use is certain. In Indiana, for example, some railway companies have planted a part of their holdings with trees for the double purpose of growing timber for economic uses and to secure the resulting reduction in taxes, which is a feature of the state forestry law.

It is often asked whether the planting or horticultural department of a railroad can be made partly self-supporting. There seems little doubt that by one means or another this department might be made at least partly self-sustaining, but the consensus of opinion among railroad men is distinctly against the advisability of making it so, except indirectly. It is conceivable that railroad nurseries and greenhouses might supply planting stock to individuals to their advantage; and possibly railway rights-of-way aggregating immense areas might be planted to crops, perhaps to fruit-trees as is done to some extent in European countries (a project which has also been recently suggested for the roads of India), but the opinion is general that legitimate railroad business is limited to the transportation of people and of freight. Even if this is true, it is still certain that
the department may legitimately be made to yield substantial financial returns. This feature of the department work is as yet in a preliminary stage that makes definite conclusions as to the extent of its benefits impossible, but enough has already been accomplished to demonstrate the usefulness of a well-conceived and correctly developed policy of protective and economic planting.

The attainable ideals are many. Railway companies can do no more effective advertising than by demonstrating the possibilities of the country traversed for home-making. Instead of desolate wastes of dust and cinders, their way-station grounds should present refreshing scenes of shade and verdure. Their grounds should be treated according to the rules of landscape art that hold good in all planting. When adjacent land drops away, giving good vistas, these should be preserved; objectionable features should, as far as possible, be "planted out;" sky-lines should be varied, banks clothed, and variety and views supplied, particularly in flat and uninteresting regions. Railroad-gardens should be in the hands of those who will adorn instead of deface them; who will look to the formation of features that will take care of themselves after planting is established—features that require considerable expenditure, a good knowledge of trees and of shrubs, and a large amount of taste in the designer at the outset, but after being established, like the island gardens of Paris, "the hand of man might be withheld for half a century without their suffering in the least." This conception of railroad improvement is therefore much larger and more inclusive than the mere adornment of station grounds; eventually it will modify the development of the entire property over which passengers ride.

FRANCES COPLEY SEAVEY.

RAISIN: Grape, page 1586.

RAJANIA (named in honor of John Ray, 1628-1705). Dioscoreaceae. Sts. from tubers, twining, and the habit of Dioscorea: lvs. alternate, undivided, hastate, cordate-oblong or linear; fls. dioecious, small, racemose, the male along the rachis often fascicled or in very short racemes, the female and sometimes both sexes simple and on short slender pedicels; perianth-segms. 6; stamens 6 in the male fls.; ovary ovoid or oblong; fr. reduced to one carpel through abortion, easy-like, indehiscent—About 10 species, W. Indies.

pleonethra, Griseb. Fig. 3338. Tubers very irregular cocks-combed: plant subshrubby, 5-6 ft. high: lvs. cordate-roundish or cordate-ovate, 2-5 in. diam., deltoid-pointed or cuspidate, 9-nerved; petiole about as long as or shorter than the lvs.; the aerial tubers produced at the base of the petiole: fls. dioecious, in racemes which are often fascicled, the male racemes compound, 3-8-fl.d., flexuose, the female simple: samara semiovate-oblong, bluntish, wing twice as long as the seed. Cuba and other islands of the W. Indies.

F. TRACY HUBBARD.

RAMIE: Boehmeria nivea, a fiber plant. See Cyclopedia of American Agriculture, Vol. II.

RAMÓNDA: Ramondia.

RAMONDIA (named for L. F. E. von Ramond de Carbonnières, French botanist and traveler, 1753-1827). Usually spelled Ramondia, but first written Ramonda. Gesneriaceae. Subcaulescent herbs with red-hamate-villous hairs, suitable for rockwork. Leaves basal, softly rugose; scapes leafless, 1- to few-fl.: fls. violet or pale purple; calyx free, 4-5-rarely 6-parted, the segms. ovate or oblong; corolla with scarcely any tube, rotate or broad-campanulate, 4-5-rarely 6-lett, the lobes broad; perfect stamens as many as the corolla-lobes, affixed at the base of the corolla; ovary superior, conical: caps. oblong, rather acute.—About 10 species, mountains of Eu.

Ramondia pyrenaica is one of the choicest and most interesting alpine plants. Few, if any, inhabitants of rock-gardens have been so often pictured. It is a small tufted, hardy perennial herb, like most alpine plants, and its scapes bear one or few flowers in spring. These are an inch or so across, and normally purple or violet, but there is a pure white variety which is in much favor. The ramondias vary in the number of their petals, or rather corolla-lobes. For example, P. Nathaliae often has four-lobed and five-lobed flowers on the same plant. The floral parts in the genus are in fours, fives, or sixes. These plants are rare and local in Europe and are interesting as being among the few alpine survivors of a family that is now essentially tropical. Although several ramondias are in the trade, only one is well known. This is R. pyrenaica, which is hardy in the eastern states. It is a beautiful dwarf alpine plant well adapted for the rock-garden. It is rather hard to establish but can be easily grown from seed. If seeds are sown in the spring, and the small plants grown along in pots for the first summer and kept in a cool shady position, they will make neat little plants by the end of autumn. They should be kept in a coldframe for the winter. These one-year-old plants grown in pots are much easier to establish than younger plants. They may be planted in small pockets in the rockery in a slightly shaded and elevated position, and given good deep peaty soil. When the plants become established they will blossom freely, and if allowed to ripen their seed they will sow themselves freely amongst the rocks. Old plants can also be increased by division. They ought to be covered in winter with hay or dry leaves so that they will not be heaved out of the ground by the alternate thawing and freezing. The plants require perfect drainage.

a. Color of fls. purple or white.

b. Corolla 6-parted, rotate.

RAMPION, Rampion, is well to mix it with sand. The seed should not be spiny, grown in the warmhouse for their bloom or pardy outdoors in the extreme southern United States. Sowing until June. For botanical description, see

Although rampion is usually biennial, it sometimes runs to seed the first year, especially if the seed is sown early. Campanula.

Soil, partial shade and water during the hot season. Each way for development. The plants like a light rich plant allowed to remain should have at least 4 inches careful waterings are necessary until the plants become ready for use in October or November and may be chiefiy used, generally in a raw state, but the leaves may also be used as a salad. The roots are white, a foot or so long, and spindle-shaped, like a long radish. They are ready for use in Asia and Afr. Closely allied to Mitrastigma and Gardenia.

AA. Shrubs or trees without spines.

RANÁNEVA (anagram of Ravenea). Ravenea of Bouché. Phalanges. One species of palm perhaps allied to Hyophorbe, from which it differs, among other things, in its dwarf habit, usually dioecious and in the fls. being arranged alternately on the short branches of the spadix. The genus Ranévea seems, however, to be of uncertain relationship. Bouché's generic name Ravenea dates from 1878. It appears in Bentham & Hooker (3:883) as Ravénia. In spelling it is so similar to Ravénia of Vellozo, 1825, that the two cannot be distinguished by pronunciation, and there-
fore a new name was given. Cult. as in Hyophorbe. Prop. by seeds in stovehouse, under glass.

Hildebrandtii, Bailey (Ravena Hildebrandtii, Bouché). Becoming 8-12 ft. high, but flowering under cult. when half that height, spineless, erect: lvs. elliptic-oblong or ovate-oblong in outline, long-stalked, pinnate, the pinna 20 or more pairs and narrow-lanceolate-acut. spadix long-stalked, the staminate recurved and with short densely fl. spreading branches, the pistillate erect, with filiform strict branches thickened at the base: fls. pale straw-color, the calyx 3-lobed, the petals 3 and joined at the base, the stamens 6: fr. black. Comoro Isls. (east of Afr.). I.F. 27:403. B.M. 6776. C.F. 4:293. An handsome dwarf palm, described by W. Wison to be "as elegant as Geonoma gracilis and as sturdy as a Kentia. It deserves to take a prominent place among garden palms, its small size, free habit, elegance, good constitution, being all in its favor, while in the freedom with the which it flowers and produces seed we have an exceptional character among dwarf palms." Perfect fls. are sometimes produced, although the plant is usually dioecious. Described as one of the most valuable recent palms.

L. H. B.

RANÚNCULUS (Latin name for a little frog; applied to the genus by Pliny in allusion to the wet places in which many of the species grow). Including Bubulcus, Victoria, Ranaeacea. Burmann, Crowfoot. Annual and perennial herbs, a number of which are grown in the garden and sometimes in the greenhouse for their showy flowers. Most of the species are hardy perennials, some of them aquatic.

Leaves entire or dissected; cauline lvs. alternate, often few: fls. white, yellow or red, terminal, solitary or panicled, rarely sessile at the branch axis; sepals 3-5, caduceus; petals all or most (up to 15) provided with a nectar-bearing pit or an enlarged conspicuous or rarely minute scale; stamens shorter than the sepals and petals, frequently numerous, sometimes only few in small-fl. species; carpels numerous, 1-ovuled: achenes compressed or subglobose, smooth or variably striate, costate, rugose, or spiny.—About 300 species dispersed all over the world, mostly in the temperate and colder regions, few in the tropics.

The structure and arrangement of the achenes is well shown in Fig. 3340.

Culture of the ranunculuses. (E. J. Canning.)

The culture of ranunculuses in gardens and by florists has been confined chiefly to the Persian and Tuban ranunculus, R. asiaticus, since the Asiatic species is far more attractive than the European. In England and in other European gardens, R. asiaticus has been in cul­tivator a very long time. Parkinson mentions it in his Paradux, published in 1629. He termed it "the double-red crownfoot of Asia." Since his time R. asiaticus and its varieties have been greatly improved, both in size of flowers and variety of colors. The flowers are very double, almost globular in outline, and often exceed 2 inches in diameter, while the colors now embrace almost every shade except blue, and some are striped and variegated. A well-grown mass of these charming flowers in full blossom is a sight not soon forgotten. They are not so well known in American gardens as in those of England or at least not in the eastern states, since the writer has rarely met with them or seldom seen any reference to them in the horticultural periodicals. They are not adapted to either spring or summer bedding. Their season of blossoming is about the last week in May and the first week in June, which is too late for spring bedding, while the season of blossoming is too short for summer bedding. Therefore a position should be given them in the herbaceous border where they will receive some shade during the warmer parts of the day, or a level place in a rock-garden with a northern exposure. The roots are tuberous, being like miniature dahlias roots. They are not hardy, at least not in any of the northern states. The tubers should be carefully lifted after the foliage has all "ripened off" (which occurs usually toward the end of August), and stored until the following spring in some cool shed where they will not freeze. They should be planted as soon as the frost is well out of the ground in spring, about 2 inches in depth and about 6 inches apart, making the soil very sandy on top so that the leaves will push through readily without heaving the soil. Like their congeners the European ranunculi, they like plenty of moisture at the roots during the growing season, and if they can be shaded from the sun when in flower their blossoming period will be materially lengthened. They may also be grown for flowering in the greenhouse. The gardener may well have a few pans each year, planting the roots in pans of light soil toward the end of January and placing them in the coolest greenhouse, where they will bloom toward the middle of April. He will probably prefer the Turban varieties, since they are stronger-growing and rather larger than the Persian. The species may be propagated by seeds, but this process is not worth while because the bulbs may be procured so cheaply. Of the native and European species of ranunculus, those of the Batrachium section, such as R. aquatilis and its varieties, are interesting aquatic plants, while R. repens var. flor-e-pleno, and R. amplexicaulis are useful as subjects for the bog-garden.—For herbaceous borders or moist corners in the rock-garden R. acuminatus var. flor-e-pleno, R. cortusafoius, R. amnonoides, R. parras siolius, and R. Ficaria are the only species worth growing. These are readily propagated from seeds or by division of the plants in spring. See the supplement list, p. 2009, for some of these.

3340. Head of buttercup achenes.

RANÚNCULUS 2905

INDEX.

A. Sepals 3 .......................... Ficaria 1.
AA. Sepals 6.

B. Achenes transversely wrinkled, emarginate; petals with a nectar-bearing pit at base.

C. Lvs. sessile or sub-sessile; st. submersed. 2. fluitans.

CC. Lvs. suberform or rounded-cordate; st. creeping in the mud. 3. hederaecus.

Bn. Achenes smooth or nearly so; petals usually with a brown-boring pit and scale, the latter sometimes imperfect or very minute in c.

H. Roots fascicled, more or less tuberous-thickened.

D. Sepals reflexed.

H. Head of achenes cylindrical-spatulate; achenes slightly recurved; beak straight, fls. numerous. 4. psilostachys.

R. Head of achenes short; achenes subglobose; beak recurved. 3. flor-e-pleno.

KEY TO THE SPECIES.

CC. Lvs. suberform or rounded-cordate; st. creeping in the mud. 3. hederaecus

Bn. Achenes smooth or nearly so; petals usually with a brown-boring pit and scale, the latter sometimes imperfect or very minute in c.

H. Roots fascicled, more or less tuberous-thickened.

D. Sepals reflexed.

H. Head of achenes cylindrical-spatulate; achenes slightly recurved; beak straight, fls. numerous. 4. psilostachys.

R. Head of achenes short; achenes subglobose; beak recurved. 3. flor-e-pleno.
1. Ficaria, Linn. (Ficaria Ficaria, Kurst.). Perennial: roots fleshy, thickened: sts. short, decumbent, branched at base, often with bulbils in the I. -

2. Shutia, Lam. Perennial, aquatic: sts. submersed, usually very long: lvs. submersed, petioled, the lower lvs. of often long-petioled, about twice 3-parted, divisions very long-linear, 2-3-cleft, segms. nearly parallel; peduncle tapering, bearing a spreading raceme: fls. large, white; petals often more than 5, broadly ovate, many-veined, contiguously persistent; achenes obovate, inflated, much rounded at the end laterally, apiculate; receptacle conical, naked. June. Rivers, Eu.

3. Hederaceus, Linn. (Batrachium hederaceum, S. F. Gray). Perennial, semi-aquatic: sts. creeping, rooting at the nodes: lvs. submersiform or rounded-cordate, 3-5 heart-shaped round lobes widening to their base and usually entire or notched at the apex, usually opposite and with a black half-moon; stipules various: peduncles usually shorter than the lvs.: fls. 5-5-5 cm. across, white; petals very narrow, 3-4, 3-5-3-nerved, sometimes hardly exceeding the calyx; stamens 5-12; style prolonging the nearly straight inner edge of the ovary: achenes few, glabrous, obovate, laterally compressed at the base, inflated or rounded at the top, microus; receptacle obovate, naked. June. Shallow ponds or mud. W. Eu. and naturalized in N. Amer., Newfoundland to S. Va. B.B. (ed. 2) 2:116.

5. Monspeliaceus, Linn. Perennial, 1½ ft. high, white-woolly or sericeous: sts. erect, few-fld.: lvs. woolly, ovate-rotund, cordate, the radical 3-lobed, lobes crenate, trifid or 3-toothed; the upper 3-parted, divisions cuneate, incised-lobed: fls. numerous, large, shining citron-yellow, 2 in. across; petals reflexed: achenes in a cylindrical spike, obovate, slightly verrucose, beak straight, as long as the body. Servia, Macedonia, and Greece. G.C. III. 40:163.

6. Orthorhynchus, Hook. Perennial, 10-18 in. high, hirsute to nearly glabrous: sts. erect from a flesciled root of thick fibers: lvs. mostly obovate, pinnately compound: lfts. or segments, 5-7, lower commonly short-petioled, usually 3-parted, fls. yellow; petals reflexed, reflexed, petals obovate: achenes numerous, pubescent, compressed, beak recurved and equaling the carpel; receptacle glabrous; head of achene ovate. April, May. Medit. region.

7. Asiaticus, Linn. (R. orientalis, Hort., not Linn.). Fig. 331. Perennial, 6-12 in. high: sts. erect, simple or branched, somewhat appressed hirsute: lowest radical lvs. cuneate-ovate, dentate at the obtuse

are the most highly cult. members of the genus. (2)

or var. africanus, Hort.

others. They are very variable in form and color, and increasing in number. They are of two main types:

wlt.h many CflSp petals, not flat and spreading but erect

bulbs. The cult. forms of R. asiaticus are constantly increasing in number. They are of two main types: (1) The florists' section, called Persian Ranunculus, or true R. asiaticus. These require more care than the others. They are very variable in form and color, and are the most highly cult. members of the genus. (2) The gardeners' section, called Turban Ranunculi, or var. africàns, Hort. (R. africàns, Hort.). Compared with the first section, these have larger, broader, 3-parted Ivs., not so much cut; fls. larger and broader, with many crisp petals, not flat and spreading but erect and curved inward, forming a spherical fl., as in the double peonies. Var. superbissimus, Hort., is a taller-growing very large semi-double-fld. form. July-Sept. R.B. 16:133.

8. cortusfollius, Wild. Perennial, 1–3 ft. high, velvety hairy: roots thick, fleshy, fascicled: fls. branched, corymbose above: lower lvs. long-petioled, subcordately reniform, incised lobes cut and dentate; cauline lvs. nearly sessile, 3–5-lobed, lobes narrow; floral lvs. sessile, lanceolate: fls. several to many in a terminal and axillary rather paniculate infl., yellow; sepals 5, ovate to lanceolate, spreading, green with pale margins; petals 5, large, broadly obovate, glossy; achenes compressed, hairy on sides, tapering into recurved beaks; nearly their own length; head of acorns short-ovoid. May. Isl. of Teneriffe, Canary Isls. B.M. 4025. Gn. 45:28. Gn.W. 8:517. J.F. 3:239.—Not very hardy and needs protection in winter and early spring. It is well suited for pot culture. It is increased by division of the roots in autumn.

glacialis, Linn. Perennial, 3–6 in. high: sts. reddish brown, 1–3-fld.: lower lvs. petioled, rather fleshy, palmately 3-parted or 3-cleft, lobes trifid, or again lobed, the lobes rather obtuse; the other lvs. similar but sessile and involucrete: sepals very hirsute; petals obovate to cuneate, obtuse, white or reddish; achenes very numerous, obliquely obovate, slightly compressed, smooth, glabrous, margin above membranaceous-winged; beak straight; receptacle glabrous. May–Aug. Alpine Eu., Arctic regions, Greenland. Gn. 45, p. 28; 48, p. 501. G.C. III, 53:117.—With age the fls. become coppery red.

10. Máthewssii, Cheesm. Perennial, 15–20 in. high, glabrous or a few weak hairs on the petioles and peduncles; radical lvs. reniform or orbicular ternate-cut, the main divisions petioled, coarsely toothed or lobed; petals stout, 3–9 in. long; cauline lvs. sessile, deeply toothed or lobed: fls. 1–4, large, pure white, sweet-scented, 2½–3 in. across; sepals 5, slightly villous, reflexed; petals numerous, 12–20, oblong-cuneate, rounded at apex; gland solitary, large and basal: achenes forming an oblong-globose head ½ in. or more diam., turgid, pilose, beak long, subulate. New Zeal. Gn. 78, p. 2.

11. aconitifollus, Linn. Perennial, 6 in. to 3 ft. high, pubescent; sts. branched; lvs. palmately 3–5-parted; segms. incise-dentate; upper lvs. sessile with linear-lanceolate lobes: fls. white, several to a st.; sepals flat, glabrous; petals oblong, cuneate or orbicular: achenes 6–15, obovate, laterally sub compressed, nerved, glabrous, beak straight, recurved at the top; receptacle villous. May, June. Mountains of Cent. Eu. Gn. 70, p. 135. G.M. 45:196. Var. flóre-plenus, Hort. (R. aconitifollius var. plénum, Hort.), called White Bachelor's Button and Fair Maids of France, has large double white fls. Gn. 45, p. 29; 48, p. 506; 65, p. 24. Gn. 4:415; 10:411; 36:226. Var. flóre-plenus, Hort., has double golden yellow fls.—This species and its varieties are well adapted for border planting.

12. alpéstris, Linn. Perennial, 3–6 in. high: st. usually 1-fld.; lvs. petioled, orbicular-cordate, 3-lobed, lobes rather obtuse, lobate-crenate at the top, sometimes the lvs. are trifid or hardly so; this is true of the sessile cauline ones: sepals glabrous, spreading; petals 5, white, rounded-obcordate, emarginate; achenes obovate-globose, glossy, glabrous; beak straight, hooked at the summit. Mountains of Eu.

15. pyrenaeus, Linn., also incorrectly offered in the trade as pyrenecus, Hort. Perennial, about 1 ft. high: lvs. linear or lanceolate, entire, all basal, bluish green: scape tomentose at the top, 1-4-in.; fls. white, rather large; sepals glabrous; petals obovate; achenes obliquely obovate-globose, side glossy, beak short, hooked; receptacle pubescent. June-Aug. S. Eu.

16. parnassifolius, Linn. Perennial, 3-8 in. high: stamens long-petioled, rather cordate or ovate-rounded, upper surface shiny green, under surface lanate on the nerves; petioles lanate; cauline lvs. sessile, ovate-lanceolate; fls. snowy white or rarely purplish; sepals pubescent, roseate, very obtuse; petals obovate; achenes in a spherical receptacle pubescent. June. Alps and Pyrenees. B.M. 386.

17. insignis, Hook. f. Perennial, 1-3 ft. high, usually villous: stamens and erect, pinnately divided: radical lvs. petioled, broad ovate, 3-5-parted, terminal division petiolated, lateral sessile or nearly so, all variously lobed or cleft: peduncles sulcate: fls. bright yellow, about 1 in. across; sepals spreading, hairy below; petals obovate, much longer than the sepals: achenes in a globose head, ovate-oblong, compress, beak very short, bowed; receptacle slightly villous. May-July. Eu., Siberia, N. Amer., Newfoundland to Va., Ont. and Brit. Col., Bermuda and Jamaica. B.B. (ed. 2) 2:1113. Var. flore-pleno, DC., Fig. 3345, is a double form not uncommon in gardens.

18. gramineus, Linn. (S. graminifolius, Salisb.). Perennial, 6-12 in. high: stamens, fibroflose at the neck, otherwise glabrous, 1-7-fl.: lvs. lanceolate or linear, entire: fls. yellow, brilliant; sepals glabrous; petals cuneate, scales of the petals minute: achenes in a head, obliquely obovate-globose, faces reticulate, nerved, beak short; receptacle glabrous. April-June. Eu. and Morocco. B.M. 164.

19. lingua, Linn. Fig. 3342. Perennial, 2-3 ft. or more high: roots densely fibrous: stamens erect, glabrous; lvs. 6-10 in. long, lanceolate, acuminate, sessile, semi-amplexicaul, entire or toothed: fls. showy, yellow, about 1½ in. across, somewhat panicled; sepals ovate, villous; petals shining: achenes 60-80, in a globose head, compressed, with a straight border which is larger at the top, beak large, short, sword-shaped; receptacle glabrous. June–Sept. Marshes, ditches and pond borders. Eu. and Temp. Asia south to the Himalayas. G. 48:500.—Useful for water-gardens and aquatic planting. Var. grandiflorus, Hort., apparently differs only in the size of fl.

20. répens, Linn. Perennial, stoloniferous: root-stock short and thick; roots fibrous: stamens decumbent, 8 in. to 2 ft. long, more or less appressed-hairy: lvs. 3-divided, the terminal segm. or all three petiolulated, all ovate, cuneate or truncate, acute, incised-lobed: peduncles sulcate: fls. yellow, about 1 in. across; sepals spreading, hairy below; petals obovate, much longer than the sepals: achenes in a globose head, plano-convex, ovate-obicular, beak slightly curved less than half the length of the body; receptacle slightly villous. May–July. Eu., Siberia, N. Amer., Newfoundland to Va., Ont. and Brit. Col., Bermuda and Jamaica. B.B. (ed. 2) 2:112.—One of the common field buttercups. Var. flore-pleno, Hort., Fig. 3343, a double form not uncommon in gardens.

21. bulbosus, Linn. (R. speciosus, Hort.). Perennial, about 1 ft. high: root a true bulb: stamens erect, hirsute: lvs. petioled, broad ovate, 3-5-parted, terminal division petiolulated, lateral sessile or nearly so, all variously lobed or cleft: peduncles sulcate: fls. yellow, about 1 in. across, terminating the branches; sepals often reflexed; petals 5-7, much larger than the sepals, ovate, shining above: achenes in a globose head, ovate, compressed, beak very short, bowed; receptacle slightly villous. Eu., Persia, N. Afr., naturalized in N. Amer., New England to N. C., Tenn., and La. B.B. (ed. 2) 2:112.—One of the common field buttercups. Var. floré-pleno, Hort. (R. speciosus flore-pleno, Hort.), is a double form not uncommon in gardens.

22. En theological. Perennial, 6-15 in. high: root-stock rather stout: stamens slender, glabrous: lvs. all radical, numerous, 1-3 in. diam., 3-5-foliate or biterinate; lfts. long-petiolulated, toothed, 3-5-lobed or 3-5 narrow cuneate incised, toothed or lobed segms., occasionally pinnately divided: scapes 1-5, longer than the lva., 1-2 in. across; sepals 5, broadly ovate; petals usually 5, rarely more, broadly obovate; achenes in a small rounded head, numerous, turgescent, glabrous, beak stout, straight or curved. New Zeal.

23. monthanus, Wild. Perennial, about 6 in. high: rootstock short, creeping; stamens pubescent, with soft appressed or spreading hairs, usually toward the top, unusually 1-fl.: radical lvs. few, petioled, glabrous, orbicular or pentagonal, palmately 3-parted, segms. obovate, trifid, obtuse, sinus sharp; cauline lvs. 3-5-parted, sessile, somewhat clasping, segms. linear-oblong, divergent, obtuse: fls. bright yellow, terminal, about 1 in. or more across; segms. petiolulated, heart-shaped, young yellowish green; petals 5, large, broadly ovate with a very short scale at base; achenes 20-30, turbid, glabrous, beak recurved, much shorter than the body; receptacle pilose. May–July. Eu., and Temp. Asia south to the Himalayas. G. 48:500.—Useful for water-gardens and aquatic planting. Var. dentatus, Baumg. (R. carpaticus, Herbich). Lvs. much more
toothed than in the type: plant much taller: fls. larger.
B.M. 7266. Gn. 52:202:

24. polyanthemos, Linn. Perennial: sts. erect, many-fld, spreading, pilose: radical lvs. broadly ovate-obovate, palmately 3–5-parted, segms. linear, dentate; petals spreading, pilose: peduncles subulate; fls. yellow: sepals reflexed: achenes plano-compressed, suborbicular, margined, one-fourth to one-third as long as the body, coiled to hooked, rising abruptly.

Turkey. Var. palestinus, Boiss. (R. palestinus, Boiss.). Lvs. 3–5-parted, divisions divergent from the base, cuneate-oblong, 2–3-lobed. Palestine and Syria; a form of this known horticulturally as R. palestinus alrococetus, with large intense scarlet fls. borne on long peduncles. Palestine.

29. anemonifolius, DC. Perennial, scarfully 1 ft. high: sts. erect, 1–2-fld.: somewhat fibrous at the neck otherwise glabrous below, appressed-pubescent above: radical lvs. pubescent, broadly orbiculate, sometimes 3 in. diam., 3-parted, divisions cuneate, deeply trifid, segms. acute, dentate: caulis lvs. few, divided into linear segms.: fls. large, yellow: peduncles finally striate: young achenes obovate, compressed, beak hooked, one-ninth the length of the body. Asia Minor.

—R. aquatilis, Linn., sometimes called lodewort, ram's foot, etc., is an interesting aquatic plant common in temperate regions, the floating lvs. often broad and 3-lobed, while the submerged lvs. are cut up into numerous thread-like segms.-R. bulbifera, B.M. 1482, has fls. of a soft shade of butter-yellow, fading white, and likes partial shade and a moist situation, according to trade-lists.-R. bulbifera, Linn., is a yellow-fld. species offered in single and double forms by Dutch bulb-dealers. Medit. region.—R. campylophyllus, Hook., offered in Colo. in 1904, is considered by Gray as R. affinis var. validus. It is an American species pictured in B.M. 2909 with yellow fls. 1 3 in. across.—R. speciosus, Muhl. Height 1 ft. June. N. Amer. Hort. 2:11—R. Elegans, Hook., the New Zealand water-lily, grows 2–4 ft. high, has petiole lvs. and waxy white fls. 4 in. across, borne in many-fl. panicles. In Eu. it is considered a cool greenhouse plant. It is a gorgeous species and sought to succeed somewhere in N. Amer. G.C. II 15:724; 23:371; Ill. 51: suppl. June 29. Gn. 67, p. 23; 74, p. 375.—R. pullatus, Waldst. & Kit., a native of the Hungarian Alps, has yellow fls. nearly an inch across.—R. septentrionalis, Pers., has been listed; a native plant allied to R. repens.—R. spectabilis is pli

Rape

RAPE (Brassica Napus). Fig. 3345. In recent years rape has become an important forage plant. The name rape includes several varieties which are grown for two purposes: (1) for seed from which oil is expressed.
long hard tap-root like that of There are Chinese types of radish that have hard roots. When grown strictly as a
soiling plant, the tops are cut and hauled to the feed-lot or stable. Dwarf Essex rape much resembles
a rutabaga turnip at first. It is like a rutabaga with an exag-
erated leafy top and without a swollen fleshy root. Rape is a
cool-weather plant and may be grown in almost any part of the
United States by sov-
ing it at the proper
time. As a cover-crop
in the orchard in the East it may be sown as late as
September 15 with good results. It is an excellent
pioneer plant in the work of renewing humus in worn-
out lands. In the Middle West, where shade is needed,
rape is used as a nurse plant for clover when the latter is
sown in orchards in midsummer. Turnips may be
used for the same purpose.

RAPHANUS (classical name, from the Greek). Some-
times spelled Raphanus. Cruciferae. Annual or bien-
nial branching herbs, one of which, R. sativus, is the
radish (which see).

Leaves various and variable, the radical and some-
times the cauline lyrate-pinnatifid; fls. small but rather
showy, slender-pedicelled, in open terminal racemes,
rose-lilac or white, or in some species yellow; sepals
eclipt; stamens 6, free: pod a long-cylindric:
1. long, few-seeded, with a long beak. It is from this
species that Carrière produced radishes by means of
plant-breeding (see Radish). To the second section
belongs R. sativus, Linn., the RADISH, considered to
be native to Eu. and Asia, but imperfectly known in
an unaltered wild state. It is usually annual, although
commonly spoken of as biennial because the roots can
be kept over winter and planted the
following spring. The winter radishes are truly biennial in northern climates. Radish has pink-lilac or nearly white fls.,
and short thick spaggy taper-pointed pods. Some-
times it runs wild in waste places, and then bears a
long hard tap-root like that of R. Raphanistrum. The
radish is extensively cultivated for its thick root, which
has been developed into many shapes and colors. There
are Chinese types of radish that have hard roots
little more than 1 in. diam., and sometimes becoming
nearly 1 ft. long. Some forms are scarcely distinguish-
able from short turnips. The Madras radish (India) is
grown for its soft tender pods, which are eaten raw
or in pickles. The rat-tailed or serpent radish, var.
caudatus (R. caudatus, Linn.), has enormously long
pods (see Fig. 3346), which are eaten either pickled,
or raw as are radish roots. Frequently the pods are 1 ft.
long. The root is slender and fleshy. This is a cultural
variety, coming true from seed.

3345. Dwarf Essex rape. (Xv2)

RAPHA (Greek, needle, referring to the fact that the fr. ends in a noticeable point). Palmae. Mone-
carps with scarious unarmored or with the sheaths only armed:
sts. erect, simple or dichotomously branched, densely
annulate: lvs. in a terminal crown, equally pinnatisect;
flts. linear-lanceolate, acuminate, rachis not produced
at the apex: sporides monoeous, large, pendulous,
cylindrical, much-branched; the branches and branch-
lets thick, compressed, the latter pectinately arranged,
densely covered with cup-shaped bracts; common
spathe none; fls. solitary in each bract, the male at the
base of the ultimate branches of the spadix, the female
at the apex; calyx tubular, entire or minutely toothed;
corolla curved, the petals 3, linear-lanceolate, valvate;
16-16: fr. large, oblong or ellipsoid, rostrate, 1-seeded.—About 15 species, Trop. Afr. and the
Masca
gene. Ia. 1 in. long, short-peduncled, with 12
Mart. Raph., var. Roppia Palm. Trunk 6-26 ft. high:
lvs. up to 63 ft. long, petiole up to 13 ft. long, nearly 1 in.

3346. Rat-tailed radish—Raphanus sativus var. caudatus. Grown for its
enormous pods. (Xv4)
RAPHIONACME (Greek, raphis, needle and, and lepis, scale; referring to the subulate bracts). Sometimes spelled Rhaphionacme. Rosaceae, subfamily Pomoceae. Ornamental shrubs grown for their handsome foliage and attractive white or pinkish flowers. Leaves tomentose when young, alternate, short-petioled, serrate, rarely entire; fls. in terminal racemes or panicles; sepals triangular; petals 5, oblong or obovate; stamens 15-20; ovary completely inferior; styles 2-3, connate toward the base; fr. subglobose, purplish black or bluish black, with 1 large subglobose or nearly compressed seeds.—Two or perhaps 4 species in S. Japan and China.

These are handsome evergreen shrubs with alternate or obscurely whorled leaves, white or slightly pinkish flowers and small pen-sized black fruits. None of the species is hardy North, but R. umbellata will stand about 10° of frost or even more with some protection; they are well suited for cultivation in the southern states and California. They will thrive in any good well-drained soil and if cultivated on a sandy loam and leaf-mold or peat will suit them. Propagation is by seeds or by cuttings of ripened wood under glass late in summer; also by layers, and sometimes grafted on hawthorn.

umbellata, Schneid. (R. japonica, Sieb. & Zucc.). Shrub, to 12 ft., with stout upright branches; fls. short-petioled, elliptic to broadly oval or obovate, obtuse or acutish, narrowed at the base, crenate-serrate, glabrous or slightly pubescent when young, thick, 1½-3 in. long, fls. white, ½ in. across, fragrant, in dense, tomentose panicles or racemes; petals obovate, obtuse; fr. to ½ in. across. May, June. S. Japan and adjacent islands. S.Z. 1:83. Gn. 22, p. 43; 32, p. 20; 34, p. 158. G. 7-106; 10-114. Var. integerrima, Rehd. (R. iva, Schneid. (R. iva, Sieb. & Zucc.). B.R. 652. R.H. 1874:270. Gn. 9:596.—A very variable species; several forms have been described as distinct species, as R. strigosus, Nichols., is the most ornamental; lvs. opposite and membranaceous: inflorescences many-fid.; stamens white or purplish, shorter than sepals; petals 5, obovate, obtuse, and pubescent; fr. subglobose, purplish black or bluish black, with 1 large subglobose or nearly compressed seeds.—Two or perhaps 4 species in S. Japan and China.

RAPHIONACME (Greek, needle and point, referring to the 5 pointed or awned scales in the throat of the corona). Aseleptadaceae. Herbs, with tuberous root-stock often furnished with an elongated woody neck; juice milky: lvs. opposite: fls. small or moderate-sized, terminal in few- or many-fl. cymes, or in the forks of the st., or subaxillary from one axil, rarely from both; calyx 5-parted; corolla-tube distinct, campanulate. Lobes 5, erect, spreading or reflexed; crown of 5 free, entire, 2-3-divided or 3-parted lobes alternating with the corolla-lobes: follicles often solitary by abortion.—About 20 species, Trop. and S. Afr. R. pulcherrimum, N.E. Br. & Stapf. Perennial herb with a turnip-shaped root 2-3 in. diam., covered with dark brown flaky bark; sts. annual, 1-4 in. long, erect or decumbent; fls. in 2-4 pairs, opposite or forming a rosette close to the ground, orbicular, elliptic or obovate-ovate, obtuse and apiculate, or subacute at the apex, rounded or subcordate at base, green above, purple beneath: fls. in small terminal and axillary cymes or clusters, bright purple; petals lanceolate, acute, purplish with green tips; corolla about ½ in. diam., deeply 5-lobed. Trop. Afr. B.M. 8:323.

RAPHIOSIS: Raphis.

RAPHTER: Raphis.

RAPHIOLEPIS (Greek, raphis, needle, and crown, referring to the linear scales of the crown). Glabrous twining shrubs: lvs. opposite and membranaceous; inflorescences long-peduncled, axillary, umbelliform cymes; fls. large, white, and long-peduncled; calyx 5-glandular inside; corolla campanulate, thick, lobes 5, erect, spreading or reflexed in bud and overlapping to the right; crown with 5 membranaceous scales which are produced into long slender linear ligules; follicles thick, acute, smooth.—About 2 species. Asia. R. pulechrum, Wall. Branches slender, smooth, and herbaceous: fls. 3-7 in. long; cymes 4-6-fl.; the pedicels very slender: fls. pure white, 1-½ in. long; sepals broad; corolla thick. Himalaya region and Burma. J.F. 4:335.

RASPBERRY (from rasp, a tool resembling a file, and berry), a name applied to certain species of the genus Rubus, particularly to Rubus idaeus, R. strigosus, and R. occidentalis, from which have been derived common cultivated forms grown for their excellent edible fruits.

Raspberry plants have perennial roots and erect or nearly cleft biennial canes bearing thimble-shaped red, yellow, black, or purple-colored fruit consisting of many cohering drupelets which separate from a partially dried receptacle. The raspberry is distinguished from the blackberries and dewberries, which belong to the same genus, in bearing fruit that separates from its juicy receptacle, while that of the blackberries and dewberries does not separate from their juicy receptacles.

Origin of horticultural varieties.

The first raspberries introduced into cultivation in America were varieties of European origin belonging to the species Rubus idaeus. These varieties, adapted to a mild humid climate, did not prove sufficiently hardy to merit their continued cultivation after hardy native varieties of good quality began to be propagated. At present but two varieties, the Antwerp and Superlative, representing the European species Rubus idaeus, have become established. These two varieties are raised only in the Pacific Coast region and are there being gradually superseded by American varieties.

By far the greater part of the varieties under cultivation at present belong to the American species Rubus strigosus and R. occidentalis. The American red raspberry, R. strigosus, is very similar to the European species, R. idaeus. Both species have erect canes, but the American species has proved much hardier and adapted to a wider range of environmental conditions. Two of the first varieties of this species to come under cultivation were the Marlboro and Cuthbert, and these are still two of the most widely grown varieties. The black raspberry, R. occidentalis, has produced canes which are longer than those of either of the red-fruited
species, and bears black fruit. The acreage of this class is, at present, much less than that of the red raspberry. The Gregg, one of the first varieties of this species introduced into cultivation, is also one of the leading varieties grown at present.

Yellow-fruited varieties have come from both the American species, the erect-growing sorts from R. strigosus, and those with recurved canes rooting at the tips from R. occidentalis. Purple-caned varieties, of which the Columbian is the most widely grown, are hybrids between R. strigosus and R. occidentalis.

Up to the present time, the greater part of the varieties under cultivation have appeared as chance seedlings. Recently, however, many promising new varieties have been originated as a result of systematic effort to produce better sorts. Thus, as the result of definite breeding work, the New York State Experiment Station has originated the June red raspberry, and the South Dakota Experiment Station the Ohta and Sunbeam red raspberries. These as well as other experimental stations, have many promising varieties under test. L. E. Wardell, a practical grower of Marlboro, New York, has originated the Empire red raspberry, another promising variety. Many others are also trying to originate better varieties, some of whom are using in their work foreign species recently introduced into this country.

Geographical distribution.

The limit of the successful culture of this fruit corresponds closely with the distribution of its wild forms. The southern limit is southern Virginia, along the mountains to northern Tennessee, westward through the Ozark Mountains and southern Oklahoma. It is chiefly grown in northern regions. The great commercial centers of the industry are, at present, in New York State and Michigan. Smaller centers of its culture, aside from the proximity of the large cities, are found near Hagerstown in western Maryland; in central New Jersey; near Kansas City, Kansas; about Loveland, Colorado, and in the Puyallup Valley of Washington. The culture of the raspberry, however, is not confined to these centers, but is widely distributed throughout the northern districts.

Propagation.

The red varieties are propagated by the use of suckers which spring from the underground parts. Nurserymen secure their stock by digging in the spring suckers sent up during the previous summer. Some growers who wish to increase their own plantation wait until young suckers begin to come up in the spring and transplant these. The black raspberries, as well as the purple varieties now raised, are propagated by encouraging the tips of the young canes to root. As the young canes bend over and the tips approach the ground, soil is thrown over the tips. Plants suitable for setting the following spring will be formed during the remainder of the growing period by these rooted tips. By pinching back the tips in early summer when the canes are about 2 feet high, they will branch and several plants may be secured from each cane.

Culture.

The raspberry thrives best in a deep fertile loam containing plenty of humus. Most varieties grow better on the heavier than on the lighter types of soil, though this is not universally true. The soil must be well drained and a location with good air-drainage will be preferred to lowlands, as certain varieties are peculiarly susceptible to poor air-drainage. Fertilizers are not generally used on raspberry fields, as among growers using them their composition varies widely. The fertilizers should depend on the needs of the particular soil, and such needs can be determined only by actual tests of the soil with varying amounts and kinds of plant-foods.

Two methods of culture are commonly used, the hill system and the solid-row system. Under the first system the plants are usually set 5 feet apart each way, while under the second system they are set 3 or 4 feet apart in the row, the rows being from 6 to 8 feet apart. Under the hill system less hand-labor is required for the returns in fruit than under the solid-row system. The plants should be set as early in the spring as possible, as the moisture conditions are usually better in early spring. In setting the plants, the principal requirement is that the soil shall be thoroughly firmed about the roots. Vegetable intercrops may be grown between the rows during the first season and should help pay for the cost of cultivation for the first year. Cabbage, cauliflower, beans, peas, and lettuce are often used for this purpose. Cultivation should be thorough and frequent, not only in early spring. In setting the plants, the principal requirement is that the soil shall be thoroughly firmed about the roots. Vegetable intercrops may be grown between the rows during the first season and should help pay for the cost of cultivation for the first year. Cabbage, cauliflower, beans, peas, and lettuce are often used for this purpose. Cultivation should be thorough and frequent, not only in early spring.
and ripening do the plants need the large supply of moisture that frequent cultivation conserves.

Training and pruning.

In training the red raspberries when the plants are set by the hill system, a stake is usually placed by each plant before the second year's growth begins and the year-old canes tied to it (Fig. 3347). This allows the new canes to grow up outside the old ones and makes picking easier. When the solid-row system is used, several methods of training are practised. (1) When the plants are vigorous but do not grow very tall, the suckers are allowed to grow up between the plants in the row, while those between the rows are destroyed by frequent cultivation (Fig. 3348). No pruning is required. (2) When the canes grow very long, they are not pruned until spring and then are sometimes cut back to a height of about 3 feet in order that the cane may support its crop of fruit. Weaker canes are removed at this time. (3) Instead of cutting the canes back as described above, they are often trained to trellises in the following ways: (a) A trellis is made by stretching a wire on posts set about 30 feet apart in the row. The old canes are tied to this wire to keep them upright when ripening their fruit (Fig. 3349). Two wires, one above the other, are sometimes used in making this kind of trellis, and the canes either tied in an erect position to both wires (Fig. 3350), or they are arched over the upper wire and tied to the lower (Fig. 3351). When tied in an erect position, those portions of the canes projecting more than 6 inches above the wire are pruned off. (b) The trellis is often made by stretching two wires along the line of posts from the ends of crosspieces about 15 inches in length (Fig. 3352). The old and new canes are kept between the wires and out of the way when the cultivating is done. Sometimes the old canes are tied to the wire, half of them being tied to the wire on one side and half to the wire on the other side (Fig. 3353). The young canes then come up between the old canes and will be out of the way of pickers and cultivators. Many variations of the above systems are in use.

RASPBERRY

Training and pruning.

In training the red raspberries when the plants are set by the hill system, a stake is usually placed by each plant before the second year's growth begins and the year-old canes tied to it (Fig. 3347). This allows the new canes to grow up outside the old ones and makes picking easier. When the solid-row system is used, several methods of training are practised. (1) When the plants are vigorous but do not grow very tall, the suckers are allowed to grow up between the plants in the row, while those between the rows are destroyed by frequent cultivation (Fig. 3348). No pruning is required. (2) When the canes grow very long, they are not pruned until spring and then are sometimes cut back to a height of about 3 feet in order that the cane may support its crop of fruit. Weaker canes are removed at this time. (3) Instead of cutting the canes back as described above, they are often trained to trellises in the following ways: (a) A trellis is made by stretching a wire on posts set about 30 feet apart in the row. The old canes are tied to this wire to keep them upright when ripening their fruit (Fig. 3349). Two wires, one above the other, are sometimes used in making this kind of trellis, and the canes either tied in an erect position to both wires (Fig. 3350), or they are arched over the upper wire and tied to the lower (Fig. 3351). When tied in an erect position, those portions of the canes projecting more than 6 inches above the wire are pruned off. (b) The trellis is often made by stretching two wires along the line of posts from the ends of crosspieces about 15 inches in length (Fig. 3352). The old and new canes are kept between the wires and out of the way when the cultivating is done. Sometimes the old canes are tied to the wire, half of them being tied to the wire on one side and half to the wire on the other side (Fig. 3353). The young canes then come up between the old canes and will be out of the way of pickers and cultivators. Many variations of the above systems are in use.

Pickling and handling.

Raspberries should be harvested as carefully as possible in order to avoid injuring them. The subsequent behavior of the berries on the market depends in a large measure on the care used in picking and handling. Berries injured or bruised in handling, or soft from being over-ripe, or from rainy weather, are quickly attacked by certain mold fungi which cause their decay. To avoid as much injury as possible, three fingers should always be used in picking; very few berries should be held in the hand at one time, to avoid mashing them; the berries should always be placed, not dropped, into the basket or cup; all decaying, over-ripe, and injured berries should be discarded and no later handling of the berries in the baskets allowed. The crates should be hauled on spring wagons to avoid jolting and neither the berries nor the crates containing them should be exposed to the sun. Pint baskets should be used in harvesting red varieties and either pint or quart baskets for the black and purple varieties. (Fig. 3354.) In Pacific Coast regions a basket, or "cup" as it is called there, holding a pound of berries, is commonly employed.

The old fruiting canes of all types of raspberries should be cut out and taken from the field immediately after the crop is picked. Some fruit is usually secured the second year after planting, often enough to pay the entire cost of cultivation for that year. The duration of the plantation depends on the varieties, the care, the locality, and the practice of the grower.

Some growers of the black raspberries harvest one crop and then plow the plantation up; most persons keep the fields for two or three crops, and still others gather six to eight crops before destroying the plantation. The red raspberry fields are usually fruited longer than are those of the black raspberry. Growers generally plan to secure eight to ten crops from a field. Yields from fields receiving good treatment will vary from 50 to 150 bushels to the acre, depending upon the locality, the soil, and the variety grown.

In many northern and western sections, varieties are grown that require winter protection. This is best secured by drawing the soil from one side of the row of plants, using either hoes or a plow, inclining the canes to that side, and covering them entirely with earth about 2 inches deep. The canes are left as late as possible in the spring before uncovering. When the buds begin to start, the canes are forced into an erect position.

Pickling and handling.

Raspberries should be harvested as carefully as possible in order to avoid injuring them. The subsequent behavior of the berries on the market depends in a large measure on the care used in picking and handling. Berries injured or bruised in handling, or soft from being over-ripe, or from rainy weather, are quickly attacked by certain mold fungi which cause their decay. To avoid as much injury as possible, three fingers should always be used in picking; very few berries should be held in the hand at one time, to avoid mashing them; the berries should always be placed, not dropped, into the basket or cup; all decaying, over-ripe, and injured berries should be discarded and no later handling of the berries in the baskets allowed. The crates should be hauled on spring wagons to avoid jolting and neither the berries nor the crates containing them should be exposed to the sun. Pint baskets should be used in harvesting red varieties and either pint or quart baskets for the black and purple varieties. (Fig. 3354.) In Pacific Coast regions a basket, or "cup" as it is called there, holding a pound of berries, is commonly employed.

The above systems are applicable to the red raspberries. The black and purple varieties do not sucker and are usually trained as follows: The tips of the young canes are pinched back when they are about 2½ feet from the ground. This causes them to branch and form bushes better able to support a heavy crop of fruit. If the side branches grow very long, they are pruned back in the spring to a length of 6 to 18 inches. Sometimes a trellis is made and they are trained on the system described above under (a).

The old fruiting canes of all types of raspberries should be cut out and taken from the field immediately after the crop is picked. Some fruit is usually secured the second year after planting, often enough to pay the entire cost of cultivation for that year. The duration of the plantation depends on the varieties, the care, the locality, and the practice of the grower.

Some growers of the black raspberries harvest one
RASPBERRY

Varieties.

The principal red varieties grown at present are Cuthbert (Fig. 3355). Herbert, King, Marlboro, Ranere (St. Regis), and Perfection (Fig. 3356). Promising new varieties are June, Empire, Sunbeam, and Ohta. Much interest has recently been shown in the fall-bearing type represented by the Ranere. Among the black raspberries, the Cumberland, Farmer, Gregg, and Kansas are the leading varieties. The Golden Queen is the principal yellow sort grown. The Columbian is the principal purple-caned variety at present, although the Shaffer (Fig. 3377) and Cardinal are also grown. The Royal is a very promising new purple-caned sort.

Enemies.

Among the more serious diseases of the raspberry are crown-gall, anthracnose, cane-blight, and orange-rust. When plants free from these diseases are set, very little trouble is likely to be experienced later from them. The means of control commonly employed when these diseases are found are eradication and destruction of plants affected by crown-gall and orange-rust, and the cutting out and removing from the field of all canes affected by anthracnose and cane-blight. Scur-frothers are considered the most serious insect enemy of the raspberry. The adults lay their eggs in the tips of the canes. When these tips are seen to be withering and dropping, they should be cut off and burned. If the cut is made well below the point of injury, these tips will contain the eggs or young larvae of the borer. GEORGE M. DARROW.

RATHBUNIA (named for Richard Rathbun, Assistant Secretary in charge of U. S. National Museum). Cactaceae. Plants not large, the stems and branches often weak; spines stout, those of the flowering areoles not differing from the others; flowers diurnal, single, only from the upper areoles, very narrow and elongated, at first straight, but in age more or less curved, oblique at thrust, scarlet, persistent; petals very short, spreading or reflexed; anthers attached near the middle of the tube, exserted; fr. spiny, globular, red, breaking open irregularly; pulp red; seeds black, compressed, minutely pitted, with a large basal oblique hilum.—Three species have been described. Native of the west coast of Mex. The species all have rather weak stems, often clambering and resembling somewhat Cereus serpeninus, but usually stouter and with different spines and flowers. The flowers are very narrow and scarlet, and more enduring.

alamosensis, Brit. & Rose (Cereus alamosensis, Coul.). Upright, columnar, about 4 ft. high by 2 in. diam.; ribs 7–9; spines numerous, stout; central spines usually 4; fr. from the upper areoles, funnelform, about 1½ in. long, red. W. Mex.

R. acaulis, Brit. & Rose, and R. Kéberli, Brit. & Rose, are sometimes confused with the above, and may be handled under this name in the trade. J. N. Rose.

RAUWÓLFIA (named for Leonhart Rauwolf, a physician of Augsburg in the sixteenth century). Apocynaceae. Trees or shrubs, mostly glabrous, sparingly grown, suitable for the greenhouse and outdoor planting in the far southern parts of the United States. Leaves opposite or verticillate, those of a whorl often very unequal: infl. terminal or pseudo-axillary, peduncled, few- or many-flowered, compound, umbelliform or corymbose, rarely racemose: frs. small; sepals 5, almost free or united into a flat 5-toothed cup; corolla salver-shaped, lobes 5, twisted and overlapping to the left; disk annular or cup-shaped, entire or slightly lobed; carpels 2, free or more or less coherent: drupes 2, distinct or somewhat united.—About 60 species from the tropics of both hemispheres.

chinensis, Hemel. A small evergreen shrub, with dark green lvs., white frs. which are borne in dense terminal trusses, and numerous red berries. China.—Intro. into Orange Co., Fla., as an ornamental, where it is semi-hardy, but always sends up strong new shoots in the spring. Requires a light rich soil and plenty of water, with some protection against the sun. Each spring, it should receive fresh rich compost.

pleioscindica, K. Schum. A shrub or small tree, up to 20 ft. high; lvs. in whorls of 3 or 4, lanceolate to elliptic, 3–7 in. long; frs. in cymes, arranged in umbels, white; corolla-tube 3–3½ in. long. Trop. Afr.

F. TRACY HUBBARD.

RAVENALA (the name of the plant in Madagascar), Musaceae. Musa-like plants becoming 20 to 30 feet high, with a palm-like trunk, cultivated for ornamental uses.

Leaves exceedingly large, crowded in 2 ranks, thus forming a fan-shaped head of foliage; petioles long, with concave bases scarcely sheathed; scapes 1–2, acuminate in the upper axis longer or shorter than the vs.; bracts spathe-like, many, boat-shaped, acuminate–frs. many, large, in a spathe or bract; petals long-exserted; sepals free; fr. a 3-valved caps.—A genus of 2 species, 1 from Madagascar and the other from Brazil and Juliana.

a. Less shorter than petioles.

madagascariensis, J. F. Gmel. TRAVELER'S TREE, so called from the clear waters sap from the large box-like cells of the leaf-stalks or caught in the leaf-sheaths, and which affords a refreshing drink. Fig. 3358. Lvs. often 30 ft. high, very large, fibrous: frs. white, in spikes about 7 in. long. G.C. III. 21:2254. A.F. 12:535. R.H. 1896, p. 152; G.C. III. 2:693; 50:460. A.G. 20:870. Cult. in Fla. and S.
RAVENAL

Calif.; also rarely under glass in the northern states. It is said that in S. Calif., the traveler’s tree was never really successful.

AA. Les. as long as the petals.

guyanensis, Steud. Becoming 15 ft. high; lvs. oval-elongated: fls. white; spathes 1 1/2 in. long.—Offered 1893 in S. Fla.

F. W. BARCLAY.

RAVÉNIA (name not explained). Rubiaceae. Tender glabrous shrubs suitable for the warmhouse. Leaves opposite, 1 3-foliate; lfts. lanceolate, entire: fls. red or white, borne on rather long axillary peduncles; sepals unequal, the 2 outer being somewhat foliaceous; corolla-tube straight, rather long; the limb nearly regular.—Two species from Cuba and Brazil.

spectabilis, Griseb. (Lemônia spectabilis, Lindl.). Tender shrub: lfts. 3: fls. purplish red, about 1 in. across, solitary or in open, few-fld. clusters on axillary peduncles as long as the lvs. Cuba. B.R. 26:59. R.H. 1844:25.—The plant once offered in Fls. as Leonomia spectabilis apparently is of some other genus. F. W. BARCLAY.

REBÜTIA (named for Rebut). Cactaceae. Plants very small, globose, covered with small tubercles, resembling in habit very much a many-milliarial fl. appearing from the side and even the base of plant, large in comparison with the plant, red or orange-colored, with slender, funnelform tube; bracts on ovary small, naked in their axis: fr. a small berry.—Originally described with 1 species, but a study of S. American material indicates that there may be 5 or 6 other species to be transferred here from other genera. The original species has been referred both to Echinopsis and Echinocactus, from both of which it is abundantly distinct.

minúsula, Schum. Plants globose, 1 2 in. diam., covered with low tubercles: spines in clusters of 25 30, 1 1/2 in. long: fls. often numerous, arising from near the base of plant, 1 1/4 in. long, bright crimson. N. Argentina. B.M. 8583 (as Echinocactus).

Flebrigii, Brit. & Rose (Echinocactus Flebrigii, Gürke). Globose, depressed at apex, 2 in. diam.: spines 30 40 in a cluster, 1/2 in. long, white, or some of the longest ones nearly 1 in. long with brownish tips: fls. nearly 1 in. long. Bolivia. Blühende Kakteen, pl. 109. J. N. ROSE.

REHMANNIA (Jos. Rehmann, 1779 1831). Scrophulariaceae. Perennial viscid-villous herbs suitable for the cool greenhouse, grown for the showy bloom. Stems leafy, branched from the base, either low, scapiform and almost leafless, or (especially in cult.) tall and few-lvd.: lvs. alternate, obovate or oblong, coarsely dentate: fls. rather large, borne in terminal racemes and short-pedicelled, brownish purple or pale, the throat intensely colored; calyx ovoid-campanulate, 5-cleft at the top; corolla pilose, slightly incurved, tube rather broadly subventricose, limb obliquely 2-lobed, the lobes spread, the rear or inner one deeply 2-cleft, the front one 3-cleft; stamens 4; caps. broad, partly included in the calyx; seeds numerous.—About 5 species, China and Japan.

angulata, Hemsl. Perennial plant, 1 3 ft. high, glandular-hairy: lvs. pinnately lobed, with red with a band of scarlet at the margin, rather coarsely dentate: fls. rather large, borne in terminal racemes and short-pedicelled, brownish purple or pale, the throat intensely colored; calyx ovoid-campanulate, 5-cleft at the top; corolla pilose, slightly incurved, tube rather broadly subventricose, limb obliquely 2-lobed, the lobes spread, the rear or inner one deeply 2-cleft, the front one 3-cleft; stamens 4; caps. broad, partly included in the calyx; seeds numerous.—About 5 species, China and Japan.
REHMANNIA

Var. tricolor, Hort. Fls. at first bright purple, later almost violet-rose. The throat is shaded with vermilion and the throat white, spotted with purple. China.

Briscui, Hort. (R. elata x R. Henryi). Intermediate in most characters, dwarfer than the former in having an erect infl. instead of a condensed one: the fls. are intermediate in color and of a soft pink: the lvs. arranged in a rosette are similar in shape to those of R. elata.

REINWARDTIA

Henryi and have the same dark veiningings, while they are much more velvety-hairy than those of R. elata but less so than those of R. Henryi. A garden hybrid. G.C. III. 47:188.

elata, N. E. Br. (R. angulata, Hort. not Hemsl.). Fig. 3350. Twice as large as R. angulata: lvs. 2-4-lobed on each side, lobes acute, entire; bracts or flowering lvs. long-cuneate at base: corolla slightly larger than R. angulata, bright rosy purple on the lips and yellow dotted red in the throat. China. B.M. 8177 (as R. glutinosa, Libosch.]

3359. Rehmannia elata. (X 1/2)

REINECKIA (J. Reinecke, a German gardener). Lilaceae. A tender perennial herb, with attractive foliage in tufts 1-1½ ft. high from a thick, creeping rootstock: lvs. rather large, channelled: scapes leafless: fls. sessile, in a loose spike; perianth-tube cylindrical; petals recurved, spreading; ovary 3-lobed, with a few seeds to each cell: berry globular, usually with 1 seed per cell. A single species from China and Japan. The following is procurable from Dutch bulb-growers.

3360. Reinwardtia trigyna. (X 1/2)

Leaves alternate, entire or crenate-serrate; stipules minute, subulate, caducous: fls. yellow, in axillary and terminal cymose fascicules, rarely solitary; sepals 5, entire, lanceolate, acuminate; petals 5, contorted, fugacious, much longer than the sepals; stamens 5; ovary 3-5-celled: caps. globose, splitting into 6-8 cocci.

—Two species, India. The genus is closely allied to the flax (Linum), and Reinwardtia trigyna is known by the gardeners, who usually accent trigynum on the second syllable instead of the first. Reinwardtia is distinguished from Linum by the yellow fls., 3-4 styles and unequal or deficient glands; Linum has mostly blue, rosy or white fls., 5 styles, and equal glands.

Reinwardtias are showy subshrubs about a foot high with bright yellow flowers. They are useful for the decoration of the conservatory in winter time, at a season when yellow is scarce. To have presentable plants, it is necessary to give them a good deal of attention. It is difficult sometimes to get suitable cuttings; the strong growths which start away from the base when the plants are cut down make the best plants. Top-shoots will grow, but seldom make good plants, as they are liable to go to bloom prematurely. Sandy loam is the best compost. Plants that have been grown in pots for...
About 15 or more species, in Malay Archi-

ves distichous on the st.: fls. in large, droop-

rather crowded, strap-shaped, 2-3

spreading, similar or the lateral sepals often

larger and of a different calm; labellum small,

Rts. very long, climbing, somewhat branched: 1vs.

movably joined to the column, spurred or

red blotches; labellum very small. Philippines. B.M.

Does not flower readily in cult., but is very showy.

spatulate, deep red, blotched with orange; lateral

form anther). 1. St. slender, climbing, 10-12 ft. high:

Lvs. alternate, oblong to linear-oblong: panicle

about 1 ft. long and nearly as broad; fls. 2-3 in. long;

petals and dorsal sepal erect, linear-spatulate, orange-

branched, climbing by means of white fleshy roots: lvs.

RENANThÉRA (named from the remi-

form anther). Orchidaceae. Tall climbing epiphytes.

Stems branched, sometimes 12-14 ft. high:

Lvs. distichous on the st.: fls. in large, dropo-

ing racemes or panicles; sepals and petals

spreading, similar or the lateral sepals often

larger and of a different color; labellum small,

movably joined to the column, spurred or

spurless, often with small, erect, lateral lobes.

—About 15 or more species, in Malay Archi-
pelago and Cochin-China. Cult. is similar to that of

Aerides and Vanda.

RENEALMIA (in honor of Paul

Renanthe, W. ARDTIA

RENEALMIA 2917

(R. annamensis Rolfe. Dwarf, erect, up to 1 ft. tall: lvs. un-

equally 2-lobed at apex, 2-3 in. long, about 5 mm. broad; racemes

very remarkable orchid.

R. annamensis Rolfe. Dwarf, erect, up to 1 ft. tall: lvs. un-

equally 2-lobed at apex, 2-3 in. long, about 5 mm. broad; racemes
terminal or scapose and either paniculate or racemose; 
fls. white, yellow or red; calyx short, 3-lobed; corolla short-tubed, the lobes erect or finally spreading, sub-
equal or the posterior broader and concave; ovary 3-celled: caps. globose. About 60 species, Trop. Amer.
as a dye-plant; also ornamental, with reddish peduncles and bracts, and yellow fls.: lvs. like a canna; the 
foliage is woody at the base. B.R. 227. Many named varieties of R. odorata are in the trade. See Mignonette.
glabra, Linn. Glabrous and somewhat glaucous perennial, less than 1 ft. tall, with many spreading sts.:
Ivs. linear, entire, or 2-toothed near the base; petals 5-6, the upper ones 3-lobed; stamens about 14. 
Pyrenees.—Recommended for dry places, as a border plant. See p. 1467.

AA. Lvs. usually prominently lobed or pinnatifid.

álba, Linn. White Upright Mignonette. Straight-
growing erect glabrous annual or biennial, 1–3 ft., 
weedy: Ivs. numerous, long-stalked, deeply and 
irregularly pinnatifid, the segms. usually linear and 
sometimes toothed: fls. glaucous white, in a very 
long slender spike; stamens about a dozen, and petals
5–6. S. Eu. G.C. III. 20:45. G.W. 8, p. 255.—A com-
mandable plant for growing as an ornamental subject 
in the R.-border with other plants. It bears many 
spikes on tall branches, making it a conspicuous 
plant; treated as a half-hardy annual; odor not pleas­
ing. It occurs somewhat in this country as an aden­
tive plant.

cristállina, Webb. Glabrous, sparingly branched, 
somewhat glaucous annual; Ivs. usually 3-parted, or 
the lowest ones entire: fls. deep yellow, in racemes. 
Canary Isls.—Has been offered as a garden annual.

L. H. B.

RÉSTIO (Latin, rope, alluding to the use made of 
the plants in S. Afr.). Restiéceae. Perennial herbs 
with a tufted or creeping rootstock, of little horticultural 
significance: sts. terete, compressed, or 4-sided, 
with remote sheathing If.-sheaths, usually more or less 
mucronate, sometimes prolonged into a linear blunt 
if.: male and female infi. similar or dissimilar, spicate, 
spikes solitary or spikelets numerous in spicate or 
panicked cymes; fls. ducous, 1-bracteate; perianth 
usually of 6, sometimes 4 segms. in 2 rows, rarely none; 
ovary 2- or 3-celled: caps. 2- or 3-celled, or by abortion 
1-celled, 1 seed in each cell. About 170 species, half 
of them from S. W. Afr. the remainder from S. W. Austral. 
R. subtervitátilis, Mast. Sts. erect, 3–4 ft. high, with 
verticillate branches: sheaths about 1 in. long, coria­
ceous, strate above, membranous, spreading, acum­
inate, smaller sheaths foliaceous from beneath a 2-lobed 
linear apex: perianth-segms., male, broadly obovate, 
the lower villous keeled, female, broader: caps.
oblquely ovate, 1-celled, 1-seeded. S. Afr. G.M. 
43:76.

REST-PERIOD IN PLANTS. The rest-period of 
plants is that period or stage when the part or parts 
at inaction are incapable of responding to favorable growing 
conditions. A rest-period of some length; either 
short or long, appears to be universal with all perennial 
plant forms. So far as known, none has a continuous 
growth. Trees and shrubs growing in the open, both in 
cold and warm climates of the tem­
perate zone, may begin to enter the rest-period in some of their branches 
as early as midsummer. This is indi­
cated by cessation of length growth 
and formation of terminal buds. 
Some may be ready to grow again in a 
week, while others are unable to 
grow for five or six months. Herbari­
eous perennials begin their rest after 
dying down in summer or fall. The 
death of the aerial parts is accom­
panied by the formation of terminal 
and formation of terminal buds.

REST-PERIOD (Latin, rope, alluding to the use made of 
the plants in S. Afr.). Restiéceae. Perennial herbs 
with a tufted or creeping rootstock, of little horticultural 
significance: sts. terete, compressed, or 4-sided, 
With alternate, simple or compound lvs., and terminal 
skips of inconspicuous perfect fls., which have 4–7 small 
greenish toothed or cleft unequal petals and 8-40 nate, smaller sheaths foliaceous from beneath a 2-lobed 
eximw, gigantea, grandtflora, pyramidalis, multiflora, 
pumila; they represent stature-forms and habit-forms 
of the horticulturists. Var. rosea quinaria, Edw. is woody at the base. B.R. 227. Many named varieties of R. odorata are in the trade. See Mignonette.
exceptions. Bulbs begin their rest when the tops die down after flowering. Many will not grow again for several months. Many seeds germinate poorly, or not at all, if planted immediately or shortly after ripening. Failure to grow is usually due to the influence of a rest-period. However, aside from the effects of a rest-period, seeds are not germinating if they are on account of a hard or tough seed-coat which is more or less impervious to water. In garden practice, seeds are stored for a few weeks or months before planting in order that they may pass through a period of "after-ripening." Those with hard or tough seed-coats are stored by stratifying in moist sand.

Investigation has shown that practically all woody plants native to the temperate zone have a rest-period. Many of these are unable to grow in late fall or early winter, even when transferred to a warm moist greenhouse. In trees and shrubs the rest-period begins to set in as early as midsummer. The length of the rest varies greatly. In some cases it may last only a few days or weeks, while in others it may persist from three to six months. Red raspberries, mountain-ash, and spireas are almost free from a rest-period, while white oak, tulip tree, and American beech commonly rest for six or seven months. Among herbaceous perennials, the life-of the annual is considerably longer than the rest-period which usually lasts for two or three months. Asparagus, rhubarb, hardy chrysanthemum, golden marguerite, calliphysis, and a host of others are ready to grow in a week or two after the old plants are pulled down. All spring-flowering bulbs appear to have a distinct rest-period lasting from three to five months. From 50 to 75 per cent of the seeds of herbaceous plants, annual and perennial, have a rest-period, while the resting phase is noticeable and generally very distinct in fully 90 per cent of the seeds of trees and shrubs.

The rest-period is commonly looked upon as the period of dormancy in plants and seeds, but this view is incorrect. The rest-period of trees, for example, begins and ends entirely independent of the winter season. While cold weather may prevent growth from taking place, it does not necessarily prevent the rest-period from coming to an end and thus leaving the trees ready to reawaken when surrounding conditions are favorable. In mild climates the rest begins and ends with great regularity. The same is true in cold climates, but in the case of trees, at least, the true condition of rest cannot be determined on account of the absence of the cold which prevents growth. In trees the rest sets in gradually and is not complete until all the growing points have ceased elongating and formed terminal buds. In like manner the trees pass out of their resting state gradually, some twigs often being ready to grow much earlier than others. These phenomena are very noticeable when trees are grown under glass.

The rest-period of many trees and shrubs may be broken or greatly shortened by special treatments. Those with a long rest-period are very difficult to arouse during the early stages of their rest. The greater part can be forced with comparative ease during the middle period of their rest and to some extent during the latter phases, although at this time the treatments must be less severe or the plants may be killed. The agents most generally used for forcing growth are ether, drying, and freezing. Submerging in warm water will sometimes start growth, particularly in dormant twigs. Twigs of flowering shrubs, such as lilac, deutzia, spireas, and golden-bell, may be caused to burst into bloom in early or midwinter by placing them in a tight vessel and pouring over them the rate of one teaspoonful of ether vapor for twenty-four hours, when they should be taken out and stood in vessels of water in a warm moist room. It is very necessary to have the air moist to keep the buds from drying out before they begin to grow. Potted plants of all kinds, both woody and herbaceous, may be similarly treated, provided the surface of the soil in the pots is dry, as moist or wet soil will absorb too much of the ether. Many herbaceous plants do not respond to the ether treatment and some are killed. The best agent for forcing very hardy herbaceous perennials is to lift them in the fall, subject them to a temperature a few degrees below freezing for twelve to twenty-four hours, and then place them in a mild hotbed. By mid- or late winter most plants may be forced with heat alone. There are perhaps thirty or forty different agents that have been successfully used for forcing plants.

Of just what value the rest-period is to the different plants and plant parts is not known. It is highly probable, however, that the period of inactivity is utilized for the conservation of energy through the special work the enzymes are able to perform while the growing parts are dormant, that they could not do in the presence of active growth.

The cause of the rest-period and the specific effects of the rest-period-breaking agents on the plant organism have been carefully studied only in connection with woody plants. It has been thought that the rest-period of trees sets in on account of the inhibition of the enzyme activity due to an over-accumulation of the products of their work. The early phases of the rest-period occur and are passed through while the plants are in full leaf and often while some of the parts are still making active growth. The parts to enter the resting state first, in fruit-trees particularly, are the so-called spurs which are short lateral outgrowths usually arising from wood that grew the previous year. These cease growing early in the season, probably because of imperfection of solution. The crude sap from the roots rises most rapidly in those branches and twigs that are nearest in a straight line upward from the ground. It would appear then that the spurs, on account of their position, are deprived of water very early in the growing season. Assimilation goes forward rapidly in those parts that first approach a state of maturity. With a decreased water-supply and a greatly increased deposition or accumulation of carbohydrates, enzyme activity is soon checked and not entirely inhibited. As the season advances, the approach of cool weather may hasten the period of dormancy, but the trees would go dormant just the same, although later, in a mild climate or under glass. It is thus seen that the rest-period of trees is gradual, beginning with the spurs and gradually involving all of the branches.

Briefly, the rest-period perhaps begins to set in on account of the inhibition of the enzymes by the over-accumulation of the products of their work. This is the early rest of mid- or late summer. In the fall, excess supplies of carbohydrates continue to be accumulated and, with trees growing in the open, the further inhibition of the enzymes is actively aided by the approach of cool weather. These factors acting together bring about the main or middle state of rest. However, since dormant trees are never completely at rest, respiration continuing all the time, and doubtless enzyme activity too, the over-accumulation of carbohydrates is gradually reduced. Toward the last of this period occurs the after-rest, which, as the enzymes become more and more active, gives place to the beginning of growth.

Research has shown that diastatic, proteolytic, fat-splitting, and oxidizing enzymes all play a prominent part in bringing about, as well as ending, the rest-period in woody plants. Any forces or agents that will reduce the activity of these ferments will be the means of causing the rest-period to set in earlier. Food, any agent that will stimulate the enzymes into activity will be the means of bringing the rest-period to an end. (See Research Bulletins Nos. 1, 15, 16, 17, 21, Missouri Agricultural Experiment Station.)
RESTREPIA (Joseph Emanuel Restrep, a student of natural history in the tropics). Orchidaceae. Very interesting little plants, allied to Masdevallia and not unlike that genus in habit and appearance. Stems tufted on creeping rhizomes, each bearing a single inf. and clothed below with scales; fl.-sts. appear from the axil of the lvs.; perennial, producing fls. for several years in succession; dorsal sepal free, ending in a filiform, clavate tail; lateral sepals united into a broad blade, bifid only at the apex; petals like the dorsal sepal, but smaller; labellum oblong or ovate, often with 2 small teeth near the base.—About 40 species, from Brazil to Mexico, few of which are cult. for their curious fls. They are easily grown at a temperature suited for cool odontoglossums (40-55°). They thrive well planted in a mixture of peat and sphagnum in pots, which are usually suspended near the glass. They have no definite resting period, but do not require so large a quantity of water in winter as during their most active growth. Pot moderately firm, and rest in a coolhouse.

A pantannifera, HBK. Sts. slender, clustered, 4-6 in. high, clothed with imbricated scales, and bearing one (rarely more) ovate-cordate petioled fl.; peduncle from the axil of the fl., slender, 1-fl.: dorsal sepal 1½ in. long, lanceolate, tapering into a slender clavate tail, yellow, with purple lines and a purple tip; lateral sepals united into an oblong blade 2-lobed at the tip, yellow, marked with red-purple dots; petals small, antenna-like, purple at the tip. Nov.-Feb. Colombia, Venezuela. B.M. 6288; 7930. I.H.16:601. A.F.6:631.

Dayana, Reichb. f. A small plant growing in dense tufts: lvs. roundish, acute, cordate: dorsal sepal free, ending in a filiform, clavate tail; lateral sepals united into a broad blade, bifid yellow and brown. Costa Rica.

Elegans, Karst. Tufted, epiphytic, 2-3 in. high: lvs. 1-1½ in. long, elliptic: peduncle usually in pairs; fls. 1½-2 in. long; dorsal sepal erect, lanceolate, white, streaked purplish, with a tail as long as itself, which is clubbed at the tip and yellow; lateral sepals connate into an oblong, emarginate, concave blade, yellow, spotted purple; petals like the dorsal sepal, but spreading and only half the size; lip half the size of the connate lateral sepals and of the same color but edged with red. Venezuela. B.M. 5966. F.S.7:2.4. R. aspericostatum, Reichb. f. Only 2-3 in. high: fls. small, deep yellow, densely spotted with crimson or chocolate-brown. Venezuela.

HESTREPIA (Joseph Emanuel Restrep, a student of natural history in the tropics). Orchidaceae. Very interesting little plants, allied to Masdevallia and not unlike that genus in habit and appearance. Stems tufted on creeping rhizomes, each bearing a single inf. and clothed below with scales; fl.-sts. appear from the axil of the lvs.; perennial, producing fls. for several years in succession; dorsal sepal free, ending in a filiform, clavate tail; lateral sepals united into a broad blade, bifid only at the apex; petals like the dorsal sepal, but smaller; labellum oblong or ovate, often with 2 small teeth near the base.—About 40 species, from Brazil to Mexico, few of which are cult. for their curious fls. They are easily grown at a temperature suited for cool odontoglossums (40-55°). They thrive well planted in a mixture of peat and sphagnum in pots, which are usually suspended near the glass. They have no definite resting period, but do not require so large a quantity of water in winter as during their most active growth. Pot moderately firm, and rest in a coolhouse.

A pantannifera, HBK. RESURRECTION PLANTS are such plants as "come to life" after being apparently dead. They are kept in a dried state as curiosities, to be "resurrected" on occasion, and sometimes they are grown for a similar purpose. Some of them are used as house plants, the tips or on the sides of the inrolled branches. (Fig. 3365.) The plants are up-rooted by the winds and blown about during the dry season, but this belief is thought by many to be "the rolling thing before the whirlwind" mentioned in Isaiah, and were brought to Europe by the crusaders. The shape of these balls might be fancifully compared to that of an unopened rose. When the winter rains descend or when the balls are blown into the Mediterranean, the branches at once open back and stretch out straight, the fruits open, and the seeds germinate very quickly, "often in the fruit," according to Warming. The dead plants do not, of course, "come to life," but they retain their hydroscopic properties for many years.

Botanically, Anastatica is distinct by reason of its short and broad fruit or silicle, which has two ear-like appendages at the top. The silicle is divided by a transverse partition into two cells, each of which contains a seed. There is only one species. The genus belongs to the Arabis tribe of the Crucifereae, but is exceptional in not having a long slender silicle. The growing plant has ovate leaves, the lower ones toothed, and the flowers are small, violet, and yellow, with purple lines and a purple tip. The plant is a native of Mexico and eaches into western Texas. Many selaginellas curl up if allowed to dry, and several of the Mexican species do so in their native places in the dry season, but this species is said to make a tighter mass than any other. When placed in lukewarm water the fronds loosen and roll back into a flat or saucer-like position. The plant may become green and grow, and it is also said that it may be dried and revived an indefinite number of times. The specimen shown in Figs. 3366, 3367 was "resurrected" four times after it came into the hands of the Editor, and showed no indications of a limit to its reviving possibilities. Selaginellas are beautiful moss-like plants. What appear to be the leaves are really the branches, and the true leaves are scale-like. See Gn. 17, p. 400; F. 1871, p. 144; also Selaginella.

1. A member of the composite family (Odontospermum pygmaeum, or Asteriscus pygmaeus) is also called rose of Jericho, has the same range as No. 1, and was also brought to Europe by the crusaders. (Fig. 3338.) The plant is a native of the sandy deserts from Arabia and Syria to Algeria. It is an annual and grows about 6 inches high. Soon after flowering the leaves fall and the branches become woody and roll up into a ball, reminding one of a "whirlwind" mentioned in Isaiah. (Fig. 3339.) The ball or the seeds are the seeds, or, in botanical language, the fruits, which are borne in a protected position near
RESURRECTION PLANTS

4. Several species of Mesembryanthemum are known to be hygroscopic. According to Kerner & Oliver, "the capsular fruits of these plants remain closed in dry weather; but the moment they are moistened the valves covering the ventral sutures of the fruit-loculi open back, dehiscence takes place along the ventral sutures, and the seeds, hitherto retained in a double shroud, are washed out of the loculi by the rain." It is doubtful whether these capsules are offered in the trade.

The cultivation of resurrection plants.

Anastatica is sometimes grown for curiosity or for botanical purposes, but the plant is anything but ornamental. It has often been grown for classes in botany, sowing the seed in February in pots and keeping the plants in pots all summer. Bottom heat is not necessary at any stage, at least in America. The plant could be grown in a window-garden. The seeds may be sown in February in 4-inch pots, using a light, sandy soil, in a house with a temperature of 60° F. As soon as the seedlings are large enough they are transplanted into other 4-inch pots, three plants to a pot.

The Selaginella lepidophylla is perennial. It is rarely cultivated in greenhouses for ornament, like the evergreen kinds of selaginellas. It is grown chiefly in botanical gardens or by fanciers of ferns and selaginellas, as it is by no means the most beautiful member of the genus. The writer grew a plant of it for four years, and once saw at one of the botanical gardens a plant which through long cultivation had developed a stem almost a foot high. It looked like a miniature tree-fern, except of course that the fronds were arranged in a dense rosette, which gave the fronds a flat rather than a pendulous appearance. Whether the plants received directly from Texas have a crop of spores on them is a question. The spores do not discharge when the plants are wetted. Many extravagant statements are made about the bird's-nest moss. The dried plants offered by the trade will turn green and grow unless they are too old or have been kept dry too long. They would probably not grow if kept over more than one season. They cannot be dried again and again indefinitely and still remain alive.

If a plant has been grown in a pot three or four years and is then dried off it will die. Most persons who grow these plants as curiosities place them in a bowl of water with perhaps a little sand and a few pebbles. The water causes them to turn green and they will grow for a time. Then if taken out of the water they may be kept dry for a time and the process repeated, but each time the plant loses its lower or outer circles of fronds much faster than new ones are made and at about the third time the plant is commonly used up.

There is a fern (Polypodium polydioides, page 2744) which could just as truly be called a resurrection plant. It is a native of the southern states, where it grows up the trunks of trees and over rocks and stones. At certain times it is dried up and parched, but as soon as moisture conditions are restored it looks as fresh as ever. In warm dry countries there are ferns of various genera that dry up and then are resurrected quickly when wet weather comes; some of these are very interesting.

EDWARD J. CANNING.

RETINISPORA. Often but not originally spelled Retinispora. A genus of conifers founded originally by Siebold and Zuccarini on the two Japan species of Chamaecyparis, distinctly distinguished from the American species by the resinous canals of the seeds (from Greek, retine, resin, and spora, seed). Afterward the genus was united with Chamaecyparis, but in horticultural nomenclature the name is applied to a number of juvenile forms of Thuja and Chamaecyparis, chiefly those introduced from Japan. As these juvenile forms all resemble each other very much, indeed much more than do the typical forms to which they belong, it is not strange that they should have been considered to be distinct species and even to belong to a separate genus. Even botanists failed to recognize the true relation of these forms and went so far as to place one of them in the genus Juniperus. With the exception of Retinispora eriostachys, which C. Koch recognized as the juvenile form of Thuja occidentalis, the origin of these juvenile forms remained doubtful until L. Beissner, after having carefully studied the subject for years, disclosed the relationship of the various forms. He showed by experiment that it is possible to raise the same form by making cuttings from seedlings which have still retained their primordial foliages, and he also published cases in which larger plants of these doubtful forms have been observed accidentally to develop branches with the foliages of the typical form. See, also, Gt. 1879, pp. 109 and 172; 1881, pp. 210 and 299, and 1882, p. 152.

There are four of these juvenile forms generally in...
cultivation, each of them with an intermediate form showing either a kind of foliage approaching that of the type or two different kinds of foliage on the same plant. There seems to be no doubt that all these forms have been secured by propagating branches of young seedling plants. All seedlings of Chamœcyparis, Thuja, and other genera of the Cupressaceae produce in their juvenile state a kind of primordial foliage very different in appearance from that of the adult plants. The first leaves are always linear and spreading, passing gradually into acicular and at last scale-like leaves. In some plants, especially if they have not sufficient nourishment, the primordial foliage is retained longer than usual and these have probably been selected for perpetuating the juvenile state, by means of cuttings. By continuing through many generations the propagation of those branches which show the juvenile state most distinctly, these forms have become well-fixed varieties and even sometimes bear seeds without changing the foliage on the fruiting branches. These seeds, however, produce plants of the typical form and only a few of them retain the primordial foliage somewhat longer than usual.

The juvenile forms very much resemble some species of Juniperus in habit and foliage. They bear linear spreading leaves in pairs, changing in winter to a brown, reddish, violet or steel color, and do not show the regular frond-like branching of the typical forms. The leaves, however, are much softer and not sharply and acutely pointed as in Juniperus; they are mostly marked with whitish or grayish green lines beneath, which is never the case in Juniperus. Only the upper side of the leaves like Juniperus. The leaves, however, are much softer and not sharply pointed as in Juniperus; they are mostly marked with whitish or grayish green lines beneath, which is never the case in Juniperus. Only the upper side of the leaves like Juniperus.

Though these Retinispora forms are described under the genera and species to which they belong, where also references to illustrations are cited, descriptions are given here to afford a closer comparison of these similar and much confused forms. The two forms of foliage in the common red cedar are well shown in Fig. 2025, Vol. III. For other pictures of Retinispora forms see Chamœcyparis and Thuja.

Chamœcyparis obtusa var. ericoides, Bochmer (Retinispora Sänderi, Sander. Juniperus Sänderi, Hort.). Dense round-headed bush with upright branches and bluish gray foliage: lvs. acicular, decussate, spreading, about 1½ in. long, thickish, concave above and with a green line in the middle, the lower lvs. often acutish, the upper ones obtuse.

Chamœcyparis pisifera var. squarrosa, Beisen. & Hochst. (Retinispora squarrosa, Sieb. & Zucc.). Fig. 893. A dense, pyramidal or round-headed bush or some-

3369. Retinispora. The specimen on the left is Thuja orientalis var. decussata; middle, Chamœcyparis thyoides var. ericoides; right, C. thyoides var. andelyensis. (×35)

These juvenile forms are valuable for formal gardening, for rockeries, small gardens and wherever slow-growing and dwarf conifers are desired. They are short-lived and usually becomes unsightly when older. They are all readily prop. by cuttings. See also Chamœcyparis and Thuja.

Thuja orientalis var. decussata, Beisen. & Hochst. (Retinispora juniperoides, Carr. R. decorata, Hort. R. squarrosa, Hort.). Fig. 3369. Dense, round-headed bush, with bluish green foliage changing to violet or steel-color in winter: lvs. linear, soft grayish green beneath. These juvenile forms are valuable for formal gardening, for rockeries, small gardens and wherever slow-growing and dwarf conifers are desired. They are short-lived and usually becomes unsightly when older. They are all readily prop. by cuttings. See also Chamœcyparis and Thuja.

Thuja orientalis var. decussata, Beisen. & Hochst. (Retinispora juniperoides, Carr. R. decorata, Hort. R. squarrosa, Hort.). Fig. 3369. Dense, round-headed bush, with bluish green foliage changing to violet or steel-color in winter: lvs. linear, soft grayish green beneath. These juvenile forms are valuable for formal gardening, for rockeries, small gardens and wherever slow-growing and dwarf conifers are desired. They are short-lived and usually becomes unsightly when older. They are all readily prop. by cuttings. See also Chamœcyparis and Thuja.

Thuja occidentalis var. decorata, Beisen. & Hochst. (Retinispora decorata, Hort. R. dubia, Carr.). Dense, broadly pyramidal or round-headed bush, with upright branches and dull green foliage, changing to brownish green in winter: lvs. linear, soft grayish green beneath. The intermediate form, var. Ellwangeriana, Beisen. (Retinispora Ellwangeriana, Hort.), has usually two kinds of lvs., but the linear lvs. are smaller than those of the preceding form.

Thuja orientalis var. decorata, Beisen. & Hochst. (Retinispora juniperoides, Carr. R. decorata, Hort. R. squarrosa, Hort.). Fig. 3369. Dense, round-headed bush, with bluish green foliage changing to violet or steel-color in winter: lvs. linear, soft grayish green beneath. These juvenile forms are valuable for formal gardening, for rockeries, small gardens and wherever slow-growing and dwarf conifers are desired. They are short-lived and usually becomes unsightly when older. They are all readily prop. by cuttings. See also Chamœcyparis and Thuja.

REYNOSIA (named for Dr. Alvaro Reynoso, 1830-1886, a Cuban agricultural chemist). Rhamnaceæ. Unarmed evergreen shrubs or trees, with rigid branches, sparingly cultivated, possibly for its edible fruit. Leaves opposite, leathery, entire and emarginate; stipules small and caducous: fls. small, perfect, yellowish, inserted on the margin of the fleshy disk; ovary almost superior, 2-3-celled: seeds, usually ovoid, 5, valvate spreading; petals wanting; stamens 5, inserted on the margin of the fleshy disk; ovary almost superior, 2-3-celled: drupe with a thin fleshy pulp and a crustaceous stone.—About 10 species, 1 in S. Fl. latifolia, Grisch. RED IRONWOOD. DARLING PLUM. Smaller tree, 20-25 ft. high: lvs. oval, oblanceolate, obtuse, usually emarginate, 1½ in. long, leathery; mar-

REYNOSIA
gins revolute: fls. in axillary umbels, borne in May: fr. ripens in Nov. or the following spring. S.S. 2: 266.

F. Tracy HUBBARD.†

RHABDOThAMNUS (Greek, rod and bush, a shrub with many rod-like branches). Generacée. Divergently branched shrub, with slender branches. Ivs. small, opposite, petioled, rotundate, commonly dentate, often dissimilar: pedicels solitary in the axils, filiform and without bracts: fls. red-striped; calyx free, deeply 5-lobed, the lobes membranaceous, acuminate; corolla tubular-campanulate; the limb slightly oblique, somewhat 2-lipped, the lobes 5, rotundate, spreading and subequal; stamens 4, perfect: caps. ovate, acuminate, coriaceous, finally 4-valved. One species, New Zeal. R. Soldanii, A. Cunn. A much-branched, hispid shrub 1-3 ft. high: branches very slender, spreading at right angles: Ivs. opposite, often in unequal pairs, oval or orbicular, coarsely toothed: fls. axillary, solitary, about 1 in. long; calyx hispid, 5-lobed, lobes lanceolate, orange, striate red, line 2-lipped, upper lip smaller, lower lip deeply 3-lobed, the lobes rounded: caps. ovoid acute. New Zeal. B.M. 8019. G.C. III. 37:146.

RHAMNÉLLA (referring to its close affinity to Rhamnus). Rhamnacée. About 6 species in E. Asia. Deciduous shrubs or small trees: Ivs. alternate, stipulate, serrulate: fls. small, green, in axillary clusters; sepals, petals, and stamens 5; ovary incompletely 2-celled: fr. a black drupex with a 1-seeded stone. In habit resembling Rhamnus, but in Ivs. and frs. more like Berchemia. Only the following species is in cult.; it seems somewhat tender and has no particular ornamental qualities; cult. and prop. like rhamnus, R. franguloides, Weberbauer (R. japonica, Miq. M. rhunthus franguloides, Maxim.). Small tree to 30 ft.: Ivs. ovate-oblong, acuminate, finely serrulate, with 5-10 pairs of veins, glabrous except on the veins beneath, 2-5 in. long; fls. in 5-15-flb. clusters: fr. cylindrical-oblong, black, ½th. long. Japan, Koror, E. China. S.I.F. 2:48.

ALFRED REHDER.

RHAMNUS (its ancient Greek name). Including Frangula. Rhambusce. Buckthorn. Ornamental woody plants grown chiefly for their handsome foliage and some also for their attractive fruit. Deciduous or evergreen shrubs or small trees, sometimes spiny: Ivs. alternate or opposite, short-petioled, with small deciduous stipules, penninerved, serrulate or entire: Ivs. small, in axillary clusters, umbellate racemes, perfect, polygamous or dioecious; sepals, petals, and stamens 4-5, petals sometimes wanting: style usually undivided; ovary 2-4-loculed: fr. a globular or oblong 2-4-seeded drupe; nutlets with a leathery usually dehiscing wall.—About 100 species native chiefly to the temperate regions of the northern hemisphere. A few species are found in the tropics and as far south as Brazil and S. Afr. Several species yield yellow or green glass and the fr. and bark of some are used medicinally. The wood of R. Frangula is made into charcoal valued for the manufacture of gunpowder.

The buckthorns are handsome shrubs with generally bright green often rather large leaves and with inconspicuous greenish flowers usually in axillary clusters followed by berry-like, usually black, rarely red, fruits. Many of the species as R. cathartica, R. dahurica, R. fallax, R. Frangula, and R. alnifolia can be depended upon as hardy, while R. Purshiana and R. lanceolata are hardly at least as far north as Massachusetts. R. immerotina and R. caroliniana are somewhat more tender. The handsome foliage on Ivs. is r. fallax and R. immerotina and the evergreen R. tisclophi and R. crocœa. R. Purshiana, R. caroliniana, R. alnifolia, R. dahurica, and R. Frangula are also noteworthy on account of pretty foliage. Of the evergreen species which are not hardy North, R. crocœa and R. tisclophi are to be recommended for their ornamental bright red fruits. Buckthorns are useful for planting in shrubberies; they like a rather moist soil, especially R. lanceolata, R. alnifolia, R. caroliniana, and R. Frangula, and grow well in shaded or partly shaded situations, but R. cathartica and its allies prefer dry soil. R. cathartica is a valuable hedge plant, though it is now not used so extensively as in the past. The species are propagated by seeds stratified or sown in fall, and by layers. Some, as R. lanceolata, R. fallax, and R. alnifolia, are propagated by cuttings; R. Purshiana, has been successfully raised in England from softwood cuttings put in mild bottom heat under glass about the middle of July. The evergreen species are propagated by cuttings of ripened wood under glass. Rarer kinds are sometimes grafted, those of the Frangula group usually on R. Frangula and the true buckthorns on R. cathartica or allied species.

CC. Foliage deciduous. 10. Alaternus

CC. Foliage evergreen. 11. californica

CC. Foliage deciduous. 12. Purshiana
1. **cathartica**, Linn. Buckthorn. HART’S-TONG. WAYTHORN. RHINEBERG. Fig. 3370. Shrub or small tree, attaining 12 ft., usually thorny: lvs. oval to elliptic or ovate, usually rounded at the base or cordate, obtuse or acute, acuminate, crenulate-serrate, beneath green, glabrous or pubescent, 1 1/4-2 in. long: fls. 2-5-fl.d. clusters, with 4 petals: fr. black, about 1/2 in. across; seed with a furrow usually open only at the base. Enu. W. and N. Asin; often escaped from cult. and naturalized in the U. S. B.B. (ed. 2) 2: 502. Gng. 9: 2. H.W. 3, p. 56.

2. **daurica**, Pall. (Rh. cathartica var. daurica, Maxim.). Fig. 3371. Large, spreading shrub, with stout thorny branches, sometimes a tree, to 30 ft.: branchlets yellowish or grayish brown, lustrous: lvs. slender-stalked, obovate to oblong-oblong, acuminate, crenulate-serrate, beneath green, somewhat coriaceous at maturity, 2-4 in. long: fls. and fr. similar to those of the preceding species, but fr. somewhat larger. Dahuria to Amurland and N. China. G.F. 9: 425 (as R. creata; adopted in Fig. 3371).—Sometimes cult. under the name of R. creata. Var. nipponica, Makino. Lvs. narrow-oblong, bright green beneath, 2-6 in. long and 1-2 in. broad. Japan.

3. **japonica**, Maxim. Spreading shrub with thorny branches, to 10 ft.: branchlets yellowish or grayish brown, lustrous: lvs. slender-stalked, obovate to oblong-obovate, short-acuminate, cuneate at the base, serrulate, sparingly pubescent or glabrous beneath, with 4-5 pairs of veins, 2-3 in. long: fls. in axillary clusters; fr. black, 1/2-1 1/2 in. across; seed usually with closed furrow. Japan. S.I.F. 2: 48.

4. **fálax**, Bois. (R. alpina, Auth., not Linn.). Shrub, to 10 ft., with stout, upright, glabrous and reddish brown branches: lvs. elliptic-oblong to oblong or obovate-oblong, cordate or rounded at the base, abruptly acuminate, crenulate-serrate, with 12-20 pairs of veins, dark green above, pale green and glabrous or nearly so beneath, 3-5 1/4 in. long: fls. in 3-7-fl.d. clusters; petals 4: fr. globose, black, 1/2 in. across or less. Mountains of S. and Cent. Eu.—This and the following species are the handomest of the deciduous-lvd. buckthornas because of the large size of their lvs.

7. **lanceolata**, Pursh. Tall, upright shrub, with puberulous branchlets: lvs. obtuse to lanceolate, to oblong-lanceolate, acuminate or obtuse, finely serrulate, glabrous or somewhat pubescent beneath, 1-3 1/2 in. long: fls. in few-fl.d. clusters, with 4 petals: fr. with 2 nutlets. Pa. to Ala., Texas, and Neb. B.B. (ed. 2) 2: 503.

8. **crocea**, Nutt. RED-BERRY. Evergreen shrub to 3 ft., with rigid often spinescent branches: lvs. orbicular to oblong-obovate, glandular-dentilicate or serrulate, dark green and lustrous above, bronze- or copper-colored and glabrous or slightly pubescent beneath, 1-3 1/2 in. long: fls. in few-fl. clusters, 4-merous, apetalous: fr. bright red, about 1 1/2 in. across, edible. Calif.

9. **iliifólia**, Kellog (R. crocea var. iliifólia, Greene). Evergreen shrub or small tree, to 12, or sometimes to 20 ft., with rather stout scarcely spinescent branchlets: lvs. ovate to orbicular, spinulose-dentate, dark green and lustrous above, often golden beneath, 1 1/2-2 in. long: fls. in short racemes, with 5 petals: fr. bluish black. S. Enu. H.W. 3, p. 59. Var. angustifólia, DC. (R. angustifólia, Hort.), has narrower, oblong-lanceolate lvs. There are also varieties with variegated foliage.

10. **alaténsus**, Linn. Evergreen shrub or small tree, attaining 20 ft., with glabrous branches: lvs. oval or ovate to ovate-lanceolate, acute, serrate or almost entire, glossey and dark green above, pale or yellowish green beneath, glabrous, 1 1/2-2 in. long: fr. in short racemes, with 5 petals: fr. bluish black. B. S. S. 2: 63, fig. 3. Var. tomentella, Brew. & Wats. (R. crocea var. tomentella, Rehd.). This species is superior to the preceding species on account of the more plenteous and somewhat larger bright red berries, also the lvs. are larger and resemble those of Prunus iliicifolia.

12. **Purshiana**, DC. CASCARA SAGRADA. Tall shrub to medium-sized tree, occasionally attaining 40 ft.: young branchlets pubescent or tomentose: lvs. elliptic to ovate-oblong, acute or obtuse, usually dentilicate, with often wavy margin, dark green above, glabrous or pubescent beneath, 1-7 in. long: peduncles longer than petals: fr. globose, changing from red to black, about 1/2 in. across, with 2-3 nutlets. Brit. Col. to Mont., Idaho, and N. Calif. S.S. 2: 62, 63.—Cascara Sagrada bark is extensively collected in Ore. and Wash. for use in drug manufacture.

13. **carolinína**, Walt. INDIAN CHERRY. Shrub or small tree, attaining 50 ft.: branchlets of young branches puberulous: lvs. elliptic to oblong, acute or acuminate, obscurely serrulate or almost entire, lustrous and dark green above, glabrous or nearly so, somewhat leathery at length, 2-6 in. long: peduncles shorter than petals: fr. globose, about 1/2 in. across, bright to black, sweet, with 3 nutlets. N. Y. to Fla., west to Neb. and Texas. S.S. 2: 61. B.B. (ed. 2) 2: 503.
14. *crenata*, Sieb. & Zucc. Shrub, to 10 ft.; young branchlets and young lvs. rusty pubescent; lvs. oblong-ovate to oblong-lanceolate or oblong-oblong, acuminate or long-acuminate, finely crenate-serrulate, pubescent beneath, at least on the veins, with 7–12 pairs of veins, 2–4 in. long; peduncles usually shorter than petioles; fr. subglobose, ½ in. across, changing from red to purplish black. Japan to Cent. China. S.I.P. 2:47.

*RHAPHIDOPHORA* (Greek _for needle-bearing; alluding to needle-like hairs)._Araceae._CLIMBING ARUMS, to be treated like Philodendron and Pothos. Species 60 in Engler, Pflanzenreich, hft. 37 (IV. 238. 1908), of the East Indies, allied to *Pothos*, but distinguished by the presence of odd hairs in the intercellular spaces and by the two-loculed rather than three-loculed ovary. The generic name is sometimes spelled *Rhaphidophora*.

It is not known that any species of *Rhaphidophora* are in the American trade. *R. pertusa*, Schott (*Pothos pertusa*, Roxb. *Scindapsus pertusa*, Schott), has large monstera-like lvs., with long and narrow side lobes and numerous holes in the blade. R.H. 1885, p. 501. *R. decorata*, Schott, is a gigantic climber with large, pubescent lvs., the segments or lfts. oblong-lanceolate-acuminate and strongly nerves; spathe yellowish. B.M. 7282. *R. Peeploa*, Schott, has entire oblong or elliptic-oblong lvs., with roundish or subcordate base; spathe yellowish.

**RHAPHITHAMNUS** (Greek _for needle-bearing._ allying to needle-like hairs)._Araceae._CLIMBING ARUMS, to be treated like Philodendron and Pothos. Species 60 in Engler, Pflanzenreich, hft. 37 (IV. 238. 1908), of the East Indies, allied to *Pothos*, but distinguished by the presence of odd hairs in the intercellular spaces and by the two-loculed rather than three-loculed ovary. The garden plant *Pothos aureus*, sometimes provisionally referred here, is to be sought in *Scindapsus*. The generic name is sometimes spelled *Raphidophora*.

It is not known that any species of *Rhaphidophora* are in the American trade. *R. pertusa*, Schott (*Pothos pertusa*, Roxb. *Scindapsus pertusa*, Schott), has large monstera-like lvs., with long and narrow side lobes and numerous holes in the blade. R.H. 1885, p. 501. *R. decorata*, Schott, is a gigantic climber with large, pubescent lvs., the segments or lfts. oblong-lanceolate-acuminate and strongly nerves; spathe yellowish. B.M. 7282. *R. Peeploa*, Schott, has entire oblong or elliptic-oblong lvs., with roundish or subcordate base; spathe yellowish.
RHAPIS (Greek, needle; alluding to the shape of the leaves or perhaps the awns. tribe Sàbalæce.) Fan palms of very distinct habit, being among the few palms that produce suckers at the base, thereby forming bushy clumps.

Low palms, with leafy densely cespitose reedy st. clothed with remains of the reticulate H.-sheaths: lvs. alternate and terminal, submembranaceous, connate or semiorbicular, irregularly and digitately 3- to many-parted; segms. linear, cuneate, or elliptical truncate, entire, dentate or lobed; nerves 3 to many; transverse veins conspicuous; rachis none; ligule very short, semicircular; petiole slender, biiconvex, smooth or serrulate on the margins; sheath long, loosely fringed on the margin; spadices shorter than the lvs., slender-peduncled: rachis sheathed by deciduous bracts: branches spreading; spathes 2-3, incomplete, membranous: fls. yellow.—About 5 species, natives of China and Japan. This genus is distinguished from its near allies (for a list of which see Licuala) by the fls. being dioecious; corolla 3-toothed; anthers dehiscing extrorsely. The name Rhapis is commonly spelled and pronounced Raphis, but this is incorrect. They can be grown in temperate house with a night temperature of 55-60°. The soil should be good loam 3 parts, leaf-mold 1 part and sand 1 part. Prop. by imported seeds or by the freely produced suckers. Hardy in S. Calif. and S. Fla., and, in fact, the hardest of all the palms with the exception of certain species of Sabal and Chamaerops.

R. cyanocarpus, Miers (Citharæglon cyanodctrum, Hook. & Arn. R. parviflora Miers). Tree, to 20 ft.; young branchlets pubescent; spines slender, ½-1 in. long; lvs. sometimes in 3's, ovate, acute, rounded at the base, entire, glabrous above and glabrous beneath except-basally hairs on the midrib, 1½-3½ in. long; fls. lilac, slender, about 1½ in. long; fr. globose, bright blue, ¼-½ in. across. Chile. B.M. 6849.—A handsome densely leafy shrub, particularly ornamental when studded with its bright blue frs.

RHAPIS hystrix, the blue palmetto or needle palmetto, is the most beautiful and elegant of our native dwarf palms. It is very local in its distribution, being found in rich low soil both in Georgia and Florida, but it is everywhere rather rare. Its most striking characteristics are the long sharp black spines projecting in every direction from the dark fibers which cover the trunk. These spines, which are often a foot long, seem to protect the inflorescence, which before opening resembles a large white egg and which is imbedded among the spines. This palm bears staminate and pistillate flowers on separate plants. The woolly clusters of fruit or seeds are borne on short stems also surrounded by the sharp spines. This palmetto is easily transplanted. The leaves are dark shiny green, relieved by a pale silvery gray on the under surface. It is a very beautiful plant, and, groups of it are striking. The stem is 2 to 3 feet high and the leaves rise to a height of 3 to 4 feet. (H. Nehrling.)

**RAPHIS HUMILIS**

*Fig. 3373. Rhapis humilis.*

**R. parvifolius,** Hort. Tree, 7.4-10 ft. high. Lvs. with 5-7 segms. and terminal, submembranaceous, connate or semiorbicular, irregularly and digitately 3- to many-parted; segms. linear, cuneate, or elliptical truncate, entire, dentate or lobed; nerves 3 to many; transverse veins conspicuous; rachis none; ligule very short, semicircular; petiole slender, biiconvex, smooth or serrulate on the margins; sheath long, loosely fringed on the margin; spadices shorter than the lvs., slender-peduncled: rachis sheathed by deciduous bracts: branches spreading; spathes 2-3, incomplete, membranous: fls. yellow.—About 5 species, natives of China and Japan. This genus is distinguished from its near allies (for a list of which see Licuala) by the fls. being dioecious; corolla 3-toothed; anthers dehiscing extrorsely. The name Rhapis is commonly spelled and pronounced Raphis, but this is incorrect. They can be grown in temperate house with a night temperature of 55-60°. The soil should be good loam 3 parts, leaf-mold 1 part and sand 1 part. Prop. by imported seeds or by the freely produced suckers. Hardy in S. Calif. and S. Fla., and, in fact, the hardest of all the palms with the exception of certain species of Sabal and Chamaerops.

**R. cyanocarpus**, Miers (Citharæglon cyanodctrum, Hook. & Arn. R. parviflora Miers). Tree, to 20 ft.; young branchlets pubescent; spines slender, ½-1 in. long; lvs. sometimes in 3's, ovate, acute, rounded at the base, entire, glabrous above and glabrous beneath except-basally hairs on the midrib, 1½-3½ in. long; fls. lilac, slender, about 1½ in. long; fr. globose, bright blue, ¼-½ in. across. Chile. B.M. 6849.—A handsome densely leafy shrub, particularly ornamental when studded with its bright blue frs.

**RAPHIS Hystrix** (Greek, probably means Rhapis-leaved). *Palmæce.* BLUE PALMETTO. NEEDLE PALM. One species ranging from S. C. to Fla. It is a dwarf fan palm with erect or creeping trunk 2-3 ft. long, and long-stalked nearly round deeply and pressed, bifid, woolly: fls. minute, orange: fr. small, unequally cleft lvs. with about 15 segms.: spadices studded with its bright blue frs. ALFRED REHDER.

**RHAPHIS** (Greek, needle-leaved) is very local in its distribution, being found in rich low soil both in Georgia and Florida, but it is everywhere rather rare. Its most striking characteristics are the long sharp black spines projecting in every direction from the dark fibers which cover the trunk. These spines, which are often a foot long, seem to protect the inflorescence, which before opening resembles a large white egg and which is imbedded among the spines. This palm bears staminate and pistillate flowers on separate plants. The woolly clusters of fruit or seeds are borne on short stems also surrounded by the sharp spines. This palmetto is easily transplanted. The leaves are dark shiny green, relieved by a pale silvery gray on the under surface. It is a very beautiful plant, and, groups of it are striking. The stem is 2 to 3 feet high and the leaves rise to a height of 3 to 4 feet. (H. Nehrling.)

**RHAPIS Hystrix**, Wendl. & Drude (Chamærops hystrix, Fraser). Fig. 3372. St. 2-3 ft., erect or creeping, proliferous, clothed with the fibrous remains of H.-sheaths intermingled with long, erect spines: lvs. 3-4 ft., somewhat glaucous especially beneath, circular in outline, with numerous 2-4-toothed segms.; petiole triangular, rough on the margins; sheaths of oblique fibers interwoven with numerous strong, erect spines; spadix 6-12 in. long, short-peduncled: petals ovate, drupe ¾-1 in. long. S. C. to Fla. I.H. 33:486.

JARED G. SMITH.

**RHAPIS** (Greek, needle; alluding to the shape of the leaves or perhaps the awns of the corolla). *Palmæce.* tribe Sàbalæce. Fan palms of very distinct habit, being among the few palms that produce suckers at the base, thereby forming bushy clumps.

Low palms, with leafy densely cespitose reedy st. clothed with remains of the reticulate H.-sheaths: lvs. alternate and terminal, submembranaceous, connate or semiorbicular, irregularly and digitately 3- to many-parted; segms. linear, cuneate, or elliptical truncate, entire, dentate or lobed; nerves 3 to many; transverse veins conspicuous; rachis none; ligule very short, semicircular; petiole slender, biiconvex, smooth or serrulate on the margins; sheath long, loosely fringed on the margin; spadices shorter than the lvs., slender-peduncled: rachis sheathed by deciduous bracts: branches spreading; spathes 2-3, incomplete, membranous: fls. yellow.—About 5 species, natives of China and Japan. This genus is distinguished from its near allies (for a list of which see Licuala) by the fls. being dioecious; corolla 3-toothed; anthers dehiscing extrorsely. The name Rhapis is commonly spelled and pronounced Raphis, but this is incorrect. They can be grown in temperate house with a night temperature of 55-60°. The soil should be good loam 3 parts, leaf-mold 1 part and sand 1 part. Prop. by imported seeds or by the freely produced suckers. Hardy in S. Calif. and S. Fla., and, in fact, the hardest of all the palms with the exception of certain species of Sabal and Chamaerops.

**R. cyanocarpus**, Miers (Citharæglon cyanodctrum, Hook. & Arn. R. parviflora Miers). Tree, to 20 ft.; young branchlets pubescent; spines slender, ½-1 in. long; lvs. sometimes in 3's, ovate, acute, rounded at the base, entire, glabrous above and glabrous beneath except-basally hairs on the midrib, 1½-3½ in. long; fls. lilac, slender, about 1½ in. long; fr. globose, bright blue, ¼-½ in. across. Chile. B.M. 6849.—A handsome densely leafy shrub, particularly ornamental when studded with its bright blue frs.

ALFRED REHDER.

RHAPIDOPHYLLUM (Greek, probably means cyanocarpus, Miers & Am. LA F.R.0.) MACRÉA. Fig. 2739. Sts. 2-3 ft., erect or creeping, proliferous, clothed with the fibrous remains of H.-sheaths intermingled with long, erect spines: lvs. 3-4 ft., somewhat glaucous especially beneath, circular in outline, with numerous 2-4-toothed segms.; petiole triangular, rough on the margins; sheaths of oblique fibers interwoven with numerous strong, erect spines; spadix 6-12 in. long, short-peduncled: petals ovate, drupe ¾-1 in. long. S. C. to Fla. I.H. 33:486.

JARED G. SMITH.
Aside from the common rhubarb, *Rheum Rhaponticum*, which is grown for the edible leaf-stalks, the species are little known in general cultivation. Few plants are more useful, however, for bold and striking foliage effects; and these effects are heightened by the towering flower-panicles. Most of the species are hardy and easy to grow, but they profit by a liberal winter mulch. Rheums are usually seen to best advantage against a heavy background of foliage or of rock (Fig. 1817, p. 1463). Even the common rhubarb is a useful ornamental subject when well placed. In order to secure large and fine foliage, the soil should be rich and moist. The species are propagated by dividing the root-masses, preferably in spring, leaving as much root as possible with each strong eye or bud.

The dried rhizomes of rhubarb are used medicinally. Several species afford the official product. The larger part of the rhubarb imported from the Orient is probably made from the crown or short stem (not the flower-stem) of *R. officinale*. *R. Rhaponticum* is sometimes grown for its medicinal roots.

**RHEUM** (Linn.)*Rheum Rhabarbarum, Blume. (R. officinale, Linn.)*

*Pterica* (Linn.)*Pterica officinale, Linn.*

*Pterica* (Linn.)*Pterica officinale, Linn.*

*Pterica* (Linn.)*Pterica officinale, Linn.*

*Pterica* (Linn.)*Pterica officinale, Linn.*
inopinatum, Prain. Small perennial of recent introduction; plant seldom more than 2 ft. high, the foliage clustered at the crown, the st. red and nearly leafless: lvs. orbicular-oval, gray-green, blades 6-9 in. long and nearly as broad, more or less blistered, not lobed but somewhat irregularly-marginated, obtuse, the petiole about 6 in. long and red-purple: inf. paniculate, bright red or crimson, produced in succession; fr. highly colored, the nutlets orbicular and 3-winged, nearly 2 in. across.

2375. Rheum officinale, showing the foliage crown before flowering.

Thibet. B.M. 8190. G.C. III. 48:391.—A handsome small species, in condition nearly all summer, with attractive red-stalked and red-nerved foliage.

Folia more or less lobed, the margins of the lvs. or segments usually toothed or notched.

c. Lvs. shallowly or obscurely lobed.

compascum, Linn. St. tall: petioles sulcate, plane above: fl.-blades thickish, broad-ovate, cordate, undulate and obscurely lobed, very obtuse, glabrous and shining above, the margin sharply toothed, the veins very prominent: panicle with drooping branches; achenes large, dark-colored. Siberia to China.

c. Lvs. deeply lobed or evenly divided.

palmarum, Linn. (R. sanguineum, Hort.). St. tall (5-6 ft.) and leafy: petioles subcylindrical, the margin rounded: fl.-blades broad, suborbicular and cordate, 8-9 ribbed, scabrous, deeply palmately lobed; the lobes obovate-oblong or lanceolate, acute, entire, dentate or pinnatifid: panicle leafy, with pubescent branches, the pedicels scarcely longer than the fls.: achenes oblong-oval and subcordate. N. E. Asia. Var. tanguticum, Regel (R. tanguticum, Hort.). Lvs. more elongated and not so deeply lobed. G.Z. 20, p. 17. Var. atrissinatum, Hort. (var. floribudum, Hort.), has a showy dark red panicle. Gn. 60, p. 10.

hybridum, Murr. Petiole long, canaliculate above and sulcate beneath: fl.-blades ovate, 3-5-ribbed, the base cuneate or scarcely cordate, incise-dentate, puberulent beneath: panicle lax, leafy: achenes large, 2 in. long, oblong-ovate, narrow-winged, blood-red, showy. Asia Minor to Persia. B.M. 7591. “Rheus” or “Ribes” is its Arabic name.—R. sanguineum, Hort. Dwarf: IVB. thick, or orbicular or broadly ovate: fls. white, in a dense spike rising about 2 ft. W. Himalayas.

RHEUM

(Rheum officinale, Baill. Fig. 3375. Robust, with a short, branching st. or crown 4-10 in. high: lvs. very large, 1-2 ft. across, round-oval, more or less pointed or acuminate, hairy, 3-7 lobed, the lobes extending one-third or one-half the depth of the blade and sharply angled-notched: fl.-sta. 3-10 ft. long, much branched, bearing numerous greenish fls. that give a feathery effect to the panicle: achenes red, winged. Thibet and W. China, on high taluslands. B.M. 6135. R.H. 1874, p. 95. Gn. 36, p. 243; 48, pp. 199, 208; 59, p. 282. G.C. III. 55:328. G. 9:341; 18:428; 23, 452, 453.—Probably the best species of the genus for general cultivation for ornament, making a striking foliage plant. It is from the short thin branching st. or caudex of this plant that most of the true official rhubarb is derived. Although known to the Chinese for centuries and the product long imported into Europe, the plant was not described botanically until 1872.

R. acuminatus, Hook f. & Thom. Dwarf plant (seldom exceeding 3 ft.), like a small form of R. emodi, with acuminate lvs., but fls. considerably larger, said to be an attractive plant in cult. but to die after flowering, st. and inf. deep red-purple. B.M. 4877. G. 36:659.—R. amurense, Hort., is a garden hybrid, of German origin, between R. emodi and R. palmatum. Himalayas. R.R. 1876, p. 266. L.H. 22:209. G.C. II. 15:793. G. 20, p. 104. A remarkable plant.—R. Rhabdanthum, Linn. 3-6 ft.; lvs. 1 ft. across, cordate to reniform, the margins crisp or undulate, the blade pubescent or bladed; fls. green, drooping: fr. about 1 in. long, oblong-ovate, narrow-winged, blood-red, showy. Asia Minor to Persia. B.M. 7591. “Rheus” or “Ribes” is its Arabic name.—R. sanguineum, Hort. Dwarf: IVB. thick, or orbicular or broadly ovate: fls. white, in a dense spike rising about 2 ft. W. Himalayas.

L. H. B.

RHEXIA

(Greek, rupture, referring to its supposed properties of healing).

Melastomaceae. MEADOW BEAVER. Low perennial often brightly herbs suitable for border and wild-garden planting.

Leaves opposite, sessile or short-petioled: fls. terminal, solitary or cymose; calyx-tube urn-shaped, adherent to the ovary below, and continued above it, persistent, 4-cleft at the apex: petals 4, oblique, falling early; stamens 8: caps. 4-celled, with 4- to many-seeded placenta.—About 12 species. N. Amer.

Rhexia virginica is found wild in company with side-saddle plants (Sarracenia purpurea) and cranberries in the low meadows of Massachusetts. It is what would be called a bog-plant. It is a pretty, low-growing, tuberous-rooted plant blooming in summer and chiefly interesting as being one of few species of a genus belonging to a family almost wholly composed of shrubby plants from tropical countries, such as Centradenia, Pietersonia, and Medinella. It increases by means of tubers and seeds, and under suitable conditions soon makes large clumps. Tubers potted in the autumn and kept in a coldframe flower nicely in springtime. (T.D. Hatfield.)

A. St. cylindical.

marilana, Linn. A slender erect usually simple-stemmed plant with red-dish purple fls. about 1 in. across, in loose cymes: lvs. short-petioled, oblone to linear-oblong, 1-1½ in. long, 2-5 lines wide, 3-nerved; anthers minutely spurred at the back. June-Sept. Pine barrens, N. J. to Fl., west to Ky. B.B. 2: 474.—Grows in drier places than R. virginica. It sometimes has white fls. and there is also a linear-lvd. form.

3376. Rhexia virginica. (X½)
RHIPSALIS 2029

AA. Bracts on ovary with hairs and bristles in their axils.

1. pilocarpa, L.f gland. Branches terete, the axes bearing 10-15 white bristles: fls. wheel-shaped, 1 in. broad. Brazil.

BB. Bracts imbedded in the branch.

BB. Bracts on ovary naked.

C. The branches of 2 kinds.

2. squidons, Schum. (Lepismium commutus, Pfeiff.). Somewhat branched, reaching a length of 2 ft.; branches very unequal in length, 2-1 in. thick, triangular, the angles winged: fls. 1-2, from the deep areoles, 5 lines long, greenish without, yellowish within. Brazil, Argentina. B.M. 3783.

BB. Bracts imbedded in the branch.

BB. Bracts on ovary naked.

C. Branches terete, slender.

3. myosurus, Schum. (Lepismium myosurus, Pfeiff.). Somewhat branched, a yard long; branches 3-6 lines thick, 3-4-angled, the angles not winged, the terminal branchlets generally acuminate, often tipped by a pencil of bristles: fls. solitary in the deep areoles, 4-5 lines long, rosy white: fr. red. Brazil. B.M. 3755.

CC. Edges of joints not winged.

BB. Bracts on ovary naked.

C. The branches of 2 kinds.

2. squidons, Schum. (Lepismium commutus, Pfeiff.). Somewhat branched, reaching a length of 2 ft.; branches very unequal in length, 2-1 in. thick, triangular, the angles winged: fls. 1-2, from the deep areoles, 5 lines long, greenish without, yellowish within. Brazil, Argentina. B.M. 3783.

BB. Bracts imbedded in the branch.

BB. Bracts on ovary naked.

C. Branches terete, slender.

3. myosurus, Schum. (Lepismium myosurus, Pfeiff.). Somewhat branched, a yard long; branches 3-6 lines thick, 3-4-angled, the angles not winged, the terminal branchlets generally acuminate, often tipped by a pencil of bristles: fls. solitary in the deep areoles, 4-5 lines long, rosy white: fr. red. Brazil. B.M. 3755.

CC. Edges of joints not winged.

AA. Bracts on ovary with hairs and bristles in their axils.

1. pilocarpa, L.f gland. Branches terete, the axes bearing 10-15 white bristles: fls. wheel-shaped, 1 in. broad. Brazil.

BB. Bracts imbedded in the branch.

BB. Bracts on ovary naked.

C. The branches of 2 kinds.
2-4 short bristles, which on the end branches project as a little brush: fis. near the tops of the short branches, flat, \( \frac{2}{3} \) in. diam., with 12 white lvs. with yellowish midstripes, berry white. Uruguay and Argentina. B.M. 4030.

5. mesembrianthemoïdes, Haw. (Hartkea mesembrianthemoides, Lem.). Upright, the ends drooping, richly branched: long branches 4-8 in. long, 1 line diam.; flat branches 3-5 lines long, not more than 2 lines diam., spirally attached, thickly crowned: areoles sparsely woolly and bristly, the blooming areoles much more copiously so: fis. greenish outside, the sides: fis. \( \frac{1}{4} \) in. long, white. Brazil.

6. trigona, Pfeiff. Richly branching, pendulous, sometimes 10 ft. long; branches rarely 2 ft. long, 1-1\( \frac{1}{2} \) lines diam., pale green; ultimate branches spirally attached: areoles with sparse woolly hairs and frequently 1-2 minute bristles: fis. lateral on the short branches, purple-red: fis. about 8 lines long, yellow with reddish tips. Brazil. B.M. 2920 (as Cactus alatus).

7. grandiflora, Haw. (R. funiflora, Salm-Dyck). Branching, cylindrical, rather stout, the branches reaching a height of 3 ft., with a diam. of more than \( \frac{2}{3} \) in.; ultimate branches short, often verticillate: areoles depressed, bordered by a red line, sometimes in old branches a bristle: fis. wheel-shaped, lateral on the branches, nearly 1 in. diam. B.M. 2740.

8. Cassytha, Gaertn. Richly branching, pendulous, sometimes 10 ft. long; branches rarely 2 ft. long, 1-1\( \frac{1}{2} \) lines diam., pale green; ultimate branches spirally attached: areoles with sparse woolly hairs and frequently 1-2 minute bristles: fis. lateral on the terminal joints, 2-3 lines diam.: berry like that of the mistletoe, 1-2 lines diam. Widely dispersed in Cent. and S. Amer., W. Indies, Mex., Mauritius, Ceylon, and Afr. B.M. 3080.

9. virgata, Web. Richly branching, pendulous, becoming a yard long; terminal branches hardly more than a line thick, spirally attached: areoles bearing sparse woolly hairs, with an occasional bristle: fis. lateral, 3-4 lines diam.: berry only 1\( \frac{1}{2} \) lines diam. Brazil. —Very much like the preceding.

cc. Branches not terete.

d. The branches narrow, angled.

10. trigema, Pfeiff. Richly branched, becoming a yard long: branches \( \frac{1}{2} \) to nearly 1 in. diam., 3-angled: areoles sparsely woolly and bristly, the blooming areoles much more copiously so: fis. greenish outside, white within, 4 or 5 lines long. Brazil.

11. paradoxa, Salm-Dyck. Sparsely branched, 1-2 ft. long; branches 1-2 in. long and \( \frac{1}{2} \)-1 in. diam., twisted at the joints, so that the angles alternate with the aërs: fis. \( \frac{2}{3} \) in. long, white. Brazil.

12. pentaptera, Pfeiff. Richly branched, 1-2 ft. long, 4-5 lines diam.: branches 2-5 in. long, 5-6-angled or almost winged: areoles in creases of the angles with scanty wool and an occasional bristle: fis. greenish white, 3-4 lines long: fr. white, bright rose-red above, crowned by the withered fl. S. Brazil, Uruguay, Argentina.

13. rosea, Lagerheim. Shrubby, more or less erect, usually 10 in. high: branches clustered, often hanging, 3-4-angled: fis. rare, large, 1\( \frac{1}{4} \) in. broad, rose-colored, fragrant. Brazil. 

dd. The branches usually flat or 3-angled, always broad.

14. rhombes, Pfeiff. (R. Swartziána, Pfeiff.). Branching, reaching a yard in length: joints green, if.-like, crenate-oblong or rhombic, 1-5 in. long, \( \frac{1}{2} \)-2 in. broad: fis. yellow, about 5 lines long. Brazil.

16. Houletiana, Lem. (R. Houletii, Lem.). Richly branched, becoming 3 ft. or more long, 1-1\( \frac{1}{4} \) in. broad, often tapering to the round midrib for a considerable distance, then becoming again broad and l.-like: fis. 8-9 lines long, yellowish white to yellow: berry red. Brazil. B.M. 4089.

J. N. Rosz.

RHIZÓPHORA (Greek, root and bearing, referring to the fact that the seeds germinate even while attached to the plant if they touch the ground). Rhizophoraceae. Trees, with thick terete scarred branches, sometimes planted to hold seashores: lvs. opposite, petioled, thick, leathery, ovate or elliptic, entire, glabrous: podunices axillary, di- or trichotomously branched, few-flowered, rather large, leathery, sessile or pedicelled: calyx-limb 4-parted; petals 4; stamens 8-12; ovary semi-inferior, 2-celled: fr. leathery, ovoid or obconical, 1-celled, 1-seeded.—About 3 species, seashores of the tropics. R. Mangle, Linn. Shrub or tree reaching a height of 30 ft.: lvs. 2-6 in. long, leathery, elliptic or elliptic-obo­vate, obtuse: peduncles 2-3-fid.; fis. pale yellow; sepals lanceolate; petals linear, or nearly so, leathery, clasp at tip. Coast of Fl. and the tropics. It forms impenetrable thickets.

RHODÁNTHE: Helipterum.

RHODAZÁLEA: a name given in France to a hybrid (R. Croezii, Hort.) between a garden rhododendron and Azalea mollis (Rhododendron sinense). Another name for this hybrid is Azaleodendron Crouzii, Hort.

RHÓDEA: Rhododendron.

RHODOCHITON (Greek, red cloak; alluding to the large rosy red calyx). Scrophulariaceae. A free-flowing graceful vine with lvs. cordate, acuminate, sparsely and acutely dentate: fis. solitary, pendulous, axillary, long-peduncled; calyx conspicuous, large, membranous, broad bell-shaped, 5-cleft; corolla-tube cylindrical, the throat not personate, 5-lobed; lobes oblong, nearly equal: caps. dehiscent by irregular perforations.—One species, Mex.

F. W. Barclay.

RHODODÉNDRON (Greek, rhodon and dendron, rose-tree; the Rhododendron of the ancient writers is Nerium). Ericaceae. Including Azalea which most botanists consider inseparable from Rhododendron, but horticulturists may be inclined to retain Azalea for the deciduous species and to use the Azalea names given in parentheses. Highly ornamental woody plants, chiefly deciduous species and to use the Azalea names given in parentheses. Highly ornamental woody plants, chiefly deciduous species. In Europe, there are several species whose flowers and many species also for their handsome foliage.

Evergreen or deciduous shrubs, rarely trees: lvs. alternate, short-petioled, entire: fis. pedicelled, in terminal umbel-like racemes, rarely lateral, in 1- to few-fid. clusters; calyx 5-parted, often very small; corolla rotate, campanulate or funnel-shaped, sometimes tubular, with 5-, sometimes 6-10-lobed limb; stamens 5-10, sometimes more; petals opening with pores at the apex; ovary 5-10-loculed; style slender with capitate stigma; caps. separating into 5-10 valves containing numerous seeds.

Another species occasionally seen in European collections but not offered in American trade.
minute seeds.—About 350 species are known, distributed through the colder and temperate regions of the northern hemisphere; in trop. Asia they occur in the mountains and extend as far south as New Guinea and Australia, the greatest segregation being in Cent. and W. China and the Himalayas; several species closely allied to those of the Malayan Archipelago are found in the Philippine Isls. but are not yet intro.; 16 species occur in N. Amer. The rhododendrons possess but few economic properties. The hardy close-grained species as R. cinnabarinum, R. glaucum, R. citatum, R. Fortunae, R. lepidotum, R. Collettianum, and the Yunnan species, as R. yunnanense, R. racemosum, R. arboreum, R. ponticum, are probably hardy; also R. arboreum, R. barbatum, R. Falconeri, R. Keysii, R. triflorum, and R. Wrightii in very sheltered positions. Species like R. Dalhousie, R. Edgeworthia, R. Griffithianum, R. farnosum, R. Mandarin, R. Nuttallii, and R. pendulum stand only a few degrees of frost. The Javanese species, as R. javanicum, R. jasminiformum, R. Brookeanum and R. Lobbi grow and bloom continually and stand no frost at all.

Variation in height.—Most of the species are shrubby; a few only, and these mostly Himalayan species, grow into small or medium-sized trees, attaining 60 feet in the case of R. barbatum, 40 feet in R. grande and R. arboreum, 30 feet in R. Falconeri and R. maximum. A number of northern and alpine species always remain dwarf, as R. ferrugineum, R. hirsutum, R. lapponicum, R. virgatum, R. lepidotum, R. racemosum, and others. A few Himalayan and Chinese species and most of the Japanese species are often epiphytal and grow on branches of large trees like orchids; e.g., R. Dalhousie, R. pendulum, R. Nuttallii, R. moupinense.

Hybrid rhododendrons.—Many hybrids have been raised and they are now more extensively cultivated than the original species. The first hybrid was probably the one raised from R. ponticum, fertilized by a hardy azalea, probably A. nudiflorum; it originated about 1800, in the nursery of Thompson, at Lambton, near London, and was first described and figured as R. ponticum var. deciduum (Andrews, Bot. Rep. 6:379). Many hybrids of similar origin were afterward raised for which the name Azaleoderinum has been propounded by Rodigas. The first hybrid between true rhododendrons was probably a cross between R. catawbiense and R. ponticum, but it seems not to have attracted much attention. It was by hybridizing the product of this cross with the Himalayan R. arboreum introduced about 1820 that the first plant was raised which became the forerunner of a countless number of beautiful hybrids. From the appearance of this cross, obtained about 1820, at Highclere, in England, and therefore called R. altaclarensis, the era of rhododendron hybrids is believed to be dated. Figs. 3378 and 3379 are common hybrid forms. A second era in the history of the rhododendron may be dated from the introduction of a large number of the beautiful Skimm rhododendrons about 1850. Raising them species like R. Griffithianum which entered into the parentage of many of the most striking tender hybrids, and from the introduction of the Javanese species shortly afterward. A third era will perhaps be trace from the recent introduction of the Chinese rhododendrons.

Their place in ornamental planting.—Rhododendrons are equally effective and desirable as single specimens on the lawn as when massed in large groups, and are especially showy when backed by the dark green foliage of conifers, which at the same time afford a most advantageous shelter. The dwarf species, which are mostly small-leaved and flower at a different time, should not be grouped with the large-leaved ones, as they do not harmonize with them; however, they are exceedingly charming plants for rockeries or in groups with other smaller evergreens. It is certainly true that the rhododendrons have not yet received the attention they deserve. They are still far from being as popular as they are in England. The beautiful Himalayan species and their numerous hybrids are still almost unknown in this country, although without doubt they could be grown as well outdoors in the Middle and South Atlantic states as they are in England. If the right hybrids were chosen. Formerly it was considered impossible to grow the beautiful hardy hybrids in the New England wood of the arborecent species is used for fuel; also for construction and for turnery work; the lvs. of some species are used medicinally; those of R. arboreum and other species are believed to be poisonous to cattle. In India the lvs. of various species are sometimes made into a subacid jelly. The honey obtained from the lvs. is believed to be poisonous.

The rhododendrons belong to our most ornamental and most beautiful flowering shrubs and are often completely covered with their showy trusses of brilliantly and variously colored flowers and the evergreen species are attractive throughout the whole year with their handsome usually large foliage. They grow best in a peaty or porous loamy soil, which does not contain lime and always retains a sufficient amount of moisture; they like as a rule half-shaded positions. In regard to their culture and particular ornamental qualities, they may be divided into three horticultural groups: Evergreen rhododendrons, hardy deciduous azaleas, and Indian azaleas.

Evergreen rhododendrons.

Here belong the largest number of species comprising the two sections Lepidophorodendron and Leiorhododendron. Although most of the species are hardy only in warm temperate regions, there are many which are hardy at least as far north as Massachusetts. They are R. maximum, R. catawbiense, R. caucasicum, R. brachycarpum, R. Metternichii, R. Smirnowii, R. mucronatum, R. dalhuricum, R. micranthum, R. lapponicum, R. ferrugineum, R. hirsutum, R. Kotaki, R. carolinianum, R. minus, and probably also R. chrysanthenum, R. Przewalskii, R. campanulatum, R. Californicum, R. Ungernii, and most of the small-leaved Chinese species. Somewhat more tender are R. ponticum, R. nivum, R. Hodgsonii, R. Thomsonii, R. Anthopogon and many of the recently introduced Chinese species, as R. disolor, R. oreodoxa, R. decorum. South of Philadelphia such species as R. cinnabarinum, R. glaucum, R. citatum, R. Fortunae, R. lepidotum, R. Collettianum, and the Yunnan species, as R. yunnanense, R. racemosum, are probably hardy; also R. arboreum, R. barbatum, R. Falconeri, R. Keysii, R. triflorum, and R. Wrightii in very sheltered positions. Species like R. Dalhousie, R. Edgeworthia, R. Griffithianum, R. farnosum, R. Mandarin, R. Nuttallii, and R. pendulum stand only a few degrees of frost. The Javanese species, as R. javanicum, R. jasminiformum, R. Brookeanum and R. Lobbi grow and bloom continually and stand no frost at all.

Variation in height.—Most of the species are shrubby; a few only, and these mostly Himalayan species, grow into small or medium-sized trees, attaining 60 feet in the case of R. barbatum, 40 feet in R. grande and R. arboreum, 30 feet in R. Falconeri and R. maximum. A number of northern and alpine species always remain dwarf, as R. ferrugineum, R. hirsutum, R. lapponicum, R. virgatum, R. lepidotum, R. racemosum, and others. A few Himalayan and Chinese species and most of the Japanese species are often epiphytal and grow on branches of large trees like orchids; e.g., R. Dalhousie, R. pendulum, R. Nuttallii, R. moupinense.

Hybrid rhododendrons.—Many hybrids have been raised and they are now more extensively cultivated than the original species. The first hybrid was probably the one raised from R. ponticum, fertilized by a hardy azalea, probably A. nudiflorum; it originated about 1800, in the nursery of Thompson, at Lambton, near London, and was first described and figured as R. ponticum var. deciduum (Andrews, Bot. Rep. 6:379). Many hybrids of similar origin were afterward raised for which the name Azaleoderinum has been propounded by Rodigas. The first hybrid between true rhododendrons was probably a cross between R. catawbiense and R. ponticum, but it seems not to have attracted much attention. It was by hybridizing the product of this cross with the Himalayan R. arboreum introduced about 1820 that the first plant was raised which became the forerunner of a countless number of beautiful hybrids. From the appearance of this cross, obtained about 1820, at Highclere, in England, and therefore called R. altaclarensis, the era of rhododendron hybrids is believed to be dated. Figs. 3378 and 3379 are common hybrid forms. A second era in the history of the rhododendron may be dated from the introduction of a large number of the beautiful Skimm rhododendrons about 1850. Raising them species like R. Griffithianum which entered into the parentage of many of the most striking tender hybrids, and from the introduction of the Javanese species shortly afterward. A third era will perhaps be trace from the recent introduction of the Chinese rhododendrons.

Their place in ornamental planting.—Rhododendrons are equally effective and desirable as single specimens on the lawn as when massed in large groups, and are especially showy when backed by the dark green foliage of conifers, which at the same time afford a most advantageous shelter. The dwarf species, which are mostly small-leaved and flower at a different time, should not be grouped with the large-leaved ones, as they do not harmonize with them; however, they are exceedingly charming plants for rockeries or in groups with other smaller evergreens. It is certainly true that the rhododendrons have not yet received the attention they deserve. They are still far from being as popular as they are in England. The beautiful Himalayan species and their numerous hybrids are still almost unknown in this country, although without doubt they could be grown as well outdoors in the Middle and South Atlantic states as they are in England. If the right hybrids were chosen. Formerly it was considered impossible to grow the beautiful hardy hybrids in the New England
states, and it was first shown by the splendid collections of H. H. Hunnewell at Wellesley, Massachusetts (see A.F. 13:24-81 and Gn. 5:375-7), that, even in a trying climate, they can be grown to perfection if the proper situations are found and the right way of cultivation is followed.

Outdoor cultivation.—The selection of a suitable situation is of foremost importance. If possible the bed should be sheltered against drying winds and the burning sun by tall conifers, but the shelter should be always light and natural, as too much shelter by dense hedges or walls close to the plants is worse than no shelter at all. Any open well-drained soil which does not contain lime or heavy clay and has a moist and fresh subsoil will prove satisfactory. Where limestone or heavy clay prevails, beds must be specially prepared and filled with suitable soil. They should be at least 2 to 3 feet deep, or deeper when the subsoil is not porous, and in this case the bottom should be filled in about 1 to 2 feet high with gravel or broken stones for drainage. A mixture of leaf-mold or peat and sandy loam will make a suitable soil. In dry spells during the summer watering is necessary if the subsoil is not very moist; it is most essential that the soil never becomes dry. In autumn the ground should be covered with leaves, pine needles, hay, or other material to protect from frost. This mulch should be allowed to remain during the summer, especially when the plants are not large enough to shade the ground. An occasional top-dressing of well-decayed stable- or cow-manure will prove of much advantage. The ground should never be disturbed, as the roots are very near the surface. After flowering, the young seed-vessels should be removed. The rhododendrons are easily transplanted either in spring or in fall, especially if they grow in peat or turfy loam, and if a good ball of earth can be preserved in moving. They should be planted firmly, especially in porous, peaty soil, and thoroughly watered after planting. If they are carefully handled they are not much affected by transplanting, and tender kinds may be dug in fall, heeled-in in a frost-proof pit, and planted out again in spring. Potted and well-budded plants transplanted in January into a temperature not exceeding 60° will develop in about six to eight weeks into very attractive and showy specimens for decoration.

Hardy varieties.—The following varieties have proved hardy in the vicinity of Boston and may be recommended for planting in similar climates and for experimental trial farther north. They are mostly hybrids of *R. catawbiense* with *R. maximum*, *R. ponticum*, *R. caucasicum* and with some infusion of *R. arboreum* and perhaps a few other species. As in most of them the parentage of *R. catawbiense* is the most predominant, they are all usually called "catawbiense hybrids." Choice kinds are (those marked with an asterisk have proved the hardiest): *Album elegans*, blush, changing to white; *Album grandiflorum*, blush, changing to white, flowers larger, less spotted; *Alexander Dancer*, bright rose, paler in center; *Astromaenum*, rich blue; *August Van Geert*, bright carmine, spotted dark purple; *Bacchus*, crimson, large flowers; *Bicolor*, purplish pink, spotted; *Blandianum*, rosy crimson (H.F. 1859:153); *Mrs. C. S. Sargent*, deep crimson; *Charles Dickens*, dark red, spotted brown, one of the most striking red ones; *Cerulescens*, pale lilac; *Coriaceum*, white, spotted yellow, dwarf and free-blooming; *Crown Prince*, carmine, spotted greenish yellow; *Deliciosissimum*, blushed pink, changing to almost white, late (Gn. 63, p. 415); *Edward S. Rand*, rich scarlet; *Everestianum*, rosy lilac with crisped edges, excellent habit and very free-flowering (Gn. 20:105); *F. L. Ames*, white center, edged pink; *F. L. Olmsted*, pink; *Giganteum*, bright rose, large clusters; *Girlysanum*, white, suffused with pink (G.M. 44:355; 48:365); *Gomer Waterer*, blush-pink; *Grandiflorum*, clear rose; *Gordonia*, deep pink; *Hannibal*, rosy carmine; *Hortensia Sargent*, pink; *Henry W. Sargent*, crimson, large clusters; *H. H. Hunnewell*, rich crimson; *John Waterer*, dark crimson; *J. D. Godman*, carmine, distinctly spotted; *Kedron*, rich crimson; *King of Purples*, purple, spotted dark brown; *Lady Armstrong*, rose-red, paler in center, distinctly spotted; *Lady Clermont*, rosy scarlet; *Lady Frances Crossley*, salmon-pink; *Lady Gray Egerton*, delicate lilac, spotted greenish brown; *Lee's Purple*, purple; *Marie Carvalho*, deep rose, changing to pure white; *Melon*, rich blood; *Mrs. C. S. Sargent*, similar to Everestianum, but pink; *Mrs. Milner*, rich crimson; *Norma*, pink; *Old Port*, plum-color; *Princess Mary of Cambridge*, white with purple margin; *Purpureum crisimum*, lilac-purple, spotted greenish; *Purpureum grandiflorum*, purple, large clusters; *R. S. Field*, scarlet; *Ralph Sanders*, rich purplish crimson; *Rosa mundi*, white slightly flushed with yellow spots, dwarf (Gn. 63, p. 368); *Roseum elegans*, rosy lilac, dwarf, rose, *Seyton*, deep maroon, large clusters; *Wellsianum*, blushed, changing to white.

For greenhouse culture, the most successful way, especially with the taller-growing species, like *R. arboreum*, *R. Griffithianum*, *R. barbatum*, and *Purpurascens*, is to plant them out in a porous peaty soil provided with good drainage. If grown in pots, the sandy compost of leaf-soil and peat, with an addition of some fibrous loam, will suit them. The pots, which should never be too large, must be well drained and the plants freely watered during the summer, while during the winter water must be carefully applied. The Himalayan species and their hybrids will do well in a cool greenhouse, where the temperature is kept a few degrees above freezing-point during the winter. The Javanese species and hybrids, however, on account of their continual growing and blooming, require a warmer greenhouse and must have a minimum temperature of 50° during the winter. They like a moist atmosphere and showy specimens for decoration. If kept in good greenhouse and have a brilliant color of their flowers. A large number of beautiful hybrids have been raised; the following are a
small selection of them: Balsamin<e>florum, with double pink flowers (Gt. 37, p. 265. G.C.II.18:239; III. 12:769. J.H. III. 43:151. G.Z. 27:241); Balsamic<e>florum album, with double white flowers (Gw. 5:373); Balsamin<e>florum aureum, with double yellow flowers; Bredel, brilliant scarlet; Corinna, old rose (G. 41:845); Diadem, orange-scarlet; Duchess of Connaught, vermillion-red; Duchess of Edinburgh, scarlet with orange-crimson (F.M. 1874:115); Eos, scarlet-carmine (G.C.III. 19:327); Equisetum, lichens light fawn-yellow flowers (G. 56:62); Fatsia, satiny rose; Jasmine<e>florum carminatum, deep crimson (G. 41:328); Little Beauty, flowers small, but bright carmine-scarlet (G. 56:242); Lord Wolseley, bright orange-yellow, tinted with rose at the margins; Luteo-roseum, flowers satiny rose, suffused with white, center light yellow (G. 33: 313); Maiden's Blush, blush, with yellowish eye (Gn. 16:394); Princess Alexandrina, white, faintly blushed; Princess Frederika, yellow, faintly edged rose; Princess Royal, pink; Princess Mary, bright pink (Gn. 42:194); Taylori, bright pink, with white tube (F. M. 1877:242); Triumphans, crimson-scarlet.

Propagation.—All rhododendrons are easily propagated by seeds, which are very small and are sown in sandy pots or boxes well drained and filled with sandy peat. Pots should be well watered previous to sowing. The seeds should be covered only a very little with fine sand or finely cut sphagnum, or merely pressed in and not covered at all. To prevent drying, a glass plate may be placed over the pan or some moss may be spread over the surface; this, however, must be taken off as soon as the seeds begin to germinate. The seeds also germinate very readily if sown on fresh sphagnum, but in this case they must be pricked off as soon as they can be handled. In any case, it is of advantage to prick off the young seedlings as soon as possible, but if they are not sown too thickly they may remain in the seed-boxes until the following spring. The seedlings of hardy rhododendrons should be placed in coolframes and gradually hardened off; those of greenhouse species kept under glass. Rhododendrons are also sometimes increased under glass by cuttings of half-ripe wood taken with a heel, and if gentle bottom heat can be given after callusing it will be of advantage. They root, however, but slowly, except those of the Javanese kinds, which are mostly propagated in this way, since they grow very readily from cuttings. Layering is sometimes practised, especially with the dwarf and small-leaved species, but the layers usually cannot be separated until the second year. For the propagation of the numerous varieties and hybrids of hardy and half-hardy rhododendrons grafting is most extensively employed. R. catawbiense or seedlings of any of its hardy hybrids may be used as stock; R. maximus is also probably as good. In English and Belgian nurseries R. ponticum, which is inferior in hardness, is mostly employed as a stock, but this often proves fatal if the grafted plants are transferred to colder climates. R. arboreum may be used for strong-growing varieties intended for cultivation in the greenhouse or South. Veneer or side-grafting is mostly practised, and sometimes cleft- and saddle-grafting (see G.C. III. 24:425 and Figs. 3380, 3381). The leaves should be removed only partly and the stock not headed back until the following year. The grafting is usually done late in summer or early in spring in the greenhouse on potted stock without using grafting-wax, and the grafted plants kept shaded until the graft has been completed. If large quantities are to be handled the plants are sometimes not potted, but taken with a sufficient ball of earth, packed close together and covered with moss. Covered with moss to stop the atmosphere is also of much advantage if the plants are potted.

Other experience with the evergreen rhododendrons. (B. M. Watson.)—Rhododendrons, in this article, mean more particularly R. maximum and the hybrid varieties of R. catawbiense; in the main, however, the directions for the various operations apply to the azalea family.

Rhododendrons as a class are increased by seeds, layers, clefts, and grafts, and occasionally by cuttings. Seeds should be sown under glass, between January 1 and March 15, in soil one-half peat and one-half pure fine sand, with good drainage. The seeds are small and require no covering, the usual watering after sowing being quite sufficient. A thin layer of sphagnum over the surface of the seed-pan is good protection from the sun and keeps the soil evenly moist; it should be removed when germination begins. Seeds may also be sown on sphagnum, a thin layer being compactly spread above the seed-soil and drainage, and an even surface being secured by clipping. Seed-pan or flats of convenient size are used and they should be plunged in sphagnum still further to insure even moisture; the temperature of the house should be 45° to 50° F. Seedlings are prone to damp-off and should be pricked off into fresh soil as soon as they are big enough to handle; wooden pincers, made from a barrel hoop, are handy for this work. They are slow growers, and must be tended carefully. Keep under glass, well shaded until the weather is settled. Frames with lath screens make good summer quarters. Winter in pits and plant out in frames in peaty soil when large enough. Never let them suffer from dryness. It has been suggested that the seed of R. maximum might be planted on living moss under high-branched trees in swamps where the water does not collect in winter. (See Jackson Dawson on the "Propagation of Trees and Shrubs from Seeds," in Transactions of the Massachusetts Horticultural Society, 1885, part I, page 145.) Layers probably make the best plants, and in the best English nurseries layering is the common method of propagation. In the United States layering in spring is preferable, but abroad it is practised in both spring and autumn. It is a slow process, but desirable for the hardy hybrids of R. catawbiense. Roots form on wood of almost any age; when removed the layers should be treated as rooted cuttings and carefully grafted in well-drained soil where water and shade are easily furnished. See Layering. See, also, G.F. 6:63 (1868) for an interesting account of layering large plants by burying them to the top.—Grafting is the common method of propagation, and is employed almost universally in continental nurseries. R. ponticum is the usual stock, a free grower and readily obtained from seeds. Attempts have been made to use R. maximum in American nurseries, because of the tenderness of R. ponticum, but no great progress has been made. It is asserted that the rate of growth is somewhat slower than that of the hybrids; this seems hardly possible, and it is to be hoped that further experiments will be made. R. ponticum should
be established in pots in spring and grafted under glass in autumn and early winter, using the veneer-graft (see Grafting, page 1382, Vol. III). Graft as near the root as possible and plant the worked parts below the surface when planting in the nursery or permanently. With these precautions, and an extra covering of leaves until the plant is established on its own roots, the defect of tenderness in this stock can be overcome. Nurse carefully the young grafted plants in frames until of sufficient size to be planted in the nursery rows. Figs. 3380 and 3381 illustrate two common methods of grafting rhododendrons and other woody plants. The details of the unions are shown in Fig. 3380, and the completed work in Fig. 3381. Statements are made that cuttings of half-ripened wood will strike, but it is not likely that this will ever prove a practical method of propagating *R. maximum* or the *R. catawbiense* hybrids; it might be worth while to experiment with wood grown under glass, particularly with some of the smaller-leaved evergreen kinds.

As to cultivation, the point on which successful American growers of rhododendrons now insist is that the water-supply shall be sufficient. (See H. H. Hunnewell, *G.F.* 3:201, 1890.) To effect this: (1) make the soil deep and fine, using materials like peat, leaf-mold, well-rotted manure and yellow loam, all of which are retentive of moisture; (2) plant in masses, at any rate while young, so that they may protect each other and prevent evaporation; (3) give the bed a northern exposure or a situation where the force of the midday sun is broken; (4) do not plant under or near trees like elm, oak, or maple, which make undue inroads on the natural water-supply, nor so near buildings that the border is sheltered from rain or overdrained by cellar walls; (5) mulch with leaves summer and winter, protect from wind and sun with evergreen boughs in winter and in summer give heavy watering whenever the weather is excessively hot or dry.

The planting-bed should be prepared by excavating to the desired dimensions and at least 3 feet deep. The poor material should be discarded, but the good soil can be replaced, adding enough peat and the like (see above) to make good that which was rejected; all should be thoroughly and carefully mixed. Peat, although excellent, is not necessary. Yellow loam or hazel loam, if not too sandy, is equally good and is improved by additions of humus. To nearly pure peat an admixture of sand is beneficial; the essential point is that all soils for these plants must be fine. The beds should be prepared in autumn and left to settle all winter, due allowance being made for shrinking. In spring level off to the grade of the adjacent land and do not leave "rounded up." A bed higher at the center than at the sides perhaps makes a better display of the plants, but is more likely to dry up and does not catch all the water possible from occasional showers. It is generally conceded that lime soils and manures containing ashes and bone-meal, are injurious to rhododendrons; in limestone regions it is undoubtedly advisable to substitute, for the natural soil, others which are free from this objectionable element.

Plant rhododendrons in spring when weather is settled and the March winds have passed. If the ball of roots is dry, soak well before setting. Plant closely, so that the tops are only 10 to 12 inches apart and pay particular attention to "facing" them, i.e., see that the best side is facing the most important point of view, and that all are faced alike. Grafted plants should, if possible, have the worked portion below the surface. Do not plant in autumn. Plants grown on the premises may be transplanted in favorable weather in summer if great care is taken to prevent the roots suffering from dryness. In planning the original border it is well to leave room for extension; when planted, as described above, the beds can be enlarged at intervals of four or five years, or new beds made from the old stock. Place the beds so that the glare of the midday sun is screened both summer and winter, and avoid situations where there is any interference, owing to trees or buildings, with a naturally good condition of the soil in respect to moisture. If permanent protection is desired, use conifers, particularly the hemlock, in preference to deciduous trees. Good positions for beds may be found along the edges of ponds and streams, and in reclaimed meadows, with their cool moist soil, but keep afloat from any ground where the water collects in summer or winter. Beds, or even single plants, if sizable, may be introduced into open spaces in woodlands if the precautions noted above are observed and plenty of air and light are obtainable. It is somewhat difficult to combine rhododendrons and many deciduous shrubs, among which are the azaleas, their near relatives. A background of dark green conifers seems most appropriate. Mountain laurels, *Pieris floribunda*, *Leucothoe Catesbaei*, and *Daphne Canescens* are proper companions, but at times these seem better apart. Our native lilies, *L. Superbus* and *L. Canadensis*, are good associates and thrive under the same conditions. In very dry weather the water should be given, not daily in driblets, as lawns are sprinkled, but in quantity, enough at one time to soak the layers below it. Give and Christmas. Let the bed be covered to the depth of the soil, but at comparatively low points or else they will heat. Leaves make good winter protection, which should be given just before cold weather,—in eastern Massachusetts, between Thanksgiving and Christmas. Let the bed be covered to the depth of 10 to 12 inches, well worked in beneath the foliage but not over it. In spring dig as much as pos-
Rhododendron well placed.—One of the Rhododendron catawbiense varieties.
sible of this material into the ground, leaving a part for the summer mulch. Shelter the tops with evergreen boughs, the butts driven into the earth a foot or more; in windy positions a temporary board fence is useful.

Experience at Rochester, New York (John Dunbar).—About fourteen years ago, rhododendrons were planted in the Rochester City Parks in beds excavated to a depth of 2 to 2½ feet (sandy soil containing lime removed), and having a slope of 10% from an adjacent swamp. Cow-manure was well-worked in the surface. Rhododendrons planted in this preparation began to root immediately, grew with vigor, and flowered splendidly. About 20,000 square feet have been planted to rhododendrons in this way with unflagging success. A ¾-inch pipe water-system is connected with all of the beds, with faucets at convenient points, and the plants are thoroughly watered in the growing season, and are never permitted to enter the winter with dry roots. The natural drainage is perfect. Rhododendrons will not tolerate stagnant moisture at their roots. They are thoroughly protected by the lay of the land from the west, northwest, and north winds, but are completely exposed to the south, summer and winter, and with the exception of a heavy mulching of leaves, spread over the beds in the autumn, they receive no other protection. The lace-fly became a serious pest for several years prior to the planting of nymphs feed on the under side of the leaves and the foliage presents a sickly yellow appearance, as if attacked by red-spider. This is promptly destroyed and kept under control by two sprayings of Ivory soap from an adjacent swamp. Cow-manure was mixed prepared to America; it is usually more profitable to buy this stock each fall than to attempt to raise it in this country, where labor is high-priced and the climate dry and hot.

Propagation is usually by seeds sown in early spring in frames or pans, in sandy peat, without covering, and kept moist and shady. When the seedlings appear they should have air and a daily spryning. In autumn they are transplanted into boxes or frames, in sandy, peaty soil. The seeds germinate very readily sown in cut sphagnum, but ought to be pricked into boxes as soon as they can be handled. The second year the seedlings should be planted out in beds, sufficiently wide apart to allow a growth of two years. Long upright branches should be shortened, to secure well-branch ed plants. The named varieties are grafted on any of the common species, usually by veneer-grafting in autumn in the greenhouse, on potted stock. They may also be increased by cuttings of mature wood 2 to 3 inches long, taken from a height of three or four feet, placed in sand in a greenhouse, on potted stock. They may also be increased by cuttings of mature wood 2 to 3 inches long, taken from a height of three or four feet, placed in sand in a greenhouse, or in a cold frame, shaded from direct heat, and with the roots covered with sand, to hasten the formation of roots. The plants are kept in a cold frame through the winter.

The following are known as Ghent azaleas or Mollis hybrids (R. Morteri, Sweet, Azalea Mortieriana, Spae. A. gandaensis), are in cultivation. They have originated chiefly from crosses of R. sinense, and later R. japonicum, with R. luteum, R. calendulaceum and R. nudiflorum, also in some cases with R. occidentale and R. viscosum. Some good varieties are the following:

Indian azaleas.

This group contains R. indicum and other species of the section Tsuchutsuki and the hybrids of them. They are well-known evergreen shrubs, in the North requiring cultivation in the greenhouse during the winter, but some, as R. Kaempferi and R. poukhanense, have proved perfectly hardy in the neighborhood of Boston; also R. ledebouri and R. ledebouriense will stand many degrees of frost in somewhat sheltered positions. Indian azaleas are rarely liable to injury by seeds, which, when sown in the greenhouse in the same way as with the former group. Usually they are propagated by cuttings or grafting. The cuttings root best when made in August from half-ripened wood, and placed in sand under a frame, with gentle bottom heat. Choicer varie-

Hardy deciduous azaleas.

These include the species of the sections Pantathera and Rhodora and some of the section Tsuchutsuki, and the hybrids known as Ghent azaleas. Most of them are hardy, but in the North and in exposed situations a protection with brush, hay, or mats should be given in winter, to protect the flower buds from sudden changes of temperature.

In the open, the flower period of hardy azaleas extends from April to July. First comes R. canescens, R. rubescens, R. Vaseyi and R. Vaseyi; then R. nudiflorum and R. japonicum, followed by R. luteum and R. calendulaceum and nearly at the same time, R. Schlippenbachii, R. Albrechtii; somewhat later, R. occidentale, and last, R. arborescens and R. viscosum. One of the most beautiful is the American R. calendulaceum, which is hardly surpassed in the brilliancy and abundance of its flowers by any of the Ghent hybrids. There may also be mentioned, A. gandavensis), are in cultivation. They have originated chiefly from crosses of R. sinense, and later R. japonicum, with R. luteum, R. calendulaceum and R. nudiflorum, also in some cases with R. occidentale and R. viscosum. Some good varieties are the following:

Indian azaleas.

This group contains R. indicum and other species of the section Tsuchutsuki and the hybrids of them. They are well-known evergreen shrubs, in the North requiring cultivation in the greenhouse during the winter, but some, as R. Kaempferi and R. poukhanense, have proved perfectly hardy in the neighborhood of Boston; also R. ledebouri and R. ledebouriense will stand many degrees of frost in somewhat sheltered positions. Indian azaleas are rarely liable to injury by seeds, which, when sown in the greenhouse in the same way as with the former group. Usually they are propagated by cuttings or grafting. The cuttings root best when made in August from half-ripened wood, and placed in sand under a frame, with gentle bottom heat. Choicer varie-
ties are usually increased by veneer- or tongue-grafting, either in winter or in July and August on vigorous growing varieties raised mostly from cuttings. Grafting on rhododendron is now used in some German nurseries with very good results. The best soil for azaleas, if grown in pots, is a sandy compost of half peat and half leaf-sole, with an addition of good fibrous loam. It is essential to plant them firmly, and to give very good drainage. The base of the stem should be just above the surface. The best time for repotting is after flowering, when the new growth commences. During the summer, they should be kept in the coldest room in the open in a sheltered spot, with the pots plunged in the soil, or planted out in prepared beds, where they make a very vigorous and healthy growth. In September they should be repotted and transferred to the greenhouse. They must have plenty of water and free syringing during the hot months. The natural flowering time is from April to June, but in the greenhouse, azaleas may be had in flower from November till June. Against the red-skipper and thrips, from which the azaleas are liable to suffer if the air is too dry, free syringing with water is the best remedy. Most of the plants used for forcing in this country are imported from Holland, Belgium, and Germany. Formerly azaleas were kept in summer in shade or partial shade, but now it is the custom of the best growers to give them full exposure to the sun, either planted out or in the pots plunged to the rim in ashes or other good drainage material; in the latter case a top-crossing of 2 or 3 inches of old cow-manure is very beneficial. The only American treatise is Halliday's "Treatise on the Propagation and Cultivation of Azalea Indica," Baltimore, 1880.

Some of the best varieties of Indian azaleas are the following (for a completer account, see August Van Geert, "Iconographie des Azalées," abbreviated here as Ic. Az. 20):

**Single-flowered:**
- **Antigone,** white, striped and spotted violet (R.B. 7:241. Ic. Az. 3);
- **Apollo,** vermilion (Ic. Az. 20);
- **Charmer,** rich amaranth, very large (F.S. 5:303, 304, 1);
- **Comtesse de Beaumont,** rich rose, blotched deep crimson;
- **Criterion,** rich salmon-pink, bordered white and blotched crimson (F.S. 8:796. F. 1849: 137);
- **Diamond,** white, blotched dark crimson (F.S. 21:2233, 2234);
- **Duc de Nassau,** rich rosy purple, very free and large;
- **Brazier Greetings,** small, flower often semi-double, crimson, very free-flowering; *Eclatante,* deep crimson, very free-flowering; *Elegante,* deep crimson, very free-flowering; *Exemplaire,* rich glowing crimson (Gn. 16:242, 4);
- **Fluer d'Eeckhaut,** white, striped red (Gn. 16: 242, Ic. Az. 13);
- **Hauert Lorraine,** small, bright pink flowers, very floriferous; *Heuze* (Firefly), deep crimson, "hose in hose," small fl. very free-flowering (R.B. 31:49);
- **Jean Verouve,** salmon, striped, bordered white (R.B. 2:145. Ic. Az. 11);
- **John Gould Veitch,** lilac-pink, bordered and netted white, striped crimson (F.S. 20:2071, 2072);
- **La Victoire,** reddish, white toward the edges, spotted maroon-crimson; *Louise von Baden,* pure white, sometimes speckled pink (F.S. 17:1796. F. 3:158);
- **Marie Charlotte Van De Eeckhaut,** pure white, with crisped edges; *Madame L. Van Houtte,* scarlet-rose, bordered white (F.S. 23:2383. Ic. Az. 5);
- **Marquis de Lorne,** brilliant scarlet, very fine; Miss E. Jarrot, pure white, with crisped edges (R.B. 14:213);
- **Mrs. Turner,** light pink, bordered white, spotted crimson (F.S. 8:451. Gn. 56, p. 306);
- **Mons. Thibaut,** orange-red; *Perle de la Belgique,* large, pure white; *President Victor Van den Hecke,* white, striped and spotted crimson, with crimson edges; *Princesse de Belgique,* pure white, one of the best; *Prince de Neufchateau,* pure white, spotted greenish yellow; *Professor Wolters,* pink, with amaranth blotch; *Reine des Paye-Bas,* rich violet-pink, bordered white (I.H. 13:149);
- **Roi de Hollande,** dark blood-red, spotted black; *Sigismund Rucker,* rich rose, bordered white, blotched crimson, very showy (F.S. 19:2010, 2011. Ic. Az. 31);
- **Stella,** orange-scarlet, tinged violet; *Wilson Saunders,* pure white, striped and blotched vivid red.

**Double-flowered:**
- **Alice,** deep rose, blotched vermilion (I.H. 23:244);
- **Baron N. de Rothschild,** rich purple-violet, large (F.S. 23:2477, 2478);
- **Bernard André,** dark violet-purple, large; *Bernard André alba,* white (I.H. 17:15. Ic. Az. 19);
- **Borsig,** pure white; *Charles Latrens,* dark salmon, blotched dark purple, good form and substance (F.S. 19:1071, 1972);
- **Charles Pynaert,** salmon, bordered white (R.B. 10:25);
- **Chicago,** deep carmine, bordered white, large; *Comtesse Eugenie de Kerchove,* white, flaked red-carmine; *Deutsche Perle,* pure white, early (R.B. 21:85. R.H. 1886: 516. Gn. 33:460. Ic. Az. 25);
- **Dominique Verouve,** bright orange; *Dr. Moore,* deep rose, shaded white and violet, very fine (R. B. 11:61);
- **Eggebrechti,* bright crimson; *Empereur du Brésil* (Emperor of Brazil), rich rose, banded white, upper petals marked red (Ic. Az. 15);
- **Ernest Eeckhaut,* deep carmine, very double; *Francois de Vos,* deep crimson (I.H. 14:512. Ic. Az. 14. F. M. 8:443);
- **Johanna Gotteschale,** white; John Lenselty, soft pink; *Louise Pynaert,* white (R.B. 4:306);
- **Madame Camille van Langenhove,** white, striped with rose, very double; *Madame Iris Lefebvre,* deep orange-carmine, shaded bright violet and blotched brownish red (F.S. 18:1862, 1863);
- **Madame Jos. Verouw,* large, pink and white, similar to *Veroutine,* Madame Pietrick, bright rose, very early; *Madame Van der Cruyssen,* pink, fine form (A.F. 12:1003);
- **Madeleine,* white, large, semi-double; *Niobe,* white, fine form; *Pharailde Mathilde,* white, spotted cherry-red (R.B. 13:145);
- **Princesse de Walle,* bright rose, upper petals spotted yellow and striped crimson; *President Oswald de Kerchove,* pink, bordered white, blotched carmine; *Raphael,* white; *Sakunatala,* white, very free-flowering; *Simon Mardner,*
large, rose, very double and very early; Sow. du Prince Alberi, rich rose, single, broadly margined white, very free-flowering (F.M. 4:201). 1e. Az. 24); Theodore Retmer, lilac; Veraneeana, rose, bordered white, sometimes striped salmon (Gn. 52, p. 137. C.L.A. 5:116. J.H. 31:423); Veraneeana alba, white (R.H. 1906:424); Vugitaeana, deep crimson, "hoso-rose."

The varieties now chiefly imported and considered the best for forcing are the following (those marked with an asterisk are adapted for early forcing):

**Single-flowered:** *Emil Liebig, Haere's Lorraine;* *Hece, Professor Wolters.

Plants grown in Germany are preferred for early forcing, because they are grown in pots over summer before shipping, while the Belgian plants are grown in the open field. Generally the Belgian plants are more compact, while the German-grown plants are of more open growth, because they do not travel well.

Augustin, 9.

1. michænium, Turcz. Shrub, to 8 ft.; lvs. lanceolate or oblanceolate, obtuse or acute, glabrous above, densely ferrugineous-lepidote beneath, \( \frac{3}{4}-1 \frac{1}{2} \) in. long; fls. in dense many-fl. clusters, white, campanulate, \( \frac{3}{4}-\frac{3}{4} \) in. across, lobes oblong or oval, longer than tube; stamens longer than corolla, glabrous; style shorter than stamens; sepals lanceolate, ciliate, \( \frac{3}{4} \) in. long. June, July. Manchuria to W. and Cent. China. B.M. 8198.-Very distinct species, resembling L. with its dense clusters of small white fls. and exerted stamens and with its small lvs. It has proved perfectly hardy at the Arnold Arboretum and is very floriferous even as a small plant.

2. ferrugineum, Linn. Shrub, 2 ft. high, glabrous; lvs. elliptic to oblong-lanceolate, acute, densely lepidote beneath, 1-2 in. long; calyx-lomes short, obtuse; corolla funnelform-campanulate, with the tube about twice as long as limb, pink or carmine, about \( \frac{3}{4} \) in. across. June-Aug. Mountains of Cent. Eu. L.B.C. 1:65. Gn. 29, p. 385. G. 8:610.—Dwarf, hardy shrub, handsome for rockeries. Var. album, Sweet, has white fls.

3. hirsutum, Linn. Shrub, 3 ft. high, with hirsute branches; lvs. oval to oblong, ciliate, light green and glanular-lepidote beneath, \( \frac{1}{2} \) in. long; clusters many-fl.; calyx-lomes short, obtuse; corolla funnelform-campanulate, with the tube about as long as limb, pink or carmine, about \( \frac{3}{4} \) in. across. June-Aug. Mountains of Cent. Eu. L.B.C. 1:65. Gn. 29, p. 385. G. 8:610.—Dwarf, hardy shrub, handsome for rockeries.

4. arbutfilum, Hort. (R. daphnoides, R. Hammondii, and R. clearifolium, Hort. R. Wilsonii, Hort., not Nutt.). A hybrid of R. ferrugineum and R. minus. Dense shrub, 4 ft. high; lvs. elliptic to elliptic-lanceolate, acute at both ends, \( \frac{1}{2}-1 \frac{1}{2} \) in. long; fls. similar to those of R. ferrugineum, but larger. June, July.—Of garden origin. Handsome hardy shrub, perhaps known by the name of R. Wilsonii; this name, however, had been given previously to another hybrid between two Himalayan species and should not be used for this plant.

6. minus, Michx. (R. punctatum, Andr. R. Cuthbertii, Small). Straggling shrub, to 10 ft.; lvs. elliptic to elliptic-lanceolate, acute at both ends, sometimes acuminate, glabrous above, glandular-lepidote beneath, \( \frac{1}{2}-1 \frac{1}{2} \) in. long; clusters many-fl.; calyx short; corolla funnelform-campanulate, about 1 in. across, rosy pink, the upper lobe spotted greenish, lepidote outside; tube nearly cylindric, longer than the ovate crisped lobes. June, July. N. C. to Ga. and Ala. B.M. 2285.—Fls. appear with or after the new lvs. Var. Hardisonii, Rehd. Fls. larger, \( \frac{1}{2} \) in. across, in dense, about 10-fl. heads. Ga. Handsomer than the type.

7. carolinianum, Rehd. (R. punctatum, Small, not Andr.). Shrub, to 6 ft., usually low and compact; lvs. oval to oblong, acute or acuminate, acuminate, broadly cuneate at the base, glabrous above, ferrugineous-lepidote beneath, often very densely so, 2-3 in. long; fls. in dense 5-10-fl. heads, broadly funnelform-campanulate, about \( \frac{1}{2} \) in. across, pale rosy purple or rarely white, not or only slightly spotted; tube gradually widened, as long or shorter than the ovate lobes, glabrous or nearly so outside. May, June. N. C. B.R. 37. G. 31:619 (as R. punctatum).—On account of its compact habit and larger fls. superior as an ornamental plant to the preceding.

8. keiskei, Miq. Low, sometimes procumbent shrub; lvs. elliptic to lanceolate, acute, dull green above, lepidote beneath, \( \frac{3}{4}-1 \) in. long; clusters 2-5-fl.; calyx minute; corolla broadly funnelform, divided to the middle into rounded lobes; pale yellow, \( \frac{1}{2} \) in. across; stamens much exerted. May. Japan. B.M. 8390.

9. Augustini, Hemsl. Shrub, to 20 ft.; branchlets pubescent when young; lvs. elliptic-ovate to oblong-lanceolate or lanceolate, acute or acuminate, broadly cuneate at the base, pale green beneath and lepidote and hirsute on the midrib and petiole, \( \frac{3}{4}-2 \) in. long; fls. 3-6; calyx-lomes short, ciliate; corolla broadly campanulate, \( \frac{1}{2} \) in. across, pale purple or rosy pink, rarely nearly white; lobes much longer than tube; stamens as long or slightly shorter than corolla, style longer. Cent. and W. China. B.M. 8497. G.C. III. 52:14. F.S.R. 3:162. R.H. 1909, p. 18.

12. racemum, Franch. Shrub, to 6 ft.; lvs. elliptic to ovate or obovate, obtuse or acute, rounded or broadly cuneate at the base, glabrous, glaucous and below and lepidote, \( \frac{3}{4}-\frac{3}{4} \) in. long; fls. 1-3, from axillary buds usually crowded at the end of the branches, sometimes along the branches; corolla funnelform-campanulate, \( \frac{3}{4} \) in. across, rose-pink, lobes oblong, about as long as tube; stamens and style exserted. B.M. 2285.—Fls. appear with or after the new lvs. Var. Harbisonii, Rehd. Fls. larger, \( \frac{1}{2} \) in. across, in dense, about 10-fl. heads. Ga. Handsomer than the type.

14. dahuricum, Linn. (Azalea dahurica, Koch). Shrub, to 10 ft.; lvs. deciduous or sometimes partly
rhododendrons; it requires a warm greenhouse.

RHODODENDRON

Section 2. LEIORHODIUM.

A. Under side of lvs. tomentose or pubescent.

B. Ovary tomentose; branches tomentose or nearly glabrous.

c. Flowers small; calyx-lobes nearly as long as pedicels; corolla campanulate, leaves much shorter than tube; pedicels about 2/3 in. long; tall shrub or tree, tender.................................. 17. arboéreum

17. 

Arboeaeum, Smith. Fig. 3383. Large shrub or tree, attaining 40 ft.; lvs. oblong to lanceolate, acute, rugose above, distinctly veined and whitish or ferrugineous-tomentose beneath, 4-6 in. long; clusters dense; pedicels short; calyx minute; corolla campanulate, blood-red, pink, or white, usually spotted, 1-1½ in. across; ovary ferrugineous-woolly or mealy, usually 7-9-celled. March-May. Himalayas. B.R. 890. B.M. 77; B. R. 1982. Var. Kingianum, Hook. (R. Kingianum, Watt). Shrub: lvs. broader, more robust, very dark lvs. deep scarlet; filaments rose-colored; calyx larger. G.C. III. 20, 306. B.M. 7096. Var. nilagiricum, Clarke. Fls. white-colored to deep crimson, spotted: lvs. ferrugineous-brown beneath. B.M. 4381. G.C. 30: 54. Var. purpureum, DC. Fls. purple or scarlet: lvs. white beneath. Var. Windsorii, Voss (R. Windsorii, Nutt.). Fls. deep crimson-scarlet; calyx with elongated lobes: lvs. white beneath. B.M. 5096.—This species is tender and suited only for warmer temperate regions, but has been crossed with hardy varieties and its blood is recognizable in many of our most beautiful hardy hybrids.

18. Smirnovii, Trautv. Shrub or small tree, to 20 ft.; young branchlets whitish or grayish woolly: lvs. elliptic-oblong, acutish, narrowed at the base into a short petiole, revolute at the margin, dark green with yellow midribs above, densely felted grayish white or pale brown beneath, 3-5 in. long; lvs. many, in a compact head; calyx small, tomentose; corolla campanulate-funnelform, rosy red, 3 in. across; lobes oval, longer than tube, with crispied darker rose-colored margin, upper lip spotted brownish; stamens 10, curved; ovary

RHODODENDRON

CC. Corolla funnelform-campanulate; pedicels 3½-8 in. long.

d. Lvs. acute at both ends.

B. Tomentum of lvs. beneath and of branchlets whitish or pale brown

ee. Tomentum of lvs. beneath and of branchlets deep brown.

P. Corolla 5-lobed, spotted greenish

ff. Corolla 8-10-lobed, spotted yellow-purple

DD. Lvs. obtuse or obtusish at both ends

BB. Ovary and branchlets glabrous.

AA. Under side of lvs. glabrous or pubescent only when young.

BB. Plants with coriaceous persistent lvs.

c. Ovary glabrous or glandular only.

D. Pedicels puberulous;

d. Calyx-lobes much shorter than ovary.

e. Pubescence of ovary rusty hirsute; pedicels glabrous...

f. Calyx-lobes nearly as long as ovary: lvs. acute at both ends.

BB. Plants with rather thin bark, falling off the second sprig: hybrids between this and the following section 28. azaleoides

17. arboeaeum, Smith. Fig. 3383. Large shrub or tree, attaining 40 ft.; lvs. oblong to lanceolate, acute, rugose above, distinctly veined and whitish or ferrugineous-tomentose beneath, 4-6 in. long; clusters dense; pedicels short; calyx minute; corolla campanulate, blood-red, pink, or white, usually spotted, 1-1½ in. across; ovary ferrugineous-woolly or mealy, usually 7-9-celled. March-May. Himalayas. B.R. 890. B.M. 77; B. R. 1982. Var. Kingianum, Hook. (R. Kingianum, Watt). Shrub: lvs. broader, more robust, very dark lvs. deep scarlet; filaments rose-colored; calyx larger. G.C. III. 20, 306. B.M. 7096. Var. nilagiricum, Clarke. Fls. white-colored to deep crimson, spotted: lvs. ferrugineous-brown beneath. B.M. 4381. G.C. 30: 54. Var. purpureum, DC. Fls. purple or scarlet: lvs. white beneath. Var. Windsorii, Voss (R. Windsorii, Nutt.). Fls. deep crimson-scarlet; calyx with elongated lobes: lvs. white beneath. B.M. 5096.—This species is tender and suited only for warmer temperate regions, but has been crossed with hardy varieties and its blood is recognizable in many of our most beautiful hardy hybrids.

18. Smirnovii, Trautv. Shrub or small tree, to 20 ft.; young branchlets whitish or grayish woolly: lvs. elliptic-oblong, acutish, narrowed at the base into a short petiole, revolute at the margin, dark green with yellow midribs above, densely felted grayish white or pale brown beneath, 3-5 in. long; lvs. many, in a compact head; calyx small, tomentose; corolla campanulate-funnelform, rosy red, 3 in. across; lobes oval, longer than tube, with crispied darker rose-colored margin, upper lip spotted brownish; stamens 10, curved; ovary

3383. Rhododendron arboeaeum. (X ½)

19. caucasicum, Pall. Dense low shrub, 2 ft. high, often with procumbent branches: lvs. oval-oblong or narrow-elliptic, acute, dark green above, ferrugineous-tomentose beneath, 2-4 in. long: clusters 7-10-fld.; pedicels short; calyx minute; corolla funnelform-campanulate, with emarginate rounded lobes, pink to yellowish white, spotted greenish within, 1½ in. across. June, July. Caucasus. B.M. 1145.—A dwarf, quite hardy species; late-flowering. Var. flavidum, Regel. Fls. straw-colored, spotted greenish within. G.W. 16: 560. Var. stramineum, Hook., is similar, but with fulvous spots. B.M. 3422. Var. rösco-álbium, Brit., with blush fls., changing to white, and var. splándens, Brit., with deep pink fls., are said to bloom very early and may be hybrids. R.H. 1868:311. Also "Coriaceum" and "Rosa mundi" (see p. 2932) are apparently forms of this species.

23. pónticum, Linn. Shrub, 10 ft. high: lvs. elliptic to oblong, acute, pale green beneath, 3-5 in. long: clusters many-fld.; pedicels longer than fls., puberulous; calyx-lobes as long as ovary, the lower ones half as long; corolla funnelform-campanulate with oval lobes, purple, spotted brownish within, about 2 in. across; ovary glandular. May, June. Spain, Portugal, Asia Minor. B.M. 650.—This species is less hardy than the two preceding and now rarely found in cult. in its typical form. Var. álbum, Hort., has white fls. There are also varieties with variegated and one with purplish lvs.

24. sutchuenense, Franch. Shrub, to 15 ft.: lvs. oblong-oblancoate, usually obtuse, narrowed at the base, dark green above, paler and glabrous beneath, 4-10 in. long; pedicels stout, 3-½-1½ in. long; fls. many, in a dense head; pedicels glabrous; corolla funnelform-campanulate, 2½-4 in. across, rose-colored, spotted below the base of the upper lobes, lobes broad, rounded, shorter than tube; stamens 18-19, shorter than the corolla, anthers purple-black; style glabrous, as long as the stamens; ovary glabrous. W. China. B.M. 8362. —Blooms freely as a small plant 2 ft. high.

25. californicum, Hook. Shrub, 8 ft. high, sometimes to 20 ft., glabrous: lvs. oblong, shortly acuminate, pale green beneath, 3-6 in. long, sometimes crowded beneath the fls.: clusters many-fld.; calyx minute; corolla broadly campanulate, with oval crisped lobes, rosy purple or pink, paler toward the center, spotted yellow within, about 2 in. across, rich carmine in bud; stamens 10, with purple anthers; ovary with appressed silky hairs. May, June. Calif. to Brit. Col. B.M. 4583. —R. macrophilium, Don, and R. washingtoniánum, Hort., are probably not different.

3384. Rhododendron brachycarpum. (X½)

3385. Rhododendron catawbiense. (X½)
27. *maximum*, Lindl. GREAT LAUREL. Fig. 3387. Shrub, or small trees, attaining 35 ft.; lvs. mostly alternate at base, narrow-oblong or lanceolate-oblong, acute or shortly acuminate, whitish beneath, 4-10 in. long; clusters many-flowered; pedicels viscid; calyx-lobes oval, as long as the corolla, glandular; stamens 10, Rocky Mts. B.M.3670, pedicels; corolla white, 5-cleft, about 1 in. broad; midrib beneath, slightly ciliate; fis. nodding, on short branchlets strigose and glandular when young: lvs. Azaleastrum albiflorum, var. album, Pursh (R. Pärshii, Don), with white fis.; var. purpureum, Pursh (R. purpureum, Don), with purple fis., and var. roseum, Pursh, with pink fis. This species and the following are now often extensively used in park-planting and taken by the carloads from the woods. If properly handled and taken from a turfy soil with a sufficient ball of earth around the roots, they are usually successfully transplanted.

28. *azaleoides*, Desf. (*R. frâgrans*, Lodd. *R. odoratum*, P. At.). Hybrid between *R. minus* and *R. nudiflorum*. Shrub, a few feet high: lvs. leathery but thin, elliptic to oblong, acute at both ends, dark green above, paler beneath, sometimes pubescent when young; fis. funnel-form-campanulate, pinkish or whitish, fragrant, June, July. Nova Scotia and Ont. to Ga. B.M.914. Em. 2:435. Mn. 1:1 and 3, p. 22. C.L.A. 3:32; 4:105. G.W.15, p. 823.—This is one of the hardest species, being hardy as far north as Que. and Ont. Three varieties have been distinguished: var. album, Pursh with white fis.; var. purpureum, Pursh with purple fis., and var. roseum, Pursh with pink fis.

29. *occidentale*, Gray (Azalea occidentalis, Torr. & Gray. *A. californica*, Durand). Shrub, 2-6 ft.: branches strigose and glandular when young: lvs. oblong, pale green, appressed-strigose above and at the midrib beneath, slightly ciliate: fis. nodding, on short pedicels; corolla white, 5-lobed, about 1 in. broad; calyx glandular; stamens 10. Rocky Mts. B.M.3670. Var. plenum, Rehd. A very handsome double form found wild, but not yet in cult.—The species is hardy, but difficult to cult.; will probably succeed best on a rockery in a cool and shady place.

Section 3. AZALEA.

Subgenus II. AZALEA.

3386. Flower-bud of Rhododendron catawbiense. These buds are formed in the fall. Unless these large terminal buds are produced, the bush will not bloom the following spring. (X 3/4)

Section 4. PENTANTHERA.

A. Stamen longer than the limb; corolla-tube long and narrow, usually glandular outside.

B. Color of fis. white or pink.

C. Fis. with or after the lvs., white.

D. Corolla soft-pubescent outside, with yellow stripes on the upper lobe: branchlets glabrous or finely pubescent... 30. occidentale

DD. Corolla kirsche, with stalked glands.

E. Lvs. beneath and branchlets glabrous... 31. arborescens

EB. Lvs. strigose beneath on the midrib and branchlets striose...

32. viscosum

OC. Fis. before the lvs., pink, rarely white.

D. Lvs. not glandular; corolla usually not glandular...

33. nudiflorum

DD. Lvs. grayish soft-pubescent beneath: corolla glandular outside...

34. canescens

NB. Color of fis. yellow to flame-red.

C. Ovary not glandular; stamens much longer than corolla: lvs. generally obovate...

35. calendula...

CC. Ovary glandular; stamens little longer than corolla: lvs. generally oblong...

36. luteum

AA. Stamen shorter than the limb: corolla-tube short, funnelform, finely pubescent outside, not glandular.

B. Under side of lvs. soft-pubescent: corolla yellow...

37. sinense

DD. Under side of lvs. only strigose on the veins: corolla brick-red to orange...

38. japonicum

31. arboréscens, Torr. (Azalea arbóricaens, Pursh). SMOOTH AZALEA. Fig. 3388. From 8–20 ft.; branchlets glabrous; lvs. obovate or obovate-oblong, acute, ciliate, glabrous, green or glaucous beneath, 2–4 in. long: fls. white or tinged rose, 2 in. long, fragrant; style and stamens red. June, July. Alleghany Mts. G.F. 1:401. (adapted in Fig. 3388). C.L.A. 11:496. Gn.M. 5:219. L.B.C. 17:1632 (as A. verticillata).

34. canescens, Don (Azalea canescens, Michx.). Shrub, 1–3 ft.: similar to the preceding; lvs. oval to elliptic or obovate, soft-pubescent beneath, at least when young, 1½–3 in. long; pedicels glaucular: fls. pink to nearly white, 1½–2 in. broad, glandular outside, very fragrant; stamens slightly exerted. April, May. N.H. to Fla. and La.

37. sinense, Sweet (R. mólle, Don. Azalea sinénsis, Lodó. A. mólus, Blume). Shrub, to 5 ft.; young branchlets glaucous and often setose: winter buds grayish pubescent: lvs. oblong to oblong-oblancoate, obtuse and mucronate, cuneate at the base, ciliate and often revolute at the margins, soft-pubescent beneath, 2½–3½ in. long; fls. in many-fl. heads; pedicels puberulous; calyx-lobes short, rounded, ciliate; corolla campanulate-funnelform, yellow, upper lobe spotted greenish, 2 in. across; stamens shorter than limb. April, May. China. B.R. 1253. L.B.C. 9:885.—Tenderer than the following species with which it has been confused. It has entered largely into the parentage of the so-called Ghent azaleas, and some of them, particularly Anthony Koster, are little different from true R. sinense.

38. japonícum, Suring. (R. mólle, Miq., not Don. Azalea japoníca, Gray. A. mólus, Hort., not Blume). Fig. 3392. Shrub, to 6 ft.; young branchlets glaucous, sometimes setose: winter buds glabrous: lvs. ovate to oblong-oblancoate, obtuse and mucronate, cuneate at the base, ciliate, glabrous or sparingly setose above, glaucous below except setose on the midrib, 1½–3 in. long: fls. in dense heads; pedicels setose; calyx-lobes ovate, setose; corolla campanulate-funnelform, 2 in. across, salmon-red, brick-red, or carmine; stamens shorter than limb. April, May. Japan. F.S. 19:2032–6. B.R. 433; 2383 (var. albíflora). C.L.A. 11:495. G. 27:15. Gn. 29, p. 550. G.M. 36:500.—A very fragrant and free-flowering species, not common in cult. Nearly all varieties referred to this species in nursery catalogues are hybrids and belong to the so-called Ghent azaleas, and some of them, particularly Anthony Koster, are little different from true R. sinense.

3389. Rhododendron nudiflorum, (X.10).

3390. Capsule of Rhododendron nudiflorum.
Section 5. Rhodora.

A. Stems 10: corolla rosy purple, not spotted
B. Lvs. deciduous, lanceolate, acute
C. Sepals obtuse, ciliate, not glandular
D. Stems 7-10, anthers purple; sepal ovate to lanceolate: lvs. elliptic, acute, persistent

39. canadense
40. Vaseyi

39. canadense, var. album, Rehd., but this is not quite so beautiful as the type.

48. obtusum, Leveille (Azalea obtusum, Kuntze). Spreading shrub, 1-3 ft. lvs. chartaceous, subpersistent, narrow-elliptic to elliptic-lanceolate, or lanceolate at the end of the branchlets, dark green above and usually sparingly strigose, paler beneath and strigose on the veins, 1-1/4-2 in. long: fls. 1-3; the inner scales of the calyx viscid; sepals 1/4-1/2 in. long, ovate-oblong, strigose and long-ciliate; corolla funnel-form-campanulate, pale lilac-purple, spotted purplish brown on the upper lobes, about 2 in. across; stamens 10, anthers purple. May. Korea.—Has proved perfectly hardy at the Arnold Arboretum and flowers freely as a small plant; the purple-lilac color of the fls. is unique among the hardy azaleas. Var. yodogawa, Rehd. (Azalea yodogawa, Hort.). Fls. double, rosy lilac, spotted dark purple: lvs. elliptic-lanceolate. G.W. 15:163. R.H. 1908:426.

ties of this species are the following: Var. album, Sweet.

47. Kaempferi, Planch. (R. indicum var. Kaempferi, Maxim.). Fig. 3393. Shrub, to 12 ft.: Ivs. membranous, deciduous, broadly elliptic to elliptic-ovate or nearly rhombic, acute at the ends, bright green above, paler beneath, stigose on both sides, with rufous hairs on midrib and petiole, 1½-2½ in. long: fls. 2-4 with or before the leaves; sepals ovate to oblong-ovate, obtuse, long-ciliate, striate or obscure; corolla broadly funnel-form, 1½-2 in. across, bright orange-red to pink; stamens yellow. April, May. Japan. S.I.F. 2:61. C.L.A. 11:496. M.D.G. 1902:417. S.T.S. 2:113.—Very handsome; hardy in New England.

Great numbers of names of rhododendrons are to be found in current literature, but the plants may be unknown in the American trade. The following list will explain most of these names. The number in parenthesis after the name refers to the section to which Carr viewed them.

3393. Rhododendron

Kaempferi. (×59)

348. japonicum, Sweet (See Azalea japonica, Lindl.). Fls. white, G.F. 9:395. Var. calyciflorum, Sweet (Geert. Ic. Az. 18); G. 1880:89. Var. narcissiflorum, Maxim. Fls. double, white, rarely purple. F. 1880:89. Var. rhombic, acute at the ends, bright green above, paler and less glandular; Ivs. 1½-2 in. long; fls. usually solitary; sepals small, ciliate; corolla funnel-form, 2-3 in. across, rosy purple to pink; stamens 5-10; anthers purple. April, May. B.R. 32:37. G.C. II. 25:585. R.H. 1876:370. Gn. 67, p. 190. Var. album, Sweet (Geert. Ic. Az. 18); G. 1880:89. Var. rhombic, acute at the ends, bright green above, paler and less glandular; Ivs. 1½-2 in. long; fls. usually solitary; sepals small, ciliate; corolla funnel-form, 2-3 in. across, rosy purple to pink; stamens 5-10; anthers purple. April, May. B.M. 4728. F.S. 9:985. G.C. III. 23: fig. 125. A.G. 15:373; 18:568. G.C. 2:385; 3:257. Possibly a hybrid of this species and R. sublanceolatum. Var. album, Sweet (Geert. Ic. Az. 18); G. 1880:89. Var. rubescens, Sweet (Firefly), deep crimson. In Japanese gardens a large number of named varieties of R. obtusum, varying in shades from white to deep crimson, are grown; one of the best known of them is Hinokigiri, with brilliant crimson fls.

Great numbers of names of rhododendrons are to be found in current literature, but the plants may be unknown in the American trade. The following list will explain most of these names. The number in parenthesis after the name refers to the section to which Carr viewed them. The number in parenthesis after the name refers to the section to which Carr viewed them.
rhododendron

lepidote beneath, 3½ in. long: fls. oval, oblong-lanceolate, pale brown or greenish buff, 1-2 in. across. Himalayas.

Ciliolate, obtuse, bifid, acuminate, pale to rusty brown and white, 2½ in. across. Himalayas.

Elliptic, acute at both ends or auriculate at the base, white, with a dark purple blotch within, 1-2 in. across. Himalayas.

Petioles slender, glabrous, 1½ in. long; fls. white to pink, 1-2 in. across. Himalayas.

Fls. in a loose, elongated, cylindrical, pedunculate spike, 1 in. across. Himalayas.

Fls. 3-5, white to rosy red, broadly campanulate, 1½-2 in. across. China.

Fls. 7-10, slender-stalked, funnel-campanulate, 1½ in. across; stamens about 20; ovary glabrous. W. China.

Fls. 3-6, white, spotted red, broadly campanulate, 2 in. across. W. China.

ALFRED REINER.

ROHDEOLÉA (Greek, rose and smooth; alluding to rose-like fls. and smooth st.). Hamamelidáceae. Small tender trees; lvs. evergreen, glabrous, long-stalked: fls. about 6 to 8 together in a compact head, having the appearance of a simple fl. surrounded by bracts, hermaphroditic; petals of each fl. turned toward the circuit of the head; stamens 7-10; ovary of 2 carpels united at base: caps. several-seeded. Two species. One is from China and the other from Java and Sumatra.

Chambéonié, Hook. A tender tree: lvs. shining, coriaceous, usually ovate, 4-5 in. long; petals 1½-2 in. long: fl.-heads resembling a semi-double cleome, 1½ in. across. White, bright pink, each head surrounded by several rows of bristly bracts; petals 15-20 to each fl.-head. China. B.M. 4509. J.F. 1:4.-Formerly in cult. in S. Calif.

F. W. BARCLAY.

RHDÓMÝRTUS (Greek, rose-myrtle, from the rose-colored flowers). Myrtáceae. Small tender trees and shrubs, one of which, R. tomentosa, is of slight economic importance in southern Asia, where it is native, and which is grown to a limited extent in California and Florida.

Leaves opposite, 5- or 3-nerved: fls. rather large, axillary; calyx-tube turbinate, the lobes persistent; petals 5 or 4; stamens numerous, free, in many series; berry globose or ovoid, with few to many seeds. - Species about 80.-The genus differs from Myrtus in having 2–3 locules in the ovary, each of which is frequent with spurious partitions or divided into numerous 1-ovulate suposed cells; while the lvs., in place of being pinnately veined, have 3 or 5 prominent nerves. The species is indigenous to India, Ceylon, Malaya, and S. China. The other species are Austral. and not cult.

tomentosa, Wight (Mýrtus tomentosa, Ait.). DOWNY MYRTLE. HILL-GOOSEBERRY. Small shrubs, up to 5 ft., the young branchlets tomentose: lvs. elliptic or obovate; obtuse, 1½-2½ in. long, hoary below; petals short: fls. 1-3 on slender peduncles about half the length of the lvs., rose-pink, ½-¾ in. broad; calyx tomentose, 5-cleft, the lobes unequal; petals downy outside, shortly clawed; berry globose, ½ in. broad, dull purple, to 3½ in. thick, covered, with numerous small compressed seeds in each cell. B.M. 250.—This plant seems to be best known in S. India, where it occurs commonly in the mountains. It is said by Macmillan to succeed in Ceylon only at high elevations. In S. China the fr. is sometimes offered in the market as a substitute for Flora. W. China.

flórida, Webb. (more properly Consólvulus flóridus, Linn. f.) Evergreen shrub: lvs. persistent, alternate, lanceolate, 6-9 ft. high, which bears white fls. something like a morning-glory. The blossoms are about an inch across and last only a day, but a succession is maintained (in S. France) from early June till Aug. A striking feature of the plant is its terminal, panniced inf. These panicles are often a foot high, 10 in. wide at the base and contain at one time as many as 20 full-blossomed fls. and 100 buds. Intro into S. Calif.

—The wood of this species is hard and white, with radiating stripes. Intro. into S. Calif. by S. Amer.

WILHELM MILLER. F. TRACY HUBBARD.

RHODÓPSATHA (Grec, rossé et spathe, referring to the color of the spathe in some species). Aráceae. Climbing shrubs suitable for the warmhouse: branches often rooting: lvs. distichous, elliptic-oblong, acuminate: spathe cymbiform, beaked and deciduous; spadix shorter than the spathe, cylindrical, densely flvd., the fls. all perfect or the lower pistillate; perianth none, stamens 4: berries small, oblong, truncate, 2-celled, many-seeded.—About a score species, Trop. Amer. See Engler, Pflanzenreich, IV. 23 B.

Forgetti. N. E. Br. St. climbing: lvs. spreading; blade oblong-lanceolate, 16-20 in. long; the petiole about 12 in. long: peduncle 6 in. long; the spathe broadly elliptic, 6 in. long, a dirty pale rose-white outside and dirty rose inside. Costa Rica.

RHÓDOSFÉRA (Grec, red and globe; referring to the reddish globose fr.). Anacardiaceae. A tree from Austral., closely related to Rhus but differing chiefly in the 10 stamens and in the very short free radicle of the embryo: lvs. odd-pinnate, subcoriaceous: fls. polygamo-dioecious, in terminal and axillary panicles, red; stamens 10; styles 3, free; fr. a globose drupe. In its native country the wood is esteemed for cabinet-work and used as a yellow dye and therefore called "yellow-wood." It is also a handsome foliage tree and is cult. in Calif. The only species is R. rhodanthema, Engl. (Rhus rhodanthema, F. Muell.). Evergreen tree to 60 or 70 ft., glabrous: lvs. 7-9, short-stalked, oblong-ovate, to 1 ft.: lvs. cuneate-oblong, acute, setosely ciliate, silky-pubescent beneath when young, 17–2 1/2 in. long: fls. purplish pink, to 1 in. across. May. Alps of E. Eu. B.M. 488. L.B.C. 15:1491. P.M. 3:169. F.S. 19:1062. F.W. 1857:321. G.C. III. 33:293. ALFRED REHDER.

RHODÓSTACHYS (Greek, rhodon, rose, and typos, type; alluding to the resemblance of the flowers to those of a single rose). Rosáceae. Ornamental shrub, grown chiefly for its large white flowers and for the handsome bright green foliage. Leaves deciduous, opposite, stipulate, short-petioled, serrate: fls. solitary, short-peduncled; sepals large, half as long as petals, outside with 4 small alternate bracts; petals 4, orbicular; stamens numerous; carpels usually 4, developing into black dry 1-seeded drupes, surrounded by the large persistent calyx.—One species in Japan. A handsome and distinct shrub, hardy as far north as Mass., with bright green foliage, conspicuous by its white fls. in spring and by its shining black fr. in autumn and winter. It thrives well in any good soil. Prop. by seeds and by greenwood cuttings under glass in summer; also by hardwood cuttings.

RHÉEO (name unexplained). Commelínaceae. One species, from Mex. and the W. Indies, R. discolor, Hance, known also as Tradescantia discolor, L. Her.
the roots, and this is the only method by which a particular type can be increased. Propagation from seed, however, sometimes proves satisfactory, and always interesting as the seedlings vary greatly. The seed germinates easily, and if started early the plants become fully large and strong the same season. The seedlings may be started in any good clean garden soil. Sow seed in early spring, in rows a foot apart and not over an inch deep. Thin the plants promptly to stand a few inches apart in the rows, and give the same thorough tillage allowed to other garden crops. In the following fall or spring take the seedlings up, and set them in the well-prepared permanent patch, not less than 4 feet apart, each way, and till frequently the entire season. In spring of the next year the stalks may be pulled freely.

From ten to twenty good plants should supply the needs of the usual family, and probably with something to spare for the neighbors. Sometimes an early supply is secured by placing a bottomless barrel or box over the plant and piling warm horse-manure about it. If the barrel, keg, or box is not too broad, the petioles will be made to a straight upright growth and will be partially blanched and very tender. Victoria and Linneas are the leading varieties.

**Forcing of rhubarb.**

In the winter and early spring months, the forcing of rhubarb in the vicinity of many city markets is a profitable industry. The plant may be forced either in the field where the roots were grown or lifted and placed in hotbeds, under greenhouse benches or in cellars. The bulk of the rhubarb forced for market and sold during the winter months is grown in cheap structures placed over the plants in the field. These houses may be of the lean-to type, although they are more commonly even-span post and rafter construction, the roof being covered with hotbed sash which is not needed for other purposes at the time. The eave walls are 4 to 5 feet high, made of rough boards and covered with cheap building-paper. The even-span houses are mostly 24 to 36 feet wide and the lean-to house half that width. Heat is usually applied in an overhead system, steam being the most popular, although late in the season if the sun is depended upon to supply the required amount of heat. When forced in the field in limited quantities, coldframes are often used, the outside walls being well banked with hot manure and the surface of the ground within the frames covered with 3 to 6 inches of the same material.

Beds intended for early spring forcing should be thoroughly cultivated in the fall and an application made of high-grade commercial fertilizer of 800 to 1,000 pounds to the acre. When growth starts, a dressing of nitrate of soda at the rate of one-half pound to a crown should be given. In field forcing, the moisture of the soil is usually sufficient so that no water is applied. When in the intention to use field for forcing for several years, the plants are usually set 2 by 3 feet and the land fertilized heavily each spring with a compost, one made from cow- and hog-manure being preferred. The sash are placed upon the first houses as soon as the roots have been frozen, five to seven weeks being necessary to bring the plants to maturity.

In field forcing, the cost of production is often greatly reduced by growing spinach or dandelion between the rows, the price obtained for these fillers usually being sufficient to pay labor and maintenance costs. The stalks are usually pulled twice, returning to the grower from $1 to $2 a sash, depending upon the season when placed upon the market.

Roots for forcing in the dark should be healthy and vigorous; the larger the roots the more satisfactory the results as a general rule. Crowns three to five years of age are mostly used, although satisfactory results are often obtained from one-year-old plants which have been grown on very rich land and have made an unchecked growth during the season. The roots should be dug early in the fall before the ground freezes and allowed to remain exposed to the weather until they are frozen solid when they should either be removed to a shed or covered with litter in the field to prevent alternate freezing and thawing. Thorough freezing is necessary, whatever the method of forcing, if the best results are to be obtained. With one-year roots very satisfactory results are sometimes secured if the roots are thoroughly dried before forcing. Anesthetics have been tried as a substitute for freezing but with unsatisfactory results. When used upon frozen roots they stimulate growth, resulting in the production of earlier and larger stalks with greater total weight of product. If the greatest benefit is to be derived from the anesthetic, it must be used in the early part of the resting-period. The most satisfactory results have been obtained by the use of 10 cubic centimeters of sulfuric ether to a cubic foot of space, exposing the roots to the fumes for forty-eight hours. Well-grown two-year-old roots seem to respond to this treatment in the most satisfactory way.

As soon as the roots are placed in position, whether it be under the greenhouse benches or in the cellar, all spaces should be filled with soil or ashes to prevent evaporation. If placed on a concrete floor, 2 or 3 inches of soil should be placed under the roots and sufficient material should be added completely to cover the roots. The bed as soon as completed should be thoroughly watered, the plants kept supplied with an abundance of moisture, which will necessitate water being applied about once a week. Care should be taken to guard against over-watering as this will result in the production of light-colored stalks, lacking in flavor and texture. In order to obtain the most attractive product, rhubarb should not be forced in full light or total darkness. If grown in diffused light, the development of the leaf-blade is very slight and the color of the stalk, instead of being green, is a beautiful dark cherry-red, giving to the product a very attractive appearance. In quality the product is superior to that forced in light, being more tender, less acid, with a skin so thin and tender as to make it unnecessary to peel the stalks. The temperature may range from 45° to 75°, the lower the temperature the greater the yield and higher the quality of the product. The time required for bringing a crop to maturity in darkness is practically the same as that required for forcing in the field.

**Local market demands to a certain extent govern the method which is used in growing this crop for the winter market.** When grown by any method which
requires the lifting of the roots, it must be remembered that they are worthless after having produced a crop. Therefore, this method cannot be practised with as great profit upon expensive land as can the method of field forcing or when roots were used for forcing which otherwise would be destroyed. Rhubarb-forcing in house cellars should receive more attention, as it adds at slight expense a pleasing vegetable to the winter dietary.

Whatever the method practised, success will be attained only when healthy well-developed roots, which have been allowed to freeze, are used. G. E. ADAMS.

Rhus (ancient Greek name). Anacardiaceae. Sumac. Ornamental woody plants, grown chiefly for their handsome foliage, often assuming brilliant autumnal colors, and some species also for showy fruiting panicles. See also Cotinus.

Deciduous or evergreen shrubs, sometimes climbing by aerial rootlets, or trees, with milky or resinous juice: lvs. alternate, without stipules, simple, 3-foliate or odd-pinnate; fls. dioecious or polygamous, small, in axillary or terminal panicles; calyx 5-parted; petals 5; stamens 5, inserted below a broad disk; ovary superior, with 3 styles: fr. a small 1-seeded dry drupe, smooth or hairy.—About 150 species in the temperate and subtropical regions of both hemispheres. Foliage and bark of most species are rich in tannin and are used for tanning leather, particularly the lvs. of R. coriaria in S. Eu. From R. verniciflua lacquer is obtained in China and Japan, used in the manufacture of lacquer-ware; R. succedanea yields a vegetable wax, used for candles in Japan, and also exported for various purposes. R. verniciflua and some other S. African species are valued for their timber.

The sumacs are shrubs or trees with handsome simple or usually compound foliage assuming in most deciduous species brilliant autumnal colors, and with small comparatively inconspicuous flowers in usually large panicles, followed by small fruits which are deep red and showy in many species. The only species with rather showy flowers of creamy white color appearing in late summer is R. javanica, while R. typhina, R. glabra, and R. copallina are chiefly valued for their large pinnate leaves coloring scarlet in autumn and also for the conspicuous panicles of deep red fruits remaining almost unchanged on the plants during the winter; they are well adapted for mass-planting on barren ground and dry hill-sides. Also R. verniciflua, R. succedanea, and R. verniz have handsome large foliage, but are poisonous like R. Toxicoidea, and for this reason are not recommended for extensive planting. The deciduous native species are hardy North, and occasionally to 30 ft.; lvs. short-stalked, oval, obtuse or acute, 1-2 in. long, very rarely 3-foliolate: panicles hoary: fr. hairy, red. 

D. Length of lvs. 1-2 in., apex usually obtuse: fr. yellow. 1. integrifolia
  2. americana
  3. littoralis
  4. mollis

B. Lvs. pubescent or glabrous. 5. laviqata
  6. lutea

C. Fr. pubescent, red. 7. trilobata

D. Length of lvs. 2-3 in., apex acute: fr. yellow. 8. canadensis

CC. Fr. glabrous, white. 9. diversiloba

DD. Lvs. in loose panicles: fr. glabrous, white. 10. toxicoidea

D. Apex of lvs. obtuse, margin crenate. 11. vernix

E. Length of lvs. usually 8-10 in., base cuneate. 12. verniciflua

DD. Under side of lvs. more or less pubescent, at least white, pale green; texture thin; pairs of veins usually 10-12. 13. succedanea

CC. Fr. pubescent: fr. glabrous, white. 14. Potaninii

DD. Under side of lvs. glabrous, grayish green, rarely green; texture firm;' with usually 18-20 pairs of veins. 15. diversiloba

DD. Fructing panicles pendulous: fr. hairy, red. 16. coriaria

CC. Fr. glabrous, white. 17. javanica

DD. Margin of lvs. crenate. 18. capallina

EE. Number of lvs. 5-7, rarely 9; rachis terete. 19. Potaninii

EE. Number of lvs. 7-15; rachis narrowly winged in the upper part. 20. punjabensis

DD. Under side of lvs. glabrous, grayish green, rarely green; texture firm; with usually 18-20 pairs of veins. 21. glabra

2. *ovata*, Wats. Shrub, to 10 ft.: lvs. short-stalked, ovate or acute, acuminate, entire or rarely sparsely toothed, 2–3 in. long; fls. in dense spikes ½ in. long, sometimes crowded into terminal panicles, light yellow; fr. ovate, flattened, dark red, ¼ in. long. Spring. S. Calif., Ariz.

3. *laurina*, Nutt. (*Lithraea laurina*, Walp.). Aromatic, glabrous shrub: branchlets purplish; lvs. oblong-ovate to lanceolate, acute and mucronulate, rounded at the base, entire, 2–3 in. long; petals ¼–½ in. long; fls. in dense panicles, to 4 in. long, greenish white: fr. ovoid, beaked, ½ in. long, whitish, with a waxy covering. Summer. S. and Low. Calif.—Will thrive in the hottest and driest places; very handsome with its dark green glossy foliage.

4. *mollis*, HBK. Tall shrub: branchlets tomentose; lvs. oval or ovate, rounded and mucronate at the apex, rounded or subcordate at the base, pubescent above, more densely so beneath, 1½–2½ in. long; petiole very short: fls. in dense pubescent panicles, about 1 in. long: fr. subglobose, pilose. Mex.

5. *levigata*, Linn. Glabrous shrub or tree: petiole 2–3 in. long; lfts. sessile or short-stalked, ovate, acuminate, cuneate at the base, entire or sometimes with 2–6 teeth, lustrous above, 2–3 in. long; panicles loose, axillary and terminal; fls. minute, whitish, slender-pedicelled: fr. globose, glabrous, lustrous, about ¼ in. across. S. Afr. Sim. For. Fl. Cape Colony 45.

6. *lactida*, Linn. Glabrous shrub, to 6 ft.: branchlets sometimes puberulous: petiole ¼–½ in. long, narrowly winged; lfts. sessile, obovate, obtuse or acuminate, entire, rarely slightly toothed, lustrous distinctly veined, 1–2½ in. long; panicles terminal and axillary, about as long as lvs.: fr. globose, glabrous, about ¼ in. across. S. Afr.

7. *triloba*, Nutt. (*Schmettisia triloba*; Small). Skunk-Bush. Ill-scented Sumac. Offensive-scented shrub, to 3, rarely to 6 ft. high: lvs. petioled, 1–2 in. long; lfts. sessile or nearly so, oval or obovate, obtuse, crenately toothed, puberulous while young, soon glabrous, the terminal one usually 3-lobed: fr. greenish, in clustered spikes before the lvs.: fr. subglobose, red, hairy, ¼ in. across. Mo. to Wash., Calif., and Texas.

8. *canadensis*, Marsh. (*Schmettisia aromatica*, Desv. *R. aromatica*, Ait. *Schmettisia crenata*, Greene). Aromatic shrub, to 3 ft., with ascending or diffuse branches: lvs. petioled, 2–4 in. long; lfts. pubescent, the terminal one ovate or obtuse, acute or acuminate, cuneate at the base; the lateral lfts. ovate, unequal at the base: fls. and frs. like those of the preceding species, but fls. yellow and frs. slightly larger. Ont. and Vt. to Minn. and south to Fla. and La.—A good cover plant for dry rocky banks; conspicuous in early spring by its yellow fls. B.B. (ed. 2) 2:482.

9. *diversifolia*, Torr. & Gray. Poison Oak. Upright shrub or sometimes climbing by rootlets: branchlets pubescent: lfts. ovate, elliptic or obovate, usually obtuse, coarsely crenate-serrate or 3-lobed, sparingly pubescent while young, 1–3 in. long; fls. yellowish green, in peduncled panicles: fr. white, ¼–½ in. across, falling soon after maturity. Brit. Col. to Calif.—Poisonous like the following and not to be recommended for planting.

10. *Toxicodendron*, Linn. (*Toxicodendron vulgare*, Mill. *R. radicans*, Linn. *R. Toxicodendron var. radicans*, Torr.). Poison Ivy. Poison Oak. Fig. 3088, p. 2728. Suberect and scrambling over walls and fences or high-climbing by aerial rootlets: lvs. ovate or rhombic, obtuse or short-acuminate, entire or sparingly dentate or sub acute, more or less pubescent beneath, 1–6 in. long; fls. greenish, in loose axillary panicles 1–3 in. long: fr. whitish, subglobose, ½ in. across, remaining on the plant: during the winter. Spring. Nova Scotia to Fla. west to Minn., Neb., and Ark. Em. 577.—It colors beautifully scarlet and orange in autumn, but is very poisonous to many and therefore should not be planted near places where persons are likely to come in contact with it; in such places it should rather be extirpated. It is, however, very difficult to eradicate, for it spreads by suckers and each piece of root left in the ground sprouts again. The plant described above is by some called *R. radicans*, Linn., and the name *R. Toxicodendron* is restricted to an upright shrubby form with pubescent crenate or crenately lobed lvs., native to the S. Atlantic states, also called *R. quercifolia*, Steud.; also several other closely related species have been distinguished.

12. *vernifolius*, Stokes (*R. vernifola*, DC.). Varnish-Tree. Lacquer Tree. Tree, to 60 ft.: lfts. usually 11–15, short-stalked, ovate-oblong to oblong-lanceolate, acuminate, rounded or broadly cuneate at the base, entire, more or less pubescent beneath while young, 3–6 in. long: fr. whitish, in slender axillary panicles about half as long as the lvs.: fr. broader than long, compressed, straw-yellow, smooth, ½ in. broad. Mav. Japan, China, Himalayas. S.I.P. 1:57. I.T. 6:201. Gn. 34, p. 158.—From this tree the lacquer used for the highly polished woodenware is obtained in Japan and China; the fr. yields a fatty oil. The tree is poisonous like the preciding species.

13. *succedanea*, Linn. Wax-Tree. Shrub or small tree, to 30 ft.: lfts. 9–15, short-stalked, elliptic-oblong to oblong-lanceolate, long-acuminate, broadly cuneate at the base, entire, lustrous above, usually grayish green or glaucous beneath, quite glabrous, usually with 15–20 pairs of veins prominent beneath, 2–4 in. long: fls. yellow-green, in axillary slender panicles: fr. broader than high, compressed, whitish, ½–⅓ in. broad. May
Japan, China, Himalayas. S.I.F. 1:57. R.H. 1863, p. 130.—From the fr. of this tree a wax-like substance chiefly used for making candles is expressed in Japan. The tree is poisonous.

15. punjabensis, Stew. Tree. To 40 ft.; branchlets densely velvety-hairy: lfts. 11-31, oblong-lanceolate, pointed, serrate, glaucous beneath, 2-5 in. long: fls. greenish, in dense terminal panicles: fr. crimson, hairy. June, July; fr. Aug., Sept. Em. 571. S.S. 3:102, 103. Gw. 54, p. 505. G.W. 2:343 (adapted in Fig. 3398). Que. to Ont., south to Ga., Ind., and Iowa. Var. laciniosa, Wood. Lfts. and bracts deeply and lacinately toothed and the inf. sometimes partly transformed into contorted bracts. Var. dissécta, Rehd. (var. laciniosa Hort.). Fig. 3399. Lfts. pinnately dissected. M.D.G. 1900:211. G.M. 53:827. R.H. 1907, pp. 10, 11. A very handsome form with finely cut foliage. R. typhina foliacea, Sprunger, is probably not different.—The staghorn sumac grows in the driest soils and is a very desirable plant on account of its brilliant fall coloring, which in dry localities begins to show in Aug., and with its crimson fr.-clusters persisting through the winter. Trained in tree form it is very picturesque, but is short-lived.

R. cotinoides, Nutt.—Cotinus americanus.—R. Cotinus, Linn — Cotinus Coggygria.—R. Delavayi, Franch. Allied to R. succedanea. Glabrous shrub: lfts. 5-7, elliptic, 1-2 in. long, light green beneath;

3398. Rhus typhina.—Staghorn sumac.

3399. Young plants of Rhus typhina var. dissecta.
Rhyncanthus (Greek,_'beak and flower,' referring to the peculiar shape of the fls.). Zingiberaceae. Slender glabrous perennial herbs with tuberous roots, suitable for the warmhouse: sts. erect, leathery, the lvs. sessile: fls. sessile, borne in a terminal, few-fld., spike, bracts solitary, elongate, and colored; calyx tubular, cylindrical; corolla funnel-shaped, the lobes ovate-lanceolate, the inferior about half as long as the standard: legume constricted between both seeds, tomentose or glabrous: seeds black, with a scarlet-yellow ring around the hilum. Panama to Brazil, W. Indies and Galapagos Isls.

Alfred Rehder.

Rhynchospermum (Greek, 'beak and seed,' referring to the form of the seed). Apocynaceae. Now referred to Trachelospermum. R. jasminoides, Lindl.—Trachelospermum jasminoides, Lem., which see. There is, however, a good botanical genus named Rhynchospermum, but it belongs to the composite family. It has only one species, R. verticillatum, a plant not in cultivation.

Rhynchostylis (Greek, 'beaked column or style'). Orchidaceae. Epiphytic herbs closely related to Saccobium and usually sold under that name. Stems monopodial and 2-ranked: lvs. crowded, leathery or fleshy; fls. in dense racemes from the axis of the lvs., medium-sized; dorsal sepal and petals subequal, lateral sepals broader, dehiscing along the column; labellum firmly joined to the base of the column; labellum ovate-lanceolate or ovate, pointed, the lip being also crimson. Var. gigantea, Hort., very much like the type. Var. alba, Hort. Fls. entirely white. Var. Dáyi and var. superba are offered.

Violacea, Reichb. f. (Saccobium violaceum, Reichb. f.). Lvs. 10-12 in. long: racemes 1-2 ft. long; fls. many-flowered; bracts rather few: corolla-tube pale yellow-green, lobes green; ovary puberulous. Bur. B.M. 6861. F. Tracy Hubbard.
Harrisoniunum, Hort. (Saccolabium Harrisoniunum, Hook.). Lvs. distichous, oblong, obliquely bident at the apex; raceme dense, cylindrical, pendulous; fls. white, fragrant; sepals ovate-oblong, somewhat incurved; petals narrower, oblong-spatulate; labelllum oblong-obovate, with a thick blunt apex, securate toward the apex; spur blunt; disk with a single thickened line. Malay Isls. B.M. 5458. F.S. 22:242.—The racemes grow to a length of 2 ft.

coléstis, Reichb. f. (Saccolabium coléstis, Reichb. f.). St. rather stout: lvs. 4-6 in. long, flatly, peduncles erect, bearing a dense raceme: fls. crowded, 3⁄4 in. across; sepals and petals similar, oval-oblong, obtuse, white with a blotch of indigo at apex; lip obvate-oblong, white at base, bright indigo at apex. Siam.

HEINRICH HASSELEBING.

GEORGE V. NASII.

PHYTIGLOSSA (Greek, wrinkle and tongue, the palate of the lower lip is wrinkled). Acanthaceae. A genus in which about 75 species have been described, now referred to Diaspere, which see.

RIBES (probably derived from ribas, the Arabic name for Rheum Ripes, or by some supposed to be the Latinized form of ribes, an old German word for currant). Currants and Gooseberries. Woody plants partly grown for their edible fruits and for their handsome flowers, fruits, or foliage.

Unarmed or prickly shrubs with deciduous or rarely evergreen foliage: lvs. alternate, oval-fascicled, simple, usually palmately lobed and mostly plaited in the bud. fls. perfect or in some species dioecious, 5-merous, rarely 4-merous, in many-fl. to few-fl. racemes, or solitary; calyx-tube cylindric to rotate, like the sepals usually rather small or medium-sized usually lobed leaves, with rather yellow; the fruits also are often attractive and either black, purple, scarlet, yellowish or greenish. The flowers appear in spring with the leaves, and the fruits ripen in June or July, but in R. fasiculatum they do not mature until September and remain on the branches all winter. Most species are hardy North except the evergreen ones; also R. sanguineum, R. Roelli, R. Lobii, R. viscinosum are not quite hardy North. The tender R. speciosum with fuchsia-like bright red flowers is perhaps the most attractive species of the genus, though also R. sanguineum, R. odoratum, R. Gordoniiunum, R. Roelli, R. Lobii, R. pinetorum, R. cereum, R. inbrans, R. nivum, and others are handsome in bloom, while some, as R. alpinum and R. fasiculatum, have fragrant, scarlet fruits. They are well adapted for borders of shrubberies and, particularly the procumbent kinds, for planting on slopes. R. alpinum is excellent for shady places and as undergrowth. R. alpense, a strong-growing and very spiny gooseberry from western Asia, may prove valuable as a hedge-plant. Many species bear edible fruits; the most important are the domestic currant, R. vulgare, and the European gooseberry, R. Grossularia; of less importance are the black currant, R. nigrum, the Buffalo or Missouri currant, R. odoratum, the European R. rubrum and some of the American gooseberries, as R. hirtellum, R. Cyanothali, R. oxyacanthoide, R. setosum, R. inermis. These plants are mostly of easy cultivation; they grow in any moderately good loamy soil, the gooseberries preferring as a rule drier and sunnier positions, while the currants like more humidity and grow well in partly shaded situations. Propagation is by seeds which germinate readily; also by hardwood cuttings in autumn and by greenwood cuttings in spring. In Europe, the plants are matured high on R. odoratum trained to one stem, to form little standard trees. See also Card's Bush Fruits, 444-84, figs. 2956 RHYNCHOSTYLIS

3401. Flower of garden currant, to show structure. (X 4)

INDEX.

KEY TO THE SPECIES.

A. Brances unarmed (or 2 small prickles below the fl. in No. 19) fls. usually in racemes; pedicels not jointed.
B. fls. tubular, red, yellow, or white.
C. Color of fl. yellow; 3. glabratus; lvs. consolute in bud.
**RIBES**

D. Calyx-tube about twice as long as sepals; sepals resolve or spreading.

DD. Calyx-tube 1–1½ times as long as sepals.

C. Color of fls. red or white; lvs. planted in bud.

D. The fls. red or red and yellow, rarely white.

E. Lvs. glabrous or nearly so beneath; fls. pale yellow and red.

EE. Lvs. white-tomentose beneath; fls. red, rarely white.

DD. The fls. white, pink, or greenish; lvs. glabrous or pubescent and green beneath.

E. Plants glandular-viscid; raceme short.

FF. Fr. black; calyx-tube cylindric-campanulate; lvs. 2–3 in. broad.

GG. Fr. white or greenish subfuscid; lvs. resinous-dotted beneath.

EE. Fr. orange, purple, or reddish.

FF. Fr. yellow; sepals reflexed.

E. Petals spatulate or flabellate: stamens about as long as sepals; style and calyx-tube inside pubescent.

G. Fr. smooth or glabrous-bristly.

H. Ovary glabrous.

I. Sepals longer than tube; stamens slightly shorter than sepals.

II. Sepals shorter than tube; stamens slightly shorter than sepals.

III. Ovary pubescent or glabrous; stamens about half as long as sepals.

CC. Color of fls. orange, purple, or bright red.

D. Fls. in racemes; sepals broader than long; stigmas broadly flat.

DD. Fls. 1–4; sepals longer than broad.

E. Stamens as long as sepals or longer.

F. Pistil 2–4; sepals yellowish brown.

G. Ovary glabrous; calyx-tube about as long as sepals; style and calyx-tube inside pubescent.

H. Stamens longer than the purple.

I. Fls. 1–4; sepals red or nearly so beneath.

II. Fls. red; style exserted.

III. Fls. red; stamens as long as sepals.

CC. Color of fls. orange, purple, or bright red.

D. Fls. 5–merous.

E. Stamens shorter than sepals.

F. Pistil 2–4; sepals purple and stamens shorter than sepals.

G. Ovary glabrous; calyx-tube about as long as sepals; style and calyx-tube inside pubescent.

H. Stamens longer than the flower.

I. Fls. 4–merous; bright red; stamens 2–4 times as long as sepals.
Section 1. RIBES. Currants.

1. odoratum, Wendl. (R. longiflorum, Nutt. R. fragraei, Lodg. R. satyrum, Thory. R. aureum, Hort. (as R. sanguineum, not Pursh. R. missouriense, Hort. Chrysobrota ramosa, Spach). Missouri currant. Buffalo currant. Golden currant. Fig. 3402. Shrub, to 6 ft.; young branchlets pubescent: lvs. ovate to orbicular-reniform, cuneate or truncate at the base, deeply 3-5-lobed and coarsely dentate, glabrate, 1-3 in. broad; petals pubescent, shorter than blade: racemes 5-8-fld.; rachis pubescent; bracts ovate to oval, foliaceous; fls. yellow, fragrant, tube about $\frac{3}{4}$ in. long, stout; sepals oblong, scarcely half as long as tube, spreading or revolute; petals nearly half as long as sepals, more or less red: fr. globose or ovoid, about $\frac{1}{2}$ in. across, black. East of Rocky Mts., S. D. to Texas, east to Minn. and Ark. L.B.C. 16: 1533. B.R. 125. L.D. 5: 301. H.F. 1872: 225 (as R. aureum).—A handsome shrub with yellow fragrant fls. appearing early in the spring with the lvs. A form with large berries nearly $\frac{3}{4}$ in. diam. is sometimes cult. for its frs. as the Cascade.

2. abrum, Pursh (R. tersiflorum, Lindl. R. jasminiflorum, Agardh. Chrysobrota intermedia and C. Lindleyana, Spach). Similar to the preceding species, but smaller and slenderer in every part; young shoots glabrous or pubescent: lvs. orbicular-reniform to obovate, 3-lobed and slightly crenate-dentate, cuneate to subcordate at the base, 1-2 in. broad, pubescent or glabrous; petals about as long as the blade: racemes 5-15-fld.; rachis oblong to ovate; fls. yellow, fragrant or slightly fragrant; calyx-tube slender, $\frac{3}{4}-1$ in. long or slightly longer; sepals $\frac{1}{2}$ to nearly $\frac{3}{4}$ in. long, spreading, upright in the fading fl.; petals shorter than the sepals; fr. globose, red or black, $\frac{1}{2}-1$ in. thick. Wash. to Calif., west to Assiniboia, Mont., Colo., and N. Mex. B.R. 1274. Var. chrysococcus, Rydb. Fr. yellow. Var. leiobrya, Zabel (R. leiobrya, Koehne). Of the glabrous, glandular while young; sepals recurved, calyx-tube longer.—The shrub cult. as R. aureum is usually the preceding species which has more showy and fragrant fls.

5. viscosissimum, Pursh. Shrub, to 3 ft.; young growth and infl. glandular-pubescent and viscid: lvs. grayish green, reniform-orbicular, 5-lobed, with rounded crenately dentate lobes, glandular-pubescent on both sides, 2-3 in. broad; petals short, yellowish green, puberul-pubescent: fls. fragrant, greenish white or pinkish, in 3-8-fl. racemes; ovary glandular; tube cylindrical-campanulate, about $\frac{3}{4}$ in. long; sepals about as long as tube: fr. black, not bloomy; glandular-hair. Brit. Col. to Mont., Colo. and Calif.

6. cereum, Douglas. Much-branched, upright shrub, to 4 ft.; young growth puberulous and glandular: lvs. reniform-orbicular, 3-5-lobed with obtuse crenulate lobes, puberulous-glandular beneath, often glabrous or nearly so above, ½-1½ in. broad; racemes few-fl., pendulous; bracts cuneate-ovate, toothed at the rounded or truncate apex; fls. white or greenish; calyx-tube pubescent, $\frac{3}{4}-1$ in. long, sepals ovate, about as long; petals minute, orbicular; ovary glandular or smooth; style usually very short. Fls. bright red, about $\frac{3}{4}$ in. across. Brit. Col. to Calif., east to Mont., Idaho, Utah, and Ariz. B. M. 3008. B.R. 1263.—Early leafing and conspicuous with its pale grayish green foliage studded with numerous white or pinkish fls.; also the bright red frs. are ornamental. Var. farinosum (var. farinosum cereum, Janetz.). Branchlets violet: lvs. whitish-puberulent: fls. bright pink.

7. inebrians, Lindl. (R. Spachtiana, Koehne). Fig. 3403. Similar to the preceding species in habit and
foliage: racemes few-fld.; bracts rhombic, usually acute, entire or occasionally with a lateral lobe; fls. usually pink; style glabrous; ovary with stalked glands; fr. bright red, usu. smaller than glandular. S. D. and Mont., Calif., Ariz. and New Mex. B. R. 1471. B. B. (ed. 2) 2:238.—A hybrid between this and the preceding species is R. Berlandieri, Janz.

8. americannum, Mill. (R. frondosum, L’Her. Pennsylvanicum, Lam. R. missourienne, Hort.). AMERICAN BLACK CURRANT. Upright shrub, to 6 ft., with rather slender arching branches; young shoots slightly pubescent and glandular; lvs. suborbicular, cordate or nearly truncate, 3-5-lobed with acute, or sometimes obtuse, dentate lobes, 3-4 in. long, sepals obtuse, longer, pubescent; ovary and calyx pubescent and glandular; calyx-tube broadly campanulate; petals minute, obtuse: fls. globose, black with whitish bloom, resinous-dotted, edible. Alaska to N. Calif. B. R. 1471. B. B. (ed. 2) 2:237.—Foliage with the peculiar heavy odor of the following species, turning crimson and yellow in autumn.

ribes nigrum, Linn. EUROPEAN BLACK CURRANT. Upright shrub, to 6 ft., with rather stout branches, of strong disagreeable odor: lvs. suborbicular, cordate, 3-5-lobed, with broad, acutish irregularly serrate lobes, sparsely pubescent and resinous-dotted beneath, to 4 in. broad, 3-5-ftd.; bracts small, much shorter than the pedicels; ovary and calyx pubescent and glandular; calyx-tube broadly campanulate; sepals oblong, recurved; petals reddish or whitish, about half as long as sepals: fr. black, subglobose, 7/2-8 in. thick. Eu., N. Asia and boreal N. Amer., south to Maine and Vt. B. B. (ed. 2) 2:237. Var. albinervium, Michx. Lvs. glabrous or nearly so beneath. N. Amer., south to N. H., Mich. and Wis.

11. glandulosum, Grauer. CALIFORNIAN BLACK CURRANT. Decumbent shrub with prostrate or spreading reclining sts. and ascending branches; young growth sparingly pubescent and sparsely glandular: lvs. thin, felted, orbicular, cordate, deeply 5-7-lobed, with ovate-acute or acutish, doubly serrate lobes, glabrous above, pubescent on the veins beneath, 1½-3 in. broad; racemes ascending, 8-12-ftd.; pedicels filiform, glandular, much longer than the narrow bracts; fls. whitish or pinkish; ovary glandular-hispid; calyx-tube cup-shaped; sepals short, spreading, glabrous outside: fr. red, glandular-bristly. Newfoundland to Brit. Col.; south to Mich. and Minn. and in the mountains to N. C. B. B. (ed. 2) 2:238.

12. triste, Pall. SWAMP RED CURRANT. Low shrub with creeping or ascending, often rooting sts.; young growth sparingly pubescent and sparingly glandular: lvs. thin, suborbicular, 3-5-lobed, with acute or obtuse, coarsely serrate lobes, dark green and glabrous above, pubescent or whitish-tomentose beneath, 2-4 in. broad: racemes drooping, 1½-3½ in. long; pedicels longer than the ovate bracts; fls. purplish; calyx-tube square-shaped; sepals spreading, obtuse; petals reddish: fr. red, smooth. N. Asia and boreal N. Amer., south to Maine and Vt. B. B. (ed. 2) 2:237.

14. multiflorum, Kit. Upright shrub with stout branches: winter buds large: lvs. roundish, subcordate or truncate, 3-5-lobed with acutish or obtusish, crenately dentate lobes, pubescent beneath, to 4 in. broad: racemes pendulous, dense, to 6 in. long, sometimes about 50-ftd.; pedicels short; fls. greenish yellow; calyx-tube square-shaped; sepals reflexed; petals minute;

19. *ascendens*, Pall. (R. saxatile, Pall.). Upright shrub, to 6 ft.; branches glabrous, slender, upright, with paired small slender prickles at the nodes or unarmed: lvs. oval or ovate-ovoblate, 3-lobed with sparingly dentate, obtusish lobes, glabrous, lustrous, with obsolete veins, 3/4-1 ½ in. long; petals about ½ in. long: fr. dioecious, small, greenish, in upright racemes, the staminate about 1 ½ in. long, the pistillate ½-¾ in. long; stamens very short: fr. subglobose, scarlet. N. Asia. — Like the preceding species desirable for its bright green more lustrous foliage and for its scarlet fr., but habit upright, not spreading.

Section 2. GROSSULARIA. Gooseberries.

21. *neveum*, Lindl. (Grossularia nivea, Spach). Shrub, to 8 ft., upright or ascending: branches reddish brown, with stout brown prickles ½-2 in. long, without bristles: lvs. suborbicular, thin, 3-5-lobed, with few-toothed obtusish lobes, sparingly pubescent or glabrous, 3½-1½ in. long: fr. 1-4, white, on slender peduncles: bracts ovate, small, much shorter than the filiform pedicels; ovary glabrous; tube campanulate; style slenderly lancedolate, ¾-1 in. long; stamens slightly longer than the sepals, with pubescent filae-

22 curvatum, Small (Grossularia curvata, Cov. & Brit.). Diffusely branched shrub, to 3 ft., with slender reddish brown or purplish branches, spines slender, about 6 mm. long; lvs. suborbicular, cuneate to subcordate, with obtuse, toothed lobes, sparingly pubescent, 1–2 in. across; fls. 1–5, white, on slender peduncles; bracts ovate, often 3-lobed, ciliate, much shorter than the slender pedicels; ovary glandular or pubescent; tube, broadly campanulate; sepals linear-spatulate, about 1/8 in. long, revolute; petals small, lanceolate, toothed; stamens conspicuous, as long as the sepals, with villous filaments: fr. globose, greenish, 1/4–1/3 in. across, glabrous. Ga. to La. and Texas.—Graceful little shrub, similar to the preceding species, but slenderer and more spreading; perfectly hardy at the Arnold Arboretum.

23. missouriense, Nutt. (R. gracile Pursh not Michx. R. rotundifolium, Janz., not Michx. Grossularia setosa, Cov. & Brit.). Shrub, to 6 ft., smooth or sometimes bristly, grayish or whitish branches: spines about 1/3 in. long or shorter: lvs. suborbicular, broadly cuneate to subcordate at the base, deeply 5-loved, with coarsely dentate obtuse lobes, pubescent; tube, 1 1/2–2 in. broad; fls. greenish white, 2–3, on slender peduncles 1–2/3 in. long; pedicels slender, much longer than the bracts; ovary glabrous; calyx-tube cylindric-campanulate; sepals linear, about 3/4 in. long; filaments glabrous, nearly twice as long as sepals; style pubescent below: fr. globose, 1/2–2/3 in. across, purplish, glabrous, subacid. Ill. to Minn., S. D., Kans., Mo. and Tenn. B.B. (ed. 2) 2:240.

24. oxyacanthoides, Linn. (Grossularia oxyacanthoides, Mill.). Low shrub with slender, often reclining branches, usually more or less bristly and with spines about 1/4 in. long, sometimes nearly wanting: lvs. suborbicular, broadly cuneate to subcordate at the base, deeply 5-loved with coarsely dentate obtuse lobes, slightly pubescent or nearly glabrous, 1–2 in. broad: pedicels short, scarcely exceeding the bud-scales, 1–2-fid.; pedicels short: fls. greenish white; sepals narrow-oblong, little longer than the tube; stamens somewhat shorter than the sepals: fr. globose, smooth, red, slightly hairy, about 3/4 in. broad; lvs. suborbicular, broadly cuneate to subcordate at the base, usually 3-loved, with coarsely dentate obtuse lobes, pubescent; tube, 1 1/2–2 in. long, sometimes bristly, grayish or whitish branches: spines subulate small spines less than 1/6 in. long, sometimes unarmored, rarely with a few bristles: lvs. suborbicular, cuneate to truncate, rarely broadly cuneate, 3–5-loved, with dentate lobes, finely pubescent and usually somewhat glandular, 1/4–1/3 in. wide; fls. 1–4, white; calyx-tube cylindric-campanulate, glabrous, about twice as long as the sepals; petals half or two-thirds as long as the sepals, as long as the stamens; style pubescent below: fr. red to black, glabrous or somewhat bristly. Idaho to Assinibois, S. D., and Wyo. B.B. (ed. 2) 2:243.

25. setosum, Lindl. (R. saximontanum, E. Nelson. Grossularia setosa, Cov. & Brit.). Shrub, to 5 ft., with reddish brown usually bristly branches: spines about 1/3 in. or less long: lvs. suborbicular, cuneate to truncate, rarely broadly cuneate, 3–5-loved, with dentate lobes, finely pubescent and usually somewhat glandular, 1/4–1/3 in. wide; fls. 1–4, white; calyx-tube cylindric-campanulate, glabrous, about twice as long as the sepals; petals half or two-thirds as long as the sepals, as long as the stamens; style pubescent below: fr. red to black, glabrous or somewhat bristly. Idaho to Assinibois, S. D., and Wyo. B.B. (ed. 2) 2:243.

26. hirtellum, Michx. (R. saxidiv. Hook. R. gracile, Janz., not Michx. R. oxyacanthoides of many authors, not Linn. Grossularia hirtella, Spach). Fls. 3405. Shrub, to 4 ft., with slender branches, usually unarmored, sometimes with subulate small spines, only at the base of vigorous shoots bristly: lvs. suborbicular, usually cuneate, incisedly 3–5-loved, with dentate, acute lobes, glabrous or sparingly pubescent, 1–2 in. broad; pedicels often with long hairs: fls. 1–3, greenish; bracts much shorter than pedicels; ovary glabrous, rarely with stalked glands; calyx-tube narrowly campanulate; sepals oblong, often purplish, glabrous; stamens as long as sepals, petals half as long; style pubescent: fr. globose, smooth or rarely with stalked glands, purple or black, edible. Newfoundland to Pa. and W. Va., west to Man. and S. D. B.M. 6892 (as R. oxyacanthoides). B.B. (ed. 2) 2:241.—This is the most important of the edible American gooseberries and there are in cult. several hybrids with R. grossularia, designated as R. xrueticum, Janz., to which such varieties as Downing, Houghton, and Smith are thought to belong, while Pale Red appears to be of pure R. hirtellum parentage.

27. rotundifolium, Michx. (R. triflorum, Willd. Grossularia rotundifolia, Cov. & Brit.). Shrub, to 3 ft., with slender green branches, or the younger ones gray; spines small, sparse, rarely over 1/2 in. long; lvs. suborbicular, broadly cuneate to subcordate at the base, usually 3-loved, with coarsely dentate obtuse lobes, minutely pubescent or nearly glabrous, 1–2 in. broad; fls. 1–3, purplish; pedicels slender; pedicels much longer than the small bracts; fls. greenish purple; calyx-tube campanulate; sepals linear, about twice as long as tube; petals obovate; stamens somewhat longer than the sepals; fr. globose, smooth, purplish. L.B.C. 11:1094. G.O.H. 3. B.B. (ed. 2) 2:241.—This species is rare in gardens; usually the following species is cult. under this name.

28. divaricatum, Douglas (R. divaricatum var. Douglasiae, Janz. R. irriguum, Koehne, not Douglas. Grossularia divaricata, Cov. & Brit.). Shrub, to 10 ft.; branches gray to brown, with stout spines 1/4–1/2 in.; lvs. suborbicular, broader, cuneate to subcordate at the base, usually 3-loved, with coarsely dentate obtuse lobes, pubescent beneath along the veins or glabrous, 1–21/2 in. broad; fls. 2–4, greenish purple; pedicels slender; bracts ovate, small; ovary glabrous; calyx-tube campanulate; sepals oblong, longer than tube; stamens slightly longer than the sepals; fr. globose, smoon, black or dark purple. Brit. Col. to Calif. B.R. 1359. Var. pubiflorum, Koehne (R. divaricatum var. silvorum, Zabel). Lvs. pubescent: fls. smaller: vigorous sts. bristly. Var. montanum, Janz. Low shrub with almost prostrate branches, smaller in every part. Calif.

29. inermé, Rydb. (R. hirtellum Purpurisii, Koehne. R. oxyacanthoides var. nevadense and var. irriguum, Janz. Grossularia inermis, Pursh, not Douglas. R. hirtellum, Cov. & Brit.). Shrub, to 6 ft.; branches with few small spines less than 1/2 in. long, sometimes unarmored, rarely with a few bristles: lvs. suborbicular, cuneate to truncate at the base, 3–5-loved with crenate-dentate obtuse lobes, glabrous or sometimes pubescent, 1–21/4 in. broad: fls. 1–4, green or purplish; bracts small; ovary glabrous; calyx-tube narrowly campanulate; sepals oblong, slightly shorter than tube; stamens shorter than sepals; fr. purplish red, smooth, edible. Mont. to Brit. Col. to Calif. and New Mex.

30. Grossularia, Linn. (Grossularia reclinata, Mill.). Shrub, to 3 ft.: branches ascending or reclining, with stout spines, about 1/4 in. long, mostly in 3’s, sts. sometimes bristly: lvs. suborbicular, cuneate to broadly

3406. Rhabdos Cyrobius. (X1/4)

31. *Cynädbati*, Linn. (*R. gracile*, Michx. *Grossularia Cynädbati*, Mill.). Fig. 3406. Shrub, to 5 ft., but usually lower, with spreading branches; spines slender, 1-3, $\frac{1}{2}$-3 in. long; bristles few and weak or none; lvs. orbicular, truncate or cordate, deeply 3-5-lobed, with crenately or incisely dentate lobes, usually pubescent beneath, $\frac{3}{4}$-1$\frac{1}{2}$ in. broad; fls. 1-3, on slender stalks, green, ovary setose; calyx-tube broadly campanulate; sepals shorter than tube; petals about half as long; stamens little longer than petals: fr. globose or ovoid, vinous-red, prickly, edible. New Bruns. to N. C., west to Man., Mo. and Ala. B.B. (ed. 2) 2:239. Var. *inerme*, Rehd. Fr. without prickles, smooth. Val. *glabratum*, Fern. Lvs. glabrous or only sparingly pilose on the veins.

32. *alpestre*, Decne. Upright shrub, to 10 ft.; branches with stout spines to $\frac{3}{4}$ in. long and usually in 3's, often bristly; lvs. cordate to truncate, 3-5-lobed, with incisely dentate, obtusish lobes, 1-2 in. broad; fls. 1-2, short-peduncled, greenish or sometimes reddish; far north as Mass.; in W. China, E. H. Wilson found hedges 6-8 ft. high so thick and spiny that a yak, an animal as strong as an ox, could not break through them.

33. *pinetrum*, Greene (*Grossularia pinetrum*, Cov. & Brit.). Shrub, to 6 ft., with spreading and reclining branches, without bristles; spines 1-3, $\frac{1}{2}$-1 in. long or less; lvs. suborbicular, thin, cordate, usually 5-angled, with obtuse irregularly incised-dentate lobes, dull green and glabrous above, puberulous beneath at least on the veins, $\frac{3}{4}$-1$\frac{1}{2}$ in. broad; fls. solitary, orange-red; bracts small, ciliate; ovary bristly; calyx-tube campanulate, pilose; sepals spatulate, reflexed, nearly twice as long as tube; petals orange, only one-third shorter than the sepals; stamens as long as petals: fr. globose, prickly, purple. Ariz., New Mex.—Hardy at the Arnold Arboretum; very striking on account of the unusual orange-red color of the fls.

34. *Roezlii*, Regel (*R. amietum*, Greene. *R. druidum*, Greene. *R. Wilsonidnum*, Greene. *Grossularia Roezlii*, Cov. & Brit.). Shrub, to 5 ft., with pubescent branchlets; bristles wanting; spines slender, about $\frac{1}{2}$ in. long; lvs. thin, reniform-orbicular, truncate or subcordate, 3-5-lobed with incisely crenate-dentate lobes, finely pubescent on both sides or glabrous above, $\frac{1}{2}$-1 in. broad; fls. 1-3, purple; bracts longer or sometimes shorter than pedicels; ovary bristly and usually white-hairy; calyx-tube cylindric-campanulate, pubescent; sepals lanceolate, longer than tube; petals white or pinkish, nearly half as long as sepals; stamens slightly longer than sepals; anthers sagittate: fr. globose, prickly, purple. Cent. and S. Calif. Gt. 28:1182, figs. 1-3. R.H. 1908, p. 32.—Very handsome in fl., particularly on account of the contrast between the purple calyx and the white petals.

35. *Lobbii*, Gray (*Grossularia Lobbii*, Cov. & Brit.). Fig. 3407. Shrub, to 7 ft.; branches pubescent, rarely with a few bristles; spines 3, $\frac{1}{2}$-3 in. long; lvs. thin, suborbicular, cordate or subcordate, 3-5-lobed, with crenate-dentate obtuse lobes, sparingly pubescent when young and glandular, or glabrous above, $\frac{3}{4}$-1$\frac{1}{2}$ in.

R. aciculare, Pursh (R. fuchsioides, Moc. & Sess.). Grossularia speciosa, Fig. 3408. Evergreen shrub, to 12 ft., with stout sts.; branches usually bristly; spines 5, stout, 1/2-3/4 in. long; lvs. coriaceous, orbicular to obovate, rounded to broadly cuneate, 3-5-lobed or crenate-dentate, glabrous or sparingly glandular-hairy, lustrous above, 1/2-1 1/2 in. long; fls. 2-4, bright red, on slender pedunculous peduncles, 4-merous; tube broadly campanulate; sepals upright, parallel, about 3/4 in. long, as about the scarlet corolla petals; stamens 2-4 times as long as petals: fr. ovoid, glandular-bristly, red. Calif. B.R. 1557. B.M. 5530. Gn. 9, p. 586; 31, p. 333; 34, p. 230. G.C. III. 34:71. R.H. 1900:98; 1908, p. 29. J.H. III. 51:407. One of the most showy gooseberries, but not hardy.

glabrous or hirsute. N. W. China.—R. pedemontanum, Mill. Allied to R. sanguineum. This species has recently been added to the genus, which see.

Herbaceous, or becoming small trees in the tropics, glabrous or rarely subspinose, branching repeatedly from below the flower-clusters; leaves large, alternate, peltate, palmately 5-12-lobed, the lobes dentate or serrate; petiole with conspicuous glands; flowers monocious, in terminal or apparently lateral racemes or subpaniculate, without petals or disk; calyx 3-5-parted, valvate; staminate flowers short-peduncled, in the upper part of the raceme; stamens many, filaments much branched, no rudimentary pistil; pistillate flowers below, longer-peduncled; styles 3, plumose; capsules generally covered with soft spinose processes, 3-celled, 1 ovule in each cell, explosively separating into 2-valved cocci when ripe; seeds ovoid, with a large aril; seed-coat crustaceous, variously marked and colored; endosperm fleshy and oily; cotyledons broad, cordate or oval. Hundreds of forms are known, many so well marked as to deserve specific rank, were they not so thoroughly connected by intermediate forms and hybridizing so freely when brought together. Most botanists follow Mueller (De Candolle’s Prodromus, vol. 15, pt. 2:1061, 1866) in referring them all to the one species. Probably a native of Africa, but now cult. and wild in most tropical and temperate lands.

Castor beans have been cultivated from the earliest times for the oil of the seeds. The Hebrew name indicates that perhaps this is the plant referred to in the Book of Jonah as a gourd. The oil (castor-oil Oleum Ricini) is used in medicine and in the arts and in some places in the preparation of food. The seed contains a poisonous principle, ricin. For the cultivation of castor beans as a field crop, see “Cyclopedia of American Agriculture,” 2:229. The chief castor-oil-producing region is in India, but some is grown in the United States, especially in Oklahoma.

Ricinus is one of the best plants for giving a tropical effect in beds and borders or planted singly. It thrives in rich well-drained sandy or clay loam, but is not suited for stiff clay or very sandy soil. For garden decoration the seeds may be planted in May where they are to grow, or sown indoors in small pots, two or three seeds each, in early spring, and after germination thinned to one plant to a pot. As they grow they may be transferred to larger pots and finally planted out. The castor beans have practically no insect or fungous enemies of importance. They have been erroneously supposed to keep away moles and malaria.

**Ricinus communis.** Linn. **CASTOR BEAN. CASTOR-OIL PLANT. PALMA CHUSTI.** Figs. 3409-3411. Three to 15 ft. high when grown as an annual, 30-40 ft. in the tropics. The various varieties are distinguished by the size, color, and outline of the plant and leaves, the glands of the petiole, the number and size of the processes on the caps., the shape of the cotyledons, and especially the size, form, color, and markings of the seed, which show variations sufficient to distinguish individual plants, and even separate branches of the same plant. So far as the forms commonly in cult. are concerned, the species may be subdivided as follows:

- **A.** Markings of seed-coat marbled, distinct from the ground-color; seed less than twice as broad as thick; cotyledons elliptical or oblong, nearly truncate at base, petiole-glands various.
- **B.** Seeds small to medium, brown-marked; petiole-glands flat, not projecting. This includes most of the oil-producing varieties and the typical *R. communis* (illustrations, variety not designated: B.M.2209. A.G. 17:363. F.W. 1858:98. G.F. 1, p. 541; 9, p. 460. G.F. 24, p. 281; 31, p. 20. Mn. 7, p. 223. R.H. 1861, pp. 9, 10. V. 2:224); also the following varieties: *giganteus* (lividus, Willd., pruinosus, f.), glaucous foliage *(V. 16:148); arboreus; major; minor; éridia, st. and lvs. green; inermis, fr. smooth; purpurascens; africana; elegantissimus; speciosus.*
- **BB.** Seeds medium to large, reddish to reddish-brown; glands of petiole large, projecting; plant usually red; st. often more hollow, short-lived and early-fruiting. The typical form is var. *sanguineus* (Oberminni, lividus, Jacq.) *(Gn. 5, p. 349. R.H. 1858, pp. 602, 603); *macrocarpus (V. 16:148); purpureus (tricolor); atropurpureus; anguinalentus; macrophyllus* *(V. 16:148); *macropurpureus; pulcherrimus.*
- **BBB.** Seeds as in BB, but dark brown to black: otherwise as in B. **Bourboniensis,** and its var. *nanus* and *arboreus* *(V. 16:148).**

- **AA.** Markings of seed-coat rather straight, slightly raised above the ground-color and distinct from it; seeds...
medium size, more than twice as broad as thick; coryledons ovate, rounded at the base, glands small, flat; foliage red to almost black. Contains var. Glabrous, dwarf, dark red with metallic lustre; Glabrous coccinea; Glabrous mirabilis, bright carmine fr.; Glabrous mica, very dark foliage; hybrida paniculata, large, dark and glaucous, a cross with zanxBeran&phispphenus.

AAA. Markings of seed-coat of fine bright red mottle, diffusing into the ground-color (gray or brown in some of the hybrids); seeds large, flat; coryledons coriaceous; glands many, large, projecting at the apex and deciduous; plants large, generally without much red color, of any. Contains var. zanxBeran&phuispphenus (A.G. 16, p. 383. G. C. III. 14:783. Gn. 44, p. 563. Gn. 43, p. 69. I.I. 41:100) and its varieties, which seem to be crosses with some of the previous groups. (G. 44, p. 77.)

Other names in the trade, but not classified above, are: ceruleus, Bismarckiana, and insignis.

J. B. S. Norton.

RIGIDÉLLA (Latin, somewhat rigid; referring to the pedicels, which after the petals fall become erect and stiff). Irídácce. Half-hardy bulbs allied to Tigrídia and useful for planting in the garden.

Leaves broad, plicate, with channeled petiole: flos. fugitivus, bright red, pedicelled; perianth-tube none; segms. very unequal, outer oblong, convolute in a cup in the lower third, then spreading or reflexed; inner small, erect, ovate, with a narrow claw.—About 3 species. Mex. Distinguished from Tigrídia by the very small inconspicuous ovate and erect perianth-segms., those of Tigrídia being larger, fiddle-shaped and spreading.

fílamea, Lindl. St. 3-5 ft. high: lvs. broadly equitant, plicate and shawding the st. below: flos. in terminal fascicles, between the 2-valved spathe; peduncles recurved but becoming erect in fr.; perianth 3-foliate, the limb concave and revolute, bright scarlet striped with brown, black at the throat, spirally twisted after anthesis: the limb concave and revolute, bright scarlet striped with brown.

fílamea, Lindl. St. 3-5 ft. high: lvs. narrowly lanceolate, acute, about as tall as the scape: flos. bright crimson, not marked with black; perianth-segms., those of Tigridia being larger, fiddle-shaped and spreading.

R. Pseudacacia Linnaeus. St. 5-7 ft. high: foliages composite, simple or singularly or very finely branched: lvs. alternate, narrow: cymes terminal, Engler’s Pflanzenreich, 4ft. 39), native of Trop. and Subtrop. Amer., but intro. into Asia and Afr.

Leaves alternate, slender-petioled, ovate, ovate-lanceolate or cordate-ovate; stipules minute and caducous: inflorescence axillary or rarely terminal; fls. small, perfect; perianth 4-parted; stamens 4: berry red, pea-like.—Species 3 (Walker, Engler’s Pflanzenreich, hft. 39), native of Trop. and Subtrop. Amer., but intro. into Asia and Afr.

humilis, Linn. (R. kivési, Linn.). ROUGE PLANT. Fig. 3412. St. with spreading branches, 3/2-2 ft. high: lvs. 1-3 in. long: racemes slender, pedicelled, in axillary racemes, as long as the lvs.; fls. white, 1-1/2 in. long; calyx pale rose: fr. 1-1/2 in. long. S. Fla. B.M. 1781. S. H. 2:111. Gn. 22, p. 68.—Variable.

F. TRACY HUBBARD.

ROBINIA (after Jean and Vespasian Robin, herbalists to the king of France in the sixteenth and seventeenth centuries). Leguminosae. LOCUST. Ornamental woody plants grown chiefly for their handsome white, pink, or purple flowers and the graceful foliage.

Deciduous trees or shrubs: branches without terminal bud, often with stipular spines; lvs. alternate, stipulate, petioled; pedicels, which after the petals fall become erect and stiff, nodding, sometimes spreading; stamens 5; ovary 4 distinct lobes; seeds large, flat; cotyledons ovate-oblancolate, dehiscent. Contains R. hispida, R. pseudacacia, R. viscosa, R. villosa, R. alata, R. foveolata, R. pennsylvanica; R. viscosa are hardy as far north as Ontario, and most other cultivated species as far north as Massachusetts. They are not particular as to the soil and they do well even in poor sandy soil and dry locations. They stand transplanting well and grow rapidly while young. Some species, particularly R. hispida, spread by suckers and may for this reason become a nuisance in lawns and mixed groups. R. pseudacacia, on account of its heat- and drought-resisting qualities, together with its ornamental beauty, has become a favorite street tree for cities, particularly in Europe; in this country it is not so much planted, as it is liable to the attacks of the borer and therefore short-lived; it stands severe pruning well. Propagation is by seeds sown in spring and germinating readily; they
may also be increased by suckers and some, particularly R. hispida, grow readily from root-cuttings. Varieties and usually grafted, either on young seedling stock in the house or outdoors in spring or on pieces of root in the greenhouse; some dwarf forms, as R. Pseudacacia var. Rehderi are propagated by division, and other varieties, particularly var. Bessoniana, by cuttings of mature wood. Some varieties, as var. Decaisneana var. monophylla, may be raised from seed, as a large percentage comes true.

A. Fls. white (light pink in one variety): branchlets glabrous or slightly pubescent: pod smooth.

1. Pseudacacia, Linn., Falsae ACACIA. BLACK LOCUST. Yellow Locust. Fig. 9413. Tree, to 80 ft., with deeply furrowed dark brown bark and prickly branches: lfts. 7; 10, oval or elliptic, rounded or truncate and mucronate at the apex, glabrous or slightly pubescent while young; fls. 1; 2 in. long; fls. white, very fragrant, about ½ in. long, in pendulous puberulous racemes 4; 5 in. long; pod linear-oblong, reddish brown, 3; 4 in. long. May, June; fr. in Aug. and Sept., become extensive naturalized in Eu. S.S. 3:112, 113. F.E. 32:393. Gn. 6:1. 61. G. M. 45:513. H. W. 3: 58. p. 104. —Many varieties are in cult., of which perhaps the following are the best known. Var. umbraculifera, DC. (var. inermis, Kirchen, not DC.). Forming a dense subglobose head, with unarmed branches: rarely flowering. Much used in Eu., when grafted in formal plantations and as ornamental street tree. M.D.G. 1903: 630. Var. Bessoniana, Nichols., with slenderer branches forming a less dense head, and var. Rehderi, Kirchen, a low subglobose form, usually grown on its own roots (G.W. 2, p. 217), are forms of var. amorphifolia, Lou., not DC. (var. inermis, Kirchen, not DC.). A slow-growing form with short pendulous branchlets: lfts. 9; 11, ovate or long-oval, acuminate, grayish pubescent beneath, ½; 1 in. long; pod oblong, densely covered with purple glandular hairs, 1½; 2 in. long. May, June. N. C. M.D. 8213. G. C. III. 41:427; 47: 391; 58:72. J. H. 36, p. 153, fig. 134. G. 33: 461, 463. M. D. 1910, p. 101. Addisoma 1:8.—Very hardy, and graceful, the purple frs. are also attractive.

2. Elliottii, Ashe (R. hispida var. rosea, Elliott). Shrub, to 5 ft.: branches with short spines; young branchlets grayish or whitish tomentose: lfts. 11; 15, elliptic, grayish pubescent beneath, ¾; 1 in. long; racemes 5; 10-fl.; peduncles, pedicels, and calyx glabrous; corolla rose-colored or purple and white: pod linear, hispid. May, June. N. C. to Ga.—A very handsome species easily distinguished by the dense grayish pubescence without glands or bristles.

3. Kelseyi, Bean. Shrub, to 10 ft.: branches with slender prickles; branchlets glabrous: lfts. 9; 11, oblong-lanceolate, acute, rounded at the base, glabrous, ¾; 1½ in. long; racemes 5; 8-fl.; racemes 5; 8-fl.; peduncles, pedicels, and calyx sparingly pubescent, or with glandular hairs; corolla rose-colored or purple and white: pod linear, hispid. May, June. N. C. to Ga.—A very handsome species easily distinguished by the dense grayish pubescence without glands or bristles.

b. Fls. pink or purple.

c. Pod smooth.

5. hispida, Linn. (B. rosea, Marsh.). ROSE ACACIA. Fig. 3414. Shrub, 1; 3 ft., rarely higher; st., branchlets, and peduncles and often the petioles hispid: lfts. 7; 13, suborbicular to oval, obtuse and mucronate, glabrous or nearly so, ¾; 1¼ in. long: fls. rose-colored or pale purple, 1 in. long, in short, 3; 5-fl.; racemes: pod rarely developed, densely hispid, few-seeded. F.S.R. 2, p. 57. J. H. 111, 53: 183. G. 4: 429. Var. macrophylla, DC. (var. inermis, Kirchen.). Branchlets and pedicels nearly destitute of bristles: lfts. and fls. often somewhat larger. Gn. 77, p. 208. G. M. 45:512.—This species spreads much by suckers, particularly in sandy soil; sometimes grafted high to form a small standard and as such displaying its large fls. to greater advantage.

6. nana, Spech (R. hispida var. nana, Elliott). Shrub, about 1 ft. high, in cult. sometimes higher: stbs.
Robinia hispida. (x½)

cc. Peduncles and branchlets glandular-hairy or viscid: Ifts. usually more than 15.

d. Branchlets and peduncles glandular-hairy.

7. neo-mexicana, Gray. Shrub or small tree, to 25 ft.; branches spiny; branchlets pubescent and glandular; Ifts. villous; Ifts. 15–21, elliptic-oblong, rounded and mucronate, silky pubescent beneath at least while young, 1–1½ in. long; racemes many-fl., dense, more or less hispid; peduncles and branchlets glandular-hairy; corolla pale rose-colored or sometimes nearly white, 2–3½ in. long. May, June. N. and S. C. to Ala.; naturalised elsewhere. S.S. 3: 115. B.M. 7726. S.S. 3: 114. F.S.R. 2: 56. G.t. 41: 1385.

8n. Rhochis of Ifts. densely covered with stalked glands.

9. Hārtwigii, Koelne. Shrub, to 12 ft.: branchlets, Ifts., petioles, leaf-rachis, and peduncles puberulous and densely covered with stipitate glands: Ifts. 13–23, elliptic to lanceolate, mucronate, grayish pubescent beneath, 1–1⅓ in. long; racemes dense; calyx pubescent and glandular-hairy; corolla rosy purple, ⅓ in. long; pod oblong, densely glandular-hispid, about 2 in. long. June, July. N. C. to Ala.

d. Branchlets and peduncles viscid.

Rubinsia (derivation not known). Legeninimum. Twining shrubs, with trifoliolate Ivs. and elongated axillary racemes: Ifts. somewhat fasicated; calyx 2-lobed; corolla papilionaceous, standard somewhat rounded, sulate at the base, wings oblong, obtuse, keel incurved, obtuse; stamens diadelphous: pod compressed, 2-valved, linear-longate.—Two or 3 species, Mex. The genus is now usually included in Pachyrhizus. R. gerriniflora, Hort., is apparently botanically unknown. U.U. 2, p. 291.

Rocambole (Allium Scorodopraefus, Linn.), is a humble member of the onion tribe, the underground bulbs of which are used abroad like garlic, known in America amongst the Canadian French and perhaps elsewhere. The plant is a hardy perennial, with a stem twisted spirally above and bears at the top an umbel of flowers, some or all of which are changed to bulbils. The presence of these bulbils distinguishes the plant from garlic. The species can be propagated by the bulbils, but quicker results are secured from the cloves of the underground bulbs. In mild climates, the bulbs should be planted in autumn or not later than February; in cold climates, plant in spring. In the autumn when the leaves decay, the bulbs are lifted, dried in the sun, and stored.

Rocambole is a native of Europe, the Caucasus region, and Syria. It has flat or keeled leaves, short spathe, bell-shaped six-parted perianth, and the three inner stamens broader than the others, three-deft, and not longer than the perianth. Good seeds are rarely produced.

- Rochea (named after de la Roche, French botanist). Syn., Kaloeodraehes, Crassulaceaef. Succulent shrubby plants suitable for the greenhouse.

Leaves opposite, ciliate at the base, oölone-obvate or lanceolate; Ifts. rather large, aggregated in corymbose-captate cymes, white, yellow, rose, or red; calyx 5-parted or 5-dept; corolla salver-shaped, the elongated claws of the petals connate with the calyx-tube, limb spreading; follicles many-seeded.—About 4 or 5 species, S. Afr.

Rocheas are amongst the showiest of our summer-flowering greenhouse plants, and are very easy to propagate. If plants are desired from a single root, cuttings about 4 inches long should be selected in March, and potted singly in sandy peat. The small pots should be placed near the glass, in a night temperature of 50°. Do not keep them too wet, as they are of a flabby nature, and are liable to rot. In a few weeks, the plants will be rooted and the points may be cut out to encourage breaks. A few days after they are cut back, repot into a pot two sizes larger, using two parts fibrous loam, one of sand, and one of broken charcoal, adding a sixth part of sheep-manure. After they are rooted, keep them near the glass, in a night temperature of not over 40°, when this is possible.
XCVII. A rock-garden.
When all danger of frost is past, set them outdoors on a bed of ashes in the full sun, making some provision to protect them from rainstorms, so as to prevent water lodging in the points of the shoots, which is liable to bring about conditions favorable to disease. Toward the end of September, have the plants housed in their winter quarters; all that is necessary during the winter is to keep them from freezing. In spring, the points of the shoots may be cut out again to encourage them breaks and soon after they may receive another shift. Treat them as advised above, and when the pots are well filled with roots, they may be watered with manure-water as advised for ixoras. Rochas may be flowered the second summer after the cuttings are struck, and after flowering the plants may be cut back to 6 inches above the pot. These cut-back plants may be shifted along, after they break, and be grown into large specimens. Fine plants of rocha may also be grown in the following manner: Take a 10- or 12-inch pot, and fill it with the compost advised above, the last 2 inches being pure sand. Insert the cuttings as thick as they can be pricked into the pot. The cuttings may be secured from a plant that has flowered. Breaks will start all over the stems of such plants, and in the fall after flowering they will be large enough to use for cuttings. In eighteen months this pot of cuttings will come in flower and will have more than doubled the number of shoots. Aphides are the only insect pests that molest the rochas, and these may be destroyed by fumigating with tobacco in some of its forms. These plants require at all times abundance of fresh air, and if this is not given, they will be attacked by fungous disease. (George F. Stewart.)

A. Clusters usually 2-fld.

jasminea, DC. (Crassula jasminia, Ker-Gawl). St. subshrubby, 4-12 in. high, decumbent, branched, flowering part erect: Ivs. fleshy, oblong-oval or spatulate, ½-2½ in. long: fls. white, tinted with crimson, sessile, not fragrant, ½ in. long. Cape B.M. 2178. L.B.C. 11:1040.—Hybrids with K. coccinea are figured in A.F. 5:433.

AA. Clusters many-fld.

coccinea, DC. (Kalosanthus coccinea, Haw. Crassula coccinea, Linn.). Plant robust, shrubby, 1-2 ft. high: Ivs. very closely imbricated, ovate-oblong or ovate, 1-1½ x ½-1 in.: fls. bright scarlet, 1½-2 in. long, fragrant, borne in summer. Cape. Gn. 46, p. 360. B.M. 495.—Showy; hybrides are in cult.

R. falcata, DC.—Crassula falcata. —R. hybridra albitora is said to be a hybrid of R. coccinea and R. odoratissima.—R. odoratissima, DC. Somewhat shrubby, 12-20 in.: Ivs. acute, erect-spreading, linear-lanceolate or subulate: fls. 1 in. long, fragrant, pale yellow or cream-colored. Cape

L. H. B.

ROCK-GARDEN. An ornamental planting in very rocky places or in areas on which rocks have been placed for the particular purpose to make congenial conditions for certain classes of plants and also to lend interest and variety to a part of the grounds; a rockery. Figs. 3415-3419. See, also, Alpine Plants, Vol. I.

Nature in time will make a garden even on the broken surface of a rock, by sending in with lith, lichens, alge, and mosses of many exquisite forms having much variety and often striking brilliancy in coloring. If there are soil-filled cracks and pockets, then ferns and flowering plants will find a place. At low elevations, however, these flowering rock-plants are comparatively few, for soil accumulates rapidly and strong-growing herbs, shrubs, and trees, aided by favorable climatic conditions, soon cover the rock surface or furnish so dense a shade that only mosses, lichens, and ferns will thrive.

The ideal rock- or alpine gardens are within that region on mountain summits between the limits of tree-growth and the edge of perpetual snow, and in the corresponding regions toward the poles, where the plants are protected from the rigors of a long winter by blankets of snow and are quickened into a short period of rapid growth by a comparatively low summer temperature. Here, where there are deep cool moist rockcrevices and pockets filled with fragments of broken stone and porous decayed vegetable matter, are the favorable conditions wherein the real alpine plants can multiply their neat and dainty cushions, tufts, and rosettes of dense and matted foliage and their abundance of exquisitely formed and brilliantly colored flowers. A successfully grown collection of these plants in contrast with ordinary garden flowers would be like a collection of cut gems as compared with one of rough minerals and rocks, for they have an exquisiteness of finish and depth of coloring that gives them as unique a place in the vegetable kingdom as they have in the plan of nature. Surely there are men and women who, if they knew these plants well, would be fired with an ambition to excel in their cultivation; and in so doing they may enter a comparatively untrdden path if they will limit their work chiefly to the alpines of this continent. They are represented in the New England mountain region by such species as Arenaria granulatca, Leioselaria procumbens, Silene acutis, Diaspasia lapponicum, Arctus alpinus, Vaccinium caespitosum, Saxifraga Aizoon var. sieularis, Veronica alpina, Geum radiatum var. Flacks, Sibbaldia procumbens, Rhododendron lapponicum, Phylloclode coccinea, Primula farinosa, Saxifraga oppositifolia, S. Aizoon, and S. aizoides, Alser polyphyllus, and Woodsia glabella; and in the Rocky Mountains and Pacific Coast ranges by Bisorger uniflora, E. lanatus, and E. urastus, Actinella Brandegii and A. grandiflora, Arctemia borealis, A. scopulorum, and A. alpina, Sericoi Solidanella, S. Fremontii, S. petraus, S. uniflora, and S. wernertii, Crepis nana, Campanula uniflora, Phyllodec coccinea, Phyllodioc coccinea, A. septentrionalis, Gentiana protonora, G. frigida, G. Newberryi, G. Parryi, and G. simplex, Parkh phryoides and P. cespitoso, Pulmonium coniferum, Cassiope Mertensiana, Phylloclode Breverdi, Draca streptocarpa, D. Parryi, and D. nudiculosa, Arabis Lylitii and A. platysperma, Smelovskia calycina, etc.
species that have been long cultivated there. Here alpines have been but little undertaken. A very few easily grown European kinds, as *Andromeda dotoidea*, *Achillea tomentosa*, *Campanula carpatica*, and *Arabis alpida*, are offered by American nurseries and cultivated in the open border. On a few private places small rock-gardens have been established, or advantage has been taken of favorable local conditions to cultivate some additional species, and in one or more botanic gardens considerable collections have been at times maintained, chiefly in frames. Generally what has passed for rock-gardens have been rockeries—mere piles of cobbles raised from the surface of turf or piled against dry banks in such a manner as rapidly to disperse instead of slowly conserve all soil-moisture. Even the most self-assertive weed fails to thrive in such a garden.

In general, we have a smaller rainfall, less humidity and a larger proportion of sunny days than in England, to which we must look for careful instruction in the cultivation of alpine plants. This must be regarded in the arrangement of our rock-gardens. Every precaution should be taken to secure the full advantage of rainfall and any natural water-supply, and there should also be a liberal and constant artificial water-supply. It must be kept in mind, also, that at low elevations the long hot summers do not allow the period of rest that such plants require. This condition must be met by devices, methods, and locations that will retard the growth in spring, check it at an early period in autumn, and keep the plants fully dormant in winter, such as shade, mulching, and, in the case of particularly difficult plants, the protection of frames. It is essential that conditions be provided that will enable the roots to extend for a long distance, often many feet, in narrow crevices and pockets between rocks to depths where there can be no possible internal supply of moisture and have an equable temperature, for frequent freezing and thawing and stagnant water are fatal. These cavities should be filled with such loose material as fragment of rock mixed with decayed vegetable matter, without manure, and arranged to provide for the free passage of hair-like roots, for perfect drainage and the free access of air. To provide these unusual conditions on the average private place in a large way would be so difficult and so expensive that it is not to be recommended. A small collection, comprising a few easily cultivated alpines and the similar rock-plants referred to in a later paragraph may, however, be successfully grown on reconstructed stone walls, on ledges, in small rock-gardens and in the open borders of almost any country or city place. People who desire a more extensive collection of true alpines should seek a situation where favorable natural or existing conditions may be taken advantage of. Such locations are likely to be found at the seashore and in rocky and hilly regions—such regions, for example, by many persons for summer homes. A ledge, a natural mass of boulders or an abandoned quarry will often provide them. Pockets and crevices of ledges may be cleared of unsuitable material, and if they are not deep enough to hold moisture and have an equable temperature their depth may be increased by the judicious use of wedges, bars, and explosives. Boulders can be arranged in such a manner as to secure suitable deep pockets and crevices of soil, springs can be diverted to supply a constant flow of water, underground pipes can be carried from an artificial source of supply to various points where conditions require them. However favorable the conditions are, it will be found that much can be done to advantage in different localities to meet the special requirements of different groups of plants. In such work, however, it should be kept constantly in mind that there are plants that will grow in all sorts of surroundings, and that it will often be much better to seek such as are adapted to existing conditions than to go to the expense of radically modifying such arrangements.

If an artificial rockery is to be constructed, it should be borne in mind that it is not for the purpose of displaying a collection of curious rocks fantastically arranged, but to provide a place for growing a class of plants that can be well grown elsewhere. To do this properly, it would be better never to think of securing mountain, valley, and rock effects in the disposition of the material to be used, but only to think of providing many varied conditions and situations as regards exposure to sun and shade, depth of pockets and crevices, the character and depth of soils, subterranean and surface water-supply, and whether it be permanent or fluctuating. Digging and arranging the rocks, freshly broken raw faces should not be exposed, but rather such faces as are already covered with a growth of lichens for sunny places and with mosses for shady spots. To take full advantage of surface water, pockets and crevices should have a decidedly downward direction from the exposed surface and not be sheltered by overhanging rock. That this does not apply in all cases, those who are familiar with the habitats of rock-plants know full well. The natural habitat of *Pellaea gracilis* in the upper Mississippi bluffs is in horizontal crevices, but it is absolutely protected from all surface water. *Pellaea atropurpurea* will grow in narrow cracks and small pockets on the face of dry limestone boulders where there can be no possible internal supply of moisture. These examples go to show that the general principles that will apply to such plants as a class will not apply to all species, and it simply gives emphasis to the importance of trying a plant under all sorts of conditions before assuming that it can not be grown. The writer remembers well an attempt to grow that most exquisite alpine flower, *Gentiana verca*, in the open border on a little pile of rocks to give it suitable drainage. It was transplanted a number of times to places where it came continually to be killed at the same, and finally a situation was secured, where, instead of barely holding its own, it increased and produced a number of its great deep blue flower-cups.
The making of a rock-garden.

A rock-garden must of necessity often be "artificial" in the sense of made by man, because few gardens or grounds contain a natural rocky slope or even a natural bank upon which one might be constructed, and if they did the position may not be an ideal one. A southern slope would be too hot and dry in this climate, unless it was shaded by tall trees. A bank with a northern or northeastern aspect free from the roots of trees would suit this class of plants much better, and very attractive it can be made, especially if the bank is on the outer edge of a garden, or skirts a lawn. There is no form of gardening in which one has more opportunity to give expression to his natural taste than in the construction and planting of a rock-garden. But since all grounds or gardens do not have a natural bank or slope upon which an "open" rock-garden might be constructed, a depressed rock-garden may be made in grounds that are perfectly level, and some of the best rock-gardens in the world are what are known as "underground," for example, the one in the Royal Botanic Gardens, Kew, London, England. Before this rockery was constructed the ground was perfectly level. A cutting was begun at one entrance, at first shallow,
but gradually deepening till a depth of some 5 or 6 feet was reached, and an average width of about 10 feet at the bottom. At all the soil taken out was placed on the top of the slopes, thus still further increasing the height. The cutting was made in a wincing manner, not formal or zigzag, but in such a form that when completed, not only would a variety of aspects be secured to suit the requirements of different plants, but each turn should seem to possess a peculiar charm of its own. The whole cutting is perhaps some 200 yards in length. The rocks are placed in the banks in such a manner as to seem possible to place them; now they stand out boldly, almost perpendicular with the edge of the path, then again they recede into hollow recesses. There are not too many rocks, nor yet too few. In one place a cascade falls over the rocks into a small pool, which on not only provides a habitat for aquatic and bog-plants, but also adds greatly to the beauty of the rockery. For the convenience of the public, a broad gravel path runs through the whole rockery. Rhododendrons and other shrubs are planted on top of the banks in groups, and not in straight lines, while behind these, for protection and shade, are planted pines and other conifers, as well as some deciduous trees. The rocks were placed in most cases so as to form "pockets" of good size into which the plants could be placed, and the soil made in the pocket to suit the requirements of the different plants. With such a variety of aspects and conditions, this rockery is able to accommodate one of the largest collections of alpine and rock-plants in the world. Deep carpets of mossy saxifrages, subroses, arabis, cerastium, sedum, and the like, hang over projecting ledges of rocks, while in fissures and holes in the rocks are growing those dainty rosette-making saxifrages, S. longifolia, S. Cotyledon, S. crassica, and S. ericoides, as well as the charming androsaces. In the smaller recesses of the rockery, are to be found the gentians from the tiny blue gentiana septemjida, while foxgloves, ver-
May they may be planted out permanently. Seeds may also be sown in a shaded frame in spring and the plants transferred to the rockery in autumn.

In planting a newly made rock-garden, it is a mistake to plant too thickly. Each plant should be given sufficient space for a reasonable growth, and to show its true character. Compact-growing and tufted plants may be planted closer than those of a spreading habit. All variegated-leaved varieties and plants having an aggressive habit or that cannot easily be kept within reasonable limits should be rigorously excluded from a rock-garden. The whole rock-garden should be replanted and fresh soil placed in the pockets about every four or five years. In dry weather a thorough watering should be given at least once in two days, and, as in other parts of a garden, weeds will insinuate themselves wherever they can gain a foothold; these, of course, should be removed as soon as they appear. In winter, the plants in the most exposed positions, such as those which overhang ledges of rocks, should be protected by branches of hemlock or pine laid lightly over them, and a light covering of half-decayed leaves or manure placed between most of the plants, especially on a southern exposure, protects them from excessive thawing and freezing. The general care required is usually much less than for an ordinary flower-garden, but the pleasure to be derived from a well-constructed and well-plant ed rock-garden is very much more.

EDWARD J. CANNING.

RODGÉRSIA (named in honor of Commodore Rodgers, United States Navy). Saxifragaceae. Hardy herbaceous perennials suitable for garden planting, with showy terminal flower-clusters.

Rootstocks horizontal, thick and black; lvs. alternate, large, petulate or digitately or pinnately compound, usually deep green; infl. tall and variously compound, paniculate; fls. very numerous, small; calyx-lobes 5; petals usually none; ovary 2-3-celled. About 8 species, China and Japan. Botanically Rodgersia is close to certain species of Astilbe, having 10 stamens and no petals; it differs in having connate carpels, scorpoid infl., and 5-cut rather than thrice-ternate foliage.

Perhaps the best-known species is R. podophylla, as it was the first introduced into cultivation. It grows to 4 feet high, and the leaves are finger-shaped, the five lobes being bold in outline, angled, and serrate. In the spring the foliage is light green; in summer it assumes a metallic bronzy hue. The plant is a vigorous grower, and under favorable circumstances has been known to make a clump 9 feet in diameter, the largest leaves being a yard across and borne on stalks 3 feet long. The flowers are borne in midsummer on stalks 4 to 5 feet high. The general style of inflorescence is that of the popular astilbe, to which it is closely allied. The flowers are very small, but make a feathery spray of white bloom. The panicle is a foot or more long and as wide at the base. Technically the flowers have no petals; what seem to be petals are the white calyx-segments. As a flowering plant it has been said by enthusiasts to be superior to astilbe, but the bloom is scantier, rather greenish at first, and perhaps does not last so long. It may not be so amenable to forcing. Rodgersia is a native of the subalpine regions of Japan and is presumably hardy in our northern states. It is offered by importers of Japanese plants. The plant is highly esteemed by English connoisseurs, but seems to be nearly unknown to American gardens. Although any deep soil will do, it is said to prosper in a moist peaty soil. It should be placed in a sunny position, with plenty of room, where high winds cannot damage it. Easily propagated. (Wilhelm Miller.)

3420. Rodgersia pinnata.

RODRIGUEZIA (Emanuel Rodriguez, Spanish botanist and apothecary). Including Bulingtònia, Orchidáceae. South American epiphytic orchids, a few of which are cultivated for graceful racemes of delicate flowers.

strobilifolia, Hems. About 2-3 ft. high: basal lvs. 9-15 in. long, long-petioled, bright green; lfts. in 3-5 widely separated pairs with an odd one at the top; the caulescent lvs. solitary or 2 uneven pinnate, 9-11-folliate; lfts. subsessile, subopposite and oblong-lanceolate; infl. small, terminal, densely cymose, paniculate; fls. white, small, and inconspicuous; sepals fleshy, ovate, subacute. China. G.C. III. 54: 131.

F. TRACY HUBBARD.
sheathing lvs. at the base; racemes erect or pendulous; dorsal sepal and petals similar, free, erect; lateral sepals united, concave but scarcely saccate; labellum spurred or saccate, with a long claw parallel to the column, and a spreading blade usually exceeding the sepal; column slender. Robert Brown's genus Gomesa (sometimes written Gomeza), founded on *G. recurva*, is by some referred to *Rodriguezia*. See *Gomeza*. The fls. are nearly always fragrant. The plants vary somewhat in habit. Some species form neat, compact tufts, while others, like *R. decorata*, have long, straggling rhizomes difficult to keep within the limits of a block or a basket.

Rodriguezias should be grown in very shallow pots filled with tough peat, and well drained. Rest them in a temperature of 50°, giving little water. The growing temperature should be from 65° to 75°. Give plenty of moisture and shade from direct sunshine. The stronger-growing kinds will need thicker potting material in baskets; they do well wired on tree-fern stems. During growth, syringing is necessary. (Wm. Mathews.)

AA. Fls. small, deep rose or spotted red.

secunda, HBK. Fig. 3421. Pseudobulbs bearing several thick, linear-oblong lvs.: raceme erect, second, 6 in. high; fls. deep rose; sepals erect, ovate convex, the lower pair keeled and gibbous; petals like the dorsal sepal; labellum obovate-oblung, emarginate, scarcely longer than the sepals. Aug. Trinidad, Guana. B.M. 1854. B.R. 930. L.B.C. 7:676 (as *R. lanceolata*).

crispa, Lindl. Pseudobulbs elongate-ovate: lvs. oblong-lanceolate, spreading, undulate; labellum pendulous, rather dense; fls. green, with yellowish borders; seeds all free, undulate-crisp; petals similar; labellum lanceolate, sigmoid. Brazil. B.R. 26:54.

AAA. Fls. greenish.

planifolia, Lindl. Pseudobulbs clustered, compressed: lvs. lanceolate: raceme long, drooping; fls. greenish yellow, fragrant; sepals oblong, waved, acute, the lower pair united except at the end; petals like the dorsal sepal; labellum broadly oblong, acute, reflexed, shorter than the petals. Feb. Brazil. B.M. 1745 (as *Gomesa recurva*) 3304. L.B.C. 7:660 (as *Gomesa recurva*). See also p. 1354.

HEINRICH HASSELBRING.

ROTTLEIRA, also spelled Rottleri. Chirita.

ROGIÉRA: Rondetia.

RÖHDEA (Mich. Rohde, physician and botanist of Bremen). Sometimes spelled *Rhodesia*. A monotypic genus of Japan and China, essentially a fodder foliage plant with numerous radical lvs. 6–15 in. long: fls. borne among the lvs. in short thick dense spikes a few inches high; perianth globular-bell-shaped; anthers sessile; stigma peltate; style nearly wanting; fr. a globular, usually 1-seeded berry. Rohdeas are excellent plants for dwelling-house decoration, doing well in the cooler positions. They are perfectly hardy at Washington.

japonica, Roth. Root a long nearly cylindrical root-stock with fleshy fibers: lvs. typically green, 9–12 in a rosette, erect, oblong-lanceolate: berry about the size of a small olive, with a red pulp. B.M. 808 (as *Orontium japonicum*). Gm. 30, p. 541. The following varieties, which differ in shape and color of the lvs., have been offered by Dutch bulb-growers: Vars. *auro-striata*, *falcata*, *latiscutulata*, *macrophylla*, *marginata minor*, *pygmaea*, *zebrina*.—This plant known as *Omato* or *Munenevi* is a favorite among the Japanese, and fine specimens often bring as much as $500, even when only a few inches high. The seven standard varieties of Japan are *Hinomoto*, *Nagashima*, *Kiyosugi*, *Shikami*, *Bunyoi*, *Hida*, and *Akitashiba*. Retired persons of means often spend their declining years in the culture of this interesting plant, of which hundreds of named varieties are known to Japanese fanciers. A number of very beautiful books have been written on this plant, and it has an extensive literature. This plant is well known in China and was adopted by the Manchus as their national flower. L. H. B.†

Fruits fleshy, compound, subglobose, resembling those of Annona, but with fls. very distinct in form from those of Annona: corolla genipetalous with the lobes corresponding to the outer petals of Annona pro-
duced into 3 rounded wings or obtuse spurs, in some species horizontally projecting, in others curved upward and inward, in others outward and downward; lobes corresponding to the 3 inner petals, alternating with the winged or spurred lobes, reduced to minute scales, almost closing the opening above the essential parts. The type species is *R. dolabripetala.*—The genus, including about 50 species, ranges from Mex. and the W. Indies southward to Argentina and Peru. It is well represented in Brazil and Paraguay. In some of the species the frs. are highly prized for the table and rival the cherimoya, for which they have sometimes been mistaken. Several have been intro. cult. through the Miami (Fla.) Station by the Office of Foreign Seed and Plant Introduction, U. S. Dept. of Agric. Much confusion has resulted from the fact that in many original descriptions of species of *Rollinia,* the frs. were not included, and that edible frs. in the markets unaccompanied by lvs. or fls. have in many cases been botanically misidentified. It is impossible here to give a key to all the species. The principal ones may be grouped according to the form of the fl. into sections or subdivisions, as indicated in the accompanying illustration (Fig. 3422).

1. *dolabripetala,* St. Hil. (*Annona dolabripetala,* Rodd. *Rollinia longifolia,* St. Hil.). *Hatchet-lobed Rollinia.* A small tree, 16½–23 ft. high: young branches, together with the lower surface of the young lvs., their petioles, and the fls. ferrugineus-tomentose: vegetative lvs. oblong-lanceolate or oblong, 1–6 in. long and about 1½ in. broad, those of the flowering branches much smaller, acutish or acute, or sometimes subacuminate at the apex, obtuse at the base, glabrous above, rufous-pubescent beneath, with the midrib prominent beneath, ferrugineous, with 20–28 lateral nerves; petiole about 3 in. long, grooved above, persistently ferrugineous-tomentose: peduncles solitary or rarely in pairs, ferrugineous-tomentose, bracteolate at the base, ½–1½ in. long: calyx-divisions cordate-ovate or suborbicular; corolla-wings rather fleshy, 1 in. long, ferrugineous-tomentose, laterally compressed in the form of a hatchet or broad knife with its blade in a vertical plane, at first ascending, at length broadly spreading: fr. (immature) globose, squamous, pubescent, with the areoles slightly convex; seeds compressed, somewhat cuneate, testa reddish yellow, thin, showing the wrinkles of the inclosed ruminate endosperm. This species, the type of the genus *Rollinia,* was first collected on Mt. Corcovado, near Rio de Janeiro, Brazil, where its fls. appeared in Feb. and its fr. in May. 

2. *rugulosa,* Baill. (*Annona rugulosa,* Jacq.). *Cachiman Montagne.* A small tree intro. by Jacquin from specimens growing spontaneously in the forests of Martinique, and said by him to be rarely cult. In habit it bears a close resemblance to the common custard-apple, *Annona reticulata,* lvs. oblong, pointed at the apex and base: corolla gamepetal in the form of a roundish body from which 3 oblong lobes spread outward in such a way that it not inaptly represents a tricorn hat: areoles of fr. gibbous (convex) not papillose nor aculeate: fleshy pulp very viscous and not very well flavored.—*R. Sieberi* has been referred to this species, but Père Duss, in his *Flora of the French Antilles* has kept the two species distinct.

3. *Sieberi,* A. DC. *Cachiman Montagne.* A small tree first described and figured from the island of Trinidad and erroneously referred by its collector to the common custard-apple, *Annona reticulata,* to which its fr. and lvs. bear a certain resemblance: lvs. oval-oblong, acute at apex and base, usually 3–5 in. long and 2–3 in. broad, thin, above puberulous with the nerves pilose, beneath paler and more pilose, narrowed at the base into plosely petioles ½ in. long, some of them at the base of the branches broadly ovate and obtuse, about 1 in. long: peduncles if-opposed, 1-fld., 1–1½ in. long, bearing 2 small ovate-acute bracteoles, one near the base, the other about the middle: corolla-wings laterally compressed, linear-oblong, rounded at the apex, diverging, straight or curving slightly upward: fr., according to Père Duss, usually larger than that of *Annona squamosa,* the surface divided into pronounced raised squamose

3423. *Rollinia deliciosa* (X 3/4)
areoles rounded at the tips; pulp fleshy, nearly white, melting in the mouth, slightly viscous, with a sugary agreeable flavor. Type collected by Sieber (No. 90), in the De Candolle Herbarium.

AA. Corolla-wings laterally compressed, widely spreading and more or less decurved. (Fig. 3423, b.)

4. deliciosa, Safford. BIRIBA. Fig. 3423. A tree yielding a delicious, large, juicy fr., resembling the cherimoya: vegetative lvs. obovate-oblong or elliptical, rounded at the base and normally acuminate at the apex, blades 5-11 in. long and 3-4 in. broad, membranaceous, when young sparsely canescent-puberulous above, densely so beneath, especially along the midrib and nerves, at length glabrous above and beneath except along the midrib and primary nerves (18-22 on each side), these reddish brown and slender but prominent beneath; petiole about ½ in. long: lvs. on flowering branches smaller, the lowermost ones relatively shorter and broader, sometimes broadly ovate or orbicular, 1½-2½ in. long and 1½-2 in. broad; peduncles If-opposed, often in pairs, sometimes solitary, rarely in 3's, 1-1½ in. long, bearing a small ovate sessile bracteole near the middle, strigillose with reddish hairs, like the petioles and nerves of the lowermost lvs. (prophylla) beneath: calyx and corolla canescent-puberulous; corolla-wings compressed laterally, widely diverging and decurved, rounded at the extremity; stamens numerous, closely crowded, the expanded conical-ovate, terminated in an obtuse beak; peduncle nectaries forming a pavement above the pollen-sacs; endosperm.—The type of this species, in the U. S. National Herbarium, is from a fr.-bearing tree cult. in the experiment station, Miami, Fla., grown from seeds sent by C. F. Baker from Para, Brazil (No. 25212) in 1908. Baker describes it as the finest annonaceous fruit of Trop. Amer. It was incorrectly referred to R. orthopetalta, but it is readily distinguished from that species by the decurved wings of its frs.

5. Pittièri, Safford. A tree resembling R. deliciosa, but with lvs. more abruptly acuminate and glaucous beneath, the vegetative ones 6-8 in. long and 5-6½ in. broad, midrib and primary nerves (18-22 on each side), reddish brown beneath: lvs. on flowering branches smaller (with 10-12 primary nerves): peduncles often in clusters of 3 or 4, graduated in length, the longest 3½ in. long, fleshy, minutely puberulent, never hairy like those of R. deliciosa, bracteolate near the middle: corolla-wings ½-¾ in. long, calate, horizontally extended and decurved, rounded at extremity, and narrowed at the base, very finely puberulent, appearing under the lens as though composed of olive-gray felt; fr. not observed.—A beautiful species with elliptical or obovate lvs. remarkable for the pale color of the lower surface and the sharply outlined lateral nerves. These correspond with the description of R. rufinervia, Triana and Planch., but the corolla-wings are decurved, not "divergent ascending," as in that species. The type, in the U. S. National Herbarium, was collected near Puerto Obaldia, Panama, by Henry Pittier (No. 4358, in whose honor the species is named).

6. Jimenezii, Safford. ANONILLA. Fig. 3424. A small tree of Costa Rica resembling R. mucosa but with lvs. in clusters of 2 or 3, having the corolla-wings horizontally spreading and slightly decurved, and with fr. resembling that of the common sugar-apple (Annona squamosa), with the component carpels red at the tips when fresh, but more or less beaked when dry: lvs. ovate to oblong-elliptical, acuminate, those of the vegetative branches 7-8 in. long and 2½-3 in. broad, obtuse at the base, with 18-22 primary nerves on each side of midrib, those of the flowering branches smaller with 12-16 pairs of primary nerves and usually rounded at the base; point of acumen either acute or more usually obtuse or reteous; young branches, petioles, and lower surface of young lvs. covered thickly with ferrugineous hairs, lvs. at length glabrous or nearly so except along the midrib and nerves beneath: peduncles If-opposed, in clusters of 2 or 3, graduated in length, the longest about ½ in. long, ferrugineous-tomentose like the ovate-acuminate calyx-lobes: corolla-wings oblong, rounded at the tip, scarcely at all narrowed at the base, widely spreading and usually decurved, never curving upward and inward, fleshy-puberulent: fr. subglobose, about 2½ in. diam., closely resembling that of Annona squamosa, the component carpels loosely adhering, very gibbous, rounded or often reteous at the tip when fresh; pulp white, edible, but not so agreeably flavored as that of Annona squamosa.—This species is based upon specimens in the U. S. National Herbarium, received from Oton Jimenez, of San José, Costa Rica, the frs. collected by him at Nuestro Amo, March, 1912 (No. 427), and the fr. from the same tree, Oct., 1912. The accompanying figure is drawn from type material, the fr. from a field photograph sent by Mr. Jimenez, in whose honor the species is named.

AAA. Corolla-wings linear-oblong or spatulate, ascending or erect and incurved. (Fig. 3425, c.)

7. orthopetala, A. DC. A shrub or small tree with the habit of R. Sieberi, but with the lvs. somewhat longer petioled: lvs. oval-oblong, acute at apex and base, pilose: peduncles in pairs: calyx-lobes smaller than in R. Sieberi; corolla-wings erect and incurved; fr. not described.—This species was described by De Candolle from a specimen in the De Candolle Herbarium collected by Parker near Demarara, British Guiana. The name has been given to several rollinias with edible fr. Of these the principal
ROLLINIA

species, from an economic point of view, is *R. deliciosa* described above, which is readily distinguished from *R. orthophylla* by its widely spreading decurved corolla-wings.

8. *laurifolia*, Schlcht. *Aratitcu mirum*. A shrub or small tree with the new branchlets, petioles, peduncles, midrib, and nerves finely appressed-subfurfuraceous puberulent, the fls. and lower surface of the fl. clothed with dense and deeper clay-colored puberulence: lvs. oblong-obovate to lanceolate, acuminate at the base, obtuse at the base, 3½-5 in. long, 1½-2 in. broad; midrib prominent beneath, lateral nerves 8-10 pairs; upper surface apparently glabrous, but as seen under a lens are covered with white hairs; peduncles solitary or in 2's or 3's; graduated in length, the longest 3 times as long as the petioles (1 in. long), bracteolate at the base, gradually thickening toward the apex: corolla-wings ascending-erect, broadened at the apex, rounded or quite obtuse, ½ in. long and ½ in. broad near the apex, clothed with minute brownish-argillaceous tomentum: fr. subglobose, about the size of a horse-chestnut, composed of many carpels distinctly outlined and containing an edible, white, mucilaginous pulp with a pleasant sweet taste.—This species is based upon 2 flowering specimens collected in Brazil by Sellow (Nos. 809 and 1190).

9. *incursa*, Moore. A diffuse shrub with long branchlets: lvs. short-petioled, lanceolate or lanceolate-oblong, obtuse, rounded at the base, coriaceous, above glabrous, often glossy, beneath paler, minutely puberulous, broad 4-5 in. long, 1½-2 in. broad, often more or less oblique at the base: midrib impressed above, rather prominent beneath, lateral nerves about 12 pairs inserted at a wide angle, undulate near the margin and curving upward: peduncles usually in pairs, sometimes solitary, longer than the petioles (1½ in. long), bracteate at the base, and bearing a small bracteole as the peduncle. *Fl.* yellowish green; calyx-lobes short and rounded, ferrugineous-pubescent, corolla-wings ferruginous-tomentose, spatulate-oblong, ascending and incurved, ½ in. long; stamina numerous, crowded; carpels albo-sericeous: fr. not observed.—This species described by Sower, Moore, was collected in Santa Cruz, Brazil, by the Matto Grosso expedition. Specimens from the type collection are in the Herbarium of the U. S. National Herbarium collected by Sellow in the province of Rio Grande do Sul by Sellow (Nos. 13509).

10. *rugulosa*, Schlcht. A shrub or small tree: lvs. short-petioled, lanceolate or broadly lanceolate, obtusely and shortly acuminate, acute at the base, on both sides glabrous, beneath glossy; young branchlets, petioles, and midrib appressed-puberulous: peduncles usually recurved or pendulous and thickened at the apex, warty and puberulous like the calyx, ½-3½ in. long; corolla-wings obovate, ascending, rounded or obtuse at the apex, narrowed at the base, tomentose-canescens, ½ in. long and ½ in. broad; fr. globose, 1-1½ in. diam., with the component carpels forming 20-30 slightly raised rounded areoles: seeds small, pale brown, conoid, somewhat flattened.—Type collected in S. Brazil by Sellow. Closely related to *R. rugulosa* and with very similar fl. but with longer and narrower lvs. (suggesting those of *R. salicifolia*), is *R. Warmingii*, R. E. Fries, the type of which was collected on Mt. Tijuca, near Rio de Janeiro, by Glaziou (No. 6079).

11. *lanceolata*, R. E. Fries. A small tree with small lanceolate lvs.: fls. acute at the apex and base, above glabrous except along the midrib; beneath densely ferrugineous-villos along the midrib: young branchlets, petioles, and solitary or rarely geminate peduncles fer-

--ROLLINIOPOSI--

2797

12. *emarginata*, Schlcht. A glabrous shrub, 6½-10 ft., growing in marshy places, with slender branches: lvs. oval or elliptical, obtuse at both ends or acute at the base, emarginate or reflexed at the apex, on both sides subglabrous and opaque: peduncles-usually solitary, slender, about 1 in. long, minutely bracteolate at the base: corolla and calyx silky-hirtellous; corolla-wings obovate-ovaricular, widely spreading, laterally compressed: fl. solid, about 1-1½ in. diam., ovate-globose, with the component carpels scarcely at all raised or distinctly outlined.—This species, very common in S. Brazil and Paraguay, is based upon specimens collected in the province of Rio Grande do Sul by Sellow.

13. *glaucescens*, Sond. A glabrous shrub closely allied to *R. emarginata*, but with the lvs. not emarginate and sometimes acute at the apex: fl.-blades 3½-5 in. long, 1½-2 in. broad, corolla-lobes short, straight and flat: fr. subglobose, about the size of a small apple, pubescent, with the component carpels forming prominent pentagonal areoles; pulp edible, somewhat like that of the cherimoya. W. E. Safford.

ROLLINIOPOSI (Greek derivative, signifying Rolinia-like, from the form of the fl.). *Annonaaceae.* FRUCTA DE MACACO. MONKEY-FRUIT. Shrubs or small trees of Brazil having fragrant 3-winged fls. like those of Rollinia, but with aromatic frs. in the form of a clust of small distinct drupes, instead of a fleshy syncarpium, as in Rollinia.—Only 4 species have thus far been described, all from Trop. Brazil. The type of the genus (R. discreta, Safford), Fig. 3425, has been successfully intro. into cult. in the S. U. S. by the Office of Foreign Seed and Plant Introduction, U. S. Dept. of Agric. (S. P. I. No. 15508). This species, discovered by Dorsett, Shamel, and Popeneo in the vicinity of Januaria, state of Minas Geraes, has orange-colored pear-shaped drupes locally known as Fruta de Macaco (monkey-fruit). The thin aromatic mesocarp surrounding the solitary seed tastes very much like the fl. of certain species of Xylopia, called malaguetas in the province of certain species of Xylopia, called malaguetas in the province of some species of Cymbopetalum. Cymbopetalum pentaliflorum) the spicy petals of which, together with vanilla, were used by the Aztecs for flavoring their chocolate in pre-Columbian times (see Cymbopetalum). The other known species were recently discovered by Rose and Russell, of the Carnegie

ROMANZÖFFIA (named in honor of Count Nicholas Romanzof). Hydrophyllaceae. Low and delicate perennial herbs with the aspect of saxifrage, suitable for outdoor planting.

Leaves mainly radical, alternate, round-cordate or reniform, crenately 7-11-lobed, long-petioled; infl. scapose, racemose or paniculately several-fl.; the pedicles filiform; fls. pale pink or purple, varying white; calyx-lobes oblong-linear or lanceolate; caps. retuse, 2-celled or nearly so.—Ten (?) species, Alaska southward to the coast range of Calif.

ROMNEYA (named for T. Romney Robinson, who discovered it about 1845). Papaveraceae. Tall showy herbs or shrubs used for garden planting.

Stems branching: lvs. petioled, pinnatifid, 2 or 3 pairs of segms.; fls. solitary at the ends of the corymbose branches, large, white and showy, 6 in. across; sepals 3, with a broad membranaceous dorsal wing; petals 6, all alike; stamens very numerous; stigmas numerous, co- nate at base into a little ring: caps. 7-11-celled, dehis- cing to the middle, the valves separating by their margins from the firm persistent pericarp.—Two species, Calif. and Mex. Monographed by Fedde in Engler's Pflanzenreich. hft. 40 (IV. 104), 1909.

Romneya grows wild in California from San Diego to Santa Barbara County and also in Mexico, and in the wild state it blooms chiefly in June and July, but in cultivation the period of bloom is increased from May to August. In the region of Los Angeles, it is said to thrive best on dry rocky soil and needs only the water it obtains from the winter rains. Romneya can be trans- planted safely if cut to the ground before it is lifted and can be raised from seed if the seed is fresh. Raising from seed under artificial conditions is not very satisfactory, however, as it takes a few years between the germination of the seed and blooming of the seedlings.

Romneya is difficult to transplant, due to the scarcity of fibrous roots; in middle California suckers which are produced in great abundance are transplanted without any loss, provided a good firm ball of earth is kept around the stout thick roots in transit, and if the stems are cut well back, almost to the base. At San Francisco it grows luxuriantly in a heavy adobe soil, producing immense flowers. The name Matilija poppy (pro- nounced Ma-til'i-ha) is the favorite in California. It comes from the Matilija Canon, Ventura County, where the plant grows in particular abundance. Miss Parsons writes: "Many people have the mistaken idea that it grows only in that region. It is not com- mon by any means; but it is found in scattered locali- ties from Santa Barbara southward into Mexico. It is very abundant near Riverside, and also upon the southern boundary and below in Lower California, where the plants cover large areas. It not only grows in fertile valleys, but seeks the seclusion of remote canons, and nothing more magnificent could be imagined than a steep tufted-side covered with the great bushy plants, thickly covered with enormous white flowers." Blossoms remain open for many days. (J. Burtt Davy.)
Romneya Coulteri, the Matilija poppy, one of the most showy of California flowers.
In the favorite species (*R. odorata*) the fls. number 10-30 in a cluster, each fl. being fully an inch across; in the other species the fls. may number 150-200 to a cluster, each fl. being less than ½ in. across. *R. cordata* is often said to have a 4-lobed fl., a mistake that dates back more than half a century to a typographical error.

Rondeletias are of slow growth, and not many cultivators of plants care to give time and space to raise them; nevertheless some of the species, e.g. *R. odorata* var. *major*, deserve to be more widely grown. Cuttings from the half-ripened wood may be rooted at any time of the year. Spring, however, is considered the best time, as one has the season's growth ahead, and good plants may be had in the fall. Insert the stem in a 3-inch pot, in a mixture of finely sifted peat and sand and place them in a tight propagating-bed, in a temperature of 70°. Water them thoroughly and shade them from the sun. In a few weeks the cuttings will be rooted, when they may be potted in small pots, in the siftings of the root of the osmundas fern, with enough sand to keep it open. If a good fibrous peat can be procured, it answers the same purpose. A night temperature of 60° is best for these plants. Large plants, however, will winter safely at 50° to 55°.

The advantage of keeping small plants warmer is that they may be grown more quickly. As soon as the young plants have a good hold on their first pot, cut them back to two joints above the soil. Place them close to the glass and syringe two or three times a day. When the sun gets strong, shade them lightly in the middle of the day. As soon as they are well rooted in their first pot, shift them into a 2½-inch pot, in a mixture of finely sifted peat and sand and place them in a tight propagating-bed, in a temperature of 70°. Water them thoroughly and shade them from the sun. In a few weeks the cuttings will be rooted, when they may be potted in small pots, in the siftings of the root of the osmundas fern, with enough sand to keep it open. If a good fibrous peat can be procured, it answers the same purpose. A night temperature of 60° is best for these plants. Large plants, however, will winter safely at 50° to 55°.

aa. Fls. pink to white.

b. Base of lvs. more or less cordate.
cordâta, Bentli. (Rogierâ cordâta, Planch. R. thyrsi­flôra, Hort., not Roth). Fig. 3427. Lvs. ovate, acuminate, cordate; generally said to have pinkish flesh-colored fls. with a yellow throat (as in F.S. 8: 754), but in R.H. 1878: 230 they are shown as pure white. B.M. 8540. J.F. 2: 122. Guatemala. Possibly also native in Mex.

lattifôlia, Hort. (Rogierâ latifôlia, Decne.). Lvs. large, heart-shaped, acuminate, short-petioled; fls. in corymbose cymes, the tubes pink, the limb white; calyx-lobes oval, obtuse. Guatemala. R.H. 1853: 121.

39. Base of lvs. not cordate.

c. Corolla-lobes ovate: stigmas broadly ovate.
amânea, Hemsl. (Rogierâ amânea, Planch.). Lvs. elliptic, broader than in R. gratissima, and shorter, acuminate, 2-5 in. long; fls. rose-pink, with a conspicuous yellow throat. Guatemala. F.S. 5: 442.—Intro. in Calif. See also R. vericolor, in supplant list below.

c. Corolla-lobes obcordate: stigmas subulate.

aaa. Fls. blue. (Hindisâa.)

longifôra, Cham. (Hindisâa longifôra, Bentli.). Lvs. opposite, entire, lanceolate, more or less oval or sometimes almost linear, petals very short, attitude at the base: infl. terminal corymb; fls. blue; calyx-tube short, lobes linear; corolla-tube very long; segments of lip oval, spreading and acuminate. R.H. 1858, p. 329. H.U. 4, p. 243.—This is now placed in the genus Hindisâa, which differs from Roneleteâia in general appearance and in the form of the corolla which is rather funnel-shaped than salver-shaped, without any callous contraction or beard at the mouth of the tube and by the capsule, which is differently dehiscent. A second species of Hindisâa is R. violettâ, Bentli., from Brazil. B.R. 30: 40.

The following species have been occasionally cult. : R. ameriçsâna, Linn. White-fld. W. Indies and S. Amer.—R. amââeâla, Hort., is an imperfectly known species said to have the lvs. in 3’s, and cori­erâd or deep scarlet fls. with a presumably yellow throat. Habitat (1)—R. Blackweli, Hook, a pink-fld. species from Trop. Amer., is easily mistaken for those mentioned above. It is much longer calyx-lobes, which are pink. B.M. 6300.—R. Pûrdicâ, Hook, a beautiful pale yellow-flld. species from Colombia, has a great pyramidal cluster 5 in. across and 4 in. deep, with an astonish­ing number of fls., perhaps 150-200 in B.M. 8540.—R. vericolor, Hook. (Rogierâ versicolor, Lindl. & Partt.,) is referred to R. amââeâla by Index Kenniâns but seems distinct. The fls. are said to be “remarkable for their play of colors: the tube is yellow; the limb is bud deep rose-color, changing when they expand to pale rose and then to white, with a yellow edge, and having a 2-lobed green spot in the center from the color of the stigmas, which protrude a little beyond the mouth.” B.M. 4579. J.F. 2: 112.

F. TRACY HUBBARD.†

ROOT-GALLS. Abnormal enlargements often appear on the roots of plants. These enlargements are much more frequent than is generally supposed, but from their position under ground are rarely observed. From an economic standpoint they have not received the attention that they merit.

Although the term root-gall is usually applied to the abnormal enlargement of roots due to insects and other animal organisms, it has a much wider application as used by most plant-growers. The presence of nodules or local enlargements on the roots of plants has been discussed by different authors under the names root-galls, root-knots, root-swellings, and the like. In cases in which the cause of the nodules of hypertrophied tissue is known, special names have been assigned to the enlargements. Thus the gall formed by the eel-worm (Heteroderâa radicicola) is known as the nematode root-gall (Fig. 3428); the enlargement on the roots of cabbage and related plants by the myxomycete (Plas­modiophora Brassicæ) is called club-root; the swellings on the roots of the peach, apricot, and many other plants, which are of characteristic appearance and usually appear at the crown of the plant, are known as crown-gall. Root-tubercules are small gall-like bodies found on the roots of many leguminous plants. They are symbiotic in nature, the organism causing them being helpful to the plant. See Legumes.

Abnormal root enlargements are due to the following causes: (1) animal parasites, as in the nematode root-gall (Fig. 3428), the galls formed on the roots of the grape by the phylloxera, woolly aphid galls on apple tree roots, and the like; (2) vegetable parasites, as in the club-root and the crown-gall (Fig. 3429); (3) mechanical injury, causing excessive callous development, root-burls, and so on. In addition to these the causes of these enlargements are often obscure or unknown.

Swellings on the roots of the mulberry are said to be due to the hypertrophy of the lenticels. Some investigators have attributed gall-like root-growth in some instances to the hypertrophy of adventitious buds.

The root-galls caused by the nematode (Heteroderâa radicicola) may usually be readily recognised from other forms of hypertrophied tissue by the numerous knotty enlargements on the smaller roots infested by the worms. By careful search, in most instances, the distended female worms may be found in the infected tissue, where they appear as small nearly spherical pearl-like bodies, readily seen with the unaided eye. This minute worm, commonly called eel-worm, feeds upon the roots of a great variety of cultivated plants and is particularly destructive in the South. It is usually injurious in the northern states only to plants growing under glass. However, ginseng and some other outdoor perennials often suffer severely as far north as Michigan and southern Canada. The most effective remedy in the case of field crops is the removal of all rubbish that would harbor the worms during the winter. In greenhouses steam can be forced through the infested soil. When potted plants are badly affected, they may be severely root-pruned and repotted in soil free from worms.

The root-swellings caused by the grape-vine gall-
The crown-gall disease appears to be the most harmful of root diseases affecting cultivated plants in this country. These galls have been reported upon the roots of the peach, apricot, almond, prune, plum, apple, pear, walnut, grape, raspberry, blackberry, cherry, poplar, and chestnut, and without doubt further investigation will find them on other plants as well. The crown-gall disease is now known to be due to a distinct species of pathogenic bacteria \((\text{Bacterium tumefaciens})\). It appears to be the same organism in all the host-plants affected by this disease. Seedlings from one to six months old appear to be most susceptible to this disease; hence it is particularly serious in the case of nursery stock. When the galls appear on young trees, they almost always occur on the side of the main root about a few inches below the surface of the soil, or in the region of the crown. With more mature trees they tend to occur at greater depth on lateral roots. At first the gall has a uniform outer appearance, but later it becomes warted from unequal growth. The tissue of the developing gall is soft and succulent, with nodules of woody tissue scattered through it. The galls vary much in size and may reach a diameter of 10 inches.

But little is known as to remedies for crown-gall. As the disease is primarily a nursery disease, the most effective remedy is in securing stock for planting from a non-infested nursery. This disease is often destructive to the roots of roses and asters in the greenhouse benches. Here the destruction of all diseased plants followed by steam sterilization of the soil is the only remedy.

\[\text{J. W. TOUMEY.}\]

\[\text{H. H. WHITTELL.}\]

**ROQUETTE, or ROCKET-SALAD** \((Eruca sativa,\text{ Mill.})\), a low-growing hardy annual from southern Europe, whose leaves resemble those of radish and turnip, is much used by the French as a spring and autumn salad and pot-herb. The flavor of the young, tender leaves, which are the parts used, bears a strong resemblance to that of horse-radish. In America it is but little grown because there are milder-flavored plants that serve the same purpose. See \emph{Eruca}.

The first sowing may be made in early spring, the seed being dropped thinly in shallow drills a foot apart, with successional plantings each second or third week through the season. The soil must be rich and well supplied with moisture, else the leaves will probably be tough and acrid. Inter-culture is the same as for spinach, lettuce, and similar crops. Frequent watering and tillage in hot dry weather to insure rapid vigorous growth should result in succulent mild-flavored leaves. In summer the plants run rapidly to seed; in spring and autumn they will produce abundantly after being cut. The pale citron-yellow flowers emit a perfume resembling that of orange blossoms.

\[\text{M. G. KAINS.}\]
are almost equally distributed through the colder and temperate regions of the northern hemisphere, in Amer, extending to N. Mex., in Afr. to Abyssinia, and in Asia to India. The fls. show a remarkable tendency to become double, and such forms have been known and cult. from time immemorial. These innumerable garden forms, increasing every year, are almost exclusively of hybrid origin and are therefore omitted in the botanical classification of the genus.

Many attempts have been made to subdivde the genus with more or less satisfactory results; the more important are those by A. DeCandolle, Lindley, Regal, and Baker. Nowadays the arrangement proposed by Crepin is considered the most natural and satisfactory and has been followed in the account given below. Now the general monograph has been published since Lindley’s “Monographia Rosarum” (1820), except a rather short one by Regel in 1877. Of the more recent publications the most important are those of Crepin, especially his “Primitiae Monographiae Rosarum.” In consulting his publications one has to bear in mind that the author changed his opinion somewhat respecting the value of the species during his studies of the genus. In his later publications he takes a broader view in regard to the specific value of the rose forms and units under one species many forms which he formerly considered as distinct species. An illustrated monograph valuable for the knowledge of the older garden forms and species is Thory and Redouté’s “Les Roses,” with 160 colored plates (1817–20). It is quoted below as Red. Ros. As the first edition in folio is found in only very few libraries, the smaller edition is cited in parenthesis by volume, groups and the sequence of the plates, neither pages nor plates being numbered continuously in this edition. The most recent book on roses is Miss Ellen Willmott’s “The Genus Rosa,” with about 150 excellent colored and numerous black plates; in this work all the important species of roses, including most of the recently introduced Chinese species and the types of our cultivated garden forms, are described and figured. It is quoted below as W. R. (with the number of the species).

The economic properties of the rose are of little importance. The most valuable product is attar of roses, a highly fragrant essential oil. It is chiefly manufactured in southeast Europe and western Asia from Rosa alba and R. damascena, and of late this industry has been successfully transplanted to Germany. See Perfumery Gardening, page 2547. The fruits of some species, especially of R. villosa and R. canina, are made into preserves.

The roses are mostly low or medium-sized shrubs, usually with prickly stems, often more or less stoloniferous, sometimes climbing or creeping, with small or medium-sized odd-pinnate deciduous or evergreen foliage and with mostly large and showy, solitary or clustered flowers ranging in color from purple, crimson, or pink to white and yellow, and followed by ornamental usually scarlet or bright red fruits remaining on the branches a long time, sometimes through the whole winter. There is probably no flower more popular and better known than the rose. From time immemorial poets have sung its praise, and the love of it can be traced through the most ancient documents in the literature of the Aryan race. It is remarkable to note, however, that the rose has played a far inferior part in the horticulture of the Chinese and Japanese. It is probably the first flower known and cultivated in a double state, and it is the double-flowered garden form whose image the word “rose” almost invariably brings to the mind, while to the wild single-flowered roses much less attention has been given. The ornamental value of single roses is rarely fully appreciated. The wild roses have a simple charm and graceful beauty of their own. No doubt the bold and dominating beauty of the double roses has eclipsed the more modest attractions of the single roses. The longer blooming season of the garden roses is also a factor in their favor. Though the wild roses cannot, perhaps, be compared with their more noble sisters of the garden, they are nevertheless fully able to rival other ornamental shrubs for the adornment of park and plot. Most of the species are hardy or almost hardy North; among the hardiest are R. rugosa, R. virginiana, R. carolina, R. acicularis, R. blanda, R. Woodsi, R. heliophila, R. palustris, R. rubrifolia, R. pendulina, R. canina, R. cinnamomea, and R. pomifera. Hardy at least as far north as Massachusetts are R. spinosissima, R. rubiginosa, R. multiflora, R. Helena, R. arvensis, R. setigera, R. gallica, R. setipoda, R. omeiensis, while others, as R. Wichuraiana, R. sempervirens, R. sericea, R. fatica, R. hemispharicosa, require some shelter or protection. Hardy only South are R. Banksia, R. bracteata, R. chinensis, R. lanigera, R. odorata, R. stellata. The recently introduced species from central and western China have not yet been sufficiently tested, but a large percentage appears to be hardy as far north as Massachusetts.

According to the habit peculiar to each species, they can be used for a variety of purposes. Most of the species are shrubby, rarely exceeding 6 or 8 feet, and may be used for borders of shrubbery or for covering slopes and rocky ridges, especially R. rugosa, R. carolina, and various American species. Some kinds, as R. rugosa and R. virginiana, make handsome ornamental hedges. The climbing species are used for covering walls, trelliswork, arbors, porches, or pillars, but perhaps display their beauty to the most advantage when allowed to ramble over shrubs or rocks. The half-evergreen R. Wichuraiana makes a beautiful ground-cover and may also be used for edging groups and flower-beds. The fruits of most species are decorative and
often remain on the branches all winter. The red stems of most of the species of the Carolinas and Cinnamomeae groups are effective in winter also. The foliage of most of the American species turns purple-orangy yellow in autumn, and so does that of R. rugosa, which is, in regard to the foliage with its dark green leathery and glossy leaves, the handsomest of the hardy roses.

With few exceptions the roses are of easy culture and grow in almost any kind of soil, except in a heavy and very sandy one. They are readily transplanted. The wild roses need little pruning; they should only be thinned out and the weak and old wood be removed; long and vigorous shoots should not be allowed to become dry, they usually do not germinate the first year, but if kept in the hips during the winter and allowed to become dry, they usually do not germinate until the second year. Mice are very fond of the seeds. Almost all species grow readily from cuttings of nearly ripened wood in summer under glass. Many species, especially the climbing roses, can be propagated by hardwood cuttings taken in fall and planted in spring. Layering is less often practised, except with a few species, like R. latifolia and R. hemisphaerica, which do not grow readily from cuttings. Some species, especially those of the groups of Cinnamomeae, Carolinas, and Gallicas, can be increased by root-cuttings; the roots are taken up in fall, stored during the winter, and then planted. In spring in drills and covered about 2 inches deep. The species of the last-named groups and some others are also often increased by suckers and division. Budding and grafting is less often done with the wild roses and should be avoided for roses in shrubberies where the individual plants cannot be carefully watched; the stock usually throws up suckers and outgrows the cion, often in a short time. For general notes on culture and varieties, see Rose.

### KEY TO THE GROUPS

For a horticultural classification of roses, founded primarily on garden values, see the article Rose.

Subgenus HULTHEMIA.

**Lvs. simple, without stipules:** *fls. yellow.*

**Section I. SImplicifolllae. Species No. 1**

Subgenus EUROSA.

**Lvs. pinnate stipulate.**

A. Styles exerted beyond the mouth of the receptacle.

B. Exserted styles connate into a column, usually as long as stamens. *fls. usually 8-5.*

**B. Stipules free or adnate only at the base, small:**

emmanuel or climbing shrubs: *fls. white or yellow.*
c. Branches glabrous: lfts. 3–5, stipules entire or denticulate.

d. Fls. small, unlobed, yellow or white: pedicels and receptacle smooth: stipules subulate, caducous.

Section 4. BANKSIANAE. Species Nos. 15, 18

dd. Fls. large, solitary, white: pedicels and receptacle bristly: stipules denticulate.

Section 14. LEVIGATAE. Species No. 59

cc. Branches tomentose or pubescent: lfts. 7–9; stipules pectinate; fls. 1 or few, white, with large bracts at the base of the short pedicel: receptacle tomentose.

Section 15. BRACTEATE. Species No. 58

bb. Stipules adnate more than one-half of their length.

c. Receptacle smooth or hispid.

d. Lvs. of flowering branchlets 3–5-foliolate, large and firm: sts. usually with prickles and bristles: fls. upright, on long pedicels; receptacle bristly: sepals usually pinnate, reflexed after flowering, caducous.

Section 5. GALLICE. Species Nos. 17–21

dd. Lvs. of flowering branchlets 5–11-foliolate (rarely 3-foliolate, the fls. then short-pedicelled, with smooth receptacle).

Section 6. CANINE. Species Nos. 22–27

kk. Fls. solitary, without bracts, only occasionally intro. from its native country. A hybrid of R. persica, Michx. (R. simplicifolia, Salisb. R. berberifolia, Pall. Lvs. short-petioled, oval to oblong, acute at both ends, serrate, bluish green, pubescent. 3/4–1 1/2 in. long: fls. solitary, yellow, with red eye, about 1 in. across; fr. prickly. June. N. Persia to Siberia. B.M. 7096. B.R. 1261. G.C. II. 6:89, 9, 78. W.R. 1.—This peculiar rose is very rare in cult., since it is very difficult to grow. It has been successfully cult. in a cool greenhouse, exposed to the full sun, kept moist during summer and dry from October to March. The only way to prop. it seems to be by suckers; seeds are occasionally intro. from its native country. A hybrid of this species with R. involucrata is R. hydrogen, Cejus, with 5–7-foliolate lvs. and large yellowish white fls., with a deep orange eye. G.C. II. 24:469. Gn. 19, p. 473. P.M. 10:195. W.R. 2.

Subgenus HULTHEMIA.

Section 1. SIMPLICIFOLIAE. Only one Asiatic species, distinguished from all other roses by the simple exstipulate lvs.

1. persica, Michx. (R. simplicifolia, Salisb. R. berberifolia, Pall. Lvs. short-petioled, oval to oblong, acute at both ends, serrate, bluish green, pubescent. 3/4–1 1/2 in. long: fls. solitary, yellow, with red eye, about 1 in. across; fr. prickly. June. N. Persia to Siberia. B.M. 7096. B.R. 1261. G.C. II. 6:89, 9, 78. W.R. 1.—This peculiar rose is very rare in cult., since it is very difficult to grow. It has been successfully cult. in a cool greenhouse, exposed to the full sun, kept moist during summer and dry from October to March. The only way to prop. it seems to be by suckers; seeds are occasionally intro. from its native country. A hybrid of this species with R. involucrata is R. hydrogen, Cejus, with 5–7-foliolate lvs. and large yellowish white fls., with a deep orange eye. G.C. II. 24:469. Gn. 19, p. 473. P.M. 10:195. W.R. 2.

Subgenus EUROSA.

Section 2. SYSTYLA. A group of about 12 species (one of them American), well marked by the styles being connate into a slender exserted column. Sts. armentae or climbing, with hooked prickles: fls. in corymba, few or many; outer sepals pinnate, rarely entire, reflexed after flowering, caducous.

aa. Stipules pedunculate: prickles usually in pairs. 

bb. Stipules entire or denticulate: prickles scattered

cc. Receptacle prickly.

d. Lvs. on flowering branchlets 3–7-foliolate; lfts. cuneate-obovate, incisely dentate. 

Section 12. MINUTIFOLIAE. Species Nos. 55–57

dd. Lvs. of flowering branchlets 7–10-foliolate; lfts. elliptic or elliptic-oblong, sharply serrate.

Section 15. MICROPHYLLAE. Species No. 60

SUMMARY OF SECTIONS.

Section 1. SIMPLICIFOLIAE. Species Nos. 1–10

Section 2. SYSTYLA. Species Nos. 11–14

Section 6. CANINE. Species Nos. 22–27

Section 7. CAROLINAE. Species Nos. 28–32

Section 8. CINNAMOMAE. Species Nos. 33–48

Section 12. MINUTIFOLIAE. Species Nos. 55–57

Section 13. BRACTEATAE. Species No. 58

Section 14. LEVIGATAE. Species No. 59

Section 15. MICROPHYLLAE. Species No. 60

Subgenus HULTHEMIA.

Section 1. SIMPLICIFOLIAE. Only one Asiatic species, distinguished from all other roses by the simple exstipulate lvs.

1. persica, Michx. (R. simplicifolia, Salisb. R. berberifolia, Pall. Lvs. short-petioled, oval to oblong, acute at both ends, serrate, bluish green, pubescent. 3/4–1 1/2 in. long: fls. solitary, yellow, with red eye, about 1 in. across; fr. prickly. June. N. Persia to Siberia. B.M. 7096. B.R. 1261. G.C. II. 6:89, 9, 78. W.R. 1.—This peculiar rose is very rare in cult., since it is very difficult to grow. It has been successfully cult. in a cool greenhouse, exposed to the full sun, kept moist during summer and dry from October to March. The only way to prop. it seems to be by suckers; seeds are occasionally intro. from its native country. A hybrid of this species with R. involucrata is R. hydrogen, Cejus, with 5–7-foliolate lvs. and large yellowish white fls., with a deep orange eye. G.C. II. 24:469. Gn. 19, p. 473. P.M. 10:195. W.R. 2.

Subgenus EUROSA.

Section 2. SYSTYLA. A group of about 12 species (one of them American), well marked by the styles being connate into a slender exserted column. Sts. armentae or climbing, with hooked prickles: fls. in corymba, few or many; outer sepals pinnate, rarely entire, reflexed after flowering, caducous.

aa. Stipules pedunculate: prickles usually in pairs. 

bb. Stipules entire or denticulate: prickles scattered

cc. Receptacle prickly.

d. Lvs. on flowering branchlets 3–7-foliolate; lfts. cuneate-obovate, incisely dentate. 

Section 12. MINUTIFOLIAE. Species Nos. 55–57

dd. Lvs. of flowering branchlets 7–10-foliolate; lfts. elliptic or elliptic-oblong, sharply serrate.

Section 15. MICROPHYLLAE. Species No. 60
2. multiflora, Thumb. (R. polyanthos, Roессig, R. thyrsiflora, Léveillé, R. intermediá, Carr. R. Wickiana, Koch.) Fig. 3435. Deciduous shrub, with vigorous, long, recurving or climbing branches; lfts. usually 9, obovate to oblong, acute or obtuse, serrate, pubescent, 14-1½ in. long; fls. in many-fld. pyramidal corymbs, usually white, ½ in. across or more; sepals ovate, abruptly acuminate; styles glabrous; fr. small, globular.

June. Japan, China. B.M. 7119. G.F. 3:405 (adapted in Fig. 3435); 4:535; 6:316, 317. A.G. 18:677. A.F. 6:1003. G.C. 5:120, 121.-The typical form which is sometimes distinguished as var. Thunbergiana, Thory, has small single white fls. and is found in Japan and Korea. Var. cathayensis, Rehd. & Wilson. FIs. pink, about 1½ in. across, in rather flat corymbs. China. This is the wild single-fld. form from which the two following varieties have been derived. Var. carnea, Thol'Y (var. pluriflora, Regel. R. floridæ, Poir.). With double light pink fls. B.M. 1059. B.R. 425. Var. platyphylla, Thory, with larger lvs. and larger double, deep pink fls. B.R. 1372.

This is known as Seven Sisters Rose. A form of this with intense red and more numerous fls. is the well-known "Crimson Rambler," one of the best climbing roses (Fig. 3436). A.G. 10:233. Many hybrids have originated in cult.; they usually show their parentage by the pectinate stipules. A hybrid with R. rugosa is R. Poedræ, Sieb., with single, rather small white fls. W.R. 61. Of the same parentage, Makino, with small-pink fls. R. polyanthæ, Hort., not Roессig, is a trade name for hybrids with R. chinensis. Gn. 29:118. G.C. III. 28:135. G. 27:347. J.H. III. 43:425. The Dawson rose, or R. Dawsoniana, is a hybrid with General Jacqueminot. G.W. 7, p. 125. Hybrids with R. setigera, R. gallica, and R. Wickuriana have also been raised.

3. Watsoniææ, Crépin (R. multiflora var. Watsoniææ, Matsum.). Fig. 3437. Deciduous shrub, with sarmentose or recurving branches; lfts. 3-5, linear-lanceolate, with entire wavy margin, pubescent beneath, 1-2½ in. long; fls. in many-fld. pyramidal corymbs, ½ in. across or less, white or pink; style glabrous; fr. small.

June, July. R.B. 14, p. 183. G.F. 3:477 (adapted in Fig. 3437). W.R. 16.-A very curious rose of unknown origin, supposed to have been intro. from Japan, but not known in a wild state. Not quite hardy North.

5. Brunniæ, Lindl. (R. Brownii, Tratt. R. moschata var. nepalénæus, Lindl.). Himalayan Musk Rose. Tall shrub, with arching or sarmentose branches, glabrous or thinly villous while young; prickles scattered, hooked, short and stout; lfts. 5-7, elliptic-oblong to oblong-lanceolate, acute or acuminate, serrulate, soft-pubescent beneath, slightly pubescent or nearly glabrous above, 1½-2½ in. long; petioles and rachis pubescent, usually with scattered prickles; fls. white, fragrant, 1½-2 in. across, in large many-fld. corymbs; sepals lanceolate, loded, much longer than receptacle; pedicels long and slender, pubescent and glandular; styles pubescent: fr. ovate, ½-1½ in. long, glabrous; sepals deciduous. June, July. Himalayas, W. China. B.M. 4990. B.R. 529. F.S. 4:366, 397. Gn. 73, p.
2986 ROSA

9. sempervirens, Linn. Evergreen shrub with long and slender, sarmentose, somewhat reddish branches: lfts. 5–7, obovate-lanceolate, acuminate, serrulate, glabrous, shining above, ¾–2 in. long; lfts. in few-fld. or rarely many-fld. corymbs, white, to 2 in. across, slightly fragrant; pedicels glandular-hispid; styles usually pubescent; fr. subglobose or ovoid, orange-red. June,
Lindl. white to purple. W. R. 111. Here belongs probably the A. arvensis, Nichols. (R. arvensis, Lindl.). Deciduous shrub, with sarmentose or creeping sts.: lfts. usually 5, large, of firmer texture: fls. long-stalked, large, usually 5, large, of firmer texture: fls. long-stalked, large, usually 5, large, of firmer texture: fls. long-stalked, large, usually 5, large, of firmer texture: fls. long-stalked, large.

A. Sts. with uniform prickles: lvs. glabrous.
b. Lvs. persistent or subpersistent.
cc. Fls. white, yellowish or light pink, very fragrant: fr. globose or depressed-globose; sepals usually entire: stamens without or with few marginal glands at the auricles.

11. odorata, Sweet (R. indica var. odoratissima, Lindl. R. Théa, Sav. R. chinensis var. fragrans, Rehd.). TEA ROSE. Shrub with long sarmentose often climbing branches armed with scattered hooked prickles: lvs. evergreen or half-evergreen: lfts. 5-7, elliptic or oblong-oblong, acute or acuminate, sharply serrate, lvs. above, glabrous, 1-3 in. long; stipules glandular-ciliate usually only above the middle.

13. Noisettiana, Thory. NOSSETTE ROSE. CHAMPENY ROSE. Supposed hybrid of R. chinensis and R. moschata. Sts. upright to 6 ft., with hooked uniform reddish prickles: lfs. 5-7, usually oblong-lanceolate or oblong-ovate, glabrous: fls. usually many in corymbs, rarely short-stalked, crimson or pink; rarely white, about 2 in. across, not or slightly fragrant; outer sepals usually petaloid: fr. obovate or turbinate, about 3/4 in. long. China. W.R. 26. The wild form recently discovered in Cent. Asia is var. spontanea, Rehd. & Wilson, with single deep red or pink, usually solitary fls. G.C. III. 31:438. The following varieties are garden forms:

Var. minima, Rehd. (R. Laurencianna, Hort. R. pendula var. pincola, Thory). Dwarf shrub, usually not over 1 ft. high, with small rose-red fls. about 1/2 in. across; petals often pointed. There are single- and double-flowered forms. The Fairy Roses belong to this variety. B.M. 1762. Red. Ros. (3:25, 6, 7).

Var. viridiflora, Dipp. GREEN ROSE. With monstrous green fls.; the petals are transformed into small, narrow green lvs. F.S. 11:1136.

Var. Manetti, Dipp. (R. Manetti, Hort.). Fig. 3441. Of vigorous growth, upright; pedicels hispid-glandular; fls. deep pink, single or semi-double. This variety has been recommended as a stock for forcing roses; grows readily from cuttings, but is not quite hardy.

3441. The Manetti rose. Much used as a stock (x1). See No. 12.

14. bourbonica, Morr. BOURBON ROSE. Supposed hybrid of R. chinensis and R. gallica. Upright shrub, with prickly and often glandular-hispid branches; fls. usually 5, ovate or ovate-lanceolate, acute, shining, slightly pubescent beneath; fls. large, on glandular pedicels, double or semi-double, usually purple, blooming in summer and fall. W.R. 114. Originated from a rose intro. about 1819 from the Island of Bourbon where it was found among seedlings of the Bengal rose by M. Périchon and sent by Mr. Breon, director of the botanic garden at Bourbon, to Jacques, gardener to the Duke of Orleans at Neuilly near Paris; this rose, called Rose Edward, by crossing with roses of the Gallica groups has given rise to the Hybrid Bourbon roses and is the origin together with crosses between this and other hybrids of R. chinensis and its varieties and R. damascena of the Hybrid Perpetual or Remontant class.

Section 4. BANKSIANJE. Contains one Chinese species with climbing, sparingly prickly or unarmed sts.: stipules quite free, pubescent, caducous; sepals entire, reflexed after flowering, caducous.

A. Pedicels glabrous; fls. small ............... 15. Banksiae
AA. Pedicels hispid; fls. large ............... 16. Fortunaeana

Section 5. GALlicas Contains one very variable species, native of Eu. and W. Asia. Low, upright shrub; the sts. with usually hooked prickles mixed with bristles; fls. few and often with narrow bracts or solitary on a usually bractless pedicel; sepals reflexed after flowering, caducous, the outer ones persistent; upper stipules not dilated.

A. Prickles very unequal: Lfs. usually doubly and glandular-serrate.
B. Texture of lfs. firm, leathery; pedicels upright ............... 17. gallica
BB. Texture of lfs. thin; lfs. sometimes simply serrate; fls. nodding, usually double ...................... 18. centifolia
AA. Prickles uniform: lfs. sickle-shaped, not glandular. (Supposed hybrids of R. gallica.)
B. Prickles numerous.
C. Receptacle glandular-hispid: Lfs. ovate-oblong, pubescent beneath ...................... 19. damascena
CC. Receptacle usually smooth: Lfs. broadly ovate or broadly elliptic, pubescent beneath ...................... 20. alba
BB. Prickles sparsely on the flowering branches rarely wanting: Lfs. glabrous beneath or pubescent only on the midrib ...................... 21. francofurtana

21. **franconfortana**, Muenchh. (R. *turbinata*, Ait.). Upright shrub, attaining 6 ft.: stns. with straight or hooked prickles: flowering branches almost unarmed: lfts. 5–7, oval, serrate, pubescent beneath, upper stipules much dilated; fls. 1–3, single or double, purple, 2–3 in. across, slightly fragrant; pedicels and receptacle glandular-hispid only at the base; sepals erect after flowering, entire or nearly so: fr. turbinate. June.

---

3442. Rosa centifolia var. muscosa.—Moss rose. (X ½)

Section 6. **Canina.** Many species in Eu., N. Afr. and W. Asia. Upright shrubs, with scattered, usually hook-stems and numerous prickles; upper stipes dilated; corollas usually many-fld., with dilated bracts; outer sepals reflexed after flowering and caduceous or erect and persistent.

A. Lvs. pubescent, at least beneath, or glandular.
   a. Prickles slender, straight or slightly curved.
      b. *Lvs. smaller; branchlets purple, more or less pubescent*. June, July. Eu., W. Asia. B.M. 7241. W.R.
     c. *Lvs. broader, partly pubescent*. June.
    b. Prickles hooked, stout.
   a. *Lvs. glabrous*.  
   b. Foliage bright or dark green. 26. *canina*. 
   b. Foliage bluish green, tinged with red. 27. *rubrifolia*. 

22. **pomifera**, Herrm. (*R. villosa*, Linn., in part) Upright, densely branched shrub, attaining 6 ft., with almost straight spines; lfts. 5-7, oval to ovate-oblong, acute or obtuse, doubly glandular-serrate, grayish green, pubescent above, tomentose beneath, rarely glabrescent, 1-2 in. long; lfts. 1-3, pink, 1½-2 in. across, on briefly and glandular-pedicles: fr. scarlet, ovoid or subglobose, about ½ in. long, with persistent erect sepals. June, July. Eu., W. Asia. B.M. 7241. W.R. 141.—Hardy rose, with large ornamental fr. 

24. **rubiginosa**, Linn. (*R. Eglantiera*, Linn.). Eglantine. Dense shrub, attaining 6 ft., with hooked prickles often mixed with bristles: lfts. 5-7, orbicular to oval, doubly glandular-serrate, dark green above and glabrous, pale beneath and often pubescent, glandular on both sides, ½-1½ in. long; lfts. 1-3, on hispid short pedicels; bright pink, 1½-2 in. across; receptacle usually glandular-hispid: fr. subglobose or ovoid, orange-red to scarlet, with upright-spreading, usually caduceous sepals. June. Eu.; naturalized in some localities in the East. B.B. (ed. 2) 2:286. W.R. 146.—A handsome hardy rose of compact habit, with bright green foliage exhal- ing a very agreeable aromatic odor. There are some double forms and hybrids with other species.

25. **dumetorum**, Thullier. Upright shrub with spreading or recurving branches with stout hooked prickles: lfts. 5-7, close, oval-orbicular to elliptic, usually simply serrate, pubescent on both sides or only below on the veins, 1-1½ in. long: lfts. solitary to many, about 2 in. across; pedicels glabrous or stipitate-glandular: fr. ovoid to subglobose, orange-red, about ½ in. long, usually glabrous. June. Eu., N. Afr., W. Asia; naturalized in some localities. W.R. 132.—Very close to the following species and chiefly distinguished by the pubescence.

27. **rubrifolia**, Vill. (*R. glauca*, Poupin & Le ruyer, Desgl., not Vill.) Upright shrub, attaining 6 ft., with purplish purplish branches covered with catkin-like bloom: prickles few, hooked or straight: lfts. 7-9, elliptic or ovate-orbicular, simply serrate, bluish green and more or less tinged with red, ½-1½ in. long; lfts. 1-3 or more, pink, 1½ in. across, on usually hispid-glandular pedicles; sepals long, with dilated apex, upright-spreading, tardily caduceous: fr. subglobose, scarlet. June. Mountains of Cent. and S. Eu. B.R. 430. G.W. 7, p. 139. W.R. 133.—A very striking rose on account of its reddish foliage: fls. less conspicuous. Hardy North and prefers partial shade.

---

3444. Rosa carolina var. triloba (×3) No. 30.
Section 7. CAROLINA. Contains only American species. Upright, mostly low shrubs: sts. slender, with usually straight prickles, placed in pairs or mixed with bristles: upper stipules usually narrow: corymbs generally few-fld.: sepals spreading after flowering; pubescent, the outer ones entire or with few erect lobs: achenes inserted exclusively at the bottom of the usually depressed-globose receptacle.

b. Lfts. finely many-toothed: prickles usually hooked: stipules convolute. 28. palustris

b. Lfts. coarsely toothed: prickles usually straight and slender: stipules flat.
c. Branches prickly only at the nodes or unarmed, only vigorous shoots bristly.
d. Prickles hooked: lfts. shining above. 29. virginiana
dd. Prickles straight or nearly so: lfts. dull above. 30. carolina

c. Branches densely bristly.

31. nitida

AA. Pedicels very short: lfts. 7-11, small and narrow

32. foliolosa

30. carolina, Linn. (R. humilis, Marsh. R. purpurea, Ehrh. R. virginiana var. humilis, Schneid. R. Ljoni, Pursh.). Fig. 3442. Shrub, 3 ft. or sometimes 6 ft. high, spreading by means of numerous suckers, with slender prickles and usually numerous bristles: lfts. 5-7, resembling those of the former, but narrower, thinner, not shining, usually pubescent beneath: fls. often solitary; outer sepals lobed. June. Maine to Ga., west to Wisc. and Okla. W.R. 64. —Much resembling the preceding, which is often considered a variety of this species. Var. villosa, Rehd. (R. humilis var. villosa, Best.). Lvs. villosa-pubescent beneath, thickish. Var. grandiflora, Rehd. (R. humilis var. grandiflora, Baker.). Fls. 2 in. across: lfts. larger. W.R. 66. Var. triloba, Rehd. (R. humilis var. triloba, Wats.). Fig. 3444. Petals 3-lobed. G.F. 2:77 (adapted in Fig. 3444).

31. nitida, Wild. Low upright shrub, 1 1/2 ft. high: branches covered with straight prickles and numerous bristles: lfts. 7-9, narrowly oblong, acute at both ends, bright green and shining above, glabrous, 1 1/2-1 in. long: fls. usually solitary, 1-2 in. across, on slender glandular-hispid pedicles; sepals entire. June, July. Newfoundland to Mass. B.B. (ed. 2) 2:285.

32. foliolosa, Nutt. Fig. 3445. Low shrub, 1 1/2 ft. high: sts. with rather few slender prickles, sometimes almost unarmed: lfts. 7-9, narrow or linear-oblong, bright green and shining above, glabrous or pubescent on the midrib beneath, 1 1/2-1 in. long: fls. solitary or few, pink, about 1 1/2 in. across; pedicels and receptacle smooth or sparingly glandular-hispid: fr. globose, with rather few achenes. May, June. Ark. and Okla. to Texas. G.F. 3:101 (adapted in Fig. 3445). — Like the preceding, a handsome dwarf shrub with graceful foliage.

Section S. CINNAMOMEA. Many American, Asiatic, and European species. Erect shrubs, with usually straight prickles, in pairs or scattered, and often with numerous bristles: lfts. 5-11; corymba usually many-fld., with dilated bracts; sepals generally entire, upright after flowering, and persistent, rarely deciduous receptacle usually smooth.

a. Branches and prickles tomentose.

AA. Branches and prickles glabrous.

b. Stipules, at least on the shoots, more or less convolute.

34. cinnamomea

bn. Stipules flat.

c. Prickles nearly always wanting (sometimes present in No. 37).

d. Lfts. simply serrate, 5-7.

e. Rachis of fl. puberulous: fls. single. 35. blanda

en. Rachis of fl. glabrous: fls. double. 36. Lheritierann

dd. Lfts. doubly serrate, 7-9: fr. oblong to ovoid. 37. pendulina

c. Prickles present.

d. Lfts. 5-7, only on shoots occasionally 9: calyx persistent.

a. Upper stipules enlarged.

f. Fls. usually several, 1-2 in. across: lfts. generally obovate, 1/2-1 1/2 in. long. 38. Woodsii

ff. Fls. usually solitary, about 2 in. across or more: lfts. 1-2 in. long.

Upright shrub, attaining 6 ft., with stout sts. densely beaet with prickles and bristles: lfts. 5-9, oval to obovate-oval, rugose, shining and dark green above, glaucous and pubescent beneath, thick and firm, 1/4-2 in. long; petioles tomentose and bristly; stipules dilated: fls. solitary or few, purple or white, 21/2-3 1/2 in. across; bracts large; pedicles prickly; receptacle smooth: fr. depressed-globose, brick-red, to 1 in. across. May-Sept. N. China, Korea. Japan. S.Z. 1:28. B.R. 420. Gt. 30:1049; 42, p. 537. G.C. II. 14:372. Gr. 46, p. 52:384; 55, p. 434. 1.H. 18:47. G.g. 1:7; 5:339. A.G. 13:342; 344: 18:507; 5:339. L.A. 2:76: 7:624. F.E. 18:6. I.H. III. 45:159.—Forms of typical R. rugosa, which is sometimes distinguished as var. Thunbergiana, C. A. Mey., are the following: Var. alba, Rehd. (var. albiflora, Koidzumi), with white fls. Gr. 9:356. G. 8:281. Var. álbo-plena, Rehd., with double white fls. Var. roséa, Hort., with pink fls. Var. rubra, Hort., with purple fls. Var. rubro-plena, Rehd., with double purple fls. Gr. 24:846. Geographical varieties, not of garden origin, are the following two: Var. Chamissoniana, C. A. Mey. (R. pubescens, Baker, not Roxby.). Bristles almost entirely absent on the branches: lfts. narrower and smaller, less rugose. A double-flld. form of this variety is sometimes cult. in Cent. China, but apparently not yet intro. into western gardens. Var. kamtschatica, Regel (R. kamtschatica, Vent.). With slenderer less densely armed branches, thinner less rugose lvs. and smaller fls. and frs. B.M. 3149. B.R. 419.—R. rugosa is one of the most ornamental and at the same time hardest of the single roses, valuable for shrubberies; it is very handsome on account of its dark green shining foliage, large fls. appearing during the whole summer, bright red conspicuous frs., and its beautiful orange and scarlet fall coloring. It is also attractive in winter by reason of its stout, densely armed sts. Large numbers of hybrids have been raised. By crossing with double-flld. garden roses, R. rugosa has given rise to a new race of hybrid roses remarkable for their hardness and long blooming season; one of the best known is Mme. Georges Bruant (Fig. 3449), with double white fls., a cross of R. rugosa and the Tea rose Sombreuil. Another cross with a form of R. chinensis is R. calocarpa, Willmott (R. rugosa var. calocarpa, Bruant), with single rose-colored fls. and handsome fr. produced very abundantly. Gr. 46, p. 538; 52, p. 384. R.H. 1895, pp. 446, 447. I.H. 42, p. 13. W.R. 60. Remarkable for its large fls. and large frs. is R. micro­gusa, Henkel (R. rugosa × R. microphila, R. Wil­mottini, Bean). Upright, very spiny shrub: fls. 7-11, small, pubescent: fls. pink, 3-4 in. across: fr. depressed-globose, about 1 1/2 in. across, prickly, orange-red. Gr. 59:1381. R.H. 1905:144. It is of vigorous growth and hardy and will probably make a good hedge plant. Hybrids are also known with R. multiflora (see E.

37. **pendulina**, Linn. (R. alpha, Linn.). Fig. 3432. Sts. slender, 3 ft. high, usually nearly unarmed, rarely prickly and bristly: lfts. 7-9, oblong-ovate or oblong-elliptic, obtuse, doubly glandular-serrate, usually glabrous, ½-1½ in. long; fls. pink, usually solitary or 2-5, to 2 in. across; pedicels and receptacle usually smooth: fr. usually nodding, oblong or ovate, with elongated neck, scarlet. May, June. Most of Eu. B.B. 424: J.H. III. 43:9. W.R. 90. —Handsome frec-flowering shrub. Var. pyrenica, W. D. Koch (R. pyrenica, Gouan). Dwarf, with the pedicels and usually also the receptacles glandular-hispid. B.M. 6724. Gn. 27:544. Possibly a hybrid of this species and R. spinosissima in R. Moly, Kerner, similar in foliage to R. spinosissima, but with bright red fls. W.R. 100; one of the handsomest of the wild roses.

39. **nutkana**, Presl. Fig. 3452. Sts. stout, 5 ft. high, with usually straight prickles and sometimes bristly: lfts. 5-7, or sometimes 9 on shoots, broadly elliptic to oblong-saccate, generally rounded at the base, usually doubly glandular-serrate, almost glabrous, often glandular beneath, ¾-2 in. long; fls. usually solitary, pink, 2-2½ in. across: fr. globose, without neck. June, July. Alaska to Ore. and Utah. G.F. 1:449 (adapted in Fig. 3452). W.R. 75.—Has the largest fls. of the western species; pink.Var. hispida, Forn., has the receptacle glandular-hispid.

40. **acicularis**, Lindl. Sts. low, densely prickly: lfts. 3-7, broadly elliptic to narrowly oblong, rounded at base, simply or doubly serrate, pubescent beneath, ¾-2 in. long; fls. solitary, deep rose, ½-1 in. long. May, June. Alaska to Ont. and Colo., N. Eu., N. Asia, Japan. B.B. (ed. 2) 2:283. —A very variable species. Var. Bourgeauiana, Crépin (R. Sáyi, Schwein. R. acicularis var. Sáyi, Rehd.). Fig. 3453. Lfts. glandular and pubescent beneath, usually somewhat doubly glandular-serrate: fls. larger, often 2½ in. across; fr. usually globular. Ont. to Brit. Col. and Colo. Var. Engelmannii, Crépin in herb. (R. Engelmannii, Wats.). Fig. 3454. Similar to the preceding: lfts. distinctly doubly glandular-serrate: fl. oblong, to 1 in. long. Colo. to Brit. Col. G.F. 2:277 (adapted in Fig. 3454). Var. nipponensis, Hook. f. Lfts. smaller, ¾-¾ in. long; pedicels bristly: branchlets and

41. **californica**, Cham. & Schlcht. Sts. 8 ft. high, with stout, hooked or straight prickles, often bristly: lfts. 7-9, broadly elliptic to oblong-obovate, sparsely or evenly glandular-serrate, pubescent beneath or on both sides, often glandular, 1¼-1½ in. long; fls. on slender, usually smooth pedicels, over 1 in. across, few or several in dense corymbs; pink: fr. globose-ovate, yellow or brown when mature. May. B.M. 8569. J.H.S. 27:486. -This handsome rose 'has a very showy in June with its ample clusters of large pink flowers and again in fall with the nodding clusters of deep red hips.

45. **macrophylla**, Lindl. Large, upright shrub: flowering branches with few prickles or unarmed: lfts. 9-11, ellipsoid-ovate to elliptico-oblong, acute, sparsely serrate, glabrous above, pubescence beneath, 1½ in. long; stipules glandular-afficate: fls. 1-3, red, about 2 in. across; pedicels and receptacle glandular-setose or naked; sepals lanceolate, long-caudate, entire; fr. oblong-ovoid, red, 1½ in. long. Himalayas. W.R. 40. This species is tender and rare in cult. but several of the allied Chinese species when first intro. were distributed as *R. macrophylla* or varieties of *R. macrophylla*, such as *R. Moesii*, *R. setipetala*, *R. Davidii*, *R. sertata*, *R. persetosa* (see suppl. list for the last three species); to *R. persetosa* belong *R. macrophylla* var. *acicularis*, Vilm., and *R. macrophylla* f. gracilis, Vilm., while *f.* Foëke, belongs partly to *R. sericata* and partly to *R. Moesii*.

46. **Moesii**, Hemsl. & Wilson (R. macrophylla var. rubro-alba, Vilm.; R. Fargesii, Hort.). Densely branched shrub, 5 ft.: branches with scattered short straight prickles: lfts. 7-13, nearly sessile or ciliate to ovate-oblong or sometimes nearly orbicular, closely serrate generally except the slight; ploose midrib beneath, 1¼-1½ in. long; racis pubescent, glandular and bristly; stipules wide, glandular-ciliate: fls. solitary or 2, deep blood-red, 1½-2 in. across; pedicels short, stipitate-glandular like the receptacle, or the latter glabrous; sepals are ovate, abruptly long-caudate: fruit deep orange-red, oblong-ovoid, narrowed into a neck, 2½-3 in. long. June. W. China. B.M. 8585. J.H.S. 27:489. V.F. 95. G. 37:427. Gn. 72, p. 313.

J.H. III. 56:587. G.M. 51:478. —A strikingly beautiful rose; its fls. vary considerably in color, from dark blood-red, the color of the typical form, through deep rose to light pink. The extreme light pink form has been distinguished as *f. rosa*, Rehd. & Wilson.

47. **gymnocarpa**, Nutt. Sts. slender, attaining 10 ft., with straight slender prickles and bristles: lfts. 5-9, broadly elliptic to oblong, doubly glandular-serrate, usually glabrous, ½-1 in. long; fls. solitary on short lateral branchlets, pale pink, about 1 in. across; sepals short: fr. orange-red, globose, small; calyx drops before maturity. June. B.M. 7646. J.H.S. 27:486. —Very pretty rose, not to be confused with *R. Willmottiana*, Lévill., which is *R. longipes* (see suppl. list), nor with *R. blanda* var. Willmottiana, Baker.
Section 9. Pimpinellifolia. Few Old-World species. Upright shrubs, usually low; prickles straight, scattered, usually numerous and mixed with bristles; lfts. very small, usually 2, stipules narrow, with divergent and dilated auricles: fls. solitary, without bracts; sepals entire, erect and persistent.

AA. Flowering branches very prickly:
fls. pink, white, or yellow; fr. black. 49. spinosissima

Section 10. Lutea. Four Asiatic species. Upright or somewhat serpentine shrubs, with scattered, straight or hooked prickles, without bristles; stipules usually narrow, with divergent and dilated auricles: fls. yellow, without bracts; sepals usually pinnae, persistent, upright.

A. Prickles straight: lfts. doubly serrate

Section 11. SERICEAE. Three Asiatic species. Erect shrubs with the prickles in pairs; stipules narrow, with erect dilated auricles; fls. solitary, without bracts; sepals entire, persistent, and upright; petals usually 4; styles somewhat exserted.

a. Lfts. generally ovate or oblong, 7–11; fr. slender-stalked...

54. omeiensis, Rolfe. Fig. 3456. Shrub, to 10 ft.: the young shoots densely bristly: lfts. 9–17, oblong or elliptic-oblong, acute, cuneate at the base, serrate, glabrous, ½–¾ in. long: fls. white, over 1 in. across; petals usually 4; fr. ellipsoid, ½–¾ in. long, red, borne on a yellow or red thickened stalk of about equal length. May, June: fl. in July, Aug. W. China. B.M. 8471.

—A graceful shrub with handsome fern-like foliage, early white fls. and especially attractive in summer on account of the contrasting color of the red fr. and its yellow or red fluffy stalk, a feature which distinguishes it at once from any other cult. rose. Has proved hardy in Mass., while R. sericea is tender.

The large wing-like prickles, which are red and translucent while young, make this rose a conspicuous and striking object.

Section 12. MINUTIFOLLE. Three American species. Low shrubs with slender, scattered prickles; stipules with dilated and divergent auricles; fls. solitary, without bracts; sepals erect, persistent, the outer one pinnate; fr. prickly.

b. Branches globose: lfts. usually 5...55. mirifica

55. mirifica, Greene. Upright shrub, 2–4 ft.; st. green, glabrous, with slender yellowish white prickles and numerous bristles: lfts. usually broadly cuneate-obovate, incised or crenately dentate, the teeth sometimes glandular-serrate, slightly pubescent on both sides or nearly glabrous, light green, ¾–1½ in. long; fls. solitary, deep rose-purple, 1½–2 in. across; fr. irregularly and broadly turbinate, wrinkled, dull red, prickly.

Rosa minutifolia. Engelm. Fig. 3457. Dense shrub, to 4 ft. high: branchlets pubescent with slender brown prickles: lfts. 5–7, ovate to oblong, incised dentate, pubescent, ½–¾ in. long: fls. short-pedicelled, pink or white, about 1 in. across; fr. subglobose, hirsut. April, May. Calif. G.F. 1:102 (adapted in Fig. 3437). J.H. S. 27:456.—Tender.

Section 13. BRACITAVE. Two Asiatic species. Shrubs with erect or sericeous and tomentose or pubescent sts.; prickles in pairs; stipules slightly adnate and pectinate: inf. with large bracts; sepals reflexed after flowering; stamens tomentose.

58. bracteata, Wendl. (R. Macrines, Dum.). MACARTNEY ROSE. Sts. usually procumbent or sericeous, villous-tomentose, with stout hooked prickles: lfts. 5–9, oval to ovate, crenately serrulate, bright green above and somewhat shining, almost glabrous beneath, ⅓–2 in. long: fls. 1 or few, short-stalked, white, 2–2½ in. across; sepals and receptacle densely tomentose. June–Oct. S. China, Formosa; naturalized in Fla. and La. B.M. 1377. B.B. (ed. 2) 2:268. Gn. 70, p. 192.—Handsome half-evergreen climber, not hardy N. There is a double-flowered form.

Section 14. LEVIGATAE. One Asiatic species. Climbing shrub, with scattered hooked prickles: lfts. generally 8; stipules almost free; fls. solitary, without bracts, large, white; sepals erect, entire, persistent.

(Rosaceae.)

**ROSA**

**ROSE**

- **Family**: Rosaceae
- **Genus**: Rosa
- **Species**: Various species and cultivars

**Description**

- **Type of plant**: Perennial or deciduous shrub
- **Leaves**: Simple, opposite, toothed or entire
- **Flowers**: Single, in clusters, white, pink, red, or yellow
- **Fruits**:uyo, flattened, orchen\n
**Cultivation**

- **Preferred soil**: Well-draining, rich in organic matter
- **Light requirements**: Full sun or partial shade
- **Watering**: Moderate to low, depend on variety

**Uses**

- **Garden**: Ornamental, edging, hedges, topiary
- **Cut flowers**: Popular for floral arrangements
- **Edible**: Ripe rose hips can be used in tea and herbal medicine

**Common Varieties**

- **R. chinensis**: Chinese rose
- **R. canina**: Dog rose
- **R. gallica**: French rose
- **R. rugosa**: Hardy rose

**Historical and Cultural Significance**

- **Roses** have been cultivated for thousands of years, symbolizing love, beauty, and romantic love throughout history.

Following are the equivalents of some of the common names of roses:

- **Ayshire** – *R. arvensis var. capreaeata*
- **Banks Rose** – *R. Banksi*
- **Bengal** – *R. chinensis*
- **Bourbon** – *R. borbonica*
- **Champney** – *R. Noisettiana*
- **Creek** – *R. chinensis*
- **Cinnamon** – *R. cinnamomea*
- **Dumask** – *R. damascena*
- **Dog** – *R. canina*
- **Eglantine** – *R. rubiginosa*
- **Macartney** – *R. bracteata*
- **Memorial** – *R. Wichurana*
- **Moss** – *R. gallica var. moschata*
- **Noisette** – *R. Noisettiana*
- **Prairie** – *R. setigera*
- **Provence** – *R. gallica*
- **Scotch** – *R. moschata*
- **Sweetbrier** – *R. rubiginosa*
- **Tean** – *R. odorata*

When one speaks of roses, the hearer is likely to think only of the large improved kinds of the gardens; and yet there are more than one hundred well-recognized species-forms of Rosa, while only a dozen or so have entered largely into the horticultural forms. The systematic account beginning on page 2981 describes sixty species, and many more are entered in the supplementary list at its conclusion. The results of domestication are marvelous, and yet the real breeding of roses is little more than begun, and it confounds the imagination if one contemplates what may appear when endless new combinations are made with the many species that are yet little modified by man. The beginnings in this endeavor by persons in this country and elsewhere, indicate a rich field for useful experiment.

These other species of Rosa, aside from the domesticated forms, are of interest and merit largely for landscape planting. Usually we do not think of roses as “shrubbery” but rather as “flowers;” yet *Rosa rugosa* is a good landscape subject, and the same is true of *R. setigera, R. multiflora, R. levisigera,* and many other species. The lists and suggestions by Rehder, on page 2982, are valuable in this connection. Some of the native wild roses are most attractive in their natural setting, not alone in flowers but in foliage, color of stems, fruit, and general habit; and if the grounds include a suitable area, these plants may well be transferred in quantity. In half-wild and informal borders, on banks, along streams and the margins of woods, many of the roses are admirable. The usual horticultural roses are of little merit in landscape work, because they do not supply sufficient foliage and they lack strong shrubby characteristics; and this fact has no doubt obscured the merits of the wild single roses as material for planting.

The highly improved roses are essentially flower-garden subjects, and they produce better bloom when grown by themselves in regular areas, plantations or beds, where they may receive tillage and such other treatment and care as are specially adapted to them. The preferable location is on the private property, not at the place, at the side or rear, and well removed from tall buildings and overhanging trees. They should be given ample space, good soil, and liberal fertilizing, as one would provide these requisites for strawberries, bush-fruits or tomatoes.

The value of the rose product is particularly difficult to estimate. A census-accounting could assemble figures for the nursery stock, the glass devoted to rose-culture, and the value of roses sold by commercial establishments; but the greatest value of the rose is the unmeasurable satisfaction that it returns in thousands of homes and the ministry that it renders to millions of persons.

The literature of the rose is voluminous. The American book writings on the subject are listed on page 1552, Vol. III. For a list of rose books in all languages, see “Bibliografia de la Rosa,” by Vergara, Madrid, 1892.

**Rose organizations.**

The American Rose Society was organized in New York, March 13, 1899, “to increase the general interest in the cultivation and improve the standard of excellence of the rose for all the people.” To organize a system of exhibitions, and otherwise “to foster, stimulate, and increase the production in every possible way of improved varieties of the rose, suitable to our American climate and requirements.” The Society is a clearing-house for those interested in roses.

Including at first primarily so-called commercial rose-growers—those who grow roses the year round for cut-flowers—the Society has gradually broadened until a considerable number of interested and capable amateur rose-growers are included. Intensive consideration for the rose is fostered by the exhibitions that the Society either gives or takes part of which it exercises authoritative supervision. For example, four so-called national flower shows, held in Chicago, New York, Boston, and Philadelphia, have had as a prominent attraction notable displays of roses forced into bloom in the early spring, usually offered in competition for the prizes gathered under the leadership of the Society. Inasmuch as these displays have included many of the better climbers and garden roses, large numbers of persons are thereby brought into contact with these advances in rose-culture.

*Rose test-gardens have been established under the supervision of The American Rose Society in several places, including, for example, Hartford (Conn.), Washington, Minneapolis, and at Cornell University, Ithaca, N. Y. In these gardens no less than five plants of certain varieties are grown*
XCIX. Rose.—White, Bride; pink, Bridesmaid.
under comparable conditions, and committees of the Society make an annual inspection at the time of bloom. The rose test-garden in Hartford, in connection with the well-known and beautiful municipal garden planted in 1904 by Theodore Wirth, has proved a wholesome attraction to the more than 115,000 persons who have annually visited it. The superintendent of the Hartford park system estimates that the area included in the rose-garden attracts visitors at the rate of 5,000 persons a year, thus increasing the use of a park system.

The Society maintains a bureau of registration for new roses, provides a scale of points for judging both blooms and plants, and awards medals and certificates for new roses. Its membership includes three classes—life, active, and associate—the latter relation being open only to amateur rose-growers. In 1916, The American Rose Society began the publication of The American Rose Annual, under the editorship of J. Horace McFarland.

Under the leadership of E. M. Mills, of Syracuse, New York, an organization was formed in that city under the title of the Syracuse Rose Society, for the purpose of stimulating local interest in rose-growing. The ideal proposed by Dr. Mills is noted in the following extract from his article in the 1916 American Rose Annual: “It is far more important that 500 people in a city have rose-gardens with from twenty-five to a few hundred bushes in each of them than that there should be only a few large show gardens.” Other societies have been formed in the Pacific Northwest directly to promote rose-growing, and various garden clubs and local societies have affiliated with The American Rose Society under its rules. There are a number of affiliated interests. Any horticultural society in the United States or Canada holding an annual exhibition of roses may affiliate with The American Rose Society, and receive medals for the exhibitors.

The present assembly on the rose, aside from the systematic account of Rose, pages 2981 to 2999, comprises the following articles:

Horticultural classification of roses.

The garden classification of roses presents considerable difficulty, as the several groups have been so much mixed that the original characteristics of each overlap at nearly all points. This is particularly true of the Perpetuals, of which any close classification is impossible. The difficulties increase as one advances. Certain clear-cut characters may be taken to mark given distinct groups in the summer roses, with which the horticulturist has not hurried himself so much. Nearly all of these characters are reproduced in the Perpetuals, and, being blended, give rise to endless confusion; thus the following scheme is merely suggestive and should be studied in comparison with the botanical classification (see page 2983).

American rose-culture, so far as garden varieties are concerned, can hardly be said to have established itself as yet. Our growers are today striving to overcome the short-lived character of the blooms, so as to secure in our gardens something of the rose beauty of Europe. The Wichuraiana, Rugosa, and Multiflora roses, combined with our native species and blended again with the best representatives of the garden-varieties already grown, with the admixture of some of the newer species from western China, seem to offer the solution. The beginning has already been made. The hot sun and trying climatic conditions of our summers are fatal to the full beauties of the roses of France and England. The flower is developed so quickly that it has no opportunity to “build” itself, and once developed it fades as rapidly. What has been accomplished for the other florists’ flowers remains yet to be accomplished for the rose, and the American rose of the future must be developed to suit the circumstances in the same way that the American carnation has been produced.

**CLASS I. SUMMER-FLOWERING ROSES, BLOOMING MOSTLY ONCE ONLY.**

A. Large-flowered (double).

b. Growth branching or pendulous; leaf wrinkled... 1. Provence
Moss
Pompon
 Sulphurea.

b. Growth firm and robust; leaf downy........ 2. Damask and French
Hybrid French
Hybrid Provence
Hybrid Bourbon
Hybrid China.

bb. Growth free: leaf whitish above, spineless...
3. Alba

aa. Small-flowered (single and double).
bb. Growth climbing: flowers produced singly... 4. Ayrshire
bb. Growth short-jointed, generally, except in Alpine and Prairie... 5. Briers

Austrian
Scotch
Sweet
Pentance
Prairie
Alpine.

bb. Growth climbing or rambling: flowers in clusters...
6. Multiflora
Baby Ramblers.

bb. Growth free; foliage persistent (more or less), shiny........ 7. Evergreen
Sempervirens
Wichuraiana
Cherokee
Banksian.

bb. Growth free; foliage wrinkled........ 8. Pompon

**CLASS II. SUMMER- AND AUTUMN-FLOWERING ROSES, BLOOMING MORE OR LESS CONTINUOUSLY.**

A. Large-flowered.

b. Foliage very rough...... 9. Hybrid Perpetual
Hybrid Tea
10. Moss

bb. Foliage rough...... 12. Bourbon
13. Bourbon Perpetual

bb. Foliage smooth...... 14. China
Txa

bb. Foliage smooth, very shiny and vigorous 15. Perpetua

aa. Smaller-flowered.

b. Foliage deciduous.

c. Habit climbing...... 16. Musk
17. Ayrshire
18. Perpetual Multifloras
Wichuraiana Hybrids

co Habit dwarfi, bushy... 19. Perpetual Briars
Rugosas
Ludida
Microphylla
Bergerii
Scotch.

bb. Foliage more or less persistent...... 20. Evergreen
Macartney
Wichuraiana
Garden-group 1. _Provençal_. Fragrant; branching or pendulous; fls. generally globular; foliage bold, broad, wrinkled, deeply serrate; prickles uncertain; sometimes fine and straight, sometimes coarse and hooked. Rich soil. Prune closely unless very vigorous. Types are: _Moss rose_, a created form of the _Provençal_ (Fig. 3442).

3462. American Beauty, one of the most popular roses in America. One of the Hybrid Perpetual class.
The picture shows a specimen grown in the open. (X 1/4)

Garden-group 2. The _Damask_ and French. Damask roses are fragrant; growth robust; spinous; lvs. light green, downy, coriaceous. Hardy; free-flowering; scent destroyed on drying.

French roses: Fragrant (moderately); more upright and compact in growth than the _Provençal_; prickles smaller and fewer; fls. generally flat. Very hardy, growing in any soil; petals bleach in strong sunlight; makes abundance of wood, which should be thinned out; perfume develops in the dried petals.

Hybrid French or Hybrid _Provençal_, a less robust group with smoother, short-jointed wood and generally light-colored flowers. Type, _Princess Clemence_.

Hybrid China (China _×_ French and _Provençal_, par-taking more of those parents). Growth more diffuse than the French rose: foliage smooth, shining, and remains on the bush late in the year; thorns numerous and strong. Vigorous of growth; very hardy, and not generally well adapted to poor soil; requires but little pruning.

Garden-group 3. _Alba_, or white roses. A very distinct group; all light-colored flowers of moderate size; leaf whitish above, deep green below; spineless (some hybrids with other groups are very thorny), of free growth; prune closely. Type, _Feleite Parmentier_ and _Maiden’s Blush_.

Garden-group 4. _Ayrshire_. Climbing roses; very hardy; slender shoots suitable for trellises and trunks of trees: fls. produced singly. Useful for pot cultivation when trained over a frame; fls. vary from white to deep crimson. Type, _Queen of the Belgians_, _Dundee Rambler_. _Ruga_ is a hybrid between this group and one of the _Teas_; fragrant.

Garden-group 5. _Briers_. Under this heading may be grouped most of the well-defined types of garden roses, mostly small-flowered and which do not readily respond to high cultivation. They are more useful as flowering shrubs in the garden than for cut-flowers. The blooms are generally short-lived.

_Austrian_ or _Yellow Briers_. Small leaflets: solitary flowers: bark chocolate-brown. Very hardy, but require free air and dry soil; will stand very little pruning, as it produces flowers from the upper ends of the old wood. Types, _Harison’s Yellow_, _Austrian Copper_, and _Persian Yellow_.

Scotch or Spiny. This group is well recognized by its excessive spininess; compact low bushes, flowering abundantly and early: flowers small, double. Multiply by underground suckers; fragrant. One hybrid of this group, _Stanwell_, is a Perpetual.

Sweetbrier. Distinguished by the fragrance of its leaves: the fruits are also decorative: foliage small: flowers light-colored and not of much merit.

_Lord Penzance Briers_. This is a group of hybrids of _R. rubiginosa_ (the _Sweetbrier_), and the older large-flowered varieties, especially _Bourbon_ and _Damask_.

The results are hardly distributed in America as yet; a few are to be found in select collections. Generally speaking they may be described as very greatly improved Sweetbriers. _Brenda_ is particularly desirable for its fruit.

_Prairie rose_ ( _R. setigera_). A native species; promises under cultivation to develop some valuable acquisitions, especially in hybridization with other groups: Type, _Baltimore Belle_ (Fig. 3439).

_Alpine_ or _Boursault_. Native of the Swiss Alps; semi-pendulous, long, flexible, smooth shoots: flowers in large clusters; mostly purple or crimson flowers. Good for pillars; very hardy; especially suitable for shady places; should be well thinned in pruning, but the flowering wood left alone: type _Amadis_. Produced by crossing _Teas_ and _R. alpina_.

Garden-group 6. _Multiflora_. The _Multiflora_ group divides itself naturally into the _Multiflora_ true and _Baby Perpetual_ Rambler. _R. multiflora_, the parent type, is characteristic of the varieties here, the flowers being produced in large corymbs and continuing over a comparatively long time. These varieties are useful as pillar and trellis roses and respond to high cultivation. In pruning, remove only the (old canes, leaving the young new growth to carry flowers next year.

The _American Pillar rose_ belongs here (Fig. 3451). This group is particularly well adapted to the wild-garden. The name _Polyantha_, sometimes applied to these roses, should be dropped to avoid confusion. The _Rosa polyantha_ of botanists is a synonym of _R. multiflora_ (p. 2985), but the _Polyantha_ of horticulturists are hybrids of _R. multiflora_ with _R. chinensis_ or _Hybrid Perpetuals_; they are low bushy plants, first described as _Polyantha_ varieties by Carrière in _Revue Horticole_, 1884.

Garden-group 7. _Evergreen_. The so-called _Evergreen_ roses hold their foliage until very late in the year and in hybridization appear likely to yield varieties which are practically evergreen.
Sempervirens, useful as pillar roses, producing flowers in corymbs: very hardy; vigorous growth: free bloomer: requires considerable thinning in pruning. Types, Felicite perpetuella.

Wichuriana (Fig. 3440), most popular of all the rampant roses: very hardy, growing in any soil: this promises to be the basis of a very valuable race of American roses: flowers in the type white. Hybrids have been raised from Hybrid Perpetual and Tea varieties giving large flowers, scented; such are Gardenia and Jersey Beauty. Many hybridists have worked on this species, and the past few years have thoroughly made good the early promise of remarkable developments.

Clementine (Rosa lavandula) of the southern states can be grown satisfactorily away from its native regions only in a greenhouse. (Figs. 3463, 3459.)

The Banksian (Rosa Banksiae). Two varieties of this are known, the yellow and the white. Requires greenhouse treatment: evergreen; needs very little pruning, merely shortening the shoots that have bloomed. Yellow variety scentless, white variety possessing the odor of violets: flowers are produced in graceful drooping clusters. See Summer Roses and Fig. 3464.)

Garden-group 9. Hybrid Perpetual, or Hybrid Remontant. A large and comprehensive group of mixed origin. The mixture with other groups has become so involved as to render separation practically impossible. The characteristics may be described as stiff, upright growth, sometimes inclined to pendulous: flowers of all types: foliage dull green, wrinkled, not shiny; embracing generally the characteristics of the Provence, Damask, French, and the Chinese groups: flowers large, inclined to flat, generally of dark colors. By far the largest and most comprehensive division. (Figs. 3462, 3463.)

Garden-group 10. Hybrid Tea. The La France group belongs here. (Fig. 3568.)

Garden-group 11. Moss. A perpetual-flowering group of the Provence. See Summer Roses and Fig. 3462.

Garden-group 12. Bourbon. Dwarf and compact growth, with rounded, more or less shining leaves, very floriferous: brilliant colors: good outline; in perfection late in the season: requires close pruning. Type, Hermosa (or Armosa).

Garden-group 14. China (Rosa chinensis). The China or Monthly rose is characterized by its positively perpetual manner of flower. Its blooms become much darkened in color from the action of the sun's rays: flowers small and irregular in shape. Somewhat tender.

The Tea-scented China or Tea Rose (Fig. 3465), Rosa odorata, is an allied species. It has large thick petals, with the characteristic tea scent: flowers generally light-colored, pink and creamy yellow: growth free: the best for forcing. The group has been hybridized with all other sections and the Tea influence is seen throughout the rose family. Some of the varieties are climbing. Type, Bon Silene and Homer.

Lawrenceana. Dwarf forms, requiring the same treatment as the Teas. Commonly known as the Fairy Rose.

Garden-group 15. Perpetua. Crosses of Hybrid Teas and "Austrian" brier. Habit generally like Hybrid Teas but more vigorous, with stout spines and coarse shiny foliage. The chief distinction, however, is in the remarkable coloring of the flowers, which is indescribable, but often spoken of as "shrimp," with blendings and shadings of burnished copper. Tendency to shed foliage unless grown on almost pure clay. Some forms, as Juliet, show affinity to Austrian in resenting pruning, but later kinds are closer to Tea. Type Madame Edouard Herriot.

Garden-group 16. The Musk. Very fragrant: rather tender: derived from Rosa moschata: flowers of pale color. This group has been much hybridized with others, and its identity is lost as a garden plant in that of its derivatives, especially the Noisette. The flower buds are elongated and the flowers produced in clusters.

Noisette (Fig. 3469). Larger flowered than the true Musk roses, flowering very late: free growth: more hardy. The group bears a certain superficial resemblance to the Teas and requires moderate pruning; will grow in any soil. The subgroup has been largely blended with the Teas and with a loss of hardness. In consequence it has fallen into disuse.

Garden-group 17. Ayrshire. Perpetual forms of the Ayrshire. For characters, see Summer Roses.

Garden-group 18. Perpetual-flowering varieties of the Multiflora group. The term in gardens is taken to include a large number of small cluster-flowered, climbing roses, and is particularly important in American rose-culture, as the basis of a new section of hybrids with the Teas and (erroneously) including hybrids of Wichuriana and Teas. M. H. Walsh in Mas
sachusetts, M. Horvath in Ohio, and Jackson Dawson in Massachusetts have accomplished important work in this field. Some of Walsh's recent introductions, as Debutante and Sweetheart, not as yet fairly tried, and the Dawson rose, may be classed here. They are valuable as trellis and pillar roses for garden decoration.

Seeds.—Roses are grown from seeds not only to obtain new varieties but also because many true species are economically procured in this way, e. g., *R. canina*, *R. multiflora*, *R. ferruginea*, *R. rugosa*, *R. rubiginosa*, and the like. The seeds should be gathered in autumn and at once stratified with moist sand or allowed to ferment in tubs with a little water, and kept in a fairly warm place. When well rotted they can be easily rubbed and washed clean and should be planted at once, either in carefully prepared and well-manured beds out-of-doors or in pans or flats in a cool greenhouse. It is sometimes advised that the hips should first be dried and then rubbed clean, but this method often causes delay in germination, a matter sufficiently troublesome without additional complications; they should always be kept moist. Whether they are planted under glass or in the garden it is difficult to forecast their coming up. It may be within a few weeks, e. g., *R. multiflora* under glass; or at the beginning of the second growing season after planting, e. g., Sweetbrier seed planted out-of-doors in November, 1914, may be expected to germinate in the spring of 1916, while *R. rugosa* sown at the same time may come up the following spring; i. e., in 1915, or, a season intervening, it will appear with the Sweetbrier in 1916. Stratifying or fermenting the seeds tends to secure uniform germination within a reasonable time. It has also been suggested, and many things confirm the idea, that early gathering helps to hasten germination; in other words, do not wait for excessive ripeness, but pick the hips as soon as the seeds harden, some time before the fruit is deep red. Until these matters are better understood, all rose seeds sown out-of-doors, either in autumn or spring, should be mulched 2 to 3 inches deep with pine needles or other litter. Frequent examinations should be made in spring and the covering at once removed when the seedlings appear; if they do not appear, let the mulch remain to keep down weeds and retain moisture in the seed-bed. Pans or flats in which seed has been planted should be kept at least eighteen months before discarding, with the soil always moist. Notwithstanding the difficulties of germination, the young seedlings make most satisfactory growth and may generally be transplanted into nursery rows when

**Garden-group 10. Perpetual Briers.** Of this group there are about five important types. Rugosa or Japan rose, a low-growing bush: hardy: useful as a hedge plant, and specially adapted for exposed situations near the seashore (Figs. 3446–3448). Hybrids have been made with other Perpetual groups, especially Teas and H. P.'s. Mme. Georges Brunat is a type. The Rugosa blood is strongly seen in all cases.

Microphylla has minute leaflets; now called *Rosa Roxburghii*.

Guarderidifolia has leaves somewhat resembling barberry; now known as *Rosa persica*.

Perpetual Scotch, a perpetual-flowering form of *Rosa spinosissima*, probably a hybrid from the Danusk.

**Garden-group 20. Evergreen.** Two types, as follows:

Macartney, slender: sweetly scented and very floriferous throughout the season. Is derived from *R. bracteata*.

Wichuraiana. The Wichuraiana hybrids already referred to under Group 7 may dubiously be included here. They have not yet been sufficiently tested. The perpetual-flowering Ramblers have foliage partaking of Wichuraiana and Tea characteristics.

**Leonard Barron.**

**Propagation of roses.**

The rose is propagated by seeds, cuttings, grafting or budding, by layers and by divisions. The genus is so large and diversified and the requirements are so many that the whole art of the propagator is needed to satisfy the claims of the Queen of Flowers.

**Seeds.**—Roses are grown from seeds not only to obtain new varieties but also because many true species are economically procured in this way, e. g., *R. canina*, *R. multiflora*, *R. ferruginea*, *R. rugosa*, *R. rubiginosa*, and the like. The seeds should be gathered in autumn and at once stratified with moist sand or allowed to ferment in tubs with a little water, and kept in a fairly warm place. When well rotted they can be easily rubbed and washed clean and should be planted at once, either in carefully prepared and well-manured beds out-of-doors or in pans or flats in a cool greenhouse. It is sometimes advised that the hips should first be dried and then rubbed clean, but this method often causes delay in germination, a matter sufficiently troublesome without additional complications; they should always be kept moist. Whether they are planted under glass or in the garden it is difficult to forecast their coming up. It may be within a few weeks, e. g., *R. multiflora* under glass; or at the beginning of the second growing season after planting, e. g., Sweetbrier seed planted out-of-doors in November, 1914, may be expected to germinate in the spring of 1916, while *R. rugosa* sown at the same time may come up the following spring; i. e., in 1915, or, a season intervening, it will appear with the Sweetbrier in 1916. Stratifying or fermenting the seeds tends to secure uniform germination within a reasonable time. It has also been suggested, and many things confirm the idea, that early gathering helps to hasten germination; in other words, do not wait for excessive ripeness, but pick the hips as soon as the seeds harden, some time before the fruit is deep red. Until these matters are better understood, all rose seeds sown out-of-doors, either in autumn or spring, should be mulched 2 to 3 inches deep with pine needles or other litter. Frequent examinations should be made in spring and the covering at once removed when the seedlings appear; if they do not appear, let the mulch remain to keep down weeds and retain moisture in the seed-bed. Pans or flats in which seed has been planted should be kept at least eighteen months before discarding, with the soil always moist. Notwithstanding the difficulties of germination, the young seedlings make most satisfactory growth and may generally be transplanted into nursery rows when
one year old. When two years old they are fit for permanent planting. A winter protection of pine boughs is helpful to the young plants. Some seedling roses are extremely precocious, blooming before they are one year old, e.g., some Hybrid Perpetuals and so-called Polyantha roses. The first flowers of seedling roses do not always indicate their real character; in hybridizing it is well to wait for the second or third season before discarding.

Cuttings.—A common means of propagation, under glass and out-of-doors, is by cuttings. Under glass short cuttings 2 to 3 inches long can be made in November and December from wood of the current year's growth. They should be firmly planted in sand, in flats or pans (Fig. 3467) and kept in a cool greenhouse. They root in February or March, and can either be potted in thumb-pots or kept on in flats until May or June, when they should be planted out in rich beds; salable plants are obtained in October. This is the shortest way to strike R. setigera and its varieties, Crimson Rambler and its allies, R. multiflora, and their various offspring, R. Wichurana and its hybrids, Madame Plantier and doubtless many others. Rosa indica, in all its forms, all tender species, and many Hybrid Perpetual roses, are propagated by cuttings of hardened wood grown under glass. Peter Henderson says the wood is in the best condition when the bud is "just open enough to show color." Blind eyes can also be used, and the smaller wood is better than the strong rampant growth. Plant in sand and in a warm house; bottom heat and a close frame are often used but are not necessary. The cuttings are from 1½ to 2 inches long; single eyes strike readily.—In the open air, cuttings of ripened wood may be planted in spring in V-shaped trenches in carefully prepared and well-manured ground. They make strong plants in autumn. Wood of the season's growth is gathered before severe frost, cut into 6-inch lengths, tied in bundles, and stored through the winter by burying in sand, moss, or earth. They root in February or March, and can be planted in pots until they can be hardened off and planted out in May or June, the point of union being well below the surface. A specimen of Dawson's work is shown in Fig. 3468, the stock being a bit of R. multiflora root; its age is about three months.

Rosa multiflora is an excellent stock for garden roses, since it does not sucker; this great advantage, is also obtained by using the root-graft as above described. (See article on roses in Country Life in America, March, 1916, by Geo. C. Thomas, Jr.) The commercial florists use Manetti stock planted in thumb-pots. Cut back to the crown, this is splice-grafted and kept in a warm close frame until united; plants are afterward grown on in pots until large enough to put out in the beds, in which they will flower the following winter. There is some difference of opinion among gardeners as to the respective merits of own-root and grafted plants: just now many of the foremost growers prefer the latter for forcing. It is a perplexing question and could be settled by only a series of exact experiments costing much time and trouble.

Rosa canina is used for standard, R. Manetti for dwarf stocks. Under glass roses are budded also, with a shield-bud, at any season when the bark slips, using for stock a vigorous variety. About Boston the yellow and white Banksian roses once had high local repute for stock for Tea and other tender kinds.

Grafting roses in the open air in this country is not often employed, but in the South, Hybrid Perpetual and other hardy roses are said to be root-grafted in winter (very much as apple stocks are grafted), tied in bundles, stored in sand, and planted out in early spring, the worked portion being set well below the surface. Root-grafting is not sucker; this great method of propagation under glass. Jackson Dawson's practice is to use the whip- or splice-graft, but the veneer-graft is also employed, with bits of R. multiflora root 2 to 3 inches long for the stock, the cion being somewhat longer but of equal diameter. They are firmly tied with raffia and waxed made into bunches, they are covered with moist moss in an open frame in a coolhouse and left until united. They are then potted off and grown on until they can be hardened off and planted out in May or June, the point of union being well below the surface. A specimen of Dawson's work is shown in Fig. 3468, the stock being a bit of R. multiflora root; its age is about three months.
money. It is also quite possible that matters of tempera­
ture, soil, moisture, and food are equally important fac­
tors.

Layering.—This method is employed only when few plants are required; it is cumbersome and wasteful. Layer in early spring, using wood of the last year’s growth; where possible, the bark of the buried portion should be abraded.

Division is an easy means of increasing. Rosa virgin­
iana, R. nitida, R. palustris, R. spinosissima, Crimson Moss and many other varieties which sucker. Plant them in rich soil, and if they are not to grow from three to four years, then lift and tear apart. It will be found that the increase is large and that plants so obtained are salable after one year’s growth in the nursery. The year in the nursery may be omitted with the quicker-growing kinds which are to form new plantations on the same estate.

B. M. Watson.

Roses for the amateur.

Roses may be successfully grown in any soil that will produce fair crops of grain, vegetables, or grass. Certainly the best results will be secured in the more favorable soils and situations, but everyone who loves a rose and possesses a few feet of ground with plenty of sunshine can have his own rose-garden and find pleasure and health in cultivating the plants.

The soil and the beds.

than on their own roots, and some are utterly worthless unless budded, notably, Reine Marie Henriette and Viscountess Folkstone, both charming roses when well grown. The budded plants are mostly grown in Europe, taken up as soon as the wood is ripened in the autumn, and shipped to us in the dormant state in time for planting in the latitude of Philadelphia before the ground is frozen. They are usually received in such excellent condition that rarely one in a hundred of the hardy sorts fail to make a good growth, and a fair bloom the following season.

With the tender sorts, dormant planting out-of-doors in late autumn is attended with much risk, because of the inability of these plants to endure the rigors of our winters before becoming established. Consequently, they need much more protection than the plants in pots. In the spring, if the plants can be safely housed through the winter. After they have become successfully established their safety is assured, and they will repay in vigor and excellence the extra work expended on them. Few amateurs, however, have the conveniences for caring for a number of plants under cover in the winter. Therefore they must take the risk of planting in the autumn or cultivate plants grown on their own roots. (For further discussions of budded and grafted roses, see page 3005.)

For budded roses, holes at least 1 foot deep and 15 inches wide should be made for each plant, the collar or point where the bud was inserted and from which the new growth starts placed 2 inches beneath the surface of the soil, the roots spread out and downward (care being taken that no roots cross each other), and all roots covered with fine soil free from clumps of manure. (Fig. 3470.) Manure should never be placed in actual contact with the roots, but near at hand, where the new feeding roots can easily fill the space. The remaining soil should then be packed in firmly, the surface leveled and covered with about 3 inches of coarse litter and manure, and the long wood cut back to about 15 inches to prevent the plant being whipped and loosened by high winds. This extra wood is left to encourage root-action in the spring and should be cut back to three or four eyes as soon as they can be detected when pushing out. Always cut above and close to a strong outside bud, without injuring it, to develop an open and free head, this admitting light and air. If the uppermost bud is on the inside surface of the shoot, the new growth will be directed inward, dwarving and hampering the plant and preventing proper development. The deep planting above described is necessary to prevent suckers from being thrown out by the roots, as these will speedily choke and kill the less vigorous wood which we are endeavoring to develop. From the writer's experience, the only objection to budded plants is this danger of suckering from the roots; therefore no one should attempt to cultivate budded roses who cannot distinguish the brier should it appear, or who is too careless to dig down at once and cut the wild shoot clean off at the root, rubbing it smooth to prevent its starting again. A very little experience will enable anyone to develop an open and healthy condition. Teas are much more likely to be attacked by insect enemies than when planted in the open. Roses grown on porches are usually attacked by aphides and slugs, the leaves becoming riddled and skeletonized, which only infrequently occurs anywhere when they are planted in the open sunny garden. If roses are wanted around porches, the Microphyllre, white and pink, and the Crimson Rambler can be safely planted, as they are not attacked by the slug; but the blooms do not come in favorably with many other roses of their habit. The other varieties usually appear a few inches outside of the regular growth, rarely inside; consequently there is little difficulty in detecting and removing them.

Roses from pots should be planted as soon as the spring weather has fairly settled and all danger of frost is over, that the plants may be firmly established before the heat of summer. Roses planted late in the season never do well. The holes need be made only a little larger than the pot in which the plant in growing. Choose a cloudy day to make a good planting, and if it starts below the minute thorns and bear seven leaflets, instead of the astrantia, at the root-action in the spring and should be cut back to three or four eyes as soon as they can be detected when pushing out. Always cut above and close to a strong outside bud, without injuring it, to develop an open and healthy head, this admitting light and air. If the uppermost bud is on the inside surface of the shoot, the new growth will be directed inward, dwarving and hampering the plant and preventing proper development. The deep planting above described is necessary to prevent suckers from being thrown out by the roots, as these will speedily choke and kill the less vigorous wood which we are endeavoring to develop. From the writer's experience, the only objection to budded plants is this danger of suckering from the roots; therefore no one should attempt to cultivate budded roses who cannot distinguish the brier should it appear, or who is too careless to dig down at once and cut the wild shoot clean off at the root, rubbing it smooth to prevent its starting again. A very little experience will enable anyone to develop an open and healthy condition. Teas are much more likely to be attacked by insect enemies than when planted in the open. Roses grown on porches are usually attacked by aphides and slugs, the leaves becoming riddled and skeletonized, which only infrequently occurs anywhere when they are planted in the open sunny garden. If roses are wanted around porches, the Microphyllre, white and pink, and the Crimson Rambler can be safely planted, as they are not attacked by the slug; but the blooms do not come in favorably with many other roses of their habit. The other varieties
may also be grown around porches, provided that they can be planted where the drippings from the roof will not fall on them and they are kept free from slugs.

Climbing Teas can be grown successfully in the latitude of Philadelphia only in the case of a few varieties.

3472. Reine Marie Henriette, the finest climbing Tea rose for the latitude of Philadelphia. This shows the vigorous growth, the trellis being 10 feet wide and 9 feet high.

Many of the finer kinds are worthless, in spite of all the protection that can be given them, unless they are covered with glass. Lamarque, Bouquet d’Or, Clion of Gold, Triomphe de Rennes, Marechial Niel, and Reve d’Or have, in the writer’s experience, all perished in the first winter, but Reine Marie Henriette, Claire de Dijon, William Allen Richardson, and Celine Forester will do well and yield satisfactory results. Reine Marie Henriette blooms finely and makes a magnificent growth, as may be seen in Fig. 3472. The trellis is 10 feet wide and 9 feet high.

Hybrid Sweetbriers, of the Marquis of Penczance kind, are a valuable addition to rose collections. The foliage is abundant, healthy, vigorous, and fragrant, and the exquisite shading of each variety forms a beautiful contrast with the others. It would be difficult to choose among them, for all are worthy of a place, when there is sufficient space for them to root. They should have a high trellis and be planted fully 8 feet apart.

Pruning roses.

Of the common garden roses, the flowers are produced on new wood of the season that arises from the canes or the crown, or else, in the case of shrubby species, from old trunks or arms. It should be the aim of the grower to secure strong clean canes for this flower-bearing, and not to have so many of them on each plant as to produce much small weak bloom.

Standard or “tree” roses are sometimes grown, but they require so much care in keeping down suckers and in staking and tying, that they are little known in this country. They are grown abroad when a few excellent blooms are desired or where space is limited. These tree roses are top-budded, on strong stocks, to the desired variety. Sometimes an effect approaching the true tree rose is produced by tying up a very few strong canes to a stake, as shown in Fig. 3474. The usual type of rose-bush in America, however, of the Hybrid Perpetual class, is shown in Fig. 3475.

Pruning the dwarf-growing Hybrid Perpetuals may be begun late in March and regulated by the quantity or quality of the blooms desired. If the effect of large masses be wanted, four or five canes may be left 3 feet in height and all very old or weak growth entirely removed. This will give a large number of flowers, effective in the mass but small and with short weak stalks scarcely able to support the weight of the heads and not effective as cut-flowers, as this sort of pruning is entirely for outside show. After the bloom is entirely past, the long shoots should be shortened back, that the plant may make good and vigorous wood for the next season of bloom. But if quality be desired, all weak growth should be removed, every remaining healthy cane retained and cut back to 6 or 8 inches. Always cut just above an outside bud, to make an open head that will admit light and air freely. After the first season’s growth, there may be about three canes to be retained, but with good care and cultivation the number will increase yearly, until after fifteen or twenty years there will be at least as many canes to be utilized as the plants are years old.

The writer had a bed over twenty years from planting, in which each plant, after close pruning, measured 15 to 18 inches in diameter, each cane throwing up four to six shoots 1 to 2 feet in length and sufficiently vigorous in most varieties to hold up the largest flowers and to give magnificent specimen flowers for cutting. Roses grown in this way do not need stakes. They are sufficiently strong and vigorous to hold erect any weight they may be called upon to bear; but late in the autumn, before the high gales of November arrive, they should be cut back to about 2 feet to prevent their being whipped by the winds, for this would loosen the plant and break the newly formed feeding-roots. The plant should not be cut back too far. This point suggested for spring pruning, as in the hot Indian summer the upper leaves will surely be forced out and the promised blooms for the ensuing season destroyed; so in pruning for protection from November blasts, enough wood should be left to avoid all danger of the lower buds being forced out. The upper buds always develop earliest. Some varieties will not produce large flower-stalks under any method of treatment, notably Prince Camille de Rohan, La Rosarie, and Rosie-riste Jacobs; but almost all the other kinds do better under this method. They may be trimmed back sparingly.

Pruning dwarf-growing Tea roses is conditioned on the fact that they will not endure such vigorous cutting back as the Hybrid Perpetuals. All good strong shoots should be retained unless they form a very close head, when it is better to remove a few from the center. The canes should be shortened about one-third of their length, the branches cut back to one or two eyes, and after each period of bloom the longest shoots should be trimmed back sparingly.

Bourbons need even less trimming. Souvenir de Malmaison, Mrs. Paul, and others of this class should have only the weak ends of each shoot removed, and no more wood cut away than is necessary to remove weak and unhealthy parts.

Climbing roses should be pruned sparingly by simply shortening-in the too vigorous shoots and cutting the laterals back to two eyes. Tie all to the trellis in a fan shape, dividing the space as evenly as possible. Fig. 3473 shows the same Reine Marie Henriette pruned and trained on trellis. These continue in flower until November, the early bloom in June being the finest.
Hybrid Teas should be pruned for quality, and the proper time is when the buds are swelling. The amount of wood to leave on the plant varies with the variety. Shortening the shoots to 4 to 8 inches gives fair results. Cut back the weak growers more severely than the vigorous kinds. To provide for good blooms later, leave three good buds in the axil of the leaves at the base of the shoot when removing flowers or withered blossoms (Beal).

Hybrid Sweetbriers require only such pruning as to shorten back the over-vigorous growth and occasionally to remove some of the oldest shoots to prevent crowding.

Tillage.

Just before growth begins in spring, the surplus rough manure should be spread over the beds and all the remaining fine particles forked in. Deep cultivation is not desirable, as the roots are likely to be injured or broken. Three inches in depth is quite sufficient for a bed that has not been trampled on, and this should be performed with a four-toothed digging-fork, which is less likely to cause injury to roots than a spade. The beds should then be neatly edged and the surface smoothed off and even. Frequent stirring of the surface with a sharp rake is all that is necessary afterward, until frequent stirring of the surface with a sharp rake is all that is necessary afterward, until

Much of the charm of growing roses is derived from the accurate knowledge of each variety by name. Yet few amateurs ever accomplish this, chiefly because the labels have been lost or misplaced, and not infrequently a plant becomes known to the cultivator by a name belonging to a neighboring specimen whose label has been placed on the wrong plant. To obviate this, a name belonging to a neighboring specimen whose label has been lost or misplaced, and not infrequently a plant becomes known to the cultivator by a name belonging to a neighboring specimen whose label has been lost or misplaced, and not infrequently a plant becomes known to the cultivator by a name belonging to a neighboring specimen whose label has been lost or misplaced, and not infrequently a plant becomes known to the cultivator by a name belonging to a neighboring specimen whose label has been lost or misplaced, and not infrequently a plant becomes known to the cultivator by a name belonging to a neighboring specimen whose label has been lost or misplaced, and not infrequently a plant becomes known to the cultivator by a name belonging to a neighboring specimen whose label has been lost or misplaced, and not infrequently a plant becomes known to the cultivator by a name belonging to a neighboring specimen whose label has been lost or misplaced, and not infrequently a plant becomes known to the cultivator by a name belonging to a neighboring specimen whose label has been lost or misplaced, and not infrequently a plant becomes known to the cultivator by a name belonging to a neighboring specimen whose label has been lost or misplaced, and not infrequently a plant becomes known to the cultivator by a name belonging to a neighboring specimen whose label has been lost or misplaced, and not infrequently a plant becomes known to the cultivator by a name belonging to a neighboring specimen whose label has been lost or misplaced, and Outdoor roses for the mid-continental region.

An intercontinental region, of which central Missouri may be considered a typical representative, often presents gardening problems which markedly differ from those in territory adjacent to large bodies of water. The longer season of intense heat combined with extreme low humidity, together with the frequency of sudden and extreme fluctuations in temperature, both during winter and summer, so influence vegetation that if the same degree of perfection is to be attained, and competition successfully met, horticultural operations must be strictly orthodox, and confined to fewer varieties than may be grown elsewhere. This appears to be preeminently true in outdoor rose-growing. This crop can be as successfully produced under the varying conditions to which the region is subject, providing well-established rules, practised by expert rose-growers everywhere in planting and cultivation, are strictly followed, and if the right varieties are chosen. The most hopeless situation is the congested city conditions with air contaminated with poisonous gases. Energy and enthusiasm in gardening in such a place are better spent with other plants.

In planning a location and the arrangement for roses, the purposes for which they are to be grown must be considered. A rose-garden separated from other features of the ground is becoming more and more an important part of parks and private estates. Into this area are grouped a general collection, or specimens of all kinds. It should have a sunny position, though the ground-surface may gradually slope in any direction. Other conditions being identical, a gentle northerly slope is preferred. The kinds may be grouped by types, the rugosas, briers, and wild roses bunched in masses, -the climbing sorts on a pergola or trellis. The kinds may be grouped by types, having their long flowering period, the character of some partaking strikingly of the delicate Teas, while others resemble the more vigorous Hybrid Perpetuals. There are exceptions with some of the varieties of both types, having their long flowering period and beautiful blooms of good substance, preeminent among which are: Gruss an Teplitz, scarlet; Jonkheer J. L. Hook, pink; General MacArthur, scarlet; LaFrance, pink; Kaiserin Augusta Victoria, white; Antoine Rivoire, pale yellow; Mrs. Aaron Ward, yellow; Lady Ashtown, soft rose; My Maryland, salmon-pink; William H. Taft, pink; Helen Gould, carmine-red; William Shean, pink.

The Hybrid Perpetual is a still harder type in which are to be found varieties producing blossoms that command the highest prices because of their large size, good substance, and long stems. The most noted representative is American Beauty, still largely grown under glass and in many localities out-of-doors, but for the latter purpose not now generally counted on for the degree of success usually attained by other kinds in plant in double rows, about 9 inches apart, the plants 18 inches to 2 feet apart, alternating in each row. Suitable hedges may be made from many varieties of roses: notably rugosa and its hybrids for a broad or thick hedge, Orleans for a dwarf, and Gruss an Teplitz for medium to tall. Hybrid Perpetual sorts may also be used. With the exception of rugosa, it is better to

this region. The limited season of flower-production, and the unattractive plant-display the remainder of the year, places this group second to the Hybrid Teas in usefulness for outdoor culture, even though little or no winter covering is required with the one, while it is important that some protection be provided for the other in the more northerly section of this region: General Jacqueminot, brilliant scarlet-crimson; Coquette des Alpes, white; Ulrich Brunner, cherry-red; Frau Karl Druschki, snow-white; Victor Verdier, crimson; Paul Neyron, dark rose; Madame Charles Wood, scarlet; Magna Charta, bright pink; Mrs. John Laing, soft pink.

Roses of the dwarf rambler class are as hardy as Hybrid Perpetuals and as ornamental as Hybrid Teas. The dwarf compact habit, together with the clustered masses of bloom, gives it a distinction all its own. The class is very showy in the garden, but with rather short stems, and therefore less valuable for cut-flowers. Occasionally the blossoms bleach a little in conditions following alternate rain and warm sunshine, but this fault is more than outdone by the wealth of color produced over most of the period from beginning of blooming to frost: Clotilde Soupert, rose white; Baby Rambler, crimson; Baby Rambler, pink; Orleans, red; Katherine Seinet, white.

The varieties and hybrids of Rosa rugosa are useful, especially in landscape masses and usually make excellent hedge-rows. (Figs. 3477-3480.) The single-flowered forms produce bright red hips or seed-vessels that remain on the bushes late in the winter. The bright green leaves give these and similar varieties an interesting and pleasing appearance a large part of the season. Good varieties are: R. rugosa alba, white; R. rugosa rosea, pink; R. rugosa rubra, red; Madame Georges Bruant, double white; and others.

Hybrids of the Sweetbriars type are most charming when in bloom, though the flowers are only medium to small in size, and endure for less than a fortnight. It produces conspicuous fruits and fragrant foliage. The plants are a little slow in making their growth, but meet all weather conditions without injury and live to a great age. The plants form a good shrubbery mass or border group. Three good varieties are: Lord Penzance, Lady Penzance, Brenda.

Many of the native species of roses are well used for mass planting, similar to the Sweetbriers. There are several American species known to thrive and bear abundant bloom at St. Louis: R. palustris, R. virginiana, R. setigera.

The most valuable climbing roses for this region fall under two types, R. multiflora and R. Wichuraiana. Isolated examples have been reported of other forms doing equally well, but the above are by far the most common, and the varieties give so wide a range of color as practically to make other forms unnecessary. They grow rapidly in good soil, and when trained to tree-stumps, trellises, walls or the sides of buildings, quickly make a thorough covering. For covering solid walls and sides of buildings it is better to provide lattice-work a few inches from the building to give opportunity for free circulation of air between the wall and the vines. The Wichuraanas are especially adapted for trailing over banks, mounds, and the like. Good varieties are: Crimson Rambler, crimson; Dorothy Perkins, both pink and white.

After several years' experience with Moss roses, the writer has never seen a plantation that was as satisfactory as other types. At St. Louis they were no more hardly than Hybrid Teas and appear to be more subject to mildew than any other roses. The blooms were not superior to other roses and are rarely grown except by persons maintaining collections of old-fashioned flowers, from whom some good results have been made. They are more valuable here for their associations than for real horticultural merit.

Roses take most kindly to a heavy clay loam enriched with well-rotted cow-manure. Such a soil is characteristically abundant in this region. Sand and ground limestone are added to the average clay loam unless it is known that the soil already contains enough of one or more of these ingredients. Except for Tea roses, lighter soils are avoided as much as possible, and even the Tea do better in ground moderately compact.

Great care must be exercised in the preparation of the soil and providing perfect drainage. Ground for a rose-bed should be excavated 2 to 2 1/2 feet deep and the lower 6 inches filled with pieces of rock or broken brick. The bottom should be connected with a drain-tile to carry the surplus water quickly to a lower level. About a foot of cow-manure, preferably rotted, should be spread over the broken rock and brick, and the excavation filled with heavy clay loam of sufficient depth to keep the surface when settled slightly lower than the surrounding level. To most soils in this region some form of lime should be added to neutralize any acidity that may occur. If there is a greater proportion of clay than loam in the soil a little pulverized sheep-manure, dried blood, or other quick-acting chemical fertilizer will provide available plant-food immediately and give the plants a better start.

Planting.

In starting a rose-plantation, the stock may be dormant wood or growing plants in 3- or 4-inch pots. The plants may have been grown from cuttings on their own roots or budded or grafted on other stock. Plants on their own roots are equally good, cheaper to buy, and there is no danger of the stock plants making growth from the roots in place of the desired kind. Most roses in this region are grown on their own roots. Dormant roses may be set out either in fall or spring, using preferably one- or two-year-old plants. Spring is the most common season, but autumn-planting is practised by some and considered equally good, or even better by many successful growers. The plants are set in the ground 2 or 3 inches deeper than they originally grew, and if planted in autumn, earth is drawn up around the stem and the ground mulched with the most convenient material suitable for the pur-
Roses are pruned in the dormant season, mainly in stronger the growth the smaller the proportion of wood removed. As a general rule, uninjured plants of Teas need to be removed. Climbers, rugosa, sweetbrier, and wild roses need only enough to keep the plants in shape and practically all of the top. All dead wood should be protected, and the severity of the preceding winter often governs the amount of pruning, especially with Teas. In setting the plants are removed from the pots with the soil intact, placed a little deeper than the ground-level, and watered. A frequent and serious error is made in setting the plants too close. They must have plenty of room for light and air. The Baby Ramblers should have about 18 inches apart; other dwarf roses about 2 feet; climbers 4 feet. The surface is cultivated a few times, and at the beginning of hot summer weather the ground is given a thorough mulch, preferably of rotted manure. This feature is probably the most important operation in making a success of monthly roses in this region. Cultivation and mulching should be continued each year, and about every fifth season Tea and Perpetuals, the potted plants usually give more bloom the following years. There is less labor in planting and the potted stock is no more expensive than dormant material. In setting, the plants are removed from the pots with the soil intact, placed a little deeper than the ground-level, and watered. A frequent and serious error is made in setting to the desired size. In pruning rose-hedges, a special effort should be made to keep the base as full of new growth as possible.

Roses in California. (Fig. 3481.)

In many localities in California the rose attains a striking and perhaps unique perfection. That this perfection is not general throughout the state is partially owing to adverse conditions, such as great range of temperature during each twenty-four hours, heavy fogs at critical periods, and the like, but as a rule, failure in whole or in part is due to the lack of intelligent treatment. In the present article, the conditions in southern California are specially in mind, but the discussion will apply, in the main, to other parts of the state.

The chief obstacle to successful rose-culture in California is the attempt to produce blooms every day of the year. Although this practice is quite an impossibility with any rose, the evil is still persisted in by ninety-nine in every hundred possessors of a garden. While roses are grown in great profusion in Los Angeles, few, if any, do as well here as in Pasadena, which, although only 9 miles distant, has the advantage of being several hundred feet higher than Los Angeles, and therefore less subject to fog or great range in daily temperature. In some places a certain few roses will produce an astonishingly fine crop of bloom, when but a mile or two distant, with no change of soil and very slight difference in altitude, they will be utterly worthless; while a like number of other varieties will give as good returns as those first mentioned.

Many roses do fairly well everywhere, and among these Duchesse de Brabant more nearly produces a continuous crop of blossoms than any other. For this reason it stands in a class by itself and is not considered in the appended list of the best dozen roses for southern California, though every one should grow at least one bush of this variety. Along with the Duchesse might well be placed the Polyantha, Mademoiselle Cecile Brunner, and the climbers Cherokee, Banksia, Ophir (or Gold of Ophir), Beauty of Glazenwood or Fortune's Double Yellow. All these produce most wonderful crops, but none more so than the last mentioned, which in favored regions produces a wealth of flowers simply dazzling to behold. Many well-known Californian writers assert that Gold of Ophir and Beauty of Glazenwood are one and the same rose, but this is not the case. Gold of Ophir was here for many years before the other made its appearance, and some of the original plants are still growing on many of the homesteads of Los Angeles and vicinity.

All the roses named thus far are worthy of a place in any garden. One of the chief causes of failure by the average amateur is the lack of an intelligent knowledge of the plant's first requirement—recurring periods of absolute rest. These necessary resting-periods are best secured by the withholding of the water-supply. Most amateurs, and a larger part of self-styled "gardeners," persist, against all rules of common sense, in planting roses either in the lawn or in mixed borders with other plants. In either case, all but the roses require a constant watering. Having planted in this fashion, the grower has cast away all chances of first-class results. Rose-beds should never be made a feature in landscape gardening, as the plants when dormant and judiciously pruned are unsightly objects at best. The most obscure spot obtainable with the proper exposure is the place to grow flowers. To obtain the best results the rose requires the same amount of rest here that it secures where the winter season leaves the grower no alternative. But the same amount of rest may here be given semi-annually, with equally good and perhaps better results than is possible with one long annual period of inactivity.
Climate is the all-important feature of rose-culture in California, and if that is satisfactory the character of the soil makes little difference. The dry summer air is a serious drawback to the growth of many roses, there being few places where Moss roses thrive, and these must be grown in whole or partial shade. Niphetos and Marechal Niel are good examples of roses requiring partial shade if good results are desired. Many localities cannot grow the two last mentioned, or such as Perle des Jardins, Meteor, Catherine Mermel, Madame Francesca Kruger, Reine Marie Henriette, and many others, on account of mildew. Even among varieties whose buds are immune, it is often impossible to get foliage unaffected. Injudicious watering is more largely to blame for these unfavorable conditions than any other agency. Laurette is a rose which often produces the only perfect flowers to be found among a hundred varieties, and this is particularly the ease in places visited by heavy frosts, Laurette remaining unscathed while all others are more or less blasted. The great rose of the eastern United States, American Beauty, is almost a complete failure here and is not worth growing except in a very few well-favored gardens, and even then it is far from being perfect.

Persons in the southern end of the state and inland sections have yet to learn that fine roses may be grown in either full or light or heavy shade. Many roses, also, are of little value in California unless budded or grafted. Of this class Marechal Niel is the most striking example. Examples may be found where this rose has thrived unusually on its own roots, but such cases are marked exceptions. Some persons maintain that all roses are best on their own roots, but such opinions are easily refuted by consulting any of our veteran rosarians. The best roses are root-grafted, but of course this procedure is too expensive for the general nurseryman, and the bulk of the local stock is budded on Manetti or Maiden's Blush, though the Dog rose (Rosa canina) and even the Banksia are often used. Those roses grown on their own roots are usually propagated from hardwood cuttings, grown out-of-doors, and December is usually the best month, although they have been successfully rooted from October to March, according to the variety.

Rust bothers but little; likewise scale, although in many neglected gardens the bush and climbers alike may be found covered with both the rose-scale and the red scale of the orange. Fuller's rose-beetle is a nuisance only in small areas, but green-aphis is a pest in winter and spring. La France for many years was the leading rose in California and grew well, budded or on its own roots, in almost any locality, but is now rapidly becoming a thing of the past, though it can never be wholly discarded, for it is still, in a few gardens, the queen of the family; its involuntary retirement from our rose-gardens is due entirely to a "die back" (anthracnose), which affects many other plants than the rose, but seems to have a special liking for La France. Thus far no cure has been found.

1 A list of the best dozen bush roses and the best half-dozen climbing sorts, as agreed upon by many experts within a range of 20 miles of Los Angeles, is as follows:

Climbing sorts.—Climbing Kaiserin Augusta Victoria, Madame Abel Chatenay, Heinrich Munch, Paul Neyron, Mlle. Cecile Brunner, Duchess de Auerstadt, Reve d'Or. Outside this list are members of widely divergent classes which should find a place in every large garden, such as the Banksias, the three Cherokees, and both the bush and the climbing Cecile Brunner.

(2) Following are lists of a dozen varieties each of the different recognized standards of color of roses which have proved best adapted to southern California conditions:

3681. California rose-bush.

(3) Following are roses suitable to California as a whole (John Gill): General MacArthur, Madame Caroline Testout, Lady Hillingdon, Juliet, George Dickson, Mrs. Aaron Ward, Radiance, Mad. Abel Chatenay, Miss Kate Moulton, Ulrich Brunner, Ophelia, Mlle. Cecile Brunner, Frau Karl Druschi,
The absence of outside walls, and the ease of construction, the lower cost of heating owing to the materials used by the large commercial rose-growers. The single house has the approval of many, while the connected, or ridge-and-furrow sections, are obtainable where more time can be given their development, which, if forced into flower by excessive heat, do not, in warm climates, produce the quality of bloom that is considered the home of the greenhouse rose industry.

The industry is widespread and embraces every section of the country. Southern California grows good roses for the markets in the open field and better quality types of rose-houses (Figs. 3482, 3483).

There are two distinct types of greenhouse construction used by the large commercial rose-growers. The single house has the approval of many, while the connected houses, or ridge-and-furrow sections, are favored by others, because of the smaller expense of construction, the lower cost of heating owing to the absence of outside walls, and the ease of superintendence. Advantages of the single house are its better control, more light, and less trouble with snow and ice, the latter being a serious consideration in the maintenance of the connected houses.

The single house is constructed with iron frame and concrete sides and built even span or two-thirds span to the south. Houses strong and permanent, with good ample ventilation and ample light, are the essentials of construction. With connected houses, the essential factor in addition to these is to have the gutter at least 12 feet from the ground, which almost entirely overcomes the effect of shade which the gutter casts by diffusing this over a larger area. A heating-pipe beneath the iron gutter to assist in melting snow and ice is a necessity.

The size of houses to be preferred is largely a question of opinion, but there are certain factors which must not be overlooked. The wide house must necessarily be high, and a house that is high is likely to be lacking in humidity, and the plants consequently will suffer. This seems to be the only objection of consequence to the wide single house. From 40 to 60 feet is the normal width and should be satisfactory, and the length is controlled by the capital of the owner or the natural lay of the land. Houses are workable with economy up to 1,000 feet provided, naturally, with crosswalks at least every 300 feet for employees. The width of connecting houses should be from 36 to 44 feet, and the length as given also applies to these connecting houses.

Beds and benches.

There is but small connection between the bed or bench and the house containing them, except that in planning new construction the approved plan is to have a walk next to the outside walls and, if the proper width house is selected, this can be accomplished without varying the width of walks and beds or benches. As the modern house is relatively high at the plate or eave, either bed or bench may be used at the discretion of the builder. The construction of the bench is simple, the essential point being durability; this is secured by using cypress lumber and double crosspieces, which enables the builder to put nails back a short distance into the bottom board and prevents the breaking of the bench at the joint, as the bottom usually decay first at the ends of the boards. Benches not over 24 inches to the bottom from the ground surface are to be preferred, being easier to work, as the larger part is on the platform itself, at least 12 inches above the bench surface and, if the bench is higher, the labor is correspondingly harder. Ample drainage must be provided by leaving cracks between bottom boards from 1/4 to 1/2 inch and using 6-inch width boards. The concrete bench for rose-growing is in the experimental stage and has not as yet shown superiority.

The solid bed, so-called, is not in reality solid, except as to side walls. Ample drainage of the ground itself is needed, if solid beds are to be built. If the soil is naturally gravelly, the making of solid beds is simple. If the soil is of heavy clay texture, the building of the solid bed necessitates not only under-draining the surface, but the supplying of coarse gravel or ashes through which the water from the soil may escape to the permanent drain-tiles. These drain-tiles should be laid crossways of the house every 100 feet, and the smaller tile running lengthwise under each bed should empty into these larger cross-tiles. Sides of solid beds are best built with concrete which can be made as thin as 2 3/4 inches thick.
at the top, and the outsides can be made perpendicular. The inside should be on an angle, and a base width of 6 inches with the flare on the inside will give the wall a purchase on the soil under the bed and hold it in place. Solid beds are cheaper of construction, provided the land is naturally well-drained. They are more expensive when much ashes or gravel must be used. There is another type of solid bed made by using plank nailed to posts for siding which is just as good, but not durable. The bed built by laying broken stone, to serve as drainage, and which elevates the bed to a better working level, is a permanent and satisfactory one, but natural conditions to stone make this impracticable under usual conditions. Results as to roses grown on raised tables or benches and on solid beds vary very little. The raised bench having the heating-pipe beneath it seems to produce better in the winter months. The solid bed having a cooler soil and a greater rooting depth will give a better quality in the summer months. On the yearly average there is small difference in quantity and quality of product, and the question of bed or bench must be settled by the opinion of the owner and the questions of cost and permanence.

Heating.

In close connection with houses and beds is the question of heating. It is a universally recognized fact that steam heat is essential to the growing of good roses. No attempt will be made to explain boilers and the piping of the houses, except to say that sufficient steam-pipes must be supplied to carry normal temperature in the coldest possible weather, that such pipes should be evenly distributed over the area inclosed, and that the heat should not be overhead, but on the level with or below the level at which the plants are set. The use of steam is due to the fact that quick heat in rose-houses is necessary. The change that comes with the dropping of the sun in the fall and winter must be counteracted by a quick steam-service to prevent a chilling of the plants. A pipe or two in all big houses in summer nights prevents the condensation of moisture on the plants and means the difference between success and failure. Hot-water heat is more uniform than steam, but loses because steam can be obtained on much shorter notice. The use of a hot-water system in conjunction with steam is admirable, and in large establishments is to be recommended. The gentle warmth radiating from the hot-water pipes during the day is not detrimental and enables the grower to use more ventilation, which is a distinct benefit.

Soils for roses.

Soils for rose-culture should be of clay body, but have enough of more friable ingredients to pulverize readily. The grower usually chooses land for the building of commercial rose-houses which has on it the character of soil required. Good heavy clay turf is the material from which to form the compost for rose soil. The fiber of the turf as it decays gives the humus required and leaves the soil open, porous, and in good condition for root-action. Winter-preparation is to be preferred, and the freshly prepared compost which is not over six months old is in ideal condition. Piling alternate layers of soil and cow-manure, using two parts of good heavy clay turf to one part of cow-manure, makes an ideal rose soil. Horse-manure may be used with good results, or a mixture of the two, but cow-manure has the preference.

Lowland soil usually has the body and fiber that is needed, and soil which is part of the year under water has been found to be free from eel-worm or nematode, which attacks the rose roots; this troublesome pest often infests the soil of the uplands. The meadow soil should be plowed into ridges in the fall and hauled on frozen ground to the place where it is to be composted. The thorough freezing of the soil is considered beneficial as it tends to make it more friable. The compost should be worked over when the frost has gotten out, and after settling will be ready to use when needed. A point should be made to lay the soil-compost near the sec-
The propagating-bed should have ample drainage, which can be secured by using coarse ashes for the bottom half of the bed. Five-inch side boards with ashes for drainage and above it 2½ inches of good clean sand constitute a workable propagating medium. Rose-cuttings can be rooted with good success in screened soft cool ashes, if sand is not available, but extra care must be taken to prevent breaking off the roots in taking the cutting from the stock. A pot for potting. Distance in the propagating-bed depends on the variety. The leaves should not be allowed to overlap and thus invite fungus. With the heating-pipes beneath the bench, and a uniform temperature of 55° to 60° in the sand and 54° to 60° overhead, the cuttings should be rooted and ready to pot in about four weeks. Do not allow the cutting to begin growth in sand, which it will if not potted when the roots have started. Be sure that clean pots are provided, and the 2¼-inch size is ample for the newly rooted cuttings. Pot carefully so that the tender roots are not broken or bruised and be sure that some soil is between the cutting and the pot. Water carefully and provide shade for the first few days until the cutting has recovered from the shock of moving. Make sure that all the soil is thoroughly moistened, but do not over-water it. Light sprinklings are all that will be required until the roots show activity, which can be assessed by knocking the plant and ball of soil carefully from the pot, taking care not to break the ball of soil. As the plant begins to grow, remove all shade and keep the plant growing. It will require more water with the increase in foliage. When the plant fills the 3-inch size will be ample for its requirements for the next six weeks. Keep the young plants clean and growing, using the same treatment as for plants on the bench for the various insects and fungi. Shift into larger pots, if necessary, but keep them growing.

Grafted roses are very distinct in handling from the own-root plants. It is best to start with strong-rooted Manetti stock, which rose species has been chosen for its strength of growth and the freedom with which the cions unite with it. Manetti is grown from hardwood cuttings taken during the winter months, and which are planted in early spring in the open field. These are kept growing rapidly throughout the summer, are dug in the fall and are ready when potted for grafting. Manetti should be disbudded or suckered, which means the removal, so far as is possible, of all eyes which are below the point at which the graft is to be made. In growing Manetti, deep planting is advisable as the stem which has been under ground all summer, cuts better and makes a better union than the harder stem which has been exposed. Manetti varies very little with the section, but varies with the method of growing and grading. The deep-planted, well-graded Manetti, whether English-, French-, Dutch- or American-grown, is equally valuable and serviceable, but the greater variation in the growing and handling has caused the erroneous opinion that Manetti from certain sections is superior. Labor values alone prevent the American grower from producing his own Manetti, but irrigation is necessary in our climate. Having pencil-size Manetti,—being for best work about the thickness of a lead-pencil,—the process of grafting is simple. A cut is made as close to the pot-level as possible diagonally across the Manetti. The cion is cut on the same plane and is tied to the stock with raffia fiber (Fig. 3484). Raffia is used because it decays and does not need to be cut away as will be necessary with string, and it covers the union more completely. The union of the cambium layer is the essential point, and if the cion is not equal in size to the stock, one should be sure of a perfect union on one side. The rapid flow of sap which occurs when the new grafted plant is put into the case covers the union and growth begins. In a temperature from 76° to 78° the first week and from 70° to 72° the two succeeding weeks, with careful ventilation and shade from hot sun, the union should be perfect and the young plant ready to be taken into the air and light when hardened sufficiently by increasing these gradually. The grafting-case is usually constructed by having sufficient steam-pipes beneath it to maintain the temperature—a miniature greenhouse.

The advantages of grafted roses over those grown on their own roots are: a stronger root-action, a more rapid-growing plant, and a root-system that will be immune to eel-worm or nematode. Experiments conducted by the Illinois Experiment Station have proved that the production from grafted roses is sufficiently larger to warrant the use of grafted plants. There may be a connection between the use of flowering wood for grafting and increased production, as all cions for grafting purposes should be from selected flowering wood. There is also a difference in varieties and a few are superior on their own roots. It has been generally stated that all yellow or yellow-tinted roses are better on their own roots, but results contradict this statement.

The after-care of the grafted plant varies little from the care of own-root plants. One should be sure to remove any Manetti suckers that appear, cutting close to the stock, and much once in small pots before shifting into larger, using for this mulch a compost of good rose-soil with a heavy sprinkling of bone-meal added. Repotting will furnish all the feed necessary, but the top mulch will often grow up the extra, which should be removed. The pots and repotting should be done under a miniature greenhouse. The blooms should be kept cut off.

General cultivation, diseases and insect pests.

Having good, clean, thrifty, young plants in 3- or 4-inch pots and a compost soil in the benches or beds, one is ready for planting. The correct spacing is about 12 by 18 inches or 14 by 16 inches; there is some difference in varieties, but the average is about as stated. Planting should be deep enough to cover the union by an inch or more with grafted plants and yet away from the bottom of the bench. Plant firmly and water thoroughly. Growth will soon begin. Keep the plants clean from red-spider by thorough and consistent spraying of the undersides of the leaves with water under pressure. Red-spider is an insect which multiplies rapidly when favored by a dry warm atmosphere, and as its sustenance is the foliage of the plant, it must be eradicated. The general care of a rose-house consists in keeping the house properly ventilated, heated and watered, in addition to keeping the plants clean from insects and fungi; and the cutting of the flowers. Ventilation should be given more attention, for it concerns the success of the whole business. How properly to ventilate a rose-house is...
The rose is subject to the attack of a nematode, or eel-worm, which infects the roots. The use of Manetti for grafting purposes has, to a large extent, relieved the trouble; the use of lowland soil is a safeguard. Sterilization by means of steam will render soil safe and its usefulness is not impaired, but this is, as a rule, unnecessary.

Rose-galls are a bacterial disease which causes growths on the plants, varying in size, and usually brown in color. These appear at the joints or where cuts have been made. Remove these at once and do not cut them open with a knife used for cutting flowers, because the infection can be carried to the other plants in this manner. Cut off the affected branch and burn it.

Thrip is an insect which attacks the leaves and petals. It is small and its work usually can be recognized by the white lines on dark-colored flowers, showing where the surface has been eaten. Green-fly is a sucking insect which attacks the new growths. Both can be readily killed by the evaporation of nicotine preparations upon the steam-pipes, this having almost entirely replaced the burning of tobacco-stems.

Feeding the plants is accomplished by top-mulching, or by liquid fertilizer, or by using both. Aside from bone-tankage, few commercial fertilizers are in use, cow-manure, well-rotted, clear or mixed with well-rotted horse-manure, being more generally used. These manures in liquid form may be used to advantage. Feed light and often is the rule when plants are well established.

Watering depends on crop-condition. Water copiously when the plants are coming into bearing. Water less when the crop is being cut, and sparingly after the crop is cut and before the new growth starts.
The question of humidity in the house is a serious one with the wide, large houses, and where the atmosphere lacks moisture the growths will be hard-wooded and the plant will fail to be prolific. It is safe to say that a house with all cement walks fails to grow good roses for lack of humility, and the gravel or ash walk will do much toward furnishing the atmosphere the needed moisture.

Varieties.

Varieties to grow depend largely on the market to which the grower caters. There are two types of greenhouse roses: those which are at their best in the warm summer months, and those which are at their best in cooler weather.

The varieties best suited for summer cutting are My Maryland and its sports, Kaiserin Augusta Victoria, Francis Scott Key, and Mrs. Aaron Ward.

For general use, the best varieties are Killarney and its sports, which are numerous, and of which Double White Killarney, Killarney Brilliant, White Killarney, and Killarney Queen are such notable examples that they must be mentioned; Ophelia, Mrs. Aaron Ward, Mrs. George Shawyer, Hoosier Beauty, Hadley, Milady, Richmond, Radiance, Lady Alice Stanley, Jonkheer J. L. Mock, Sunburst, Mrs. Charles Russell, American Beauty, and the Polyantha roses—Cecile Brunner, Perle d’Or, and George Elgar, which are widely used for corsage bouquets and decorative work. Mrs. Aaron Ward, Double White Killarney, Mrs. George Shawyer, Killarney Brilliant, and Ophelia are the best varieties for cutting continuously for the entire year. Of these varieties mentioned, American Beauty, Mrs. George Shawyer, Radiance, Lady Alice Stanley, and Sunburst are better grown upon their own roots, while the balance of the varieties are superior when grafted on manetti. Mrs. W. C. Whitney was formerly grown as a forcing rose.

Cutting the flowers.

Proper care and cutting of the flowers has as much to do with financial success in the rose industry as the proper growing of the plants. Just when flowers are mature enough to cut is a matter of variety to a considerable extent. Those varieties which do not have many petals should be cut in the bud, while many of the varieties with large petals, such as Francis Scott Key and Mrs. Charles Russell, should be allowed to expand before being taken from the plant. How much wood to leave when cutting the flowers is also a question of variety to a certain degree, but as a rule two good eyes are sufficient. Certain varieties which naturally throw strong flowering growth from the main stems or hard wood can be cut to one eye from good-sized plants. There is a tendency of plants to increase in size and become awkward to handle if much growth is left in cutting, and production from large overgrown plants is as a rule no greater than from plants more closely headed in by carefully cutting the flowers.

It is customary with some growers to “pinch” all flowering shoots when the bud has reached the size of a pen, and this removal of the bud and first leaf causes a new flowering growth and gives a longer stem, as the flower is cut back to the proper place in the older growth. This method of pinching allows the grower to control the time of maturity of the crop very accurately, eight weeks in the early winter months and seven weeks in February and March being the necessary time for the maturity of the new flowering shoot. This varies a few days with the character of the growth when the pinching is done; those shoots nearer maturity will require less time than the softer or more immature growths.

There is also a slight difference in varieties as to the time of the year to commence the pinching. Thus pinching allows the grower to bring in a crop at the holiday season and produce flowers for exhibition use.

The stronger and more vigorous the growth pinched, the better the quality of the resultant flower and by selection of strong heavy flowering growths and by pinching and careful timing, the roses for exhibition purposes are produced.

When flowers are cut they should at once be placed in water and kept at a temperature from 35° to 42° for several hours to harden them. The stems and flowers fill with water and are then in a condition to be graded. The American Rose Society has established a grading standard to which the leading growers adhere in preparing the product for market. Length of stem is the basis, but quality and substance of bud should be in proportion to length of stem, and a poor quality flower on a large stem on the open market will by no means command the price of a good flower on a stem of the same length. In grading, keep the flowers uniform in length of stem and quality.

Marketing cut roses.

There are three methods of marketing cut roses, viz.: retailing direct to the consumer; supplying flower shops direct; and the shipment of the product to the commission stores which supply the large city florists. It is of first importance to have the product reach the consumer fresh, well hardened, and not too open, for the demand for open flowers is limited. Careful packing for the wholesale market necessitates wooden boxes with crockets to hold the flowers snugly in the box, which bruises the flowers. Wooden boxes allow the use of ice to keep the flowers in condition for sale. Heavy waxed paper between the layers of flowers in the boxes aids in handling them conveniently. Any precaution taken to insure the product reaching the consumer in perfect condition is a paying investment, for a good product has little value when bruised and inferior in condition for consumption.

The sale of flowers direct to the consumer by the grower is becoming greater every year, many of the leading florists operating their own ranges of glass and using the product in their own store. The demand from the large cities where this is not possible to any great extent is increasing yearly. Returns from money invested is in fair proportion to the money earned by investments in any well-conducted line of production, but is dependent upon the skill of the grower and the business-like conduct of the enterprise. The risk of handling a perishable product and the property risk also is heavy, owing to wind, hail, snow, and ice. Deterioration is also heavy because of the excessive humidity necessary to good culture. Rose-growing is an industry catering to the demand for a luxury, and the profit is often a thorny one.

W. R. Pedersen.

Rose insects.

ROSE APHIS (Macrosiphum rosae).—Greenish or pinkish plant-louse about one-twelfth inch in length, that cluster on the rose and injure the bloom; injurious both in the open and on roses grown under glass. The insect hibernates in the egg stage in the North, but in the South breeding continues throughout the winter. The eggs hatch as the buds are bursting. The aphid of the first generation are each female being capable of producing thirty to forty-five young one-twelfth inch in length. that cluster in great number about one-tenth inch long. They multiply with great rapidity, and injurious both in the open and on roses grown under glass.

The aphids are protected from the air by a waxy secretion, and when crowded together the tip of the abdomen bursts, and the waxy secretion exudes from the wound. This secretion is of a sticky nature, and the aphids of the second and succeeding generations are protected from the air by this secretion.

W. R. Pedersen.
C. Rose, American Beauty.
are laid in the tissue of the leaves by a shining black four-winged fly.

**BRIEFLY ROSE SLUG (Cadius pettinctoria).—**Yellowish, or greenish, more or less brassy, larvae about \( \frac{1}{4} \) inch in length that show up when young but burrow out holes in the leaves, often leaving only the larger veins. In the North there are three generations of the summer brood which place the leaves on twigs, those of the winter brood on the ground. The eggs of this species are inserted in the pedicel of the leaf in the South. The adult rosette is a rose shaped, somewhat pinnate red or brownish with a metallic lustre. The larval stage is goth in a cabinet and is highly destructive to the foliage of roses grown in the greenhouse. The grubs are somewhat curved, 2 to 3 times as long as the leaf, and feed upon the leaves of the roses.

**CHRISIIL ROSE SLUG (Emplasia cinctus).—**Larvae about \( \frac{1}{4} \) inch in length that feed on the edge of the leaf with the body coiled beneath it. The larva is metallic green spotted with white; above, green or orange; first segment of the thorax blue and the last two gray. Pupation takes place in the pith of a dead twig.

**Treatment for rose slugs.—**An arsenate of lead, two pounds in fifty gallons of water, or in the dry form diluted with double its weight of powdered plaster or lime, is effective. Rose slugs may also be killed with nicotine solution as recommended for the rose aphid.

**RUSTY ROSE SLUG (Lepidostyla annularis).—**Small nearly white last-hopper, feeding on the under side of the leaves, extracting the juices and causing the leaves to turn yellowish. The insect spends the winter as eggs which are inserted in the bark.

**Treatment.—**This last-hopper may be controlled by thorough spraying of the under side of the leaves with nicotine solution as recommended for the rose aphid.

**BRIEFLY ROSE BLISTER (Archips subpustulatus).—**Long-legged un­
galaered beetles that swarm into the rose-garden, and devour the leaves, petals, and opening buds. The grubs from which these insects develop feed on the blossom or buds of roses in sandy soil only. In New York the beetles emerge from the ground about the middle of June and disappear in about a month or six weeks. In the summer the beetles are numerous, for much damage will be done before the poison has had time to take effect. In the ease of a few choice plants it is safer to protect them with careful netting during the period when the beetles are most abundant.

**ROSE CURCULIO (Macroductylus subspinosus).—**Long-legged un­
galaered beetles that swarm into the rose-garden, and devour the leaves, petals, and opening buds. The grubs from which these insects develop feed on the blossom or buds of roses in sandy soil only. In New York the beetles emerge from the ground about the middle of June and disappear in about a month or six weeks. As a rule the maggots are most troublesome during June and July. This insect is more injurious to roses grown under glass than out of doors.

**Treatment.—**This is a difficult insect to control because the beetles will avoid feeding on foliage poisoned with an arsenical. The grubs are dried with live with an arsenate of lead made up of molasses. This method, however, cannot be relied upon to protect the plants when the beetles are numerous, for much damage will be done before the poison has had time to take effect. In the ease of a few choice plants it is safer to protect them with careful netting during the period when the beetles are most abundant.

**ROSE MIDGE (Neonotus thysanoides).—**Small whitish or pinkish maggot about one-fourteenth inch in length that infest opening buds, either killing them or causing the leaves and blossoms to be more or less stunted. Mature maggots become full grown in two or seven days, leave the buds and complete their transformation in the ground in the summer. They complete their total life cycle as completed in about two weeks. As a rule the maggots are most troublesome during June and July. This insect is more injurious to roses grown under glass than out of doors.

**Treatment.—**This is a difficult pest to eradicate once it has become established in a greenhouse. Rotation with some other crop, such as violets, may be practised to advantage. Fumigation with hydrocyanic acid gas in March, when the growth of the adult stage has ceased, will be effective. The only alternative is the thorough disinfection of the benches, and so on, is the only remedy that has been recommended for the rose midge.

**BRISTLY ROSE SLUG (Lasiocampa rosae).—**Small greyish brown maggot about \( \frac{1}{4} \) inch in length which often injure the opening blossom-buds of roses grown under glass. They may be controlled by spraying with tobacco extract or by the use of a sweetened poison made according to the following formula: Water, twelve quarts; parts green, one tablespoonful; sugar, three. ROSE 3017

**C. R. CROSBY AND M. D. LEONARD.**

**ROSE DISEASES.**

**POWDERY MILDEW, caused by the fungus Sphaerotheca pannosa,** is one of the commonest and most injurious diseases known to roses, greater or less, they are grown. It is usually first noticed as greyish or whitish spots on the young leaves or shoots. Later as the spots enlarge, they have a white, powdery appearance, a felt-like coating being formed, especially on the thorns. The young leaves, shoots, and flowers are dwarved, curled, or twisted, and soon drop, and growth and flower-production is seriously interfered with. Frequently the thorns and branches are attacked by the fungus, rendering the flowers worthless.

**Treatment.—**(1) Under glass. Thoroughly dusting with sulfur, or spraying with potassium sulfide, is practicable, and with two applications at intervals of a week or ten days being sometimes necessary. Ammoniacal copper carbonate is also effective. Vapors of hydrocyanic acid gas, either by blowing sulfur in a pot over an alcoholic lamp, or by painting the heating apparatus with equal parts of sulfur, lime, and water, can be successfully used. No time should be lost in applying one of these treatments as soon as the mildew appears. Burned sulfur is likely to injure the plants. As one of the conditions favorable to the spread of mildew is dry, cool air, such as would come into the greenhouse from ventilation, broken down in any way, it is therefore desirable to eliminate all drafts. (2) Out-of-doors. Outside, rose mildew can be controlled by dusting with finely ground sulfur. Frequent applications should be made, starting with the first appearance.

**BLACK SPOT, caused by the fungus Dispoanrops rose (more commonly known as Actinomma rose),** is the most common and injurious disease known to roses. Roses grown both out-of-doors and under glass are affected. The disease is most destructive during the summer. The more or less circular spots may attain a diameter of a centimeter or more, are of a black color, and are characterized by an irregularly fringed border. The spots occur on the upper surface of the leaf, and by confluence may involve the entire surface. Frequently the leaves become yellow, both in the invaded and adjacent areas, and soon drop. Bushy sorts are more susceptible than the climbing varieties.

**Treatment.—**The fungus lives over winter on fallen leaves. Therefore, the source of spring infection will be eliminated by gathering and burning all the leaves about the plants, preferably in the spring before the buds expand. However, this is not sufficient entirely to control the disease. Rotation of the greenhouse is essential, as the spores must be sprayed as soon as the disease becomes manifest, several applications at intervals of a week or ten days being sometimes necessary. Bordeaux mixture is said to be effective, but it is not recommended by some authorities, in that it coats the foliage. As a spray of ammoniacal copper carbonate is just as effective and lacks this objectionable feature of Bordeaux mixture, it is to be given the preference.

**ROSE BLOTCH, caused by the fungus Phragmidium (several species),** has been reported occurring on indoor and out-of-doors roses. It is abundant on wild roses. The disease manifests itself in early spring as orange powdery patches on leaves, shoots, and buds. Frequently the greater portion of the surface of the leaf may be covered. The patches on the wood are often large, and distortion or curving of the part affected may occur. Black spots are to be found on the under side of the leaves and on the stems, the latter often infested with scale. The disease is contagious, all fallen infected leaves and all diseased plants or plant parts should be collected and burned. Spraying with potassium sulfur has been recommended, but further experimentation with this fungicide is desirable.

**SYN CANKER, caused by the fungus Cynomyces veronicae (probably the same as C. fulciu),** cankers are formed on the stem and branches, being characterized by a brown center with a black border, outside of which is an orange zone. Pustules are to be found on the under side of the leaves and on the stems, the latter often infested with scale. The disease is contagious, all fallen infected leaves and all diseased plants or plant parts should be collected and burned. Spraying with potassium sulfur has been recommended, but further experimentation with this fungicide is desirable.

**TREATMENT.—**Diced canes should be cut and burned.

**CROWN GALL, a bacterial disease caused by Bacterium tumefaciens,** the disease occurs on stems and roots of all plants that come in contact with soil containing the bacterium. It is characterized by galls or tubercles being formed on the stems or roots, or both. The treatment consists in the removal of the affected portion of the plant and burning the diseased area, thorough disinfection of the benches, and so on, is the only remedy that has been suggested. Injection of all stock showing any indication of gall is advisable.

**CROWN GALL.**—A bacterial disease caused by Bacterium tumefaciens. The disease occurs on stems and roots of all plants that come in contact with soil containing the bacterium. It is characterized by galls or tubercles being formed on the stems or roots, or both. The treatment consists in the removal of the affected portion of the plant and burning the diseased area, thorough disinfection of the benches, and so on, is the only remedy that has been suggested. Injection of all stock showing any indication of gall is advisable.
ROSE

Downy mildew is caused by the fungus Peronospora sparsa. It is a persistent disease of greenhouse roses, and is of somewhat rare occurrence. The disease is characterized by wilting and rapid blighting of young leaves.

Treatment. - Dusting with sulfur is bold to be effective against this disease.

L. M. Massey.

R. rock: A good plant for the rockery. F. Tracy Hubbard.

ROSELE. An annual herbaceous (H. Sobardar, page 1485, Vol. III), cultivated in tropical and subtropical regions for the acid of the immature calices and involucels or bracteoles; known also as red sorrel and Jamaica sorrel; it also yields a fiber.

The rose is used in the making of an acid drink and also for jellies, jams, sauces, and marmalades, being a good substitute for cranberry and currant in regions where these fruits do not grow. It is grown somewhat in the southernmost parts of the United States. The culture is essentially that of the eggplant. Seeds are sown in a seed-bed, and the young plants transferred to rows in the field far enough apart to allow of horse-tilling 1.5 to 2 feet apart in the row. The plant usually grows 4 to 5 feet high if not too highly fertilized, and produces a bush of many stalks. No special tillage or care is required. Before the bolls are woody or stringy, they are broken off by hand. They may be utilized fresh, or dried for future use. The common forms of rosele are rich red and make very attractive products: the yellowish forms appear not to be grown in this country. The yield of one plant may be three to sixteen pounds.

ROSMARINUS (Latin, sea-dew; the plant is common on the chalk hills of the south of France and near the seacoast). Labiatae. Rosemary: Hardy evergreen shrub; a well-known garden plant, with aromatic leaves used for seasoning.

Leaves narrow, entire, with revolute margins; fls. in short axillary racemes, few, approximate, opposite, subsericeous, bluish or white; calyx ovoid-campanulate, perfect stamens 2: nutlets smooth, ovoid-subglobose.

Species: floridus, C. floridus, the golden hairs covering the upper parts of the st. and petals. Brazil. - Rare and imperfectly known.

R. floridus, Hort., is a plant offered by Siebrecht which does not appear in botanical works.

F. W. Barclay.

ROUPELIA: Strophanthus.

ROYENA (named for Prof. J. T. Rotherock). Asclepiadaceae. Perennial twining herb hardy in the southeastern United States. Stems somewhat woody at base; lvs. opposite, cor- date-acuminate, long-petioled; fls. loose axillary cymes; fls. white; calyx 5-parted; corolla rotate, deeply 5-delt, the lobes oblong; crown simple, inserted at the junction of the corolla and stamen-tube, 5-parted; follicles thickened, acuminate, smooth. - Three species, N. W. Mex. and Ariz.

cordifolia, Gray. Lvs. opposite, slender-petioled, corhaitic, acuminate; fls. white or whitish, in racemes; corolla-lobes 3-4 lines long. N. W. Mex. - Grows on gravelly slopes near the borders of Ariz. Also in Ariz. - Cult. in S. Calif.

F. Tracy Hubbard.

ROTTBOELLIA (Christen Friis Rottbøell, a Danish botanist, 1727-1797). Gomphrena. Annual or perennial, usually robust, grasses of the tribe Andropogoneae, found mostly in warmer regions of the world. The species furnish some forage but they are scarcely horticulturally. Spikelets in pairs as in Andropogon, awnless, arranged in cylindrical spikes, more or less embedded in the axis, the first glume narrow and covering the excavation of the rachis-joint. The genus is more properly referred to Manisuris by recent authors, this name being taken up on technical grounds.

A. S. Hitchcock.

ROUPALA (probably a native name in Guatemala). Also spelled Ropala, Rupala, Rhopala. Proteaceae. Trees, smooth or ferrugineous-tomentose, suitable only for the warmhouse.

Leaves alternate, leathery, stiff, entire or dentate, undivided, or those of the st. branches (and younger trees?) pinnate: fls. in axillary or terminal racemes pedicelled in pairs, perfect; perianth cylindrical, slightly dilated at base, the limb scarcely broader, subglobose, oblong or elongated, finally reflexed; ovary sessile; caps. hard, calyptra-valved, short-stipitate. - About 40 species, Trop. Amer.

A. Hairs rust-colored.

Pohili, Mein. (R. corcovadensis, Hort.). A tree, with branches clothed with rusty colored woolly tomentum: lvs. 1 ft. or more long, pinnate, with 5-8 pairs of lfts. which are 3-5 in. long, on stout petioles 1 in. or less long, ovate or obliquely ovate, acuminate, narrowly serrate; fls. many, long; ovaries sessile in nearly sessile axillary racemes 3-5 in. long. B.M. 6985.

A. Hairs golden.

R. aurea, Lind. According to Belg. Hart. 1866:202, this species was named for the golden hairs covering the upper parts of the st. and petals. Brazil. - Rare and imperfectly known.

R. fragilis, Hort., is a plant offered by Siebrecht which does not appear in botanical works.

F. W. Barclay.

ROUPÈLIA: Strophanthus.

ROYAL PERN: Osmanthus regalis. R. Palm: Osmunda regalis.

ROYENA (named for Adrian van Royen, of Leyden; died 1770). Ebenaceae. Evergreen trees or shrubs suitable for the warmhouse.

Leaves alternate: infl. axillary; fls. small, hemaphro- dite; calyx deeply 5- (rarely 4-) lobed, often accrescent in fr., lobes more or less pubescent or silky; corolla campanulate or urceolate, 3-delt, lobes obtuse, reflexed; stamens 10 in one rank; ovary conical, pubescent: fr. globose, ovate or oblong, leathery, indeliscient or splitting. - About 20 species, natives of Trop. and S. Afr. The genus is distinguished from the other genera of the ebony family by the fls. being hemaphrodite instead of dicoceous and the stamens in a single series.

Royena lucida is one of the old-time Cape shrubs formerly cultivated under glass for ornament in England and lately offered in southern California. It has small white flowers about ½ inch across, with five more or less reflexed lobes.
lédica, Linn. Tender evergreen shrub, 4–12 ft. high, or a small tree; bark nearly smooth, dusky gray or whitish; lvs. oval or somewhat ovate, leathery, shining above, more or less hisutate beneath; fls. solitary, axillary, white or yellowish; calyx 5-toothed; corolla-tube, ovoidate, limb reflexed, 5-parted, puberulous; segms. rounded; fr. oval or subglobose, red or purple and fleshy when ripe. S. Afr. B.R. 32:40.

ROYSTÓNÉA: Oreoédos.

RUBBER PLANTS. Various plants furnish rubber. The best gutta-percha is said to be produced by Isomandrá Guita (which see), a native of India. For the rubber tree of South America, see Hevea brasilíentis. The rubber tree of tropical Africa is Landolphiá florídeá; see B.R. 6963. The rubber plant of horticulturists is Ficus elástica. For an agricultural account of rubber, see “Cyclopedia of American Agriculture,” Vol. II.

RÚBIA (Latin, red; referring to the color of the dye extracted from the root). Rubiácées. Mostly hardy herbs, sometimes shrubby at base, of little horticultural worth, but one, R. tinctórum, is of economic value.

Plants frequently rather stiff, hispid, or aculeate; lvs. in whorls of 4–8 or very rarely opposite and stipul., sessile or petiolate, lanceolate or ovate, round, cordate; fls. small or minute, in axillary or terminal cymes, 5-merous; involucr. none; calyx-tube ovate or globose, limb lacking; corolla rotate or subcampanulátus, ovate, reflexed, 5-toothed; fr. didymous, fleshy, 2 rare-1 celled.—About 40 species. Medit. region, Trop. and S. Afr., Temp. Asia, Trop. and S. Temp. Amer. R. tinctórum is the dye-plant called madder, the long, fleshy roots of which are ground to powder. Madder is said to furnish a good green fodder if cut the second year when in flower.

RúBUS (Latin, name, ultimately connected with ruber, red). Including Boskéria, Rubícer, Oreóborá, Batíida, and others, but excluding Dalíbarda. Rosácées. Brambile, Blackberries, Dewberries, Raspberries, and Thimbleberries. Low and diffuse mostly woody plants, usually producing canes, grown for the edible fruits, some of the species for ground-cover, and others for the more or less ornamental character of habit, foliage, and bloom.

Trailing, decumbent, ascending, or erect plants, the tips of long growths usually recurring even if otherwise erect, glabrous, hairy or variously glanular, mostly thorny or prickly; st. usually short-lived and pithy (sometimes semi-herbaceous); lvs. simple or compound, alternate, the compounding on the pinnate order and the leaflets largely 3 (several in many of the tropical and oriental species); fls. mostly white or rose-colored, usually in corymb umbels or racemes but sometimes solitary; calyx 5-parted (rarely 3–5-parted), the lobes persistent; petals 5, usually ovate; stamens many, inserted on the torus-rim; pistils many (or sometimes few), closely packed on the torus, usually becoming druplets but sometimes dry when ripe, the style nearly terminal.—A most variable and perplexing genus, containing perhaps 400 fairly well-marked species and numberless intermediate forms. More than 3,000 species-names have been applied. The genus is particularly strong in Europe, where great numbers of species names have been made (see Weide & Née, Rubí Germaniá, 1822–7; Focke, Synopsis Rubíner Germaniá, 1877; Babbington, Britísh Rubí, 1889; Focke, in Ascherson & Grabner, Synopsis der Mittel-
europálschen Flora, 1902; Rogers, Handbook of British Rubí, 1900, and many other publications). Focke in 1877 described 72 species inhabiting Germany. In 1902 he admitted 87 full species to the mid-European flora. There is also a large extension of the genus in the Himalayan region, about 50 species being recognized (J. D. Hooker admits 41 species in the Flora of British India). The species extend eastward into China and Japan. Hemsley, in his Flora of China, admits 41 species. In Japan, Franchet and Savatier admit 22 species. In the North American Flora, Rydberg admits 112 species, in 1913, counting those in Mexico and southward and excluding certain species that are referred to other genera. Students of the American forms should consult the recent writings of Blanchard, Brainerd, Bicknell, and Rydberg. There is no agreement as to the number of species in N. Amer. or elsewhere, and recently other genera have been segregated. Rubus is widely distributed in the northern hemisphere, particularly in temperate and warm-temperate parts. Some of the species are alpine and arctic. In tropical climates the genus is relatively poorly represented. Oliver admits only 4 in the Flora of Tropical Africa. Only 2 species are described in Grisebach’s Flora of the British West Indies. Baker admits 3 species in the Flora of Mauritius and the Seychelles. Hillebrand describes 3 species in Flora of the Hawaiian Islands. The southern hemisphere has few species. Bentham’s Flora Australiánsís has but 5 species. Cheeseman’s Manual of the New Zealand Flora mentions only 4 indigenous species. There are also 5 species described in Harvey and Sonder’s work (Flora Capensis) on the flora of the Cape of Good Hope region. In his Species Rubíera (Bibil. Bot. parts 72 and 83. 1810–14) Focke describes 429 or more species from all around the world.

The genus Rubus tempts the species-maker. The lines of demarcation are obscure or indefinite, the variables are numberless, the botanical characters differ widely on old and young canes and even on spring and autumn foliage of the same cane, and the plants respond readily to conditions. There are marked shade-forms and sun-forms, moisture-forms and dry-land forms, apparently only environmental modifications of prevailing types. The tendency, therefore, on the one hand is to recognize a very few stem-types as species (Bentham reduced all the British rubi of the blackberry...
type to one species, *R. fruticosus*), and on the other hand to make species of the marked departures (Rogers makes more than 100 species and many varieties of the "Rubi fruticosi" of Britain). The herbarium usually provides few checks; the student needs constantly to supplement his specimens with careful observations in the field under many varying conditions, if he is to arrive at an independent judgment on the group. We do not yet know how far the older herbarium definition corresponds with phylogenetic facts. There is indication that rubi hybridize freely, particularly in the blackberry group, and artificial hybrids are produced easily; but to assume hybridity from the herbarium specimen alone is inconclusive, particularly when we have now learned that intermediateness is not a proof of hybridity and that hybrids may even show little departure from one or the other parent. If to the variability of plants in the wild is to be added the variation under cultivation, the difficulties are intensified if one endeavors to name and separate very closely; and if very many species are to be made, then it may be practically impossible to identify the horticultural forms with any of the minutely defined wild species. This difficulty is likely to be little taken into account in the usual study of wild material, and yet it is an obligation of the systematist to give the horticulturist; it would be a pity to serve the horticulturist without the knowledge of the close forms with a Latin name. This procedure, however, may be properly imperfect and because the American species had not then been studied critically; the problem must therefore be worked out mostly as a current systematic study.

Rubus is closely allied to Rosa, from which it differs chiefly in the structure of the flower. In Rosa, the torus or hypanthium is hollow and contains the dry fruits or achenes. In Rubus the torus is convex, conical or elongated, and bears the mostly soft or pulpy fruits on its surface. Rubi are chiefly shrubs with stems (canes) that die after one or two years, but some of them have herbaceous tops. In raspberries and blackberries, the canes bear the second year and then die or become very weak. The fruit is an aggregate of carpels. The drupelets are usually more or less coherent at maturity, the collective body forming the "fruit" or "berry" of horticulturists. In the raspberries, the coherent fruits are referred to the torus at maturity, thus causing the berry to be hollow or concave on the under side. In the blackberries, the coherent drupelets adhere to the torus, which separates at maturity and forms the "core" of the berry. Usually the tops are not long-lived, and commercial plantations require frequent renewal.

The horticultural and controlled hybrids in Rubus are now many. Raspberry-blackberry crosses have been frequently effected, but they appear to have little popular interest. The illustration (Fig. 3486) shows a hybrid between *Fontouze* raspberry (*R. idaeus*) and "the common blackberry" of England as shown by Veitch at London in 1897 (G.C. Oct. 2, 1897, from which the illustration is reduced). The fruits were described as of a purplish black color with gray bloom, produced abundantly.

Relatively few of the rubi have horticultural merit, although some of them are of great importance. As pomological subjects they are more important in North America than elsewhere. Here are grown only raspberries, which are popular elsewhere, but also great quantities of improved blackberries, a fruit that is less known as a regular cultivated product in other countries. Although the European raspberry, *R. idaeus*, is grown in North America, it is mostly of a purplish black color with gray bloom, produced abundantly. The beauty of most shrubby rubi depends largely on the removal of the canes after they have bloomed once. After flowering, the cane becomes weak or may die outright. It should be removed to the ground. In the meantime other canes have arisen from the root, and these will bloom the following year. That is, the stumps of rubi are usually more or less perfectly biennial: the first year they make their growth in stature; the second year they throw out side branches on which the flowers are borne; after fruiting, the entire cane becomes weak or dies. Removing
these canes not only contributes to conserve the vigor of the plant, but it also adds to its appearance of tidiness. These remarks apply particularly to the cultivation of raspberries, blackberries, and dewberries.

For other accounts, see Blackberry, Dewberry, Himalaya Berry, Loganberry, Lowberry, and Raspberry, at their respective entries.

In recent years, many of the Chinese species of Rubus, mostly in the subgenus Malachobatus and Ideobatus, have been introduced to cultivation for ornament, some of them with promise of providing desirable edible fruits. Many of them make long vine-like canes and are excellent for training to posts, pillars, on pergolas and arbors. The foliage is often very ornamental and several of them have white or bluish white canes that render them useful for winter effect. Some of the species are evergreen. These oriental rubusces are known in cultivation mostly in England, but are being tested in this country, particularly at the Arnold Arboretum, Boston; at the latter place, none of the species has proved to be perfectly hardy. The following species have survived, although mostly much killed back each winter: R. floccosus, R. Lambertianus, R. lasiostylus, R. Giraldianus, R. mesogonus, R. inominaatus, R. adenophorus; R. conduplicatus and R. teledapos stood the winter of 1915–16.

The species of Rubus require no special place or care in cultivation except to provide in a general way the conditions as to moisture and exposure under which the plants grow in the wild. They are plants of wide adaptability. Propagation is by dividing the clumps in some cases, but better by the use of the natural stolons, or if artificial propagation must be employed, root-cuttings 2 or 3 inches long may be used for many species. They are grown readily from seeds.

INDEX.

INDEX.

of No. 33.

44.

Potaninianus, 5.

Gowreephul, 35.

12. AMIBH., 51.

Smalilfts., and drooping fls. in mostly short clusters; stipules linear to lanceolate. Nos. 25–55.

BB. Raspberries, with the coherent drupelets separating from the torus; upright or ascending shrubs, with simple or ternate lvs., small lfts., and drooping fls. in mostly short clusters; stipules linear to lanceolate. Nos. 25–55.

B. Plant spineless.

9.

R. roezli, 9.

Section III. DALIBARTIUS.

The species described are prostrate and spineless, woody, brown-hairy: lvs. simple, evergreen, cordate; fls.-stls. erect, the fls. large and white. No. 7.

Section IV. ANOPLOBATUS (batas is Greek for bramble). Upright rather soft-stemmed shrubs, usually 3–5 ft. high, shaggy with barb-like leaf-like bristles, large, lobed lvs., large erect fls., and broad torus. Nos. 8–11.

AA. Species shrubby; flowering shoots arising from woody canes of 2 or more years' growth, the plants small or large but usually large.

B. Plant spineless.

Section III. DALIBARTIUS. The species here described are prostrate and spineless, woody, brown-hairy: lvs. simple, evergreen, cordate; fls.-stls. erect, the fls. large and white. No. 7.

Section IV. ANOPLOBATUS (batas is Greek for bramble). Upright rather soft-stemmed shrubs, usually 3–5 ft. high, shaggy with barb-like leaf-like bristles, large, lobed lvs., large erect fls., and broad torus. Nos. 8–11.

Section V. MALACHOBATUS. Climbing or prostrate shrubs with entire or palmately lobed seldom compound lvs. and mostly not showy fls.; stipules broad, fugacious. Nos. 12–24.

1. Chamæemorus, Linn. Cloudberry. Bakeapple-Berry. Yellow Berry. Molka. Salmonberry improperly (see No. 32). Fig. 3487. Creeping: branches herbaceous, covering the ground, pubescent or almost glabrous: lvs. round-tipped or reniform, shallowly 3–5-lobed, finely dentate: fls. large and white, in solitary terminal peduncles: fr. large, globose, red or yellowish, composed of few soft drupelets, edible. Entirely across the continent in high northern and arctic regions, and reaching as far south, in the E., as the high land of Maine and N. H. and eastern end of L. I.; also in Eu. and Asia.—The cloudberry is an inhabitant of peat-bogs and cool places. It is much prized for its fr., which is gathered from the wild in large quantities. It is sometimes planted farther south as a rock-garden plant. R. arcticus, Linn., a pink-flowered species with trifoliolate lvs., occurs in nearly the same range, and produces small edible berries; this species belongs to Section II.

Section II. CYLACTIS.

2. pubescens, Raf. (R. americanus, Brit. R. trifolius, Rich.). Sts. slender and trailing, 1–2 ft. long, herbaceous, without prickles, glabrous or nearly so: lvs. thin and soft, light green, with 3 or 5 ovate or rhomboid-ovate, coarsely serrate lfts.: fls. 1–3 on each peduncle, small and white, the calyx reflexed: fr. small, reddish. Cold swamps, N. J. west and north.—Offered as a rock-garden plant for moist places.

3. pedatus, Smith. Low creeping unarmed herbaceous coptis-like perennial, rarely cult., probably apple-berry of arctic or subarctic regions, and much prized for its frs., belongs here. No. 1.

Section II. CYLACTIS.

AA. Species shrubby; flowering shoots arising from woody canes of 2 or more years' growth, the plants small or large but usually large.

B. Plant spineless.

Section III. DALIBARTIUS. The species here described are prostrate and spineless, woody, brown-hairy: lvs. simple, evergreen, cordate; fls.-stls. erect, the fls. large and white. No. 7.

Section IV. ANOPLOBATUS (batas is Greek for bramble). Upright rather soft-stemmed shrubs, usually 3–5 ft. high, shaggy with barb-like leaf-like bristles, large, lobed lvs., large erect fls., and broad torus. Nos. 8–11.

Plant spine-bearing (exceptions in some blackberries).

Section V. MALACHOBATUS. Climbing or prostrate shrubs with entire or palmately lobed seldom compound lvs. and mostly not showy fls.; stipules broad, fugacious. Nos. 12–24.

AA. Species shrubby; flowering shoots arising from woody canes of 2 or more years' growth, the plants small or large but usually large.

B. Plant spineless.

Section III. DALIBARTIUS. The species here described are prostrate and spineless, woody, brown-hairy: lvs. simple, evergreen, cordate; fls.-stls. erect, the fls. large and white. No. 7.

Section IV. ANOPLOBATUS (batas is Greek for bramble). Upright rather soft-stemmed shrubs, usually 3–5 ft. high, shaggy with barb-like leaf-like bristles, large, lobed lvs., large erect fls., and broad torus. Nos. 8–11.

BB. Plant spine-bearing (exceptions in some blackberries).

Section V. MALACHOBATUS. Climbing or prostrate shrubs with entire or palmately lobed seldom compound lvs. and mostly not showy fls.; stipules broad, fugacious. Nos. 12–24.

Section VI. IDEOBATUS. Raspberries, with the coherent drupelets separating from the torus; upright or ascending shrubs, with simple or ternate lvs., small lfts., and drooping fls. in mostly short clusters; stipules linear to lanceolate. Nos. 25–55.

Section VII. EUBATUS. Blackberries and dewberries, with the drupelets adhering to the torus when ripe; stipules linear. Nos. 56–66.

1. Chamæemorus, Linn. Cloudberry. Bakeapple-Berry. Yellow Berry. Molka. Salmonberry improperly (see No. 32). Fig. 3487. Creeping: branches herbaceous, covering the ground, pubescent or almost glabrous: lvs. round-tipped or reniform, shallowly 3–5-lobed, finely dentate: fls. large and white, in solitary terminal peduncles: fr. large, globose, red or yellowish, composed of few soft drupelets, edible. Entirely across the continent in high northern and arctic regions, and reaching as far south, in the E., as the high land of Maine and N. H. and eastern end of L. I.; also in Eu. and Asia.—The cloudberry is an inhabitant of peat-bogs and cool places. It is much prized for its fr., which is gathered from the wild in large quantities. It is sometimes planted farther south as a rock-garden plant. R. arcticus, Linn., a pink-flowered species with trifoliolate lvs., occurs in nearly the same range, and produces small edible berries; this species belongs to Section II.

Section II. CYLACTIS.

2. pubescens, Raf. (R. americanus, Brit. R. trifolius, Rich.). Sts. slender and trailing, 1–2 ft. long, herbaceous, without prickles, glabrous or nearly so: lvs. thin and soft, light green, with 3 or 5 ovate or rhomboid-ovate, coarsely serrate lfts.: fls. 1–3 on each peduncle, small and white, the calyx reflexed: fr. small, reddish. Cold swamps, N. J. west and north.—Offered as a rock-garden plant for moist places.

3. pedatus, Smith. Low creeping unarmed herbaceous coptis-like perennial, rarely cult., probably adapted to cool woods or rock-gardens: lvs. pedately 3–5-foliolate, with thin obovate or rhombic-obovate irregularly cut lfts. which are glabrous or only sparsely
hairy on veins beneath; fls. solitary and terminal on short shoots, white, about 1 in. across. N. Calif. and Idaho to Alaska; reported in Japan.—By Focke referred to the subgenus Dalibarda; if kept in a distinct genus, the plant becomes Dalibarda pedata, Stepp. Interesting as a rock-garden plant.

4. stellatus, Smith. produces an edible fr. prized in Alaska, where it is native, as well as in Yukon and Kamchatka: st. simple and herbaceous, only a few inches long, 1-fld.: lvs. cordate, 3-lobed or 3-parted, reinform in outline, pubescent on both sides or glabrate in age, simply or doubly serrate; fls. solitary and terminal, rose-colored: fr. red, globose, with 20 or more druplets, said to be known locally as a dewberry.

5. xanthocarpus, Bur. & Franch. (R. Potaninii, Regel). Trailing, the sts. dying back every year, the sts. ploose and weak-spiny: lvs. pinnately 3-foliolate, the fls. ovate, acute or obtuse, strongly and unequally dentate, the terminal one twice larger than the others: fls. solitary or twin in the axils of the upper lvs., the peduncle and calyx weak-prickly, the petals white: fr. large, ovate, bright yellow, fragrant, and palatable, the calyx persistent. China; discovered in 1885 in the Province of Kansu, 40° north latitude, and later found in provinces Szechuan and Yunnan.—Intro. into the U.S. in 1898 by the Dept. of Agric. through N. E. Hansen, to be tried for its edible raspberry-like fr. It is said to provide a good cover; fairly hardy in Minn; it appears not to have found favor in this country and its value is doubtful.

Section III. Dalibardastefum.
7. triflorus, Focke. (R. polycirrus, Franch., not Prog.). A distinct dwarf species with prostrate spineless brown-yellowish-hairy sts., growing several feet in a season under moist shady conditions: lvs. simple, about 3 in. long: cordate, evergreen, sharply toothed, dark green above but with rows of hairs between the chief veins, white-tomentose beneath and with brown bristle-hairs on the rib and chief veins of the lvs.: fr. white, 1 in. across, erect fl. sts.: fr. rather large, bright red. W. China, up to 10,000 ft.—Probably worthy as a wild-garden and rock-garden subject.

Section IV. Anploratus.

8. triflatus, Thunb. First Raspberry. Strong-growing and erect, 7-10 ft. tall: lvs. large, palmately ribbed, 3-5- or even 7-lobed, serrate; fls. solitary, the peduncles villous: berry of medium size, scarlet, with pointed druplets. Japan.—Sparingly intro. and prized for its bright autumn foliage (whence the name "fire raspberry").

3489. Clump of Rubus odoratus (flower X½). No. 10.

10. odoratus, Linn. (R. grandifolius, Salisb. Bossekia odorata, Greene. Rubécer odoratum, Rydb.). Flowering Raspberry. Mulberry (erroneously). Fig. 3489. Strong-growing plant, with the shreedy canes reaching 3-6 ft.: lvs. very large, pubescent beneath, 3-5-lobed, the lobes triangular-acuminate with broad triangular teeth and sharp-serrate; fls. 1-2 in. across, rose-purple, several to many in the cluster, the sepals with a long point, the peduncles and pedicels glandular-pubescent: berry flattish and broad (½ in. across), rather dry, light red, edible but not valued. Nova Scotia to Mich. and Ala. Gn. 34, p. 230. B.M. 323. J.H. III. 31:133. F.E. 22:557. Var. columnaruis, Millsp. (Rubber columnarum, Rydb.), native in W. Va., has lanceolate incised-dentate or doubly dentate lobes. Var. albicus, growing with the type, has whitish fls. and lighter-colored bark.—R. odoratus prefers rich shady woods and banks. It makes a bold subject in a foliage mass, and its fls. are nearly as large as many single roses, although the color is less bright. It spreads rapidly from the root and overtops weaker plants.

11. parviflorus, Nutt. (R. nuttânus, Moq. R. lacer, Kunze Bossekia variiflora, Greene. Rubécer parvi-
florum, Rydb.)). Differs from the last in having white florets in few-flowered clusters and less glandular peduncles. N. Mich. to the Pacific Coast and southw. in the Rockies; the western representative of R. odoratus. B.M. 3453. B.R. 1306. Gn. 45, p. 75; 59, p. 61; 62, p. 249; 67, p. 255.

Section V. Malachobatus.

a. Lvs. compound (in R. Henryi 3-lobed lvs. sometimes occurring).

12. Hénryi, Hemsl. & Kuntze (R. bambusiforme, Focke). Evergreen, with trailing shoots 10-15 ft. long, with few spines and gray-tomentose when young: lvs. 3-lobed and of 3 lfts. often on same branch, rarely of 5, the lfts. long-lanceolate, 3 in. or more long, minutely and more or less distinctly toothed, tomentose beneath: fls. small, pink, in terminal racemes 2-3 in. long: fr. ½ in. or less diam., shining black, not unpleasant in flavor. W. China, 4,000-7,000 ft. altitude. G.C. III. 42:251; 51:148. G. 28:630.—A handsome plant for pillars and pergolas, because of its graceful growth and interesting foliage. It has been considerably advertised abroad.

13. Pláyfairi, Hemsl. (R. Playfairi, H. Hort.). A rambling or diffuse shrub, evergreen, with thin wiry-sts. which bear small curved spines and are cobwebby when young: lvs. of 3-5 linear-lanceolate or lanceolate serrate lfts., the terminal one 5-7 in. long, all bright green above and gray-felty beneath, the stipules ½ in. long and cut: fls. ½ in. across, in irregular clusters, the petals shorter than calyx-lobes: fr. black of fair or moderate flavor. China. G.C. III. 51:106.—Makes a handsome plant when trained up on stakes.

b. Lvs. not compound, although sometimes lobed.

16. Lvs. usually paniculate or thyroid, the peduncles mostly fascicled (except perhaps in No. 20).

17. ichangénis, Hemsl. & Kuntze (R. eugénis, Focke). Sts. long and slender, with few small prickles, evergreen: lvs. simple (the older ones sometimes more or less 3-lobed), broad-lanceolate, cordate at base, 3-4 in. long, light green on both surfaces, remotely toothed, long-pedioled: fls. very small, in small panicles: fr. small, red, of good flavor. Cent. and W. China, to 7,000 ft. altitude. G.C. III. 48:275.—The lvs. have a metallic luster.

3490. Rubus cratagifolius (X J.) No. 27.

cc. Lobes of lvs. usually prominent, and the lvs. mallow-like.

d. Sts. herbaceous or only half-shrubby.

20. irenénus, Focke. Unarmed or with very small prickles, with slender creeping sts., evergreen: lvs. simple, nearly orbicular, 5 or 6 in. either way, cordate at base, slightly 3-5-lobed, white-tomentose and rusty along the nerves beneath, glabrous and metallic green above: fls. ½ in. or more across, the petals roundish, white, exceeding the sepals; fr. yellow. Cent. China, 4,000-8,000 ft. altitude.—Probably useful in mild climates and moist places for covering slopes.

DD. Sts. shrubby.

22. flagellifórus, Focke (R. flagelliformis, Hort., not Smith). Evergreen or nearly so, of attractive habit. 8 ft. or more, the sts. and under surface of lvs. dull tomentose, the spines few: lvs. simple, cordate, acum-
23. *R. moluccanus*, Linn. A large raspberry-like plant in many forms, common in India and Malaya, and to be expected as an intro. plant in many warm countries. Very robust, the tomentose canes and branches reddish and with short curved scattered prickles: lvs. simple, very variable, large, usually hairy, gray- or yellow-woolly beneath, mostly broad-ovate or orbicular and deep-cordate, shallowly 3–5-lobed, irregularly serrate: fls. white, in contracted terminal clusters: fr. in shades of red or succulent. Gn. 63, p. 408. G.M. 46, p. 323.

—Probably not in the American trade.

Section VI. IDAEBATUS. Raspberries.

A. Lvs. simple, often 3-lobed on strong shoots.

25. *R. corchorifolius*, Linn. f. Nearly or quite erect, 4–6 ft., the terete sts. downy and bearing small straight spines: lvs. simple, cordate-ovate, mostly 3-lobed on the verdurous shoots, 4–7 in. long, dull green above and pubescent beneath, the margins coarsely toothed, midrib and petiole with hooked prickles: fls. white, solitary, on short lateral twigs: fr. bright red, large, said to be excellent in quality. Cent. and W. China, to 7,000 ft. altitude. Japan. G.C. III. 51:149.—There are several forms or very closely related species.

26. *R. palmatus*, Thumb. Spreading, often slender-stemmed plant growing 4–5 ft. tall, with many short, but stout nearly straight spines: lvs. rather small, 2–3 in. long as a rule, narrow-ovate-acuminate, or somewhat nearly triangular-ovate-acuminate, rather deeply 3–5-lobed and the middle lobe long and acuminate, the margins very sharply serrate: fls. white, nearly or quite small, ½ in. across, with broadly ovate petals: fr. small (red?), of little value. China, Japan. B.M. 7801.—Sparingly intro. as an ornamental plant, but little known here. The Mayberry, intro. by Luther Burbank, is said to be a hybrid between this species and the Cuthbert raspberry (*R. strictus*). The Mayberry is described as producing a large yellow edible berry, ripening in advance of the strawberry. *R. palmatus* is doubtfully referable to *R. microphyllus*, Linn. f.

27. *R. cratregifolius*, Bunge. Fig. 3490. Strong, erect or diffuse much-spreading plant (3–5 ft.), with terete reddish glabrous canes that bear few and small straight spines: lvs. oblong-ovate to cordate-ovate, acuminate, 3–5-lobed, and the margin coarsely serrate and notched: fls. white, in small clusters terminating slender leafy shoots, about ½ in. across: fr. small, orange-red, of no value. China, Japan.—An excellent plant for holding banks and for covering waste places, and giving fine deep reds in the fall. Perfectly hardy in Cent. N. Y.

30. *R. conduplicatus*, Duthie, perhaps the same as *R. trianthus*, but described as differing in the pale green (not white) under surfaces of lvs., smaller fls., prickles on st. stronger and more curved. China.—A scendent glandless shrub, with simple petiolate lvs. which are ovate-lanceolate and acuminate and sometimes obscurely 3-lobed, the margins unequally incised-serrate: fls. 3–4, terminal, white.

31. *R. koehneanus*, Focke (*R. incisus*, Hort., not Thumb. *R. morifolius*, Hort., not Sieb.). Nearly erect shrub, 3–4 ft. high, the branches with purplish bloom and unarmed or sparingly prickly: lvs. simple, varying from almost entire to 3–5-lobed, 5 in. or less long, and nearly as broad, mostly deep-cordate at base, green above and white-pubescent beneath, the lobes more or less acute, petioles somewhat prickly: fls. few, in loose terminal corymbs, white, the petals about ½ in. long: fr. small and globose, orange. Japan. B.M. 8246. Gt. 53, p. 555 (as *R. incisus*).

AA. Lvs. ternately compound, running to 5-foliate forms, often on the pedate order.

B. Fls. large, solitary or few together.

32. *R. spectabilis*, Pursh (*Parmenia spectabilis*, Greene). *Salmonberry*. Fig. 3491. Strong-growing, reaching 5–15 ft., glabrous: spines few or often none, weak: lvs. of 3 ovate-acuminate lfts., which are doubly serrate-toothed and sometimes indistinctly lobed, long-stalked, thin, glabrous or becoming so beneath: fls. solitary or in 2's, large, red or purple: fr. large, somewhat conical, salmon-color or wine-red, edible, the drupelets bearing the persistent styles. Calif. and Idaho to Alaska. B.R. 1424. L.B.C. 17:1602. F.S. 21:2260. Mn. 4, p. 57.

Rubus phenicolasius, Maxim. 

WINEBERRY. Fig. 3492.

Interesting as an ornamental plant, and also recommended for its fr. In the N. it often kills to the ground, but the strong young recurving canes and white-bottomed foliage make it a handsome plant. Sparingly run wild in the E. U. S.

Rubus ellipticus, Smith (R. flavus, Hamilt. R. Gounerk- bid, Roxbg.). Fig. 3493. A yellow-fruited species from the Himalayas (X4½). No. 35.

34. adenoporus, Rolfe (R. sagitus, Focke). Resem bles R. phenicolasius: stts. stout, with short red prick­les, the exposed parts dark red, densely covered, as are the sepals and petals, with purple stalked glands: lvs. un­ternate or the upper ones simple, the lfts. unequal (rarely 5), the terminal largest and cordate-ovate, the lateral subsessile, all dull green above, hairy on both sides: fls. 6-10, in short terminal clusters, rose-colored, the broadly clawed petals about ½ in. long: fr. about ½ in. across, edible, the druplets red with black tips. China.—The erect red stts. are ornamental in winter and also recommended for its fro. In the N. it often kills to the ground, but the strong young recurving canes and white-bottomed foliage make it a handsome plant. Sparingly run wild in the E. U. S.

35. ellipticus, Smith (R. flavus, Hamilt. R. Gounerk­ bed, Roxbg.). Fig. 3493. Tall and erect or nearly so (6-10 ft.), the canes stout and densely beset with straight red-brown or crimson hairs and bearing a few stout, short, nearly straight prickles: lfts. 3, the terminal one much the largest, ovate to orbicular-ovate, not lobed, evenly doubly serrate, thickish, soft pubescent and strongly veined and prickly on the midrib beneath: fls. white, ½ in or less across, in small, many-fl. clusters: berry the size of a common raspberry, yellow, of good quality. Himalayas.—Grown in S. Fla., where it is said to be the only raspberry that perfects its fr. Advertised in Calif. as Golden Evergreen raspberry, and recommended for pergolas and covering sheds. Naturalized in Jamaica.

36. macilentus, Camb. Shrub, to 5 ft., the branches bearing strong straight or hooked prickles, the plant glandless and nearly glabrous: lvs. glabrous, with many hooked prickles, the lfts. 3, of which the terminal one is 2 in or less long and ovate-oblong, the lateral ones small, all doubly toothed: fls. white, usually 3 together on end of short lateral growths: fr. orange, yellow, or red, glabrous, inclosed in the calyx. Himalayan region.

37. lasiostylus, Focke. A species apparently of variable forms, having bluish white bristly strong arch­ing sts.: lvs. pinnate, small, silvery white beneath, the lfts. 3-5 and coarsely unequally double-serrate and sometimes 3-lobed: fls. magenta-red, of good size, the petals erect and clawed: fr. rose-color but woolly, sweet but said to be useless for eating. China. G.C. III. 51:167. G. 28:631.

38. bihorus, Hamilt. Strong shrub prized in cult. for its glaucous-white canes: reaches 8-10 ft., with arching canes that bear stout, recurved prickles: lfts. 3-5, ovate or oval, incise-serrate, whitish beneath: fls. large and white, 1-3 on drooping pedicels: berry golden yellow or amber-colored, size of the common raspberry, the calyx at first erect, but finally spreading. Temp. Himalaya. B.M. 4678. R.H. 1555:5. Gt. 54, p. 456. Var. quinquefiorus, Focke. A striking plant with sts. reaching 12 ft. high and 4-5 in. circum. at base, covered with a waxy white bloom and therefore very showy, the spines stiff and ¼ in. long: pinnate lvs. about 1 ft. long, the lfts. about 5 and white beneath: panicles terminal and axillary and about 5-fl., the fls. white and ½ in. across: fr. golden yellow, good. W. China. Gt. 75, p. 624.—A promising fr.-bearing as well as ornamental plant.

39. Wilsonii, Duthie. Scandent shrub with tense very spiny brown-purple glaucous sts., the branches quadrangular and red-purple and more or less winged between the nodes: lvs. pinnate, of 3-5 ovate more or less cordate strongly double serrate lfts. which are gla­brous and deep green above and paler beneath and sparsely prickly on the ribs underneath: fls. purple, in axillary and terminal few-fl. fascicles (terminal clusters 4-5-fl., axillary 2-3-fl.), the petals about ½ in. broad and long. Cent. China.

E. Infl. usu­ally 1- to 6-fl.

40. innominatus, S. Moore. Raspberry-like in appearance, with strong upright very soft-pubescent and sparingly prickly sts. 6-8 ft. high: lvs. pinnate,
large (often 9 in. long), dark green, grayish white beneath and thickly covered with glandulodes, with 3 or 5 (usually 3) ovate lfts., the terminal one much larger than the others and often 3-lobed; lfts. small, pink, in panicles 15 in. long in Sept.: fr. orange-red, edible. Cent. and W. China. G.C. III. 58:291. R. B. 33, p. 390. — R. Kuntzeanus, Hensli., is distinguished by its glandless lvs.; perhaps not specifically separate; the plants in cult. as R. immonimus apparently belong to this species.

41. telêdapos, Focke. Arching or procumbent, with few strong incurved prickles; lvs. ternate or somewhat quinate, opaque above but densely pubescent when young, white or somewhat yellow beneath; lateral lfts. oblong or oval, dark red; yellow or whitish produced more or less continuously throughout the flowerIng shoots, petioles, and calyx, the latter less pubescent or hirsute:

fl.-clusters more open or scattered: fr. bright light red, or rarely yellow or whitish, not produced continuously. Widely spread in the northern states as far west as Missouri, also in the mountains to Ariz. and northward to Alaska, extending farther north than the Blackcap; also in Asia.—Under cult. the glandular hairs usually disappear. The light red garden berries, like Cuthbert, belong here. Var. altus, Fuller, has amber-white frs.

This plant belongs to a variable group, and other species have been separated from it, as: R. carolinus, Rydb., from N. C., with young sts. puberulent and densely retrorsely glandular-hirsute; R. Egglestonii, Blanch. (R. idaeus var. anomlia, Forn.) from Vt., perhaps an aberrant form, with lvs. of floral branches mostly simple and reniform and somewhat rounded-3-lobed; and others.

45. neglctus, Peck. PURPLE-CANE RASPBERRIES. Fig. 3494. A large and variable race of hybrids between R. strigosus and R. occidentalis occurs both naturally (Rubus neglectus, Peck, 22d Rep. Reg. N. Y. State Univ. 53, 1890) and in the garden (Bailey, Amer. Gard. Univ. 53, 1869) and in the garden (Bailey, Amer. Gard. Univ. 53, 1869) and in the garden (Bailey, Amer. Gard. Univ. 53, 1869) and in the garden (Bailey, Amer. Gard. Univ. 53, 1869) and in the garden (Bailey, Amer. Gard. Univ. 53, 1869). These plants prop. either by "tips" or suckers, usually by the latter. The fl.-clusters are open and sprawling, and the fr. ranges in color from yellow to purple. As a rule, the fr. is aggregated at the end of the cluster, but is scattering below. The Purple-Cane type of raspberry belongs here. Prominent varieties are Shaffer, Philadelphia (now nearly out of cult.), Gladstone, and probably Caroline.

DD. Fr. black at maturity (yellow-fruited forms are known).

46. occidentalis, Linn. COMMON BLACKCAP. Figs. 3485, 3486. Strong, erect bush, the canes finally recurving and rooting at the tips, furnished with straight spines, glaucous, not bristly; lfts. broadly ovate, dull green above and white beneath, finely and sharply serrate and notched, the petioles usually bearing short prick­less fls. in small, dense, prickly clusters with sometimes a few scattering pedicels, the petals shorter than the long-pointed whitish woolly sepals; fr. rather small, hemispherical, firm or even hard, black or occasionally amber-white, dry and sweet. Plentiful in fields and clearings in the northeastern states and Canada to Ore. and Brit. Col. and southward to Ga. in the mountains, and to Mo.—In cult. known in many forms, as Ohio, Gregg, etc. Var. pilillis, Bailey, has amber­yellow fr.; sometimes found in the wild.

47. leucoderms, Douglas (R. occidentalis var. leucoderms, Card.) Branches oft. yellow-tinged: lfts. more coarsely dentate-serrate, sometimes nearly incise­serrate, more gradually acuminate, yellowish green above, the prickles strong and more hooked and those of the infl. flattened laterally: fr. reddish black or black. Rocky Mts. and west to the Coast Range.

AAA. Lvs. long-pinnate, usually with 3 or more pairs of narrow lfts.

48. roseolius, Smith (R. floribundus and R. sinenis, Hort. R. rosæformis, Roxb.) Erect and tall-growing,
evergreen in warm countries, glabrous or somewhat pubescent-hirsute: lvs. odd-pinnate, the lateral lfts. 2-7 pairs, all the lfts. ovate-lanceolate or lance-oblong, acuminate, strongly many-veined and very sharp-ser-rate, more or less silky-hairy beneath: fls. solitary or in few-fld. clusters, white, 1½-2 in. across, showy: fr. erect, bright red, long thimble-shaped, usually about 1-1½ in. high, very showy, edible but insipid. Widely distributed in tropical countries, but native to the Himalayan region and eastward to China and Japan; naturalized in W. Indies. B.M. 6970. F.S. 17:1714. A.G. 20:82, 87. Var. coronarius, Sims (R. grandiflorus, Hort.), is a double form, sometimes cult. as the "Brier Rose" and "Bridal Rose" (B.M. 1783. G.C. II. 11:77. G.Z. 26, p. 266). The double-flowered form is often grown under glass and in pots.

49. illecebrosus, Focke. A vigorous species, with mostly perennial canes, and fls. usually borne on the ends of the main shoots.

50. coreanus, Miq. Of upright or erect growth, with straight prickles on the sts. and hooked prickles on the petioles, self-supporting, 6-7 ft. or more high, the sts. hoary, bluish white and the young growths dark brown: lvs. pinnate, 7-9 in. long, usually of 7 or 9 ovate serrate pointed light green lfts.; fls. rose-purple, in large terminal panicles: fr. said to be of no value. China, Korea. G.C. III. 51:149.

51. amabilis, Focke. Shrub, 6 ft., slightly prickly or unarmed above: lvs. pinnate, with about 9 ovate or ovate-lanceolate, deeply double-serrate lfts. 2 in. or less long, the petiole and rachis weak-prickly, the stipules small and linear: fls. solitary, terminal, large (about 2 in. across), white: fr. large and red, of good flavor. W. China.

52. fuscatus, Focke. Erect, about 7 ft., the dark brown sts. bearing stiff prickles: lvs. pinnate, silvery white beneath, with 5-7 lfts. which are distant, lanceolate or narrowly rhomb-lanceolate, serrate, white-tomentose beneath: fls. about 12, small, pale purple, in a panicle, appearing in Sept.: fr. small (size of a pea), dark red becoming black. Cent. and W. China, 4,000-6,000 ft.

53. thibetanus, Franch. (R. Velthii, Rolfe). A curious deciduous rubus, said by Focke to represent perhaps the type of a well-marked section in the genus: shrub with terete prickly branches and graceful fern-like foliage: sts. at first erect, but arching with age, blue-white: lvs. 6-9 in. long, pinnate, with 5-11 elliptic or ovate coarsely toothed lfts., puberulous or silky-hairy above and white beneath, the terminal lft. ovate-lanceolate or rhomboid and 2-3 in. long and sometimes almost pinnatifid: fls. rose-purple, in terminal few-flowered prickly and pubescent panicles, the orbicular-obovate petals small: fr. globose, red or blue-black, of moderate size. W. China. G.C. III. 51:149.

54. niveus, Thunb. Very strong-growing, the sts. reaching 12 ft. and 6 in. in circumference, with many stiff brown hairs and small spines, arching at the ends: lvs. pinnate, with 3-11 lfts. variable in shape but mostly rhomb-oblong or ovate-oblong, coarsely serrate, whitish-tomentose beneath, the lateral ones scarcely stalked: fls. small, white, many in terminal and axillary panicles: fr. dull black, of medium size. Cent. and W. China, 3,000-8,000 ft. altitude.

55. Giralddianus, Focke. Said to be an elegant bush reaching 8-9 ft. in height, the sts. white, branching and gracefully curving above, terete, glabrous, prickly: lfts. usually 7, the terminal ovate-lanceolate, the lateral oblong-lanceolate, unequally coarsely serrate, glabrous above, tomentose beneath: fls. in terminal panicles, 4-5 in. long, small, white: fr. black. N. and Cent. China. Gn. 76, p. 824. G.C. III. 51:147 (as an unnamed species).

Section VII. EUBATUS. Blackberries and Dewberries.

a. Blackberries: plant usually erect or essentially so (strong canes often recurring and very long ones often repent).

b. Species exotic, with mostly perennial canes, and fls. usually borne on the ends of the main shoots.

56. thrysanthus, Focke. A vigorous species, with suberect or decumbent canes which are prostrate when very long, the strong prolonged sts. angled and
grooved, thorny with flattened declined or curved prickles, mostly thinly hairy or pubescent; petioles and midribs recurved prickly; lfts. 3 or 5, thick, green above and white-tomentose beneath, round-elliptic or round-ovate, the terminal one broad-elliptic or ovate, abruptly pointed, sharply and mostly doubly serrate-dentate: infl. thyrsoid-paniculate, narrow, short or elongated, sometimes compound, densely pubescent or tomentose, leafy; fls. about medium size, white, the small reflexed sepals white-tomentose: fr. black.—Germany, and probably scattered by cult., regarded by Focke as one form of the collective species R. thyrsanthus, Wimm. Inserted here because the plant grown in this country as the Himalaya berry (p. 1492) is perhaps referable to it.

57. Linkianus, Ser. St. angled with many very strong and sharp hooked prickles and mostly finely pubescent: petioles and midribs strongly prickly; lfts. 3–5, oval or elliptic and acute, strongly and mostly doubly toothed, green and nearly or quite glabrous above but white-tomentose beneath: infl. short-paniculate, beset with strong prickles and often more or less leafy, pubescent or tomentose: fls. mostly double, white, the petals oblong and about 1/2–1/3 in. long; fr. black.—Species founded on garden specimens, the native country being unknown. It is said to be sometimes escaped from cult. and occurs now and then on ballast. A similar plant (not double-fid.) occurs under R. bellidiformis, but differs in its very different foliage. This group is much in need of careful study; Focke regards it as one of the forms of R. thyrsanthus. The plant sometimes grown as R. fruticosus flore alboplena and R. spectabilis, Hort. (not Pursh), probably belongs here or with the following.

58. ulmifolius, Schott (R. fruticosus flore rubroplena, Hort. R. bellidiflorus, C. Koch). Sts. or canes reflexed unarmd tomentose sepals and red broad-ovate or suborbicular petals, sometimes double: fr. black. Eu.; sometimes grown for its evergreen foliage and in the form with double red or pink fls.

59. laciniatus, Wild. (R. fruticosus var. laciniatus, Hort.). CUT-LEAVED or EVEIWREEN BLACKBERRY. Fig. 3499. A tall, straggling bush with permanent or perennial canes in mild climates, and lvs. more or less evergreen, the sts. provided with recurved prickles: lfts. 3, broadly ovate in general outline, cut into several or many oblong or almost linear sharply toothed divisions, the ribs prickly below and the petioles strongly so: fls. in terminal panicles, white or blush, the calyx and pedicels pubescent or even tomentose: fr. usually thimble-shaped, late, black, often excellent. Gn. 21, p. 57; 45, p. 78. G.M. 49: 765.—This blackberry is probably native to Eu., where it has been long known in gardens. It is apparently only a cut-lvd. form of the European R. vulgaris, Welw. & Nees. It is now widely scattered, and seems to thrive particularly well in Hawaii and other Pacific islands and on the Pacific slope. By some it is supposed to be native to the South Sea Isls. (see Bull. 64, Utah Exp. Sta.). It is probable that the plant has been intro. into the W. from those sources, but such fact does not prove its original nativity. It has aroused considerable attention in Ore. and other parts of the W., and has been known as the Oregon Everbearing blackberry. In mild climates the lower parts of the canes often live from year to year until they become as thick as one’s wrist; and in such climates the lvs. persist for the greater part of the winter. The plant has long been grown for ornament in the eastern states, but it has not attracted attention as a fr.-plant in this region. The fruits are of fair size and quality, and ripen from midsummer or late summer to Oct. The plant is a good ornamental subject, although it is likely to cause trouble by sprouting at the root.

BB. Species-group of native American origin, with essentially biennial canes: fl.-clusters from lateral shoots as well as terminal.

60. Cultivated American blackberry. A large group of confused or at least undetermined origin, developed within 50 to 75 years from native American species: mostly erect and thorny plants, the canes commonly tall and more or less recurving at the ends: lfts. 3–5, from ovate-acuminate to rarely nearly
broad-lanceolate, usually pubescent and hairy on the ribs beneath; infl. on elongated raceme-like cluster of which the center or terminal fl. is commonly the oldest (the long-cluster blackberries), or nearly as broad as long, due both to shorter axis and longer lower pedicels (short-cluster blackberries), sometimes with small lvs. intermixed (leafy-cluster blackberries), the rachis and pedicels usually glabular-pubescent but in some forms nearly or quite glabrous: fr. various, from long and thimble-shaped to ovoid or nearly globose.—The more or less well-recognized wild native species-types, variously defined and re-defined, from which some or all of the prevailing pomological blackberries are probably derived, are as follows: R. argittus, Link, an erect or prostrate plant, usually not over 3-4 ft. tall, the prickles many, mostly hooked, and very strong, the young growths white-tomentose; lfts. on bearing canes mostly small and thick, wedge-oblong to wedge-obovate, obtuse or nearly so, densely white-tomentose beneath, the margins sharp-toothed: fl. clusters 4-10-fl., short, more or less leafy and thorny, the fl.-buds globular and pubescent: fr. medium in size, firm, often sweet and good. See discussion under R. Lankians, No. 57.

a. Dewberries: plant trailing or strongly decumbent (often trained to stakes or on trellises under cult.):—The pomological dewberries of the American origin.

61. Cultivated American dewberry. A variable group of American origin, from the native species: trailing or prostrate plants, the weak slender canes lying on the ground or sometimes making low mounds, mostly prickly or thorny: lfts. usually 3: infl. short and mostly interrupted or leafy, or the fls. axillary, pubescent or glabrous: fr. blackberry-like.—The wild thornless blackberry, R. cuneifolius, Pursh, growing in dry fields from Conn. to Fla. and La., appears not to be in cult. or to have contributed to the admixture of the garden blackberries. (Fig. 581, Vol. I.) It is a stiff and thorny plant, usually not over 3-4 ft. tall, the prickles many, mostly hooked, and very strong, the young growths white-tomentose: lfts. on bearing canes mostly small and thick, wedge-oblong to wedge-obovate, obtuse or nearly so, densely white-tomentose beneath, the margins sharp-toothed: fl. clusters 4-10-fl., short, more or less leafy and thorny, the fl.-buds globular and pubescent: fr. medium in size, firm, often sweet and good. See discussion under R. Lankians, No. 57.

RUBUS 3031

3500. Rubus allegheniensis (X3). No. 60.

3501. Rubus procumbens, a common northern wild dewberry (X3). No. 61.
increased by the fact that the same plant may bear 3
medium size, mostly on simple, more or less pricky
toothed, the petiole and midribs usually prickly: fis. of
pointed, rather shallowly and sometimes bluntly
seldom that the lvs. of sterile and flowering shoots of
armed with prickers and sometimes bearing reddish
bristles: lfts. usually 3, narrow-ovate to oblong, short-
over winter and remain at flowering-time; the small ivs.
the canes that are to bear fr. and which often persist
the young verdurous sterile shoots; the smaller lvs. on
the canes that are to bear fr. and which often persist
the vigorous shoots usually 3-foho late: fis. white, the
petals of staminate fis. about 1⁄4 in. long and of
the pistillate fis. or less: fr. black, mostly oblong,
sweet, the drupelate pubescent. Calif., along streams
and moist places.—A perplexing species, by some sepa-
rated into two: R. vitifolius, with lvs. sparingly pubes-
cent on both surfaces and glabrate with age, the
st. only slightly hairy, fr. distinctly longer than
broad, lvs. on vigorous shoots often unifoliate;
and R. ursinus, Cham. & Schlecht., with st.
and lvs. densely pubescent beneath and fr. only
slightly elongate. Certain horticultural dew-
berries appear to be of this species, but they
are of minor importance. The loganberry (which
see, p. 1900) is said to be a hybrid between this
species and probably R. ursinus, but the botanical
origin of it is by no means clear. The Phenomenal is said
also to have sprung from R. vitifolius through hybridization
(p. 1900). The Mammoth black-
berry of California is said to be a cross between R. vitifolius
and the wild blackberry of
Texas (R. arguta). See Pacific
Rural Press, Sept. 4, 1897, for
description and portrait. The
account says that the Mammoth
"produces berries of immense
size, supposed to be the largest
peduncles: fr. usually oblong, sometimes ex-
cellent but often dry and seedy. From Va.
to Fla. and Tex., and in cult. in two or
three forms for its fr.—This is the common
wild dewberry or running blackberry of the
southern states, often a serious pest in old
fields, ranging as far north as Va. and west
to Okla. What are apparently forms of this
species have been intro. for cult. for the fr.
in the southern states.

BBB. The swamp dewberry, with mostly
pubescent lvs. and fis. often imperf rt:
species variable.

BBB. The southern dewberry or running
blackberry.

62. hispidus, Linn. (R. obovatus, Michx. R. sempervirens, Bigel.). Fig.
3505. Sts. very slender, scarcely woody but usually persisting over winter,
creeping, bearing many weak reflexed small bristles: lfts. usually 3, thick,
shining above, wedge-obovate or oval-obovate, usually obtuse, doubly ser-
rate: fis. small, white, on few-fld., herbaceous nearly or
quite leafless peduncles arising from
the creeping canes: fr. small and of few
drupelates, red to red-
black, sour. Swamps or low sandy soils,
Nova Scotia to Ga.
and Kans.—Of no
value for fr., but
sometimes offered by
dealers for covering
the ground in moist
places. The lvs. usu-
ally persist through
the winter, and in
sunny places they
assume a fine bronzy
hue.

BBB. The swamp dewberry or running
blackberry.

63. trivialis, Michx. SOUTHERN DEWBERRY. A variable
and perplexing species, the difficulties being
increased by the fact that the same plant may bear 3
kinds of lvs.: the large, broad blackberry-like lvs. on
the young verdurous sterile shoots; the smaller lvs. on
the canes that are to bear fr. and which often persist
over winter and remain at flowering-time; the small lvs.
that appear with or somewhat before the fis. It is
seldom that the lvs. of sterile and flowering shoots of
the same plant are preserved in herbaria. Canes very long,
usually wholly prostrate (sometimes 10–15 ft.), thickly
armed with prickles and sometimes bearing reddish
bristles: lfts. usually 3, narrow-ovate to oblong, short-
pointed, rather shallowly and sometimes bluntly
toothed, the petiole and midribs usually prickly: fis. of
medium size, mostly on simple, more or less prickly

BBB. The southern dewberry or running
blackberry.
blackberry ever grown, berries 2½ in. in length being frequently found. . . . The canes of the Mammoth are very peculiar, being very large and thickly covered with small, short spines. The canes start early in March, grow thick and stout until about 5 ft. high; they then take on a running habit and grow from 25–30 ft. in a season. Late in the fall the tips of the canes seek the ground and take root. ’The Mammoth is partially evergreen in Calif. The fr. is said to be more acid than the old Lawton blackberry, but “when perfectly ripe is sweet and of superior flavor.”

65. *macropétal us*, Douglas (R. *myricacínthus*, Douglas). By many writers combined with *R. vitífolus*, but differs in its glabrous fr., always terean lvs. which are green and sparingly hirsute on both sides, and larger lfts.: it grows in low woods and on stream-banks from N. Calif. to Idaho and Brit. Col.: sts. trailing or scandent, slightly hairy or glabrate, with weak prickles, and prickles on the petioles and midveins: terminal lft. broad-ovate, subcordate, doubly serrate, often somewhat lobed, acute or acuminate; lfts. ovate: infl. slightly glandular, weak-prickly; lfts. white; petals of staminate lfts. about ½ in. long and those of the pistillate somewhat shorter: fr. half-globular or slightly elongate, black, sweet, about ½ in. long.

**The exotic dewberry, with long prickly glaucescent canes and large very sharp-toothed lfts.**

66. * dumetum *, Weihe. Fig. 3506. Canes long and slender, terete, often 10–25 ft. long, trailing or half-prostrate, glaucescent, thickly beset with rather small somewhat curved spines: lfts. usually 3, mostly broad-ovate pointed to acuminate, irregularly sharp-toothed, becoming bronzy and brown in autumn: lfts. small, white, the calyx white-tomentose, on short pedicels in a cluster terminating leafy growths of the season: fr. of a few large black drupellets. Eu.—Intro. for the covering of banks and stony places, for which it is highly recommended. Its autumn color is attractive. Hardy in New England.

**RUBUS** (after the two Professors Rudbeck, father and son). *Compáctus*. Cone-Flower. Very attractive summer-blooming perennials or biennials, usually with yellow flowers.

Leaves usually alternate, the blades undivided or in some species much cut, as in the common Golden Glow: lfts. both tubular and ray-like, the former usually purplish, the latter always yellow; involucre hemispheric, its bracts imbricated in 2–4 series; receptacle conic or very rarely convex, with chaffy concave scales subtending the disk-fls.; disk-fls. perfect, fertile, their corollas 5-lobed; achenes 4-angled, obtuse or truncate at the apex; pappus none or of 2–4 short teeth.—There are about 31 species, not counting Echinacea, all of N. Amer. Of these scarcely a dozen are of horticultural importance. Under Rudbeckia are often included in nursery catalogues certain plants here referred to Echinacea and Lepachys. These three genera form an interesting horticultural group. Rudbeckia and Lepachys are typically yellow-flowered genera, while Echinacea is predominately rose-purple-flowered. The chaft of the receptacle is usually persistent in Rudbeckia and deciduous in Lepachys. Among the hardy herbaceous species, there are several with striking habit and distinct foliage. There is a wide range of color in the rays of wild plants and many new races are yet to be perpetuated. Some of these with variations in the shape, color, length, color of disk-fls., and so on may serve as the basis of many fine forms. The season of bloom could doubtless be extended. The only full double form, apparently, is the Golden Glow, one of the best perennials of recent intro. Its origin is uncertain, but it appears to be a form of *R. laciniata*. About 1840 John Lewis Childs found it among some plants sent by correspondents. See Gg. 6:370. For structure of the Rudbeckia inflorescence or head, see Vol. III, Fig. 1535.

The cone-flowers are of easy cultivation in almost any soil and situation, from a semi-shady position to one in full sun. Most of the species are found inhabiting moist locations, but thrive well in the garden under the ordinary methods of cultivation, although *R. laciniata* and its double form, Golden Glow, do much better if abundantly supplied with moisture. *R. hirta*, the black-eyed Susan,—sometimes called by the children out West “nigger-heads,”—will thrive in the driest hottest situation, where many others would fail. The best known as a garden plant, and probably the sweetest, is Golden Glow. If cut back severely when through blooming and well watered, it often produces a second crop of flowers. Autumn Glory will be well liked when better known. It is fine for masses and has a much longer blooming period than Golden Glow, commencing earlier and continuing until frost. It resembles *R. nitida*, an improved form of which, known as Autumn Sun, with bright primrose-yellow flowers, is a splendid acquisition. It grows 2 to 6 feet high, blooming from August to October. *R. triloba* is one of the very best, and, while a biennial, perpetuates itself through self-sown plants. It forms a dense twiggy bush somewhat over 3 feet high and nearly as broad if kept moderately well watered, and much smaller if in a dry situation. These plants may be used with effect as a border to a large bed of hybrid delphiniums, as the latter will tower above them and bloom in their young state. By the time the delphiniums are cut down for their second flowering, the rudbeckias hide their untidiness and are in their prime. The flowers are somewhat like those of the ordinary field black-eyed Susan, but smaller, and much more numerous. While doing best in full sun, they also do remark-
RUDBECKIA

ably well in semi-shade, as under overhanging shrubs or in shady corners such as the north side of a house would afford. They like a good open soil. When grown in the open with one stake to the center or main stem, and a string run loosely around the whole plant—being, in fact, a string hoop—catching the larger outer branches to prevent breakage by the wind at the connection with the main stem, they make a very handsome compact plant. If well soaked at the roots, they may be taken up when in full bloom, and potted in a 10-inch pot, placed in a dark sheltered place over night, and then used for decorative purposes. They remain in good form for a month in a room or on the porch if not in a draft. They may also be taken up carefully and all the soil washed from the roots, and the roots placed in a large vase filled with water, where they present a bouquet arranged as Nature intended. An effective fall-flowering group may be formed by using the lighter colored flower forms of *Hibiscus syriacus*—such as *Totus albus*, Lady Stanley, and *elegantissima*—for a center or background, and interspersing groups of the taller rudbeckias (except *Golden Glow*, which is too tall and spreading) and boltomias next to them. In front of these place *R. speciosa* and *R. triloba*, with the blue form of *Aconitum Napellus*, and for a border use *R. bicolor* var. *superba*, placed well to the front to be pulled up when its bloom is past. This group will give color from July until frost. The allied *Echinacea purpurea* and *E. angustifolia* are well adapted for grouping in open bays in shrubby borders, as their flowers are extremely durable and seem in harmony with such surroundings. Rudbeckias are easily increased by seeds, cuttings, or division. (C.W. C. Egan.)

INDEX.

| a. Base of upper lvs. cordate-clasping. |
| b. Color of disk brown or dark purple: shape of disk never cylindrical. |
| c. Lower lvs. deeply 3-cut. |
| d. Duration biennial: disk black-purple. |

cc. Lower lvs. not deeply 3-cut.

d. Plants bristly hairy.

e. Rays 1–2 in. long.

dd. Plants nearly glabrous.

e. Lvs. mostly entire.

dd. Duration perennial: disk dull brownish.

3507. Rudbeckia triloba. (× 34)

3508. Rudbeckia laciniata. (X nearly 3/4)
**Rudbeckia**

Hort., is a dwarf compact-growing form. Var. variabilis, Hort., is a form growing about 3 ft. high, with numerous rigid sts.; fls.-heads with yellow and brown ray-florets and dark purple disk-florets.

**EE.** Les. irregularly serrate.

8. nitida, Nutt. This and the next are southern perennials, with lvs. entire or barely dentate; rays drooping, pure yellow, several or numerous; disk finally columnar, 1-2 in. long. Wet ground, Ga. to Fla. and Texas. Gn. 47:201.

10. laciniosa, Linn. (R. maxima, A. Nels.). Fig. 3508. Perennial, 2-7 ft. high; lower st.-lvs. 3-5-parted, upper ones 5-cleft, rays yellow, few or several, soon drooping; disk cylindric in fr. Most ground, Canada to Fla., west to Mont. and New Mex. G.F. 2:281 (adapted in Fig. 3508). Golden Glow is a full double form, 2 1/2-3 1/2 ft. high. Gg. 3509. Gns. 5:5, 117; 6:370. A.F. 12:274, 275. Ga. 50, p. 411; 62, p. 305. G.C. III. 20:339.
**RUÉLLIA**

cc. Fls. rose, 2-6 in. long.

macràntha, Mart. It forms a compact, many-stemmed shrub, 1-6 ft. high, with ovate-lanceolate lvs. 4-6 in. long; fls. large, bell-shaped, with tubular ñææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææææ æ
when in fr., glabrous: root-lvs. (Fig. 1336, Vol. II) elliptic-ovate, tapering both ways, the margins undulate, the blade 8-12 in. long; st.-lvs. ovate-lanceolate, long-acuminate, more or less rounded at the base: infl. long and compound (often 2 ft. long), dense in fr.; wings of theтвержда across, veiny, entire, one of them bearing a small tubercle near the base. Eu., but naturalized in π many places.—An excellent plant for greens, the strong root-lvs. being used in early spring.

crispus, Linn. CURLY DOCK. YELLOW DOCK. Tall, often 3-3½ ft.: lvs. long-lanceolate, wavy-margined, rounded at the base; valves entire, the tubercles usually 3, the infl. not leafy. Naturalized from Eu., and now one of the common docks about yards and in old fields.

—Not cult., but the lvs. sometimes used for greens.

obtusifolius, Linn. BITTER DOCK. A common weed: lvs. much broader, very obtuse or even coriaceous at base, obtuse at apex, not wavy-margined: valves long-tubercled, the tubercle usually 1, the infl. somewhat leafy below. Eu.

RB. Wings of calyx not tubercle-bearing.

venosus, Pursh. Perennial, 1½ ft. or less tall, glabrous, branched: lvs. oblong-ovate or ovate-lanceolate, usually tapering at both ends, entire, the stipular sheath (ochraceous) funnelform and prominent: valves of fr. large and thin, entire, 1 in. or more across, red-veined and showy, the pedicels hanging in fr. Mo., north and west.—Once offered as an ornamental plant because of the very showy wide-winged fruiting calices. Eu., Madeira, and Caucasus. The foliage of this species, New S. Wales. The genus is closely allied to Epacris.

Hydropapathum, Huds. GREAT WATER-DOCK of Great Britain and elsewhere in Eu., a stout perennial 4-6 ft. high, with very large lvs., sometimes planted for bold effects along water-courses: lvs. broadly oblong-lanceolate to lanceolate, sometimes 2 ft. long, tapering below but the base often somewhat rounded, acute at apex, the margin entire: pedicile very large, with rather crowded mostly leafless whorls, the fruiting pedicels jointed near the base and equaling or exceeding the sepal: valves broad, nearly entire, all tubercle-bearing.

Hydrophilum, Britton. GREAT WATER-DOCK of Eu., a stout perennial, 2-3 ft. high, with large lvs. (Fig. 3511) composed of lvs.-like branches or cladodia which are alternate, leathery, persistent, and spreading; the tubercle, usually 1, the infl. large and ample, the larger part of the fr. sterile (plant sometimes dioecious): valves entire or very pearly so, not over ¼ in. across, cordate-ovate, each with a callosity near the base, the outer small scales reflexed. Eu. and Asia, naturalized in some places in this country.

—Useful for early spring greens, but later in foliage than R. Patientia.

Rupicola (named for F. F. Runge). Acaenthacea. Creeping, diffuse or erect herbs, glabrous or villous; warmhouse plants: lvs. entire: spikes cone-like; bracts in 4 ranks (whereof 2 alternate are sterile), much larger than the calyx, broad with prominently scarious margins; calyx 5-parted, segments acuminate; corolla-tube short, straight, limb 2-lipped, posterior lip entire or 2-toothed, anterior often longer, spreading and 3-cleft; staminodia none; disk annular or short-cup-shaped; caps. ovoid or oblong.—About 30 species in the warmer parts of the Old World. R. eriostachya, Hua. St. pubescent: lvs. ovate-lanceolate, 2-3 in. long: fr. white and yellow in crowded racemes, the barbs and calices covered with long white hairs. Trop. Afr.

Rupicola (Greek rock and grower, presumably referring to its place of growth). Eparidaceae. Shrub: lvs. small, short-petioled, solitary in the axil of the bracteate pedicels which are shorter than the fr.; calyx-lobes 5; corolla 5-cleft, with a very short tube and with spreading divisions which cover themselves in the bud in the form of a quincunx; ovary 5-celled, with numerous seeds.—One species, New S. Wales. The genus is closely allied to Eparica. R. sphenoglandulosa, Maiden. Shrub 2½ ft. high with twiggy branches: lvs. linear-lanceolate ½-1 in. long, rigid: fls. solitary, axillary, forming a raceme-like leafy inf. with a barren apex; corolla subulate, almost ½ in. across, milky white; segments, ovate. B.M. 8435.

Ruscus (an old Latin name). Lithocereus. BURCHET'S BROOM. Erect shrubs with branched partially woody stems, hardy in southern Europe and the southernmost United States.

Leaves minute, bract-like, on lf.-like branches (cladodia) which are alternate, leathery, persistent, and sessile: fls. small, fasicled in the middle of the upper, rarely lower surface of the cladodia, diclinous; berry globose, pulpy, and indehiscent.—Three to 5 species, Eu., Madeira, and Caucasus. The foliage of this plant (Fig. 3511) is composed of lf.-like branches or cladophylls, as in the florists' smilax. D.V., blanched, and 3037
colored sprays (mostly dyed red) are now much used in florists' decorations.

aculeatus, Linn. Shrub, 1 ½-3 ½ ft. high; phyllodia ovate-lanceolate, ½-1 ½ in. long, tapering into a spiny point: fls. 1-2, short-pedicelled: berry red, ½ in. thick. Spring. Gn. 34, p. 291. R.H. 1984, p. 343.—Cult. in Fla. and S. Calif.

R. androgynus, Linn.—Semele androgyna, Kunth.—R. Hypoglossum, Linn., has been highly commended in Germany as a decorative subject. This is the same as R. Hypophyllum, Linn., are both natives of S. Eu., where they have been studied by several botanists, some of whom distinguish them by various characters, while others unite them into a single species. J.G. Baker considers R. Hypoglossum a variety of R. Hypophyllum, differing in having the young shoots elongated in the cluster of fls. in the form of a large leafy bract lacking entirely the texture of the phyllodium. In B.M. 1919, R. Hypophyllum is shown with minute white fls. and handsome red berries nearly ½ in. thick.—R. racemosa, Lam.—Danae racemosa, Moench.

F. TRACY HUBBARD.

RUSSELLIA (in honor of Alexander Russell). Scrophulariaceae. Shrubs with angled, usually slender, and often pendulous branches, grown in the warmhouse for their showy flowers. Leaves opposite or verticillate, usually small, reduced to scales on the branches: fls. in bracteate dichotomous cymes, either laxly or densely many-flowered, sometimes solitary, or becoming minute bracts on the branches: raceme very loose, remotely fl-d.: peduncles elongated. B.R. 1773. P.M. 4:79. G.W. 5, p. 379. Var. semperflorens, Hort., has been mentioned. Gt. 1:5.

Lemoinei, Hort. (R. junccea var. Lemoinei, Hort.), is a garden hybrid between R. junccea and R. sarmentosa, said to be more floriferous, especially during the winter, than the parents.

elegantissima, Hort. (R. junccea var. elegantissima, Hort.), is another product of the same cross as the above and said to have similar characters.

AA. Peduncles many-fl.d.

F. TRACY HUBBARD.

RUSTS. The plant rusts are fungi constituting the large and well-defined order Uredinales, which contains approximately 3,000 species distributed in about forty genera. They are all obligate parasites, mostly on angiosperms, few on gymnosperms, and a small number on ferns.

Relations between host and parasite.

The mycelium of the rust fungi (see Puccini) lives symbiotically within the tissues of the host. It is generally confined to the intercellular spaces, but short branches or haustoria penetrate the cells and absorb nutrient from them. Usually not more than one or two haustoria are found within a single cell and only a small proportion of the host cells are thus invaded, although the mycelium itself is abundant in the intercellular spaces.

The extent to which the mycelium spreads within the tissues of the host and its duration of life vary greatly with different species of rusts. In most of the species which inhabit annual parts of plants, as leaves and stems, the mycelium resulting from individual infections is localized within a more or less restricted area, as in case of hollyhock rust, carnation rust, and wheat rust, and generally persists as long as the infected parts remain alive. That plants thus infected nevertheless become completely covered with rust spots is attributable to the large number of separate infections which occur and not to the spreading of the mycelium through the whole plant. When biennial or perennial parts are locally infected, the mycelium often persists for two years, as in the rust of the red cedar, Gymnosporangium globosum and G. juniperi-virginianae, and becomes perennial, as in the rust of juniper, Gymnosporangium clavaria-forme, and the blister rust on sycamore, Pseudopeziza vulgaris. Many rusts have mycelia which extend throughout the tissues of the host. This type of mycelial distribution is characteristic of the orange rust of the species of brambles, Gymnocoronis interstitialis, and of a number of rusts infecting herbaceous perennial plants, as the rust of Canada thistle, Puccinia suaveolens and the pea rust (Uromyces pisii) on the cucumber spurge (Euphorbia Cyparissias). In such cases the mycelium of the fungus remains dormant in the rhizomes or in the roots and in spring grows out into the developing shoots which are usually characterized by splitting growth with long internodes and small and somewhat deformed leaves. Shoots which are normally trailing or prostrate and branches which are naturally horizontal tend to become erect. This effect is sometimes observed in annual plants also, as in the case of Euphorbia maculata infected by Uromyces euphorbiae. Blackberry canes growing out from roots infected by Gymnomaenia resembles the characteristic growth described above, are free from thorns.

In spite of the intimate association of rust fungi with their hosts, very little apparent injury results to the...
RUSTS

Plants during the vegetative growth of the parasites. Deformations of various kinds are common in plants attacked by these fungi. Aside from those described above there is in many cases a marked stimulation to abnormal growth which results in the formation of galls, as the well-known cedar apple rust, or in enlarged and distorted flowers, fruits, and branches, or in the production of witches' brooms. The greater number of rusts, however, do not cause any abnormal deformation of their hosts, and the presence of the fungus is usually not evident until the time of spore-production, although it may be assumed, and is sometimes apparent, that the plants have been weakened or retarded in growth, particularly when the mycelium is widely dispersed in the tissue. At the time of spore-production, the injury to the host becomes unmistakable. The spores are produced in pustules beneath the epidermis. This is finally ruptured and the spores break forth forming the characteristic orange, brown, or black spots and patches to which these fungi owe their name. The injury is brought about both by the withdrawal of nutrient from the host cells and by the extensive destruction of the epidermis of the host and the resulting loss of water from beneath. The magnitude of the injury differs with the extent to which the plant is infected. Plants which are severely infected often lose their leaves, which wither and die prematurely. In annual or biennial plants this injury hastens the death of the plant, as in the hollyhock and the cereals, or, as in greenhouse carnations, impairs their vigor to such a degree that the plants are of little commercial value. In perennial plants like asparagus, the yearly injury of the assimilating parts results in the slow weakening of the plant and finally in the death of the plants. Apple trees are frequently defoliated as a result of infection by the cedar rust (Gymnosporangium). In plants grown for crops, whether flowers, fruits, or other parts are sought, these injuries diminish the yield, but in ornamentals the mere presence of the fungus can be considered sufficient damage. Rust fungi do not attack various plants indiscriminately. In general, each morphologically distinguishable species is confined to one or to a relatively small group of closely related host plants. Nevertheless, the degree of adaptation to particular hosts varies much with different species of fungi. Some species are truly plurivorous. A striking example of this habit is furnished by the hollyhock rust (Puccinia malvacearum) which inhabits about forty species belonging to many different genera of the subfamily Malvae, and passes readily from one host to another. Many rusts which are apparently plurivorous have been found on closer investigation to be divisible into a number of so-called biological or physiological races, each of which is restricted to a comparatively small group of host plants. This type is illustrated by the common cereal rust (Puccinia graminis): This occurs on all the common cultivated cereals and on about 180 species of wild grasses. The forms on the different hosts are not morphologically distinguishable but culture experiments with this rust on the cereals and the common grasses have shown that it falls into a number of biological races each of which is more or less restricted to a small group of host plants, and cannot readily be transferred to plants outside of that group. Thus the form on barley infects also orchard grass and a few other grasses, but not wheat, rye, or oats; the form on rye infects also barley and some other grasses, but not wheat; and the form on wheat infects less readily barley, oat, rye, and some other grasses. This type of specialization is very common and occurs in many species which have a wide range of host plants. The separation into physiological races is not always sharp and clear-cut and often a transfer of a race from one host to another can be accomplished by so-called bridging species of host plants, i.e., species which act as a common host to two races of rust. It appears also that the degree of specialization of different forms is not the same in different geographical regions. It is readily seen that the matter of specialization of rusts is one of considerable economic significance. In the case of truly plurivorous species of rusts, many wild plants may be the source of infection for cultivated plants. Thus the hollyhock is easily infected from Malex rotundifolia and other Malva; but, in the case of species which, like the cereal rust, have become differentiated into a number of physiological races, there is comparatively little danger of infection from wild plants unless the host on which each host has become more or less strictly adapted to its particular host. Thus, for example, different members of the pink family are inhabited by the carnation rust (Uromyces carophylli) but each genus has its own physiological race which does not infect the members of other genera of the family. The specialization of rusts to particular hosts has also another economic bearing. When a given rust is restricted to one or more species of a genus but does not infect the others, these are said to be immune and there are numerous instances in which there may be immune varieties within a species, as the phrases "disease-resistant cowpeas," or "rust-resistant carnations," indicate. This fact, that the cultivated varieties of a given plant may show various degrees of resistance, furnishes the basis for the breeding of immune varieties, which is one of the most promising means of overcoming the danger from attacks of rust.

Remedial measures

Of the various groups of fungi, the rusts are the most difficult to combat. For most forms, especially those infecting cereals and other agricultural crops, no satisfactory methods of control have been developed since the usual methods of disease-prevention are either unprofitable or not applicable here. Even with horticultural crops, direct remedial measures have proved successful only in a few cases, as with the apple rust, which can be successfully controlled by spraying with Bordeaux mixture. Various mixtures, such as copper sulfate (one pound to fifteen gallons of water) and potassium sulfide (one ounce to one gallon), have been recommended and tried for carnation rust, but the growers are far from being in accord as to the effectiveness of these remedies. Environmental conditions have much to do with the prevalence of rust. Thus the severity of outbreaks of asparagus rust and probably of other rusts also is dependent on the environment in which the host is growing. In greenhouse it has also been found that the environment has much to do with the presence of rust on carnations and chrysanthemums, and that the maintenance of the best cultural conditions is one of the surest means of controlling rust on these plants. This method of control is, however, applicable in the field only in a restricted degree.

While the methods of direct control of rusts have not on the whole proved very successful, the indirect method by the breeding of resistant varieties seems to offer the most promising solution of the problem. Although the so-called rustproof varieties of plants have not generally proved to be entirely resistant, yet different degrees of resistance have long been noticed by growers, and varieties particularly susceptible to rust have been gradually eliminated. The history of the carnation rust in the United States probably furnishes an illustration of this process. Twenty years ago horticultural literature was replete with discussions of the carnation rust and its control; today, however, there is no mention of this disease. At that time much was written of "rustproof" varieties, and mention is frequently made of varieties thrown out on account of rust. At the present time the rust once regarded as the "most dreaded of the carnation diseases" attracts but little attention, and within
the last few years has been scarcely mentioned in florists' journals. That a part of this result at least is due to the gradual elimination of susceptible varieties cannot be doubted, but the fact should not be overlooked that the seriousness of the early rust invasion may have been exaggerated, for even then conservative men felt impelled to warn against the agitated state of mind which caused growers to see rust in every discolored leaf. (McBride, Am. Pho. 8 p. 390, 1893; Herr, ibid. p. 980.)

**Botanical features.**

Botanically the rusts are of great interest because their life-cycle consists typically of two distinct generations. These are technically known as the gametophytic generation and the sporophytic generation, but for simplicity they may be designated respectively as the acellular stage and the telial stage, terms derived from the names of the principal spore-producing structures which characterize the two phases. Each of these generations may produce one or more spore forms. The life-cycle of a rust is best understood by means of an example. One of the most familiar is the wheat rust. If barley bushes in the neighborhood of wheat-fields are examined in spring (May and June), there will usually be found on some of the leaves yellowish spots. Within the discolored area, on the under side of the leaf, there are a number of small cup-like openings with fringed margins. (Fig. 3513.) These are termed acidia and from them yellow acinacoids, which can be seen scattered like dust around the cups, are discharged. About the same time or a little earlier, flask-like pycnidia break through the epidermis on the upper side of the leaf. These discharge minute spore-like bodies whose function is not known. They do not infect either the wheat or the barley. The acinacoid is incapable of reinfecting the barley. They can infect only the wheat and a few other grasses susceptible to this particular biologic race. On the wheat the germ-tubes of the acinacoids penetrate the stomata of the leaf and stem and produce local colonies of mycelium which gives rise to uredospores (Fig. 3514). These are one-celled spores which are produced in many generations and which serve to propagate and spread the fungus during the summer. To them the rusty appearance of infected grain-fields is due. They can infect only wheat and the other gramineous hosts of the fungus but not the barley. Toward autumn the same mycelium which produces uredospores during the summer gives rise to uredospores. These occur as black streaks and patches on the stems and leaves, upon which they remain during the winter. In spring the uredospores germinate in place and produce short germ-tubes termed promycelium from which four minute sporia are apportioned. The sporia are borne away by the wind and when they alight on the blackberry the acidia are again produced. The sporia do not reinfect grain.

Puccinia graminis represents the complete life-cycle of a rust of the most complex type. Rusts of this character, which alternate regularly between two hosts, are said to be heteroecious. Those which produce acinacoids on the same host on which the other spore forms are borne, are said to be autecious. Not all have the entire complement of spore forms, one or more of which may be dropped from the cycle. Thus, neglecting the pycnospores which, so far as known, have no significance in the life of a rust fungus, the red cedar rust (Gymnosporangium) has only acinacoids which germinate immediately or which may survive the winter and reinfect plants in spring; the blackberry rust (Gymnoconia) has only acinacoids which germinate like teleutospores. Many rusts, like some of the grain rusts, are able to maintain themselves by means of uredospores which are capable of enduring the winter. The occurrence of persistence of spore forms must be considered as a special and accidental adaptation to particular conditions, for it is not likely that any form of rust has become permanently reduced to the uredospore stage since this is merely a propagative spore-form of little morphological significance. Continuous uredospore production is likely to occur where plants are kept uninterrupted in a growing condition like carnations in greenhouses, or fig trees and species of Vitis in tropical and subtropical regions. Under such conditions teleutospores are produced with comparative rarity.

**Some common rusts.**

The following are some of the common rusts on horticultural plants:

*Uromyces carpophyllinus*, the common carnation rust, occurs on several members of the pink family but is known in America chiefly in its uredo stage on the carnation upon which teleutospores are also sometimes found. Different physiological races occur on various members of the pink family, some of the European forms on tanacies and on saponaria have acidia on *Euphorbia Herbaceana*, but in America the acellular stage of the race on *daucus* is not known. The presence of the fungus is indicated by the appearance of lead-colored pustules which appear first on the lower leaves and stems of the plants. The pasty seen yellow and discolored pustules which are produced late in the season sometimes survive the winter, but in the northern states the fungus lives through the winter and reinfects the plants in spring; the blackberry rust (*Gymnoconia*) has only acinacoids which germinate like teleutospores. Most rusts, like some of the grain rusts, are able to maintain themselves by means of uredospores which are capable of enduring the winter. The occurrence of persistence of spore forms must be considered as a special and accidental adaptation to particular conditions, for it is not likely that any form of rust has become permanently reduced to the uredospore stage since this is merely a propagative spore-form of little morphological significance. Continuous uredospore production is likely to occur where plants are kept uninterrupted in a growing condition like carnations in greenhouses, or fig trees and species of Vitis in tropical and subtropical regions. Under such conditions teleutospores are produced with comparative rarity.

*Uromyces appendiculatus*, on bean, cowpea and related genera, sometimes causes damage but not commonly. *Epicoccum nigrum* produces on the leaves, teleutospores mostly on the stems, on which they remain during the winter. The infected material should be destroyed.

*Uromyces pisi* produces its uredospores and teleutospores on the pea. The sporia produced by the teleutospore infect the dormant buds of the subterranean shoots of *Euphorbia Cupaniana* in which the mycelium becomes perennial. From the infected thionemes deformed shoots arise, on the leaves of which acidia are borne.

*Puccinia asparagi* has all its spore-forms on *Asparagus officinalis*. This is the most serious parasite of the garden asparagus. It was first noticed as a menace in the eastern United States in 1896. It has since spread over the entire country. As a result of its ravages the system of asparagus-growing has been greatly modified in some regions while in other sections the commercial cultivation of asparagus has been practically abandoned. The palmetto varieties appear to be somewhat resistant to the disease. Sprays of sulfur-soda soap, and of bordeaux mixture, and dusting with sulfur in dry regions have proved more or less successful. Ornamental species grown in the United States are not affected by this rust.

*Puccinia graminis*, the black rust of cereals and grasses, while of great importance agriculturally is of little value from a systematic point of view. It is of interest to horticulturists, however, for the reason that the acellular stage sometimes disfigures the leaves of *Berberis vulgaris* planted for ornamental purposes.

*Puccinia malvacearum*, the hollyhock rust, has only teleutospores which are produced in successive generations. The teleutospores produced during the summer germinate immediately or which may survive the winter and spread the rust. In regions where the winter is not too severe, those produced late in the season sometimes survive the winter, but in the northern states the fungus lives through the winter in the mycelial stage in the stems and petioles of *Malus domestica*, on which developing sets can be found during the entire season. Destruction...
of wild hosts and of diseased portions of plants is a partly successful method of control.

Puccinia chrysanthemi, the chrysanthemum rust, is known in the United States chiefly in the uplands on chrysanthemums of which only some varieties appear to be susceptible. The rust rarely produces serious damage, and is readily controlled by the elimination of susceptible varieties.

Gymnosporangium lasiospermum, cedar rust, apple rust. The telial stage produces the galls known as cedar apples on the red cedar. After rains in the fall the teliospores ooze from the galls in the form of horn-like gelatinous masses, an inch or more in length. They germinate in place and the spordia infect the leaves and fruits of the apple on which the telial stage is produced. No appreciable damage is caused to the cedar, but apple trees are sometimes defoliated by this rust and the damage to orchards is often extensive where cedar trees are abundant. Removal of cedar trees prevents the occurrence of this rust on the apple. The fungus can be controlled also by spraying with Bordeaux mixture.

Gymnosporangium globosum, another species much like the foregoing, is the common cause of apple rust in the East.

Cronartium ribicola has uredospores and teleutospores on various species of currants, but is chiefly of importance on account of the destructiveness of its telial stage to the white pine and other five-leaved pines. Introduced from Europe probably about 1895. Local in northeastern United States at present.

Coleosporium solidagoe is on aster, solidago, and other Composites. It is chiefly of interest because it also attacks the cultivated aster (Callistephus chinensis) causing considerable damage. The telial stage occurs on pines. The intervention of this stage is, however, not essential for the maintenance of the fungus since the uredospores persist through the winter on the rossette leaves of solidago and other Composites.

Melampsora tremulae is the common orange rust of poplars in the United States. Several races exist which have aecia on hazel, pine, and other plants. Numerous other species or subspecies of Melampsora are upon willows. The injury caused by these is not great.

Gymnosporangium interstitialts, of the blackberry, has but one spore form, the urediospores which germinate like teleutospores. The rust is exceedingly common on the blackberry and raspberry covering the whole under surface of the leaves with blisters which burst and display the brilliant orange spore-powder. The mycelium is perennial and permeates the entire host. No satisfactory remedy has been found.

Uredo fici, an unattached uredo-form which is common on fig trees, causing a rusty brown appearance and premature falling of the leaves. Where figs are grown, for fruit; or fig trees, causing the same damage results to the crop from the loss of leaves. Common also in the tropics.

HEINRICH HASSELBRING.

RÜTA (classical name of rue). Rutačae. Perennial, glandular, punctate herbs, hardy or half-hardy North, quite hardy South but of no great horticultural value.

Plants often woody at the base, with terete branched sts.: lvs. alternate, simple, 3-foliolate, pinnately cut or compound: fls. in leafy-bracted terminal or axillary panicles, numerous, yellow or greenish; calyx short, persistent, 4-5-lobed or parted; petals 4-5, limb arched, often dentate or ciliate; stamens 8-10; ovary sessile: caps. 4-5-lobed, the lobes indehiscent or dehiscent at the apex.—About 40 species, mostly in the Medit. region and a few in W. and Cent. Asia.

gravelens, Linn. RUE. Herb of Grace. Fig. 3515. A hardy perennial, woody at the base, 1½-2 ft. high; lvs. fragrant, much divided; lobes oblong, the terminal obovate; fls. yellow. July.—Prop. by division and seeds. An old medicinal plant, with a very strong aromatic odor; sometimes spontaneous in this country.

Patavina, Linn. (Hoplophyllum Patuceum, Hort.). A hardy perennial herb 4-6 in. high; lvs. glabrous, the lower oblong-spatulate, narrowed at the base, the others oblong and leafy, clustered; corymb dense; pedicels somewhat longer than the fls.; fls. golden yellow. June, July.

F. W. BARCLAY.

RUTABAGA: Brassica.

F. TRACY HUBBARD.†
SÁBAL (possibly a native name in South America, but the author of the genus does not explain). *Palmaeae*, tribe *Coryphe*. Spineless palms, low, tall, or almost stemless.

Trunk slender or robust, ringed or nearly smooth, creeping or erect, ascending at the base, clothed above with dead lf.-sheaths; lvs. terminal, orbicular or cuneate at the base, flabellately multifid; segms. linear, bifid, filamentous on the margins, induplicate in the bud; rachis short or long; ligule short, adnate to the rachis; petiole concave above, the margins smooth, acute; sheath short; spadixes large, elongated, decompound, at first erect, the branches and branchlets slender, recurving, pendent; spathes sheathing the branches and peduncules tubular, oblique at the throat: bracts and bractlets minute; fls. small, glabrous, white or green: frs. small, globose, black, the short style basal. — Species probably 20, if *Inodes* is not separated. Fla. to Venezuela, and in Mex. Here belongs the palmetto or cabbage palm of the southern states. The best botanical ac-count of the genus is Beccari's, Le Palmae Americane della tribu delle Coryphere, pp. 10-83 (1907). Most of the species can be cult. in the temperate house, but any that may come into the trade from S. Amer. would require stove conditions. *S. Palmetto* can be grown outdoors from Charleston southward. *S. texana* and *S. exul* are handsomer species, and hardy in parts of Texas.

The arboreous species of *Sabal* have been separated by Cook (Bull. Torr. Bot. Club, 28:529) as *Inodes*. These species also differ in their foliage. "The leaves of *Sabal* are adapted for standing erect and avoid resistance to the wind by being split down the middle. The leaves of *Inodes* which are held horizontal from the erect axis have attained the unique adaptation of a decurved midrib which braces the sloping sides of the leaf and effectively prevents the breaking above the ligule."

The cabbage palmetto (*S. Palmetto*) grows in groups of a few specimens to several hundreds or even thousands in the rich black soil on the banks of the St. Johns and Ocklawaha rivers of Florida, forming a glorious sight. They are found northward to South Carolina, but they attain their fullest development in Florida, where they always form an important feature of the landscape. Generally they grow in dense groups, but they are more beautiful in all their parts where they have room enough to spread. In southern Florida underneat the crown of leaves is often found a dense wreath of ferns (*Polypodium aureum*), which heightens the charm of these palms considerably. On the St. Johns the trunk is often covered with the trumpet creeper (*Campsis radicans*), or it is hidden by the dense foliage of the cross-vine (*Bignonia capreolata*), both of which form a beautiful ornament, especially when in flower. These suggestions of nature are often followed by planters who have a feeling for nature-like landscape effects. The cabbage palmetto thrives even in the poor sandy soil, and it is greatly improved by cultivation. Even good-sized trees are not difficult to transplant if the whole stem is carefully dug out and all of the roots and leaves are cut off. If the stem has been set at least 3 feet deep and the soil is kept well watered after planting, the palmetto is almost sure to live. In addition to the palmetto, all of the sabals mentioned in this work arc cultivated by the undersigned on high pine land in southern Florida. Under these conditions the sabals have proved a great success, as also all species of *Phenix* and all Coco's of the australis type, while the species of *Washingtonia* I rythea.  

3516. *Sabal Palmetto*, the cabbage palmetto of the southern states.
Livistona, and Trachycarpus have been an entire failure. S. Blackburniana is, in the judgment of some, the finest of all the fan-leaved palms that can be grown in Florida. All the species that form trunks are objects of great beauty when well grown. They need to be well fertilized, or the lower leaves will suffer and finally die, thus detracting much from the elegance of the specimen. They all grow naturally in rich black soil, but all thrive exceedingly well in the sandy pine-woods soil if well fertilized and watered; in fact, they can hardly be fertilized too much, and the more nitrogenous manure and water they get the faster they grow. When transplanted they must be set deep. In planting palms make a hollow about 6 feet in diameter and about 2 feet deep in the center. This center, which receives the plant, is the deepest point, while the ground all around is slightly sloping. Care must be taken to remove the sand after heavy rains or the crown will soon be buried and the little plant dies. As the palm first forms the trunk in the soil and as the growth is rather rapid, this precaution is not necessary after the plant has attained a few feet in size. (H. Nehrling.)

a. Trunk evident, usually tall.
b. Foliage very glaucous.

uresâna, Trel. (Inodes ursesana, Cook). Trunk 15-35 ft. high and upward of 1 ft. diam.: Ivs. glabrous, very glaucous; petiole stout, concavo-convex, unarmored, about 40 in. long, nearly 1 in. wide and nearly 3/4 in. thick; blade about 40 in. long and wide, multifid, with coarse straw-colored fibers from the sinuses, the center arcuately recurved; fr. of a single developed carpel, depressed globose, 3/4 in. or less in diam., edible, green, or when dry dingy brown and somewhat glossy, the mesocarp then corynoid; endocarp whitish straw-color, glaucous, with the persistent bases of the old fibers between the bifiid lobes: spadix very long and much branched, appearing below the Ivs.: fr. globose or inverted pear-shaped, about 1 1/2 in. long. W. Indies.—The name mauritiformis does not appear in the American trade, but S. glaucescens, Lodd., and Hort, probably belongs here, according to Grisebach. Nehrling writes: "S. glaucescens of the trade rivals S. Blackburniana in beauty and rapidity of growth. Its Ivs., though smaller, have a beautiful bluish green color."

Palmétt. Loddi. (Inodes Palmétt, Cook). CABBAGE PALMETTO. Fig. 3516. St. erect, 20-50 ft. high; Ivs. 5-8 ft. long, cordate in outline, recurved at the summit, shorter than the petiole; segms. deeply cleft; spadix spreading, shorter than the Ivs.: fr. drupe black, 3/4-4 in. long. N. C. to Fla. and Bahamas. S.S. 10:508. G.C. II. 2:777. Loudon's Gard. Mag. 5:52-7, with several figures. E.B. 35, p. 36, fig. 12:628. —S. Mocinitis, Hort., is referred to S. Palmétt by Voss, but Nehrling describes it as a stemless plant from Mex., more beautiful than the dwarf palmétt, bearing immense Ivs. on strong stalks, the Ivs. attaining a height of 6-8 ft. Others think S. Mocinitis is the same as S. Blackburniana. S. Palmétt has been confused in the European trade with S. texana. Very commonly planted as a shade and avenue tree in the southern states.

Blackburniana, Glazeb. (S. umbraulifera, Mart. Inodes Blackburniana, Cook). St. 30-40 ft. high, thickened at the middle; blade ample, orbicular, glaucous, rather rigid, shorter than the petiole; lobes about 40, cuneiform, bifiid, filamentous, rather rigid; spadix more branched than in any other species: fr. inverted pear-shaped, about 1 1/2 in. long. W. Indies. G.F. 4:307. G.C. II 2:777. Loudon's Gard. Mag. 5:52-7, with several figures. E.B. 35, p. 36. caúsiârum, Becc. (Inodes caúsiârum, Cook). Pouro Rico HAT-PALM. YARAY. Trunk to 40 or 50 ft. and 2 ft. thick, columnar or nearly so, light gray or nearly white: Ifs.-bases splitting into fibers and more or less remaining as long ribbons: blade 12-20 ft. long, the blade and petiole about equal in length but both surpassed by the infl., the petiole keeled near the end above: fr. 1 1/2-2 in. diam., grayish, with a finely rugose or nearly smooth chestnut-brown seed.

texâna, Becc. (S. mexicana, Auth., not Mart. Inodes texâna, Cook). Robust palm, to 50 ft. and 2 1/2 ft. diam. of trunk which is bright reddish brown: Ivs. 5-7 ft. across, shining and yellowish green, the segms. often parted and filamentous, the petiole stout and equaling or exceeding the blade: terminal branches of infl. slender: seed about 1/2 in. broad, with a prominent micropylo. S. Texas. S.S. 10:508.

exúl, Bailey (Inodes exúl, Cook). A strong vigorous tree with large crown of vivid green Ivs., and green trunk due to the color retained in the sheathing Ifs.-bases: Ivs. otherwise much like those of S. texâna; branches of infl. thickened: fr. solitary, with large seed not wrinkled above nor hollowed below.—Described from handsome trees planted at Victoria, Texas, probably native of Mex. Hardy and promising, princeps, Hort. (Inodes princeps, Cook). A species with a stout trunk which is covered with the persistent bases of the old Ivs.: Ivs. very large, about 5 ft. long; blade divided into about 100 segms., chartaceous, green; segms. all

SABAL

3044 SABAL
rather shortly cleft at the apex, about 3 ft. long by 1½ ft. in. across, acuminate, pointed, fruiting spadix pendent, about 6 ft. long, forming a very dense panicle; spathe tubular-funnel-shaped, striate, obliquely truncate: fr. black, shining, globose. Habitat unknown; cult. in S. Calif.—Resembles S. Blackburniana.

AA. Trunk none or creeping.

glabra, Sarg. (S. Adamsii, Guerne, S. minus or minor, Pers. Caryophyla minor, Jacq.; not Lam.). Dwarf PALMETTO. Fig. 5317. St. short, rooting in the earth so that the palm appears stemless: lvs. 2–3 ft. long; blade circular in its outline, somewhat longer than the petiole; glaucous, segments, slightly cleft at the apex: spadix erect, much longer than the lvs. 3½–6 ft. long. Black, Southern states. B.M. 1434. —Often cult. outdoors in the southern states. There are different forms, apparently unknown to the trade.

megacarpa, Small (S. Etiomia, Swingle). Scrub PALMETTO. Low shrub, the sts. elongated, creeping, and contorted; lvs. standing 4–5 ft. high, the sharp-pointed petioles exceeding the nearly orbicular blades which are 1½–2½ ft. across, deeply cleft at apex and segms., longer than body, filamenteous: fls. 2–2½ ft. long, ascending but becoming prostrate, branching; perianth yellow, white, or nearly globose, ½–1 in. diam.

The following are mostly trade names, but at present they can be only imperfectly described: S. carvelapecta, Bull. A native of Colombia. Possibly only the juvenile state has been described. Lvs. elongate, linear-lanceolate, plicate, with a bluish or glossy green color which is very strongly marked on the under surface. Nehrling says that he cannot distinguish at present his specimens of S. carvelapecta from S. glauca.—S. dehida, Hort. *This species* is described. Nehrling, "reminisces one of S. Moeuvis, although it is smaller in all its parts. The lvs. are numerous, glaucous green and c a fine fan-shaped form. Compared with the Sabals that form a trunk, these stemless species have little beauty, though they look well as foliage plants in company with eucalyptus.—The name 'Matthews' means what it is; but it appears to be unrecognized in botanical literature in connection with Sabal.—S. Gladiolosum, Hort. is S. Palmetto, at least so far as some gardens are concerned, but Bengtsson considers it an European name applied to cult. plants of S. Palmetto.—S. gigante, Hort., Pitcher & Mand. 1895, may possibly be meant for S. glauca.—S. harringtoni, Dodd. according to Nehrling, "is a more upright grower than S. Blackburniana, has a slender st. and the fl-stalks are longer and thinner. The lvs. have a bluish green color while young, changing to a fine dark green when they get older. Habitat unknown and the name has no botanical standing. —S. hastatorpora, Hort. is Livistona Hoogendoornii.—S. javanica, Hort., is possibly meant for S. javanensis, S. Sabal is an American genus and is not known in Java.—S. longifolia, Hort., according to Nehrling "has very numerous, long and slender lvs. which are bright green above and silvery below."—S. longa-pulchra, Hort., according to Nehrling, "is a stemless plant with a small trunk of S. Moeuvis and very long slender stalks." Reasoner adds that the lvs. are glossy green. The last two are known only by these trade names, and are not certainly referable to any maintained species. L. H. B. 4

SABÁTIA (named after Liberatus Sabati, an Italian botanist of the eighteenth century); also spelled Sabatia. Gentianaceous. Hardy annual or biennial (rarely perennial by stolons) herbs, making showy garden or border plants, although little grown.

Leaves opposite, sessile or clasping: fls. showy, rose-pink or purple-white, in cymose panicles terminating the branches; calyx 5–12-parted, the lobes slender; corolla rotate, 5–12-parted, usually with a yellow eye: caps. globose or ovoid, 2-valved.—About 18 or 20 species. N. Amer. and Cuba, mostly on the coastal plains, forming showy gardens or ornamental borders. The chief ornamental feature of this species. L. L. REHDER.

SACCHARUM (saccharon, old Greek name for sugar). Gramineae. The sugar-cane group, little grown for ornament, although making bold specimens. Tall grasses with stout culm and ample panicles, the branches many-jointed: spikelets small, slender, 1–4 in. long, rounded by long silky hairs.—Species 12 in tropical regions, mostly of the Old World. Differences from Erianthus in having awhinless spikelets. The most important species is the sugar-cane, which is extensively cultivated in tropical and subtropical countries for the production of sugar. Prop. by cuttings of the st. Native country unknown, but probably E. Asia. Cult. from time immemorial by cuttings, for which reason many varieties have lost the power to flower or at least to produce fertile seed. Rum is produced from the fermented molasses.

SUCCHARUM 8:261 (under the name Saccharum officinarum, Linn.). Apparently perennial, usually in brackish marshes near the coast from Long Island southward to 2 ft. high; lvs. oblong to oblong-lanceolate, blunt or somewhat acute: calyx-lobes herbaceous, 3–3½-nerved; corolla red-colored or white with yellow spot at base of each oblong-apatulate or oblaneate segm. S. Kennedyana, Fern., is the New England representative, of fresh pond-shores, earlier-flowering; freely strioliferous, to 2½ ft.: basal lvs. oblancoate-acuminate; fls. white, in round, compact, acuminate and subulate: calyx-lobes not herbaceous, linear-subulate; corolla-lobes cuneate-ovate, rounded or emarginate at summit, with much broader yellow spot. L. H. B. 4

SÁBIA (from its Bengal name, Sabja-lat). Saccidaceae. A genus of about 20 species of woody vines or sarcenose shrubs native to India, China, and Japan, with alternate petioled entire deciduous lvs. and axillary, solitary, or cymose, rather small and dull-colored, greenish, purplish, brownish, or yellow fls. followed by small blue drupe-like frs. Fls. perfect, 5, rarely 4–merous; petals short, semi-orbicular to ovate; petals oval to oblong; stamens shorter than petals; ovary superior, 2-celled, each cell with 2 ovules: drupes usually reniform, blue, solitary or 2 and slightly cohering at the base, 1-seeded; stone reticulate.—Only the following recently intro. species is in cult., but little is yet known of its cultural requirements; at the Arnold Arboretum it is growing well under ordinary conditions and has proved hardy. Prop. is by seeds and probably by cuttings. S. Schumanniana, Deis. Climbing shrub, to 10 ft.; glabrous; branchlets green; lvs. petiolar, oblong-lanceolate, rarely elliptic; flowers much smaller, broadly cuneate at the base, bright green, reticulate beneath, ¼–1 in. long: frs. greenish to greenish-purple, cup-shaped, ½ in. across, in slender-stalked, nodding, usually few-fl.d. cymes; pedicel filiform, 1½ in. long; fr. reniform, ½ in. broad; stone slightly compressed, reticulate. W. China.—The drooping blue frs., if freely produced under cult., apparently constitute the chief ornamental feature of this species. Alfred Rehder.
SACCHARUM

Spontaneum, Linn. Less tall and stout than sugar-cane, freely blooming, found in the Molucca region, where it is sometimes cultivated as a hedge-plant, and throughout the tropics of the Old World. A variety of this, S. meyliatum, is shown in Gn. 11, p. 78; 16, p. 323.

ciliare, Anders. Lvs. very narrow, channelled, glaucous, the lower erect. Intro. from India. Said to make large clumps and to be hardy at Santa Barbara, Calif., but not known to bloom there. A. S. HITCHCOCK.

SACCOLABIUM (name refers to the saccate label-

lum). Orchidaceae. Epiphytic herbs with erect leafy stems increasing in length by continued growth at the apex, grown in warm glasshouses.

Leaves distichous, leathery and fleshy, usually channelled; inf. lateral, in the cultivated species a long, densely ftd. cylindrical raceme; Fls. medium or small; sepals subequal, free, spreading, the lateral pair not decurrent on the base of the column; petals similar, sometimes wider; labellum united with the base of the column, spurred, the mouth of the spur open; pollinia on a bifid stipe.—About 20 or more species. Can be prop. by offsets and by cut-backs. Fresh stock is constantly imported.

This interesting genus embraces a number of pretty and distinct species from Borneo, Cochin-China, India, Java, and Philippines. They are closely allied to the genera Aerides, Phalanopsis and Vanda, and require somewhat similar treatment, but do not always aclimatize themselves as readily to artificial cultivation unless given a location with more or less natural surroundings, although some of the more free-growing species, like S. ampuilaceum, S. curvifolium, S. celeste, and S. Hendersonianum, can usually be grown successfully in the cattleya or cypripedium department. The large-growing species with thick succulent leaves require a warm moist atmosphere where the winter temperature can be retained at 65° to 70° F. by night and about 75° during the day, and in the summer or growing season 10° in advance of this. All succeed best when suspended from the roof in pans, baskets or on blocks where they can have free circulation of air about them at all times, receive indirect benefit of the sun’s influence, which will harden their tissue, and where the compost may readily and frequently dry out, during the resting period especially. Grown otherwise the more succulent species, such as S. giganteum (a Vanda), make soft weak tissue, which is wet-splot, a usually fatal disease. Clean chopped sphagnum, freely interspersed with broken pieces of charcoal, is the most satisfactory growing material, and this should not be pressed in so firmly as entirely to exclude access of air to the roots, but the plants must always be firmly secured with pieces of charcoal, potsherds or other similar material, or securely fastened with copper wire to keep them in position, otherwise being more or less top-heavy they are liable to work loose, under which conditions they cannot become properly established. Shading should be applied to the glass from February until November to break the sun’s direct rays, but during the remainder of the year when the solar light is weak its direct influence will be found beneficial. In bright weather in the growing season the plants need a liberal supply of water, both at the roots and over the foliage, but during the resting period and in wet inclement weather, water and syringing must be carefully and sparingly administered. Judgment in this respect is very essential to the successful culture of these plants. The supply of succulums is kept up by fresh importation. These cultural directions apply also to the genus Rhynchostylis. (Robert M. Grey.)

a. Fls. rose-colored.

Hendersonianum. Reichb. f. Dwarf: Lvs. 4-6 in. long, strap-shaped, subacute, distichous on the sts. but spreading in various directions; raceme upright, about as long as the lvs.; Fls. forming a cylindrical mass, bright rose, ½ in. across; dorsal sepals orbicular, concave, lateral ones larger, obvate-oblong; petals obvate; labellum a blunt, straight spur with 3 teeth at the mouth, white. Borneo. B.M. 6222.

ampullaceum. Lindl. Fig. 3518. Dwarf: st. 6-8 in. high, with 2 rows of lvs.: Lvs. strap-shaped, channelled, apex truncate and dentate; racemes nearly erect, 4-6 in. high; Fls. deep rose-color; sepals and petals ovate, veined, spreading out flat; labellum linear-falcate, one-half as long as the petals; spur slender, straight. May. June. N. India. B.M. 5586. F.M. 13:40. J.H. III. 32:463. Var. moulemeinense, Hort., is a geographical variety with stronger growth and larger Fls.

AA. Fls. orange or scarlet-orange.

curufo!ium. Lindl. Sts. short: Lvs. linear, 8-10 in. long, 2-toothed at the apex: racemes somewhat drooping, 6 in. long, dense; Fls. 1 in. across, bright orange-scarlet; sepals and petals ovate to obvate, spreading; In the growing season the plants need a liberal supply of water, both at the roots and over the foliage, but during the resting period and in wet inclement weather, water and syringing must be carefully and sparingly administered. Judgment in this respect is very essential to the successful culture of these plants. The supply of succulums is kept up by fresh importation. These cultural directions apply also to the genus Rhynchostylis. (Robert M. Grey.)

AA. Fls. white, spotted with blue.

SACCOLOMIA
 giriş (Greek for sac and edge, referring to the indusia). Polyopodiaceae. A group of tropical ferns, somewhat related to Davallia. They are pinnae, divided into pinnules, often of large size, and with large axillary sori; pinnules and pinnules not jointed to their points of attachment: indusia attached along both sides at the base.

inequale, Mett. (Davallia brasilensis, Hook). A large strow fern with creeping rootstock: lv. as much as 18 in. long, three-pinnate or more. Common in the American tropics.

SADILÉRA (named after Joseph Sadler). Polypodiaceae. Arborose ferns suitable only for the warmest parts of the country. They are pinnate, divided into pinnules, often of large size, and with large axillary sori; pinnules and pinnules not jointed to their points of attachment: indusia attached along both sides at the base.

SAGE (Salvia officinalis). A sweet herb, used for seasoning, and somewhat in domestic medicine.

For at least three centuries this shrubby fibrous-rooted perennial from southern Europe has been widely cultivated in kitchen-gardens for its aromatic whilish green wrinkled and papery leaves. These are arranged oppositely on ascending or decumbent branched stems to 4 ft. high; spike-heads, are left in the cutting-bed until the fol­lowing year. For dryng upon a commercial scale, since this plan is

...
July after harvesting an early crop, such as beets, cabbage or peas. About twice in the three weeks after setting the plants, the field is raked to destroy sprouting weeds and to keep the surface loose, after which, if well done, but slight hoeing is necessary. In September, when the plants crowd each other, each alternate plant or row of plants is cut for sale and the remainder allowed to fill the space. At the first cutting each plant should make about two marketable bunches; at the second at least three. This practice not only insures placing all full of leaves at each cutting but at least doubles the quantity in the end.

In America the green broad-leaved varieties are in far greater demand than the colored and the narrow-leaved kinds. The best variety known to the writer is Hult Mammoth, which is exceptionally prolific of large leaves. It is said to produce no seed. M. G. Kains.

SAGÉNIA. A generic name for a group of tropical ferns here referred to Tectaria, from which there is no valid distinction. For S. decurrens see Tectaria decurrens.

SAGÉRÉTIA (after Augustin Sageret, French botanist, 1763-1851). Phanerogamae. A genus of about 15 species of armed or unarmed often scandent shrubs native to the warmer parts of Asia, in Amer. from N. C. to Mex., with opposite or nearly opposite, entire or serrulate, small, deciduous or persistent lvs. and with minute white fls. in terminal or axillary spikes or panicles, followed by small berry-like, mostly purple lfs. Fls. perfect, 5-merous; the hooded petals and the stamens not exceeding the sepals; disk cup-shaped, 5-lobed style: frs. a small globose drupe with 2-3 leathery nutlets.—These plants are little known in cult. S. theezans, Wimm. has been recently intro. by the Dept. of Agric.; according to F. N. Meyer it may be useful as a hedge-plant and its lfs. have a delightful fragrance which attracts numerous insects; it is apparently not hardy N., while S. pycnophylla has proved hardy at the Arnold Arboretum. The American S. minutiflora is not recorded as being in cult., but may possibly have been planted in collections in the southern states. The frs. of some species are sweet and edible. Prop. is by seeds and probably by cuttings like berchamia which it resembles in habit and general appearance. S. theezans, Brongn. Spinescent shrub, to 6 ft., with slender spreading branches: lvs. persistent, or subpersistent, short-petioled, ovate or oval, obtuse or subacute, subcordate or rounded at the base, minutely serrulate, lustrous above, glabrous or at first slightly villous beneath, ½-1 in. long: fls. sessile in villous spikes ⅔-1 in. long or sometimes longer and forming terminal panicles leafy at the base; sepals slightly pubescent outside: fr. purplish black, about ⅔ in. across. Fls. in autumn; fr. in spring. China. S. pycnophylla, Schneid. Similar to the preceding species: lvs. smaller, ⅓-½ in. long, nearly ½ in. long, sometimes acutish; fls. white, glabrous, in slender glabrous spikes ⅓-½ in. long, usually only 1-4 at the ends of the branches. W. China. S. minutiflora, Trel. (S. Macabuzoit, Brongn.). Spinescent, straggling or trailing shrub: lvs. short-petioled, leathery, ovate to ovate-oblong, acute, serrulate, pubescent while young, glabrous and lustrous at maturity, ⅓-½ in. long: fls. ⅓ in. across, in terminal and axillary slender sometimes panicked spikes: fr. ⅓ in. across, often gibbous, purple. Fls. in autumn: fr. in spring. N. C. to Fla. and Ala.

ALFRED REHDER.

SAGITTARIA (from Latin, sagitta is Latin for arrow, referring to the arrow-shaped leaves). Alismaceae. Arrowhead. Perennial hardy herbs useful for foliage effects in bogs and shallow ponds and also for their white buttercup-like flowers.

Plants of mostly erect habit, aquatic, the lvs. and scapes arising from more or less cormous or knotted rootstocks: lvs. typically arrow-shaped, with long basal lobes, but sometimes long and linear: fls. imperfect, monoeious, the lvs. usually in successive whorls or dichose, with 3 white broad petals and 3 small greenish sepals, the stamens and pistils numerous, the latter ripening into small achenes; infl. compound of sessile or peduncled clusters of 3 stalked fls. Sometimes the lvs. are floating. The number of species admitted is variable, but Buchenau in the last treatment of the genus in Engler's Das Pflanzenreich, hft. 16 (iv. 1903) describes 31. Temperate and tropical regions of the world though lacking in Afr. and Austral. Sagittarias are mostly used for colonizing in the open, but S. montevidensis—now the most popular species—is grown in indoor aquaria or plunged in open ponds in the summer. The arrowheads are perennials of easy culture, although likely to be infested with aphids. Propagation is by division, sometimes by seeds.

A. Sepals of pistillate fls. (usually in the lower whorls) erect after flowering, and the pedicels of these fls. thick: carpels not glandular.

SAGITTARIA

3519. Common arrowhead. — Sagittaria latifolia; often known as S. variabilis. (X⅓).
and lily-ponds. Tender to frost. It is sparingly naturalized in the southern parts of the U. S., on both the Atlantic and Pacific sides.

**AA.** Sepals of pistillate fls. reflexed after flowering: pedicels of these fls. slender: carpels somewhat glandular.

**BB.** Bracts at base of whorls united, as if only 1.

**S. subulata**, Buch. (S. natans, in part. S. puella, Nutt.). Slender and simple, usually only a few inches high: lvs. linear or narrowly oblongate, rigid: fls. few, usually in 1 whorl, white, ½-¾ in. across, the filaments broad. N. Y. to Ala., along the coast.—Offered by dealers in native plants. A plant once sold as *S. natans* is said to have come from the Amazon Valley; from this the form known as “New Era” was derived; and a cross of the latter with “S. lanceolata” (S. lanceolata), native in Lo., gave the form “Francis M.” *S. natans*, Pallas, the accepted species under this name, is native in N. Eu. and Siberia.

**BB.** Bracts at base of the whorls.

**c. Lvs. usually distinct and sagittate.**

**latifolia**, Wild. (S. variabilis, Engelm.). Fig. 3519. Very variable in stature and shape of lvs., ranging from a few inches to 3-4 ft. tall: lvs. mostly broad-sagittate with long basal lobes, but running into very narrow forms: fls. clear white, about 1 in. across, usually monocious, the filaments slender: achene winged, with a lateral or oblique beak. Common everywhere in margins of ponds and lakes, and offered by dealers in native plants for colonizing in bog-gardens and in lily-ponds. There is a double-flowered form known as *S. variabilis fl.-pl.*, Hort., which probably belongs here. G. 29:31.

**S. sagittifolia**, Linn. OLD-WORLD ARROWHEAD. Rhizome thick and tuberous, stolon-bearing: lvs. broad and sagittate, very variable in form and size: scapes erect, simple or branched, overtopping the lvs.: bracts narrow-ovate, free or slightly connate at base, shorter than the pedicels: petals large, white; filaments glabrous: achene monocious, the filaments slender: achene winged, with a lateral or oblique beak. Common everywhere in margins of ponds and lakes, and offered by dealers in native plants for colonizing in bog-gardens and in lily-ponds. There is a double-flowered form known as *S. variabilis fl.-pl.*, Hort., which probably belongs here. G. 29:31.

**bb.** Lvs. usually oblong or linear and not sagittate.

**d. Filaments slender, tapering upward, crenate.**

**lancifolia**, Linn. Erect and somewhat rigid, glabrous, the scapes sometimes reaching 5 ft.: lvs. lanceolate to narrow-oblong to nearly linear, nerved from the thick midrib: fls. white, in several whorls. Swamp, Del. to the tropics.

**dd. Filaments abruptly broadened, pubescent.**

**graminum**, Michx. Erect and simple, glabrous, 2 ft. or less high: lvs. reduced to phyllodia, flat, broad-linear to lance-oblong, pointed: fls. small, white, in 2 or 3 whorls. Newfoundland to Gulf.

*S. micropylina* has appeared in trade-lists as “a variety with large foliars and tall blue spikes of white fls.” Its botanical position is uncertain as there are two distinct things of this name, one a valid species, the other a large-flowered form of *S. sagittifolia*.

**F. TRACY HUBBARD.†**

**SAGUÉRUS** (East Indian name). *Palmææae*. An older name for Arénga, but discarded by the "nomina reicienda" of the Vienna rules. *Arenga mindorensis*, Becc. (Saguérus mindorensis, O. F. Cook), has recently been intro. by the U. S. Dept. Agric, from the Philippines. It is described as a palm 5-10 ft. high, and probably of decided ornamental value for greenhouses and probably also in S. Calif. and S. Fla. Yet little known in this country.

**SÁGUS RÚFFIA**: Raphia.

**ST. JOHN’S-WORT**: Hypericum.

**SAINTPAULIA** (from the discoverer of the plant, Baron Walter von Saint Paul). *Genérvaceæ*. Hairy often stemless perennial herbs, used for greenhouse flowering, the blossoms providing an attractive blue.

Leaves long-petioled, ovate; peduncles radical (or axillary in the caulescent species), 1-5 in. high, bearing several (or 1) fls. in a loose cyme: calyx small, deeply 5-lobed; corolla wide-campanulate, tube short, the lobes elliptic, blue; perfect stamens 2; ovary hairy: caps. oblong, loculicidally 2-valved; seeds small, ellipsoid.—Four species, Trop. Afr.

The end of March is a good time to propagate saintpaulias, when the ripened leaves should be cut off with about an inch of the stalk attached, and inserted in the sand-bed, covering only a small part of the leaf-blade. The sand should not be kept too wet during the process of rooting. Their propagation from seed and general culture is similar to that of gloxinia. The plants may be flowered the entire year or given a period of rest by partly withholding water. (G. W. Oliver.)

**kewensis**, C. B. Clarke. Lvs. entire, with numerous long white hairs: calyx-lobes linear: caps. 2 or 3 times as broad as the preceding and more shaggy, white-hairy. Trop. Afr. B.M. 7408. R.B. 20:100 (both as *S. ionantha*).—Very closely related to *S. ionantha* and confused with it.

*S. puella*, Engler, and *S. Guettarda*, Engler, of German East Africa, appear not to be in cult. **F. TRACY HUBBARD.**
SALAD PLANTS

SALAD PLANTS are those with soft and edible leaves or stems, or both, that may be used raw or in the preparation of uncooked dishes.

The principal salad plant in America is lettuce, which is used exclusively, but not always expertly, for salads. For full directions for growing lettuce in the garden and under glass, see Lettuce and Forcing. Next to lettuce is the best-known salad plant in this country is probably endive, which is excellent, especially when well-blanched plants are to be had in the winter. Endive is much like its relative, as regards its freshness, either in the garden or in the salad-dish. Like endive, it is frequently seen in the larger city markets. The common dandelion should be mentioned in this category. When forced and blanched it makes a salad fit for the most cultivated epicure. For ordinary home cultivation and use, however, the common garden cress (Lepidium sativum, not water-cress, nor upland cress) ranks next to lettuce in value. Its rapid growth and high flavor equally recommend it. This plant is said to be a great favorite in English gardens and forcing-houses, where it is grown in mixture with white mustard and is pulled very young and eaten roots and all. Corn salad is another plant sometimes grown in gardens and used for salad-making. It is most acceptable to those who do not relish the pungency of mustard and cress. Chives is used by many persons as an ingredient of lettuce and other salads; also young onions. Many other plants are used in various places and by various persons for salads.

Besides the salad plants proper, many vegetables are used in a cooked or raw condition for salads. Such are cabbage, cauliflower, brussels sprouts, potatoes, lima beans, beets, Jerusalem artichoke, and the like. With salad plants may also be included pot-herbs, or "greens." The plants especially to be mentioned in this category are swiss chard, beet-tops, spinach, kale, endive, witloof and mustard. Many other plants find occasional or local favor. See Greens.

The only general cultural directions which can be given for salad plants are that blanching is often desirable and a quick unchecked growth is always a requisite. An abundance of rapidly available fertilizer and plenty of water are therefore to be insisted on. A warm light, good and a quick unchecked growth is always a requisite. An abundance of rapidly available fertilizer and plenty of water are therefore to be insisted on. A warm light, good soil, and the best mechanical condition, is necessary for the same reasons.

F. A. WAUGH.

SALICORNIA (Latin, salt and horn; saline plants with horn-like branches). Chenopodiaceae. Glasswort. Marsh Samphire. A group of about 12 widely scattered species of leafless seaside herbs, hardy or tender, annual or perennial. This and other chenopods which grow in large quantities in the Medit. region were formerly used in making soap and glass, as they yield a large percentage of soda. The ashes of such plants were known to the trade as barilla. The species have probably never been regularly in culture and have no horticultural interest.

MARSH SAMPHIRE. A group of about 12 widely scattered species of leafless seashore herbs, hardy or tender, annual or perennial. This and other chenopods which grow in large quantities in the Medit. region were formerly used in making soap and glass, as they yield a large percentage of soda. The ashes of such plants were known to the trade as barilla. The species have probably never been regularly in culture and have no horticultural interest.

SALISBURY: Ginkgo.

SALIX (ancient Latin name of willow). Salicaceae. Willow. Dioecious trees and shrubs, planted for the foliage and interesting habit, for shade, screens, and cover; flowers in catkins, mostly in spring and in many species very early.

Erect, or some arctic and alpine species prostrate, glabrous, pubescent or tomentose; leaves simple, alternate, mostly elongated and pointed, the stipules persistent and prominent or caducous; buds with a single bud-scale; fls. in lax scaly spikes (aments or catkins), each fl. subtended by a single entire scale and nearly or quite destitute of perianth; the staminate fl. with 1, 2, or 3-6 stamens; the pistillate fl. of a single pistil composed of 2 carpels and 2 more or less divided stigmas; at maturity the pistil dehisces, setting free the small appendaged seeds.—Species and species-like hybrids probably 300, widely spread in the northern hemisphere and a few in the southern hemisphere; no native species are reported in New Zeal, and Austral. In temperate regions, they are mostly plants of water-courses, shores, and swamps; but a good number run into the far N. and the high elevations where conditions of moisture are maintained. The wood is light, soft, and porous. For the staminate and pistillate fls. of willow, see Fig. 1528, Vol. III. The catkins or "pussies" are also shown in Figs. 3521 and 3522 herewith. In rare cases, a willow may be monoecious.

Many hybrids have been described based on specimens found in nature that presented characters intermediate between recognized species. Artificial hybrids have also been made between many species. The dioecious habit of the species seems to facilitate cross-pollination, and it is probable that the intermediate forms so frequently met with and designated in the monographs as varieties are natural hybrids. Upward of one hundred hybrid willows have been described as growing in Europe. Although as many or even more species occur in America, fewer hybrids have been detected here. The hybrids described as growing in America are for the most part between native species and those introduced from Europe. Because of the hybridity and the fact that the sexes are separated, the genus Salix is considered to be very critical and difficult for the systematist.
The role that the willow plays in the north temperate regions is to a certain extent analogous to that of the eucalyptus in sub-tropical regions; it flourishes in wet ground and absorbs and transpires immense quantities of water. It has been used to plant around cesspools for sanitary effect. But while most of the species occur spontaneously in wet ground or along stream-banks, the willows may be cultivated in various situations. The white willow (S. alba) has been used very effectively to fix stream-banks against erosion. (Figs. 3523, 3524.) Its root-system is very extensive and when well established withstands the effect of heavy rapid streams and, becoming anchored in the muddy banks, grow readily. It is one of the most aggressive trees in occupying such places. Willows may also be propagated by seed. The small seeds are very small and contain a green and short-lived embryo. A very short exposure of the seeds to the air will so dry them out that they will not germinate. The safest way to secure seedlings is to plant the seeds in a moist bed of sand or peat moss and cover with a thin layer of the same material. A very high percentage of the seeds will germinate in this manner. S. alba, S. discolor, and S. viminalis appear to be the favorite species for this purpose. Basket willow is now extensively planted in central New York, and considerable manufacturing of this material is under way. It is probable that the Chinese and Japanese willows recently described will yield useful forms for American planting; in Plants Wilsonianae, III, pt. 1, describing Chinese plants, Schneider admits regularly 183 species.

Temperate, Tropical and South Temperate zones are the species increase in size. Some of the species of North Temperate, Tropical and South Temperate zones are large trees. The arborescent species all form wood very rapidly. Specimens of white willow which may not be of great age look venerable from their great thickness of trunk and size of top. The wood is light in weight and color, finely and evenly porous. The wood has been extensively used in manufacture of gunpowder. It has also been used for many other purposes. Certain species have been extensively cultivated for many years in Europe for materials with which to manufacture baskets. S. viminalis appears to be the favorite species for this purpose. Basket willow is now extensively planted in central New York, and considerable manufacturing of this material is under way. It is probable that the Chinese and Japanese willows recently described will yield useful forms for American planting; in Plants Wilsonianae, III, pt. 1, describing Chinese plants, Schneider admits regularly 183 species.

INDEX.

A. Species of the usual upright kinds.
B. Scales of ament green, deciduous:
   mostly trees.
   c. Stamens more than 3.
   d. Foliage persistent.
   d. Foliage not persistent.
   e. Buds small.
   f. Lvs. green beneath.
   f. Lvs. glaucous beneath.
   g. Buds large; lvs. very shining above.
   h. ruderalis, 7.
   i. purpurea, 30.
   j. pyrenaeica, 35.
   k. ramulosa aurea, 6.
   l. regalis, 7.
   m. repensa, 8.
   n. reticulata, 27.
   o. retusa, 38.
   p. rigida, 27.
   q. rosmarinifolius, 29.
   r. rostrata, 19.
   s. rubra, 14.
   t. Russeliaria, 6.
   u. Saftaf, 13.
   v. Salamoni, 10.
   w. sepaloides, 10.
   x. sceptrum, 22.
   y. servitifolia, 38.
   z. Sieboldii, 12.
   {setchawia, 31.
   q. ephedra, 31.
   r. tesciner, 17.
   s. trutta, 21.
   t. vicina, 24.
   u. viridis, 6.
   v. vitellina, 8.

b. viridis, 6
b. vitellina, 8

3524. Same tree as in Fig. 3523, in summer dress.

3525. Old roadside trees of Salix alba.

for slower-growing trees that require partial shade while young. The red and yellow branches of certain willows are very bright and cheering in winter. The weeping forms are very popular, but they are often planted with little sense of fitness. The cultural remarks under Ficus will apply to willows. The species of willows are readily propagated by cuttings. It has been suggested that the brittleness at base of twigs of some species, notably the black willow (S. nigra), is an adaptation to facilitate the natural distribution of the species. Certain it is that twigs broken from the tree by the wind are carried down streams and, becoming anchored in the muddy banks, grow readily.
1. BONPLANDIANA, Kunth. A branching shrub or low tree with coriaceous lvs. 5-6 in. long, dark green above and glaucous beneath: aments usually precocious in the axis of mature lvs. Native of Mex. and the S. W. U. S.

2. nigra, Marsh. BLACK WILLOW. Fig. 3526. Tree, 30-40 ft. high: bark flaky, often becoming shaggy: twigs brittle at base: buds small: lvs. lanceolate, green both sides, nearly siliquary--white while young, The forms of this species not easily distinguishable from one another, can be readily distinguished from the following species.

4. lucida, Muhl. Shrubs or small trees, 6-15 ft. high: branches yellowish brown and thick trunk, not excurrent in habit: branches yellowish brown: lvs. ashy gray and glaucous beneath, 2-4 in. long, elliptical. Eu. N. Asia, seldom bearing good seed, slender; scales deciduous. Eu. N. Asia. Gn. 19, p. 517; 55, p. 89.—Frequently cult. and also growing spontaneously in many places. A company of promoters induced many American farmers to plant hundreds of this willow some 50 years ago. Many of these occur now throughout the country, the trees being 40-50 ft. high. A stake cut from a tree and driven in the ground will soon establish itself and grow into a tree. Var. decipiens, Hoffm. Twigs yellow: buds black in winter: lvs. smaller and brighter green. Probably a hybrid with another species.

5. alba, Linn. WHITE WILLOW. Fig. 3527; also Figs. 3523-3525. Large tree, with short and thick trunk, not excurrent in habit: branches yellowish brown: lvs. ash-gray and silky throughout, giving a white appearance to the whole tree, 2-4 in. long, elliptical. Eu. Gn. 55, p. 57; 61, p. 7.—Hereford, associated with the next species, from which it differs in color of twigs and vesture and color of lvs., as also in its general habit. It is only occasionally seen in Amer. Var. splendens, Anders. (S. alba var. regalis, Wimm. 'Regalis, Hort.'). Lvs. densely silky on both sides, nearly silvery-white while young. The forms of this species not easily distinguishable from one another, can be readily distinguished from the following species.

6. vitellina, Linn. (S. blanda, Anders.). YELLOW WILLOW. Becoming a very large and venerable appearing tree, the rather short trunk often 4 ft. or more in diameter. It is often pollarded. The crown is deliquescent and thin, and driven in the ground will soon establish itself and grow into a tree, Var. decipiens, Hoffm. Twigs yellow: buds black in winter: lvs. silky-hairy when young, glabrous when mature, glaucous beneath, the whiteness intensified after the lvs. fall: aments appearing with the lvs. Abundant in E. N. Amer.

7. salicaria, Linn. (S. viridis, Fries. S. Russetiana, Smith). BRITTLE WILLOW. Fig. 3526. Tree, 50-60 ft. high, excurrent in habit and of very rapid growth: branches brown, obliquely ascending: buds medium size, pointed: lvs. large, lanceolate-acuminate, glabrous or slightly hairy when young, scarcely paler beneath, glaucular serrate: aments appearing with the lvs. (the staminate tree rare in Amer.), seldom bearing good seed, slender; scales deciduous. Eu. N. Asia. Gn. 19, p. 517; 55, p. 89.—Frequently cult. and also growing spontaneously in many places. A company of promoters induced many American farmers to plant hundreds of this willow some 50 years ago. Many of these occur now throughout the country, the trees being 40-50 ft. high. A stake cut from a tree and driven in the ground will soon establish itself and grow into a tree. Var. decipiens, Hoffm. Twigs yellow: buds black in winter: lvs. smaller and brighter green. Probably a hybrid with another species.

8. babylonica, Linn. (S. alba).—Displaying many variations, the most obvious of which are: Var. aurea, Salis. (var. aurantia, Hort.), branches golden yellow, especially just before the lvs. appear in spring. Var. britzensis, Hort., bark red. These as well as other choice varieties are grafted. Var. pendula, Hort. (S. aerea pendula, Hort., S. alba var. stellata pendula, Rehd. S. babylonica aurea and S. babylonica rosea, Rehd.). Tree of weeping habit, similar to S. babylonica ramulis aureis, with yellow branches. M.D.G. 1898:88. Gn. 55, pp. 15, 22. S.H. 2:301, 371.

9. babylonica, Linn. (S. pendula, Moench). NAPOLIEN'S WILLOW. Fig. 3527. A tree of weeping habit, 30-40 ft. high, with long slender olive-green or purplish branches: buds small, acute: lvs. 2-6 in. long, attenuate at base and apex: aments appearing with the lvs. slender, the staminate green, 1 in. long, caps. small. China. Gn. 1, p. 371; 34, p. 527; 39, p. 73; 55, p. 92. S.H. 1:261. F.E. 19:574. G.W. 2, p. 31.—Long known in cult. and often grown in cemeteries. Tender N. Var. annularis, Forbes, lvs. twisted back so as to form a sort of ring.

10. salamoni, Carr. (S. babylonica var. Salamoni, Carr.; sometimes erroneously spelled Salamoni or Salamoni). Hybrid between S. alba and S. babylonica. Similar to S. babylonica, but less pendulous: tree having branches and pendulous branchlets: lvs. similar to those of S. babylonica, but sparingly silky-pubescent on both sides: pistillate catkins with more pubescent.
a most conspicuous object: lvs. narrowly lanceolate, closely sessile, entirely or rarely minor. Large shrub, 12-18 ft. high, forming dense thickets but not growing in clumps: branches turning near anthesis, becomes more so as the capsule mature, an and above: caps. sessile, clothed when young with glabrous or somewhat hairy toward the base, longer leafy branches, very loosely flvd.: fists of terminal interval between the fascicles, first appearing in May and often bearing a second set of fascicled sparsely canescent to extremely canescent, streams and lake-shores: twigs smooth and denticulate, deciduous: aments of late spring on short lateral peduncles, which bear 4--6 of S. babylonica. Of garden origin. 

11. blanda, Anders. (S. Pétzoldi, Hort. S. babylonica var. doroasa, Rowen; possibly also S. pendulina). WISCONSIN WEEPING WILLOW. A hybrid of S. babylonica and S. fragilis. Tree with spreading limbs and pendulous branches; branches brownish green or brown: lvs. lanceolate or narrow-lanceolate, long-acuminate, serrulate, glabrous, dark green above, glaucous beneath, 3-6 in. long and 14-34 in. broad: fists with the lvs.; stamens 2; ovary short-stalked, glabrous, with one gland at the base, half as long as the pedicel. Of garden origin. 

13. Sáafa, Forsk. EGYPTIAN WILLOW. A tree in general appearance like S. alba or S. babylonica. Several varieties have been described. The mature lvs. are bright green above and glaucous beneath, 3-5 in. long and over 12 in. wide. N. E. Afr., where it is frequently cult. along highways. — Intro. into Italy many years ago. 

14. longifolia, Muhl. (S. rébna, Rich., not Huds. S. interiér, Rowlee. S. flerdélía, Sarg., and other recent authors in part, not Nut.). Fig. 3527. Varying in stature from a low shrub to a small tree, usually growing along streams and lake-shores: twigs smooth and brown to densely tomentose and gray: buds of medium size, brown to densely tomentose and gray: lvs. lanceolate or narrow-lanceolate, 3-5 in. long and 14-34 in. broad: fists and reddish purple young wood. 

15. argophylla, Nutt. (S. longifólia var. argophylla, Anders. S. flerdélía var. argophylla, Sarg. S. hindíša, Benth.). Tree or large shrub, 12-18 ft. high, forming dense thickets but not growing in clumps: branches nearly glabrous and exceedingly tough: lark turning from brown to bright yellows, pale brown to densely white, just before blooming, making a thicket of it a most conspicuous object: lvs. narrowly lanceolate, closely sessile, entirely or rarely minorly and remotely denticulate, clothed equally on both sides with an appressed silky pubescence, which more or less conceals the veins; stigmas obsolete: scales oblong and obtuse in the staminate ament, narrower and more acute in the pistillate; lower half of the filament densely gray-hairy: caps. lanceolate, covered with straight appressed silky hairs, closely sessile; stigma sessile; mature caps. often nearly glabrous. Occasionally the lvs. remain upon the plant over winter, the young shoots appearing in their axils in spring. Ament surpassed in length by its leafy peduncles; appearing in May in Ore. and N. Calif. and flowering intermittently all summer. This species is distinguished by its narrowly lanceolate, entire lvs., obsolete stipules, small and rather narrow aments, coarse scales, and hairy caps. S. argophylla occurs on the Pacific slope from S. Calif. to Brit. Col. It is a western representative of the long-lvd. willows. Not advertised, but a beautiful species common along streams and irrigation ditches. 

16. balsamifera, Bbl. Figg. 3527. A much-branched clear-looking shrub, with shining colored twigs, sometime aromatic foliage: glabrous: lvs. short-oval to lance-oblong, rounded and sometimes somewhat cordate at base, glandular-serrulate, thinish and fragrant, dark green above and pale or glaucous and also prominently reticulate beneath: fertile aments becoming lax and open, the slender pedicels of the carpels much longer than the glands, the style short. Along the northern borders of the U. S. and far northward; an attractive species. G.F. 6:29 (reduced in Fig. 3528). 

17. Cáprea, Linn. GOAT WILLOW. Fig. 3529. A small tree, 12--25 ft. high, with upright branches: lvs. large, 2-5 in. long, 1-3 in. wide, rounded or subcordate at base, rugose, very variable: aments appearing before the lvs., large and showy, especially the staminate ones. Eu., Asia. — The typical form often occurs in yards where it has sprouted from the stock upon which the more popular but scarcely more ornamental variety, pendula, has been grafted. Var. pendula, Hort. KILMARNOCK WILLOW. Dwarfed form, grafted on stock about 3 ft. high, and forming a weeping shrub. Often planted in yards. S. multínérmis is supposed to be a hybrid, and probably belongs with S. Cáprea. S. Cáprea var. trícolor, Hort., is said by F. W. Kelsey to be a round-headed tree, with "tri colored foliage," probably a form of S. aurita. S. palmáfólia, Hort., is said by F. W. Kelsey to be of vigorous growth, with large, deep green lvs. and reddish purple young wood. 

18. discolor, Muhl. PESSY WILLOW. Figs. 3521, 3522, 3527. A shrub or short-trunked tree, 10-20 ft. high: buds very large and nearly black: lvs. smooth and bright green above, whitish beneath, irregularly crenate-serrate: aments appear early in spring, before the lvs., closely sessile, enveloped in long silky hairs. E. N. Amer. — Worthy of more extended cult. and thriving in dry ground. 

19. rostráta, Rich. (P. Bobbétána, Sarg.). Fig. 3527. A small tree, 10-20 ft. high, with short but distinct trunk: buds of medium size, conical, brownish lvs. dull green and downy above, prominently veined and hairy beneath: aments appearing with the lvs., the staminate beautiful golden when in flower; scales narrow
and shorter than the pedicels: caps. long-rostrate. E. N. Amer.—Prefers dry soil and can be used to good advantage against walls and in rockeries.

20. **humilis**, Marsh. **Prairie Willow**. A shrub, 3–8 ft. high, varying much in stature, and in size and shape of lvs.; branches hairy: lvs. oblanceolate to oblong, nearly entire, more or less revolute: aments densely and many-fld. E. N. Amer.—Grows in dry situations.

21. **tristis**, Ait. **Dwarf Willow**. Fig. 3527. A diffuse shrub, 1–1 1/2 ft., with long deep-set root: branches gray, slender: lvs. small, 1 in. long, linear-lanceolate, very short-petioled: aments small and rather few-fld.; stamens reddish. N. E. N. Amer.

22. **sericea**, Marsh. **Silky Willow**. A shrub usually 4–8 ft. high, diffusely spreading from base: branches often reddish: buds obtuse and rounded at apex, cylindrical: lvs. very silky beneath, sometimes becoming less so at maturity: aments densely fld., appearing with the lvs.; stamens often orange-red: caps. short-pedicelled, ovate-oblong, nearly truncate at apex. N. E. N. Amer.—This species hybridizes freely with *S. cordata*, and several natural hybrids have been described.

23. **petiolaris**, Smith, not Hort. Fig. 3526. A low shrub, 3–5 ft. high: branches slender, the whole plant much slenderer than *S. sericea*, with which it frequently grows: buds smaller and more pointed: lvs. only slightly silky when young, soon glabrous, more evidently toothed: aments rather loosely fld.: caps. rostrate and pointed, distinctly pedicelled. Cent. and N. E. N. Amer.—*S. petiolaris* of the trade is *S. incana*.

24. **viminalis**, Linn. **Osier Willow**. A shrub or small tree, 10–20 ft. high: branches slender and straight: lvs. linear-lanceolate, beautifully silvery, 4–10 in. long; margins revolute, entire: aments appearing before the lvs., golden yellow. Eu., Asia.—Most often seen in plantations for basket material, for the production of which the plants are cut near the ground every year. Willow-culture in experienced hands is often profitable. (For details, see Simpson, *Osier Culture*, Bull. 19, Div. of For., U. S. Dept. Agric. 1898.) This species does not thrive in this country as well as in Eu.

25. **candida**, Fluegge. **Hoary Willow**. Fig. 3526. A shrub, 2–5 ft. high: young branches hoary, becoming smooth and red with age: buds reddish, rounded at the apex: lvs. lanceolate or linear-lanceolate, 2–4 in. long, dark green and wrinkled above, covered below with dense white tomentum, revolute: aments sessile, appearing before the lvs.: staminate of reddish anthers: caps. densely white-woolly, with red style and stigmas. N. Amer.—This species hybridizes freely with *S. cordata*, and several natural hybrids have been described.

26. **myrtilloides**, Linn. Fig. 3526. A shrub, 2–5 ft. high, with rather slender brown twigs: lvs. oblong or elliptic-obovate, usually obtuse at both ends, entire and smooth, reticulate-veined: aments rather few-fld.: caps. reddish, glabrous. N. E. N. Amer. and Eu. Usually grows in cold peat-bogs.—Probably not in cult. The plant sold under this name is probably some form of *S. purpurea*, which *S. myrtilloides* closely resembles in general appearance.

27. **cordata**, Muhl. (S. *rigida*, Muhl.), **Heart-leaved Willow**. Fig. 3530. A large shrub or small tree, 10–30 ft. high: branches stout: buds large, flattened against the branch: lvs. oblong-lanceolate, green on both sides, finely serrate, glabrous and rather rigid at maturity: aments rather slender, appearing with the lvs.: caps. glabrous, greenish or brownish. N. Amer.—This is a variable species and undoubtedly some of the forms included in it are hybrids; several supposed natural hybrids have been described. Var. *pendula*, Hort., is a decumbent form.

29. **incana**, Schrank (*S. petiolaris*, and *S. rosmarinifolia* of American gardeners, but not of botanists). Shrub or small round-topped tree, with long, slender branches: lvs. linear, revolute, 2–5 in. long, very narrow, green above, white-tomentose beneath: aments long and slender, appearing with the lvs.: caps. glabrous; filaments of stamens more or less connate. Eu.—This species is frequently grafted upon hardy stock (*S. Caprea*) when sold from nurseries.

31. sitchenisis, Sans. Stretta Willow. A shrub, 10-12 ft. high and more; lvs. obovate, glabrous, clothed beneath with a soft white down. The aments appearing after the lvs., large, cylindrical and graceful, also satiny. N. W. N. Amer.—This willow, which, so far as known, has not been used as an ornamental plant, is one that would be at once novel and beautiful. The nomenclature here given is provisional. Salix sitchenisis, the type of the genus, is preserved in plants in culture.

32. Cotettii, Kerner. A low shrub differing from S. rehus mainly in the larger size of the whole plant as well as the lvs. Cent. Eu. G.W. 9, p. 342.

33. herbaeae, Linn. A very dwarf species usually not more than an inch or so in height, forming dense mats; lvs. orbicular, serrate, usually emargnate at both base and apex. Alpine regions of Amer. and Eurasia, White Mts., N. H.

34. myrsinites, Linn. (S. Jactuati, Host). An alpine shrub a foot or less high, either erect or more or less creeping; lancesolate, coriaceous, shining, green both sides. Arctic and alpine regions.

35. pyreneaca, Gouan. A dwarf caulescent shrub usually more or less depressed in habit, with slender brown shining twigs; lvs. membranous, about 1 in. long and half as wide, entire, ciliata on the margin. In the alpine regions of the Pyrenees.

36. repens, Linn. A shrub of variable stature and vestiture: lvs. oval to linear, entire or remotely serrulate, shining above, silver-silky or glabrous beneath, stipules wanting. N. Eu. and Asia. Var. argentea has silver-silky lvs. G.L. 22:325.

37. reticulata, Linn. A depressed shrub with few oval or orbicular lvs. glaucous beneath, green above, rugose-runcinate: aments slender, borne on a long peduncle. Arctic regions of both hemispheres.

38. retusa, Linn. (S. seryphylofoia, Scop.). A depressed shrub: lvs. characteristically "parallel"-veined, oblong or slightly retuse at the apex, entire, less than 1 in. wide. Alpine regions of Eu. and Asia.

S. aglaia, Hort.—S. daphnoides.—S. ammopolola, Linn. (S. triandra, Linn.). Usually shrubby, to 12 ft.; branchlets glabrous, 5-6 in. long, the lvs. lanceolate, glabrous, pale green or white below, to 3 in. long; fls. shortly before or with the lvs.; stamens 3; ovary long-stalked, glabrous. Eu.—S. Biberi, Steenb. An ornamental dwarf species: lvs. oblong or oval, 1/2-1 in. long, mucronate, dark green and glabrescent above, silvery with silvery margined hair beneath; aments 1-2 in. long, produced in Oct. and Nov. before the fall of the lvs. China.—S. phylloides, Dode. A hybrid between S. babylonica and S. retusa. Salix retusa, the type of the genus, is preserved in plants in culture.

SALPICHROA (Greek, tube and skin; in reference to the form and texture of the flower). Syn. Salpichroma. Solanaceae. Shrubs, subshrubs, or herbs, sometimes grown in the greenhouse and now used for outdoor planting in southern California.

Leaves often small, erect, long-petioled; fls. white or yellow, 2-3 in. long (Section Salpichroma) or only about 1/2 in. long (Section Perizoma); calyx tubular or short, 5-cleft or -parted, the lobes linear; corolla tubular or urn-shaped, without a crown in the throat; lobes 5, ample, often short induplicate-valvate; berry ovate or oblong, 2-celled; seeds numerous, compressed.—About 10 species, extra-trop. S. Amer. The species described below is said to have the advantage of being an exceedingly rapid grower, with a thick mass of foliage and will thrive in alkali soil and under intense heat. The small white berries are sold everywhere in Paraguay as "cock's eggs." It grows with astonishing rapidity from the fleshy roots, which, however, are destroyed by frost.

SALPICHROA (Greek, tube and skin; in reference to the form and texture of the flower). Syn. Salpichroma. Solanaceae. Shrubs, subshrubs, or herbs, sometimes grown in the greenhouse and now used for outdoor planting in southern California.

Leaves often small, erect, long-petioled; fls. white or yellow, 2-3 in. long (Section Salpichroma) or only about 1/2 in. long (Section Perizoma); calyx tubular or short, 5-cleft or -parted, the lobes linear; corolla tubular or urn-shaped, without a crown in the throat; lobes 5, ample, often short induplicate-valvate; berry ovate or oblong, 2-celled; seeds numerous, compressed.—About 10 species, extra-trop. S. Amer. The species described below is said to have the advantage of being an exceedingly rapid grower, with a thick mass of foliage and will thrive in alkali soil and under intense heat. The small white berries are sold everywhere in Paraguay as "cock's eggs." It grows with astonishing rapidity from the fleshy roots, which, however, are destroyed by frost.

rhomboides, Miers (Salpichroma rhomboides, Miers). A half-hardy climber, somewhat wooly, with green, flexuous branches: lvs. small (blade: 2-3 in. long), ovo-v - rhomboid: fls. small, usually less than 1/2 in. long, solitary, nodding, white; corolla short, centri­nate at the middle, high, and at the throat, and bearing on the inside a fleshy, woolly ring: berry ovate-oblong, yellowish or white, edible, but of poor flavor. Argentina. G.C. III. 24: 450. R. H. III. 8: 45. C. 39: 367. F. E. 32: 448.

The plant appears to be offered as Withania origenifolia, although the genus Withania itself has good stand­
SALPÍGLOSSIS (Greek, tube and tongue; alluding to the form of the corolla and the appearance of the style). Solandraceae. Viscous-pubescent half-hardy annual, biennial, or perennial herbs, chiefly used for garden flowers, but sometimes also grown in the greenhouse; of rich and attractive colors.

Plants about 18 in. high, erect, covered with short glandular hairs: lvs. entire, wavy-margined, dentate or pinnatifid: fls. long-stemmed, large, funnel-shaped, ranging in color from various shades of purple and blue, through numerous reds and yellows to creamy white, and usually beautifully marbled and penciled with several colors; calyx tubular, 5-crested, corolla funnelform, widely bell-shaped at the throat; lobes 5, pleate, emarginate; stamina 4, didynamous: caps. oblong-ovoid; valves 2-crested.—About 8 species, natives of Chile.

The usual species in cultivation is *S. sinuata*, which was formerly divided into about 6 species mainly on the color of the flowers. *S. sinuata* has greatly increased in size of flowers and range of color until it is at the present time amongst the very finest half-hardy annuals. The varieties of salpiglossis require the general treatment given half-hardy annuals. They prefer a deep light rich soil not given to sudden extremes of moisture and dryness. The seeds may be sown indoors by the middle of March or later, or may be sown outdoors in early spring. Care must be taken that the early sown plants do not become stunted before being planted out. They bloom for several weeks in late summer. The flowers are useful for cutting and last well. The plant is also excellent as a greenhouse annual for late winter bloom. Seeds for this purpose may be sown in late summer. (F. W. Barchay.)

*S. atropurpurea*, Graham. St. procumbent at base, then erect, about 2 ft. high: lvs. scattered, various in shape, lanceolate-elliptical, elliptical, or ovate-elliptical, scattered, assected, the segments generally blunt and entire: fls. deep rich purple on rather long pedicels. Chile. B.M. 2921. Included in 8 *S. sinuata* by many authorities—*S. atropurpurea*, Hook. (S. *picta*, Sweet. S. *straminea* var. *picta*, Hook.). Included in 8 *S. sinuata* by many authorities from which it differs in the color of the corolla, which is whitish tinted yellow at the throat and often purple-veined. The top of the style of *S. straminea* is toothless while that of *S. sinuata* is toothed. Chile. B. M. 1965. Probably not in the trade. (F. Tracy Hubbard.)

SALSIFY (Greek, trumpet, referring to the shape of the calyx). Melastomaceae. Erect glabrous branching herbs, including the warmhouse foliage plant known to the trade as *Bertolonia marginatae*. Leaves often unequal, oblong or lanceolate, long-petiolated, under surface pubescent. Fls. spicate, on terminal, simple or dichotomously branched peduncles, second, sessile or pedicellate; calyx glabrous, tube tubular or campanulate, 10-ribbed, the lobes short, tuberculate outside; petals 5, oblong or obovate; stamina 10; ovary free, oblong, 3-celled; caps. 3-edged, included in the perete, thickened, ribbed calyx.—Four species, Guiana, Brazil, and Peru.

*margaritacea*, Triana (Bertolonia *marginatae*, Hort. Bull. Gravcsia *guithia* var. *marginatae*, Nichols.). Tender perennial herb: st. 1½-4 in. high, erect, usually 4-angled, simple: lvs. long-petiolated, thin-membraneous, ovate, base rounded or frequently distinctly emarginate-cordate, upper surface dark dull green, white-spotted between the veins, lower surface dull green, reddish or bright red; slender-branched, the branches red, rather long; fls. white or sometimes whitish rose; calyx-tube purplish, 10-ribbed, the ribs red; segms. green with pink tips; petals erect or erose at base: caps. pale, obscurely 3-sided. Brazil. F.S. 16:1697.

*S. longifolia*, Triana (Bertolonia *longifolia*, Cham.). St. short, herbaceous: lvs. oblong, rarely ovate-oblong, base rounded or slightly cordate, upper surface bright green, lower surface paler, searly-pubescent; cymes terminal; fls. white: caps. pale, 3-silled. Brazil.—S. *secunda*, Schrank & Mart. St. subshrubby, erect; lvs. narrow-ovate or ovate-oblong, base rather obtuse or short-acute, upper surface light green, lower surface paler: cymes terminal and axillary; fls. unknown: caps. pale red-brown, narrowly oblong, subcilindrial. Brazil. (F. Tracy Hubbard.)

SALPIGLÓSSIS
SALSOULA (Latin, sols, salty; the plants grow in salty places). *Chenopodiaceae*. Weedy annual and perennial branching herbaceous plants of some 50 species of very wide distribution, mostly on seashores and in saline soils, of no horticultural interest. Leaves narrow, usually awl-shaped or long-pointed, commonly fleshy; fls. very small, sessile in the axils (Fig. 3533), perfect, provided with 2 bractlets; calyx 5-parted, the segments winged on the back; petals 0; stamens usually 5; styles 2: fr. a flattened utricle, with a horizontal seed. Of interest because it includes the Russian thistle, *S. Káli*, Linn., var. tenuifólia, Mey. (*S. péstifer*, Nels.), now a widespread weed along railway rights of way and very abundant in the prairie and plains regions; of relatively recent intro. from Eurasia. With good tillage and short rotations it is not to be feared; when young or bowing, it may have some value as forage. It is a bushy annual (Fig. 3534), and when broken off in autumn forms one of the tumble-weeds, and is carried long distances before the wind.

SALVIA (Latin name used as far back as Pliny, meaning to be well or healthy, referring to the medicinal properties of some species). *Labbiáceae*. Herbs, subshrubs, and shrubs, certain of which are of economic use, such as sage and clary, while others are grown for ornament both indoors and out.

Leaves entire, dentate-incised or pinnatisect; the floral lvs. are frequently changed to bracts, rarely similar to the cauline lvs.; floral whorls 2- to many-fl., variously arranged, spirate, racemose, paniculate or rarely all axillary; fls. variously colored, rarely yellow, and various-sized from large and showy tubular or campanulate, 2-lipped; corolla-tube included or exserted, limb 2-lipped; perfect stamens 2, the connective linear, transversely articulate with the filament: nutlets ovoid-3-edged or minute; calyx ovate, tubular or campanulate, 2-lipped; corolla and calyx are of different colors. The bracts range from minute and deciduous to a larger size and more attractive color than the fls. There are usually about 6 fls. in a whorl, sometimes 2, sometimes many. In spite of these and many other wide variations, few attempts have been made to split up Salvia into many genera, presumably from the feeling that the structure of the stamens makes the Salvia a natural, not an artificial group.

Cultivation of salvias. (Wilhelm Miller.)

Three salvias are cultivated for their leaves, which are used in seasoning and also in medicine. These are the common sage, *S. officinalis*; clary, *S. Sclarea*; and *S. Horminum*. For commercial cultivation of *S. officinalis*, see Sage.

Clary is a perennial plant, but is cultivated as an annual or biennial. The plants run to seed the second year, after which it is better to pull up the old plants. The seed may be sown in spring, in drills 12 to 20 inches apart or in a seed-bed, from which the seedlings are picked out in May. In August the first leaves may be gathered and the plants will continue to yield until June or July of the following year.

Clary (*S. Sclarea*) and its near relative, *S. Horminum*, are plants of exceptional interest. They are cultivated for their culinary and medicinal value and also for ornament, but their ornamental value lies not in the flowers (which are usually insignificant) but in the colored bracts or floral leaves at the tops of the branches. The various varieties are known as the Purple-top clary, Red-top clary; also Red sage and Purple sage. The two species (*S. Sclarea* and *S. Horminum*) seem to be much confused in the catalogues.

Among the salvias grown for ornament there are two large cultural groups, the hardy and the tender. The hardy species are mostly border plants, blooming in spring and early summer. The tender species are generally used for summer bedding, sometimes for conservatory decoration in winter. Many of them bloom in summer and late fall, especially when they are treated as half-hardy annuals.

As regards color of fls., there are also two important groups, the scarlet-flowered, and the kinds with blue, purple, violet, white, or variegated flowers. Of the scarlet kinds, *S. splendens* is the most called for; of the blue-flowered kinds, *S. patens* is the most popular of the bedding class, and *S. pratensis* the most sought of the hardy class. *S. patens* probably has the largest flowers of any of the blue-flowered kinds in cultivation. The most widely used of all salvias cultivated for ornament is *S. splendens*, or scarlet sage. This is
one of the most brilliant red-flowered bedding plants in cultivation. It is generally grown in large masses. It does best in full sunshine, but may be used in shady places to light up dark woody recesses. It should have a dark background of some kind by way of contrast. A well-mown and clean plot of saget may be maintained in full splendor from the middle of July to frost. It is propagated by either cuttings or seed. It is rather troublesome to keep cuttings or plants over winter, as they are particularly liable to attacks of aphis and red-spider. It is, therefore, important to get seeds of an early-blooming variety of compact habit, and to sow the seed early indoors or in a frame in time to get good plants to set outdoors in May. A good raceem is over a foot long, with 30 or more flowers in a raceem, and 2 to 6 flowers in a whorl, each flower being 2 inches or more long. Some varieties have erect raceemes, others pendulous, and there are white varieties, together with some intermediate colors. A poorly managed bed of scarlet sage gives few flowers in September and is cut off in a short time by frost. Wet seasons delay the bloom, and, if the soil is too rich in nitrogen, the plants will make too much growth and the flowers will be late and relatively few. The same principles of cultivation apply to other tender salvias used for bedding. Florists sometimes lift a few plants of scarlet sage before frost, pot them and find that they make attractive plants under glass for a month or two. One advantage that S. splendens has over many other red-flowered salvias is that its calyx is as brilliant scarlet as the corolla.

**SALVIA**

**Key to Genera and Sections.**

A. *Salvia* without a hairy ring inside.

B. Anterior portion of connective deflexed, linear, longitudinally connate or closely approximated, subulate.

**CC. Calyx tubular or campanulate.**

**AA. Calyces with a hairy ring inside.**

**2. officinalis** Linn. Sage. Hardy, white-woolly subshrub, 6-12 in. high: st. shrubby, the flowering branches compact, 1-2 in. high, subshrub, filamentous, 3-4-fl.; calyx pedicellate, campanulate, somewhat 2- or 3-lipped, 5-toothed, viscosous-pubescent; corolla with the upper lip yellowish, white or streaked, the lower violet. July. S. Spain. B.M. 5017. F.S. 13:1344.

**3. grandiflora** Linn. Sage. Hardy, white-woolly subshrub, 6-12 in. high: st. shrubby, the flowering branches compact, 1-2 in. high, subshrub, filamentous, 3-4-fl.; calyx pedicellate, campanulate, somewhat 2- or 3-lipped, 5-toothed, viscosous-pubescent; corolla with the upper lip yellowish, white or streaked, the lower violet. July. S. Spain. B.M. 5017. F.S. 13:1344.

**4. ringens** Linn. Sage. Hardy, white-woolly subshrub, 6-12 in. high: st. shrubby, the flowering branches compact, 1-2 in. high, subshrub, filamentous, 3-4-fl.; calyx pedicellate, campanulate, somewhat 2- or 3-lipped, 5-toothed, viscosous-pubescent; corolla with the upper lip yellowish, white or streaked, the lower violet. July. S. Spain. B.M. 5017. F.S. 13:1344.
Canary lsls.—Probably not in common cult. colored; corolla purplish, the galea somewhat falcate. 

3. grandiflora, Edling. Shrub. 2 ft. or more high: st. woody, white-lanate; the flowering branches tomentose: lvs. entire, petiolate, ovate, acute, the base broad-rotund or cordate, pubescent, the lower ones lanate beneath; floral lvs. herbaceous or the uppermost membranaceous, ovate, acute: racemes sub-simple: floral whorls 6-10-fld., distinct; calyx campanulate, colored, striate, hispid; corolla blue. July. June, July. Asia Minor.—Rare in cult. The name is sometimes used in horticulture for plants which belong under S. aurea var. grandiflora or S. splendens var. grandiflora.

4. ringens, Sibth. & Smith. Hardy shrub, 1-2 ft. high: sts. glabrous or spreading, pilose at base, viscoso-pubescent above: lvs. petiolate, irregularly pinnate, the segments unequal, ovate-oblong, base rotundate, both surfaces villous, scarcely canescent beneath, the petioles long-ciliate; floral lvs. membranaceous, deciduous: raceme simple: floral whorls 2-fld., lax, remote: calyx campanulate, villose, viscid, the teeth rather acute; corolla reddish purple or light blue, the tube recurved-ascending, the throat very broad. Summer. Greece. Gt. 2:226.

Section 2. HYMENOPACE.

5. aurea, Linn. Shrub, 3 ft. or more high, white-tomentose: lvs. ½-1 in. long, petiolate, ovate-subrotund, obtuse, entire or sinuate, leathery, hoary; floral lvs. sessile, villous, persistent: racemes dense, 2-4 in. long, somewhat branched; floral whorls 3-fld., approximately: calyx broad-campanulate, villous, the lips membranous dilated, veined, and colored, the lobes ovate-rotundate; corolla very beautiful, golden yellow, the galea somewhat falcate. July. S. Afr. B.M. 182. G.C. II. 26:745.—Intro into Calif. According to one grower the fls. are at first sulfur-yellow turning very quickly to a dusty color.

6. canariensis, Linn. Shrub, about 6 ft. high: st. shrubby, white-lanate; lvs. petiolate, lanceolate, hastate-triangular, subglabrous; floral lvs. ovate-lanceolate, membranaceous and colored: racemes branched: floral whorls 2-fld., distinct, about 6-fld.; calyx incurved-campanulate, the lips dilated membranaceous, colored; corolla purplish, the galea somewhat falcate. Canary Isls.—Probably not in common cult.

7. glutinosa, Linn. (S. subulata, Wall.). Perennial. about 3 ft. high: st. herbaceous, erect, glutinous-pilose, divergently branched; lvs. petiolate, the lowest 7-8 in. long, the upper smaller, ovate-oblong, acuminate, dentate, the base cordate-sagittate; floral lvs. ovate, acuminate: racemes simple; floral whorls about 8-fld.; calyx lobes elliptic-oblong, pilose, viscid; corolla pale yellow, often 1½ in. long, the tube exserted with its throat broadened. July. Eu. and Asia.

8. nipponica, Miq. Herb. 6-12 in. high, slightly branched: sts. ascending-erect; lvs. petiolate, opposite, ovate-trilobed or triangular from a truncate cordate-base, the basal lobes horizontal-spreadmg, the midlobe ovate, larger or equal, all short-acuminate, dentate-crenate, sparsely hirtellus-pubescent above and especially so on the nerves beneath; cauline lvs. 1-3½ in. long; floral lvs. ovate, entire: racemes rather lax, 2-4 in. long; floral whorls frequently 4-fld.; calyx obconic- or subcampanulate-tubular, pilose, glandular-punctate; corolla whitish glandular, punctulate when dry, tube half exserted. Japan.

9. yunnanensis, C. H. Wright. Perennial herb, about 1 ft. high: rhizomes creeping, bearing fusiform tubers: lvs. 1½-3 x ½-1 in., the radical frequently very long and slender-petioled, obtuse, crenate, green above, purple beneath: spikes simple; floral whorls 4-6-fld.; calyx glandular; corolla coeruleobalt, 1 in. long, pubescent outside. China.

10. hians, Royle (S. himalayaca, Hort.). Fig. 3535. Hardy perennial, about 2 ft. high: st. herbaceous, erect, villous: lvs. long-petioled; ovate, broadly cordate-sagittate or truncate; floral lvs. ovate, acuminate: racemes somewhat branched; floral whorls 6-fld.; calyx campanulate, striate, bluish, glutinous; corolla...

11. Przewalskii, Maxim. Sts. ascending, 3–5 ft. high, herbaceous, pubescent, glandular above; radical lvs. long-petioled, crenate-dentate, hoary, the teeth all subulate-spinose; corolla white, the upper lip reddish, tube contracted at the middle; connectives not toothed. S. Eu., N. Afr., and the Orient.—Probably not common in cult. S. athiopica, Brot., not Linn., equals S. argentea, which see.

15. argentea, Linn. (S. palastra, Desf.). Biennial, 2–4 ft. high; sts. herbaceous, erect, villous; lvs. radical and lower villose, 6–8 x 4–6 in., broad-ovate, sinuate-lunate; corolla white, the uppermost abortive; calyx campanulate, striate, the teeth all subspinosae; corolla showy, rose-white, whitish, purplish or yellowish, the galea or upper lip much longer than the lower. June. Medit. region of Eu. and Afr. F.C. 3:112. Gt. 73, p. 517.—For some reason this species is considered a hardy perennial by American gardeners, and it is a very decorative plant.

16. verbascifolia, Bieb. (S. microstegia, Bois. & Bal.). Perennial; sts. herbaceous, erect, villose; lower lvs. petiolate, broadly ovate, base cordate, sinuate-lunate, erose, thick, very wrinkled, scarcely lanate above, white; corolla white, beset with blue hairs, galea very large and falcate. Caucasus region. Var. kurdica, Hort., is offered in the trade.

17. Montbréti, Benth. Perennial subshrub, low; sts. erect, the base white-lanate, the top viscous-villose; lvs. lanceolate, the lower petiolate, the upper clasping, crenate or obscurely pinnatifid-dentate, lady white-lanate above, densely so beneath; floral lvs. very broad, lanate beneath; racemes simple; floral whorls 6–10-fl.; calyx white-lanate, vious-pubescence; corolla blue. Asia Minor and Syria.

3536. Salvia pratensis. (XIV)
SALVIA

18. bicolor, Lam. Biennial, sometimes perennial (?), hardy; sts. herbaceous, erect, 2-3 ft. high, scarcely branched; lvs., the lowest petiolate, broad-ovate, incise-dentate, pinnatifid or pinnate-lanceolate; the upper sessile, lanceolate, all cordate at base and glabrous-pubescent; floral lvs. ovate-lanceolate, acuminate, red-veined; racemes 1½-2 ft. long, many-fl.; floral whorls distinct, about 6-fl.; calyx campanulate, striate, glabrous, the teeth subulate-acuminate; upper lip of corolla hooded, bluish violet dotted with yellow, the lower white, said to fade quickly to a rusty brown. May-July. Spain and N. Afr. J. M. 1774. G. M. 40:487. P. M. 9:271.

19. dichroa, Hook. f. Half-hardy perennial; sts. 2-3 ft. or more high, quadrangular with obtuse thickened yellowish angles, which are retrorse ciliate; radical lvs. petiolate, oblong-ovate or ovate-lanceolate, obtusely and very irregularly sinuately serrate, pubescent; upper caule lvs. sessile-oblung or elliptic-oblong; floral lvs. ovate, long-acuminate, red-veined; raceme about 4-5 in. long; floral whorls 2-3-fl.; calyx subcampanulate, glandular-pubescent, strongly ribbed, green; corolla 1-1½ in. long, upper lip bright blue, arcuate, pubescent, lower lip 3-lobed, the lateral lobes pale blue, the midlobe of corolla hooded, bluish violet dotted with yellow; the lower lip white. 'A plant which grows 2 ft. high and with deep bluish-purple flowers.' Presumably an error for S. splendens, Wild. (S. splendens, Wild.), a white form, is offered in the trade. Var. rosea, Hort. (S. sylvestris var. flore-dabo, Hort.), is a white-fl. form.

20. pratensis, Linn. Hardy perennial, 2-3 ft. high; sts. herbaceous, subsimple, pubescent to nearly naked; lvs. few, the lower long-petiolated, ovate-oblong, 4-5 in. long, double-crenate, the base subcordate; floral lvs. minute, orbicular: racemes short, 1-1½ in. long, paniculate, long-peduncled, nodding after anthesis; floral whorls about 6-fl., approximate; calyx reflexed, pubescent; corolla violet, the galea straight and spreading. July. S. E. Eu. B. M. 2438.

21. virgata, Ait. (S. gigantea, Desf.). Hardy perennial, 2 ft. or more high; sts. herbaceous, erect, branched, pubescent-villosous: radical lvs. petiolate, broad-ovate, base cordate; lower caule lvs. short-petioled, broad ovate-oblong, base round or cordate, upper ones sessile and smaller, the uppermost cordate, clasping; all the lvs. erose-crenate, rather glabrous above, pubescent or hispid on the nerves beneath; floral lvs. ovate-acuminated somewhat reflexed: racemes branched, elongated, few-fl.; floral whorls 6-fl., distant; calyx short-peduncled, campanulate, striate, villous-villosous; corolla light blue, the tube included. S. E. Eu. and the Orient. Var. alba, Hort., a white form, is offered in the trade.

22. sylvestris, Linn. Hardy perennial, 6 in. to 3 ft. high; sts. herbaceous, paniculate above; lvs. often small, scarcely 2 in., sometimes 3-4 in. or more long, the lower petiolate, the upper sessile, all oblong-lanceolate, crenate, base rounded or frequently cordate, glabrous above, paler, pubescent or canescent beneath; floral lvs. orbiculate, acuminate, colored: racemes elongated, somewhat branched; floral whorls 6-10-fl., distinct; calyx ovate-tubular; corolla purple-violet. Aug. Eu. and Asia. Var. alba, Hort. (S. sylvestris var. flore-dabo, Hort.), is a white-fl. form.

23. nemorosa, Crantz (S. virgina, Hort., not Ait. S. virgina nemorosa, Hort.). Fig. 3537. Perennial, 2-3 ft. high, much branched: radical lvs. short-petioled, cuneate sessile, lanceolate, 2½-3 in. long, the upper lvs. gradually reduced in size, glabrous and dull green above, pale and finely pubescent beneath; fls. small, in very long slender spikes terminating all the branches, up to 16 in. long; floral whorls approximate, 6-fl.; corolla bright violet or purple. June-Oct. Eu. and W. Asia. G. M. 56:714. R. H. 1913, p. 471. —The fls. are sometimes described as being brassy purple. Var. alba, Hort., is said to grow 18 in. high and to have larger spikes of white fls. This may be the same as S. sylvestris var. alba, as S. nemorosa, Linn., is a synonym of S. sylvestris.
All American species.

Section 7. Calosphace.

Herbs, subshrubs or shrubs.

A. Lvs. pubescent: corolla-tube slightly exserted, straight, ventricose or broadened above, the lips subequal or the upper longer.

Subsection Erianthina.

(See also Nos. 36, 39, 43 and 44.)

AA. Lvs. seldom pubescent (rugose in No. 36, 39, 43, and 44).

b. Corolla about 5½ in., occasionally a little longer.

Subsection Brachyanthis.

c. The lvs. cordiform

c. The lvs. linear, lanceolate, or ovate-lanceolate.

d. Calyx densely white or violet-lanate.

e. Floral lvs. lanceolate-linear; floral whorls about 8-fld.

EE. Floral lvs. broad-ovate; floral whorls 10–20-fld.

29. uliginosa

BB. Calyx rugose (rugose in Nos. 36, 39, 43 and 44).

Calyx pubescent or slightly tomentose but not densely lanate.

Calyx not inflated, usually pubescent.

Subsection Longiflorae.

c. Base of some or all the lvs. hastate or angulate-cordate.

d. Under surface of lf. hispid or pubescent.

DD. Under surface of lf. glabrous.

CC. Base of lvs. sometimes cordate, but not angulate or so.

DD. Calyx not inflated, usually tubular-campanulate.

E. Lvs. membranaceous

EE. Lvs. more or less coriaceous.

F. Tube of corolla not ventricose.

GG. Tube of corolla ventricose.

a. Corolla usually bluish, purple, or violet.

h. The lvs. cuneate or ovate-oblong, tomentose above.

II. Under surface of lf. pubescent

II. Under surface of lf. glabrous

GG. Corolla usually scarlet or crimson, sometimes in shades of purple (cf. No. 33).

H. Lvs. ½–2 in. long.

1. Blade of lf. ovate or oblong-oblong.

II. Blade of lf. narrowed-oblong to linear-lanceolate.

i. Lvs. more than 1 in. long

Subsection Brachyanthis.

27. azurea, Lam. (S. acuminata, Michx., not Cav.). Perennial, 1–6 ft. high; sts. herbaceous, erect, glabrous: lvs. petiolate, oblong-lanceolate or linear, rather obtuse or acute, base long-narrowed, somewhat serrate, base surfaces green and glabrous; floral lvs. lanceolate-linear, deciduous; racemes simple, elongated; floral whorls distant, about 6-fld.; calyx green or bluish, subsessile, tubular, striate, the 3 teeth rather acute; corolla blue. Aug. S. C. to Fla. and Texas. B.M. 1728. Var. grandiflora, Benth. (S. Pitcheri, Torr.), which differs in being cineraceous-puberulent, in its denser infl. and tomentulose-sericaceous calyx. G.C. II. 14:665. Gn. 19:600; 61, p. 300. G.Z. 26:121.—Probably the plant formerly offered as S. Pitcheri var. angustifolia, Hort., belongs here. It is quite probable that some of the material in the trade as S. azurea var. grandiflora is in reality S. farinacea. Var. grandiflora alba, Hort. (S. azurea var. alba grandiflora, Hort.), is a white-fld. form of the variety.

28. farinacea, Benth. Perennial, 2–3 ft. high; sts. herbaceous, erect, tomentose: lvs. petiolate, ovate-oblong, or lanceolate, rather obtuse, irregularly serrate-crenate, rather glabrous, both surfaces green or the lower crenate; floral lvs. small, deciduous; racemes elongated, simple; floral whorls many-fld., subsecund, remote or the uppermost approximate; calyx subsessile, tubular, purplish colored, densely white-lanate; corolla purple or violet, the tube scarcely exserted. Summer. Texas, where it is reported as growing in rich soil. G.M. 56:711. G.Z. 26:121.—A showy frequently cultivated species, the fls. quite attractive, the darker corollas being set off by the mealy violet-white calices. Var. alba, Hort., is a white-fld. form with the midlobe of the lower corolla-lip obcordate, 2-lobed.

29. uliginosa, Benth. Sts. herbaceous, erect, 2–6 ft. high, virgate, branched, glabrous or villous: lvs. 2–4 in. long, petiolate, oblong-lanceolate, acute, serrate, base narrowed, glabrous or pubescent; floral lvs. membranaceous, broad-ovate, acuminate, deciduous; racemes dense, long-peduncled, somewhat branched; floral whorls many-fld.; calyx campanulate, variable, sometimes colored; corolla blue or white, tube somewhat or nearly included. Brazil, Argentina, and Uruguay. B.M. 8544. Gn. 77, p. 484. G.M. 56:711. R.R. 1912, p. 469.

Subsection Erianthina.

31. leucantha, Cav. Fig. 3535. Shrub, about 1½–2 ft. high; st. shrubby, with elongated branches which are subtended, and white-lanate, the wool finely caducous: lvs. short-petiolate, lanceolate-linear, acute, crenate, base rotundate, pubescent and rugose above, white-lanate beneath; floral lvs. ovate, acuminate, deciduous; raceme elongated, often purplish, 6–10 in. long; floral whorls many-fl.; the lower remote; calyx subtrigose, ovate, densely lavender- or violet-lanate; corolla white, white-lanate outside. June. Mex. B.M. 4318. Gn. 21:328.—Probably not very common in cultivation, at least in N. Amer.
Subsection LONGIFLORA.

Nobles.

33. Sessei, Benth. (S. Rokéitii, Scheidw.). Fig. 3535. Subshrub, about 1½ ft. high: st. shrubby with rather glabrous branches: lvs. petiolate, oval, obtuse, base rounded or cuneate, irregularly crenate in the center, subglabrous; floral lvs. ovate, acuminate, ciliate, deciduous; racemes elongated, more than 1 ft. long; floral whorls 2-fl.d.; calyx tubular, striate-nerved, pubescent, frequently colored; corolla deep crimson or when older purplish, the midlobe of the lower lip, which is large and obcordate, two small white spots. Summer. Mexico. B.R. 1370. L.B.C. 15:1798. G.W. 15, p. 48.

34. Grégoii, Gray. Shrub, 1-3 ft. high: st. shrubby with glabrous or very slightly pubescent branches: lvs. petiolate, oval, obtuse, base rounded or cuneate, irregularly crenate in the center, subglabrous; floral lvs. ovate, acuminate, ciliate, deciduous; racemes elongated, more than 1 ft. long; floral whorls 2-fl.d.; calyx tubular, striate-nerved, pubescent, frequently colored; corolla deep crimson or when older purplish, the midlobe of the lower lip, which is large and obcordate, two small white spots. Summer. Texas and Mexico. B.M. 6812. Var. alba, Hort., is a white-fl.d. form.

36. fulgens, Cav. (S. cardinális, HBK.). CARDINAL SALVIA. MEXICAN RED SALVIA. Perennial shrub, 2–3 ft. high: the numerous branches almost glabrous or pilose-blanco: lvs. petiolate, 1–3 in. long, ovate, acute, crenate-serrate, base cordate, pubescent above, white-tomentose or lanate beneath; floral lvs. sessile, ovate, deciduous; racemes 6–12 in. long; floral whorls 6-fl.d., rather distant; calyx pedicelled, tubular-campanulate, pubescent, corollas showy scarlet, about 2 in. long, villous. July. Mexico. B.R. 1356. L.B.C. 20: 1810.—The fls. are darker red than those of S. splendens and the calyx is said to be dull colored and conspicuously striate. Apparently not very frequently cult. Var. Boucheana, Benth. (S. Boucheana, Kunth), has the lvs. narrowly deltoid-ovate, truncate or subcordate at the base. Mex.

Cyanex.

41. *cyanea*, Benth. St. shrubby: branches 4-angled, hoary-pubescent or glabrous: lvs. petiolate, ovate, acuminate, serrate-crate, pubescent, or frequently canescent beneath; floral lvs. ovate, acuminate, membranaceous, deciduous: racemes simple: floral whorls lady 6–10-fl., subsecund: calyx tubar, bluish, glandular-villous; corolla blue, the tube exerted and ventricose. Mex and Cent. Amer.

Tubuliflorum.

42. *Goudotii*, Benth. (S. *lantanaefolia*, Hort., not Mart. & Gal.). Shrub, about 2 ft. high, with the branches red-puberulent or glabrous: lvs. about 3 in. long, ovate or ovate-lanceolate, acuminate, serrate-crate, base narrowed, both surfaces pubescent; floral lvs. lanceolate-subulate, deciduous: racemes simple: floral whorls 6–10-fl., subsecund: calyx tubular-campanulate, the teeth ovate, ciliate-margined; corolla red, more than 1 in. long. Colombia. R.B. 25:121.

43. *coccinea*, Linn. (S. *rásec*, Vahl). Annual or sometimes perennial and subshrubby: st. herbaceous, erect, 1–2 ft. high, canescent-pubescent: lvs. petiolate, 1–2 in. long, ovate, acute, crenate, base cordate, pubescent above, hoary-tomentose beneath; floral lvs. ovate, acuminate, deciduous: racemes simple: floral whors remote, 6–10-fl.; calyx tubular-campanulate, striate, often purplish, the teeth acute; corolla scarlet, glabrous. July. S. C. to Fla. and Texas, Mex. W. Indies, Drop. Amer., and cult. and occasionally escaped in India and Austral.—Probably all of the material grown as this is not true to name, possibly the larger part of it is in reality *S. splendens*. Var. *bicolor*, Hort., has the upper lip white, the lower lip brilliant carmine-red. Var. *lactea*, Hort., has white f., and *S. major*, Regel (S. *filamentosa*, Tausch. S. *Roemeriana*, Hort., not Scheele), becomes a subshrub up to 4½ ft. high, is apt to be less canescent-pubescent and has larger bright scarlet-red f., June to late autumn. Gt. 7:292. Var. *nana*, Hort., is a dwarf much-branched form. Var. *nana carmesina*, Hort., is offered in the trade. Var. *nana compacta*, Hort., is a dwarfer and more bushy form than the variety proper.

Var. *pseudo-coccinea*, Gray (S. *pseudo-coccinea*, Jacq.), grows 2–4 ft. high, and has the st., petioles, and often the margins of the floral lvs. conspicuously beset with hirsute hairs. Mex. and Cent. Amer. B.M. 2864.

Hortatan.

45. *patens*, Cav. Half-hardy perennial, 1–2½ ft. high: sts. herbaceous, erect, pilose: lvs. petiolate, ovate-
Section 11. Notosphace.

51. japonica, Thumb. Perennial subshrub, about 1 1/2 ft. high; sts. herbaceous, erect, branched, glabrous; lvs. 3-4 in. or more long, petiolate, pinnatisect, the segments ovate, acuminate, the base narrow, incised-dentate or pinnatilobate, glabrous; floral whorls 4-5 in. long, many-fld., subsimple; floral whorls distinct, about 6-fld.; calyx tubular-campanulate, glabrous, striate; corolla dark lilac or blue (?), the tube scarcely exerted. Japan. Var. alba, Hort., is a white-fld. form.

Section 12. Hemisphecia.

52. verticillata, Linn. Perennial, 2-3 ft. high; sts. herbaceous, erect, pilleose-hispous; lvs. the base cordate, lanceolate: racemes branched, often a foot or more long; floral whorls 20-40-fld., remote; calyx villos, corolla lilac-blue, the tube included. July and Aug. Eu., Asia Minor and Caucasus region.

The following species have been cultivated, or are not sufficiently known to be classified: S. angustifolia, C. (See 1). S. amplexicaule, Cav. (See 1). S. amplexicaulis, Hort. (See 1). S. arborea, Hort., is a tree-like form of the scarlet sage, but growing in a tree-like form. Possibly only a variant of S. splendens. S. aspera, O. Ktze. (See 1). S. auriculata, Hort., is offered in the trade. S. candelabra, F. H. (See 3). S. candida, Hort., is offered in the trade.—S. candidissima, Vahl (S. odorata, Willk.) (See 3). Subsp. or herb, about 3 ft. high, with ovate-lanceolate or orbicular lvs.: corolla white. Ort. 

53. conifera, Hort. (Sec. 5). Perennial herb, 3-4 ft. high with ovate-lanceolate leaves; corolla bright purple. Caucasus.

54. balearica, Hort. (Sec. 5). Perennial, 2-3 ft. high, with ovate-lanceolate leaves; corolla yellow spotted with purple. Syria. B. M. 3808 -8.

Subgenus IV. LEONIA.

Section 8. Echinosphace.

47. carduacea, Benth. Fig. 3535. Perennial, 1 ft. or more: sts. herbaceous, erect, subsimple, white-lanceolate, long-petioled, the base angulate, broad subhastate-cordate, rather thick, pubescent above, reddish or whitish and soft-villous beneath; lvs. small: racemes branched; calyx 2-fld.; calyx campanulate, pilose, the teeth aristate-acuminate; corolla deep blue, pilose, the midlobe of the lower lip fimbriate. July. Calif. B. M. 4874. G. C. II. 19: 56. Gn. 65, p. 365; 70, p. 238. A. G. 25: 589.—A unique species on account of its whistle-like foliage.

Section 9. Pycnosphace.

Section 10. Heterosphace.

49. lyrata, Linn. Hardy perennial with a thickened root: sts. herbaceous, erect, 8-24 in. high, subsimple, pilose: radial lvs. 2-3 in. long, lirate, crenate-dentate, both surfaces hispidulous: cauline lvs. few, oblong-lanceolate, the base long-narrowed; lvs. oblong-linear; racemes subsumers, disrupted; floral whors 6-fld., lax, distant: calyx tubular-campanulate, nodding, pilose; corolla blue-purple, about 1 in. long. May and June. Conn. to Ill., south to Fla. and Texas.—Not frequent in cult.

51. juliflora, Linn. White-flowered, 5-8 ft. high, with ovate-lanceolate leaves, glossy, white to blue; corolla yellow and purple. 2 ft. high. Plants are offered in the trade.—S. argentea, Vahl (Sec. 2). Subshrub or herb, about 1 ft. high, with ovate-oblong lvs. which are hoary-tomentose beneath: calyx often purplish; corolla blue, the lip very broad. Mex. 808, L. B. C. 6: 576.—S. controversa, Pobl. (Sec. 7). Subshrub or herb, 3-5 ft. high, with ovate-oblong-cordate lvs.: corolla brownish-purple, about 1 in. long. Probably Mex. 2574. F. H. 11: 1418.—S. phorata, O. Ktze. (Sec. 6). Subshrub or herb, about 3 ft. high, with ovate-cordate leaves: corolla reddish-violet.ハードyイン S. England and Ireland. Botanically unknown—S. petiolaris, Linn, (Sec. 5). Sts. herbaceous, white-lanceolate at base; lvs. deeply pinnatifid, nearly or entire, subacute-crenate, the base cordate, densely many-flowered, the lobes oblong-linear, the teeth aristate-acuminate; corolla dark blue, the midlobe of the lower lip fringed. July. Calif. B. M. 4874. G. C. II. 19: 56. Gn. 65, p. 365; 70, p. 238. A. G. 25: 589.—A unique species on account of its whistle-like foliage.

Section 11. Notosphace.

51. japonica, Thumb. Perennial subshrub, about 1 1/2 ft. high: sts. herbaceous, erect, branched, glabrous; lvs. 3-4 in. or more long, petiolate, pinnatisect, the segments ovate, acuminate, the base narrow, incised-dentate or pinnatilobate, glabrous; floral whorls 4-5 in. long, many-fld., subsimple; floral whorls distinct, about 6-fld.; calyx tubular-campanulate, glabrous, striate; corolla dark lilac or blue (?), the tube scarcely exerted. Japan. Var. alba, Hort., is a white-fld. form.

Section 12. Hemisphecia.

52. verticillata, Linn. Perennial, 2-3 ft. high; sts. herbaceous, erect, pilleose-hispous; lvs. the base cordate, lanceolate: racemes branched, often a foot or more long; floral whorls 20-40-fld., remote; calyx villos, corolla lilac-blue, the tube included. July and Aug. Eu., Asia Minor and Caucasus region.

The following species have been cultivated, or are not sufficiently known to be classified: S. angustifolia, C. (See 1). S. amplexicaule, Cav. (See 1). S. amplexicaulis, Hort. (See 1). S. arborea, Hort., is a tree-like form of the scarlet sage, but growing in a tree-like form. Possibly only a variant of S. splendens. S. aspera, O. Ktze. (See 1). S. auriculata, Hort., is offered in the trade. S. candelabra, F. H. (See 3). S. candida, Hort., is offered in the trade.—S. candidissima, Vahl (S. odorata, Willk.) (See 3). Subsp. or herb, about 3 ft. high, with ovate-lanceolate or orbicular lvs.: corolla white. Ort. 

53. conifera, Hort. (Sec. 5). Perennial herb, 3-4 ft. high with ovate-lanceolate leaves; corolla bright purple. Caucasus.

54. balearica, Hort. (Sec. 5). Perennial, 2-3 ft. high, with ovate-lanceolate leaves; corolla yellow spotted with purple. Syria. B. M. 3808 -8.
Salvia (Antonio Maria Salvini, 1633-1729, Italian scientist). "Marsiliaca." An interesting plant for the small home aquarium. Salvia is a genus of fern-allies found mostly in the tropics and comprising about a dozen species, only one of which, *S. natans*, Linnaeus, is cultivated.

Plants floating, with slender stems, bearing apparently 2-ranked, oblong leaves 4-6 lines or even 1 inch long; upper surface of leaves covered with papillose or minute warts; lower surface densely covered with brown, papillose hairs. The plant is supposed to have no true roots. What look like roots are believed to be finely dissected leaves; one of these occurs with each pair of the foliage-leaves. Many aquatic plants have these 2 types of foliage, e.g., the water lettuce, *Vallisneria spiralis*. Salvinia looks much like a flowering plant but it is a spore plant and has 2 kinds of spores, large and small ones. These spores are produced in small oval bodies known as sporocarps, each of which contains a solitary macrosorophore. The other sporocarps in the cluster contain numerous microsporocarps, each of which contains numerous microspores.

The plant is of easy culture in summer, but many persons have lost it over winter by not understanding its habits. It is an aquatic fern, and often dies in the winter after forming a broad crop. Secure it 2 to 3 feet full of foam and then fill the pan with water. After the water has cleared place the salvinias on the surface. In the winter watch for the formation of the spore-capsules. These grow in masses near the top of the clusters of root-like leaves. After the plants die the spore-capsules will remain in the soil. The plant often passes the winter in greenhouses in a growing condition, producing no spores.

Samanea (a corruption of its native Spanish name of zanam). *Leguminosae.* Spindleless or rarely spiny trees or shrubs of the American tropics, where one or two of them are much planted for shade.
SAMBUCUS (old Latin name for the elder, also spelled Sabucus). Caprifoliaceae. Elder. Ornamental mostly woody plants grown for their handsome foliage, showy clusters of white flowers, and the attractive red or black berries.

Deciduous shrubs or small trees, with stout very pithy branches, rarely perennial herbs: lvs. opposite, odd-pinnate, with serrate lfts., with or without stipules and stipels: fls. small, usually perfect, white, in terminal compound cymes or panicles, usually 5-merous, rarely 3- or 4-merous; calyx-lobes minute; corolla rotate with short tube and oval to obovate-lanceolate lobes; stamens with short filaments; ovary inferior, 3-5-celled; style short, 3-5-lobed: fr. a drupe with 3-5 1-seeded nutlets.—About 20 species in the temperate and subtropical regions of both hemispheres. Some species, particularly S. nigra and S. canadensis, possess medicinal properties; the fr. of these species and also that of S. cerulea is used in cookery, also elderberry wine is made from it. The hard wood, the large pithy shoots which are easily hollowed and the pith are put to various uses. Monograph of the genus by Count Schwerin in M.D. 1909, pp. 1-56.

The elders are large and rather coarse shrubs, rarely tree-like, or perennials spreading by suckers, with pinnate foliage and large flat or panicked clusters of white or creamy white small flowers followed by red or black, rarely glaucous or in some varieties green or yellow fruits. They are well adapted for mass planting by root-cuttings; the perennial species and also S. nigra is used in cookery, also elderberry wine is made from it. The hard wood, the large pithy shoots which are easily hollowed and the pith are put to various uses.

cc. Fr. glaucous.

3. cerulea, Raf. (S. glauca, Nutt.). Large shrub or small tree, occasionally to 50 ft.: branchlets rather slender, bloomy when young: lfs. 5-7, oblong, long-acuminate, coarsely serrate, the lower lfts. often 3-parted or pinnate, bright green, glabrous, 2-6 in. long: fls. yellowish white, in flat cymes 4-6 in. wide: fr. sub-globose, 1/4-in. thick, blue-black, whitened by a thick bloom. June, July; fr. in Aug. and Sept. Brit. Col. to Calif., east to Mont. and Utah. S. 5:222. G.W. 8:116. Var. velutina, Schwerin (S. velutina, Durand). Young branchlets and lvs. covered with a dense and short whitish pubescence. Calif. Var. neo-mexicana, Reich. (S. glauca var. neo-mexicana, S. Nels. S. inter-media, Carr.). Lfs. 3-5, narrow-lanceolate, grayish green, slightly pubescent beneath. New Mex., Ariz. M.D. 1909:8, fig. 1.—This species is similar to S. canadensis, but habit looser and taller, very striking with its large clusters of bluish white fra.; the typical
4. racemosa, Linn. Red-Berried Elder. Shrub, to 12 ft.; branches light brown; young branches glabrous or nearly so, 2–3½ in. long; infl. ovate or oblong, dense; lfts. 5–7, ovate or elliptic to ovate-lanceolate, glabrous, 2–3 in. long; fls. yellowish white: fr. scarlet. fr. ⅛ in. across, 3-seeded; nutlets yellowish white, minutely rugose. April, May; fr. in June, July. Eu. to E. Asia. H.W. 3, p. 133. R.F.G. 12:781.

Var. nana, Carr. Dwarf compact form. Var. plumosa, Carr. Lfts. incised serrate to about the middle, teeth long and narrow, purplish when unfolding. Var. plumos-aurea (S. rosiflora Crafts, Barbour). Allied to S. pubens; shrub, to 10 ft.: lfts. oblong to lanceolate, pubescent on the veins beneath; fr. ⅛ in. thick; nutlets broadly ovoid, smooth. W. China.—Handsome with its clusters of bright red fruit; it spreads rapidly by suckers and may become a weed difficult to eradicate, therefore it should not be planted where it is likely to become troublesome.

6. Schweriniana, Rehd. Herbaceous or suffruti-ose, stoloniferous, glabrous, 3–5 ft.: lfts. 5–7, oblong-lanceolate, the lower ones short-stalked, the upper ones adnate and decurrent, acuminate, very unequal at the base, serrate, 3–5 in. long; cymes flat, long-stalked, 5-rayed. pubemous: fr. salmon-red, 3-seeded, ⅛ in. thick. nutlets broadly ovoid, smooth. W. China.—Handsome with its clusters of bright red fruit; it spreads rapidly by suckers and may become a weed difficult to eradicate, therefore it should not be planted where it is likely to become troublesome.

grown upon sandy or gravelly soil, and watered frequently and plentifully with weak salt- and soda-solutions. It may be propagated by root-division, but better by sowing the seed as soon as ripe, the plants being thinned to stand from 1 to 1 1/2 feet asunder in rows 2 to 4 feet apart.

Golden samphire (Inula chromium), a native of the marshes and seacoast of Great Britain, is an erect hardy perennial, 1 to 1 1/2 feet tall, with small, fleshy leaves and yellow flowers in small, umbel-like clusters. Though grown and used like true samphire, for which it is often sold, it lacks the pleasing, aromatic taste of the genuine. It belongs to the family Compositae.

For marsh samphire, see Salicornia. M. G. RANS.

SANDERSONIA (named after John Sanderson). Liliaceae. Herb, suitable for the greenhouse: sts. suberect, simple, leafy: lvs. linear-lanceolate: lvs. showy, orange, solitary in the axils, without bracts; perianth persistent, urn-shaped to globose, somewhat inflated; stamens 6; ovari sessile; fr. unknown. — One species, S. Afr. Treatment the same as for gloriosas.

SANGUINARIA (Latin, blood; referring to the yellowish red juice of the plant). Papaveraceae. Bloodroot. Low spring-blooming perennial used for borders and for rock-gardens.

nobilis, Hook. Plants stout, erect, smooth, except the infl.: st. 4-angled: lvs. 3-9 in. long, oblong-ovate to oblong-lanceolate, obtusely toothed, narrowed into winged petioles, compast: lvs. 2 in. long, yellow, in heads subtended by bright red bracts, the heads forming a panicle. Ecuador. B.M. 5594. F.S. 23:2437. G.W. 10, p. 610. G.Z. 11:16. H.F. 8:936. Var. glauca, Lem. (var. variegata, Hort.). Lvs. variegated with pale yellow or white along the veins. F. 1867, p. 154. I.H. 14:528 (as S. nobilis); 16:580.— A hothouse plant which is very attractive when well grown, but which becomes straggling and weedy if neglected. Grown mostly for its foliage. S. parvibracteata, Sprague & Hutch. Allied to S. nobilis, from which it differs in having wingless petioles, smaller bracts with fewer (3-5) fls. and longer staminodes. Corolla yellow. Trop. Amer. HEINRICH HASSELBRING.
SANGUISORBA (Latin, blood and drink up, from reputed styptic properties in folk-medicine). Rosaceae. Chieflv perennial herbs, grown as salad plants and also sometimes in the hardy border. Leaves unequally pinnate; stipules adherent to the petiole; fls. small, often polygonal or denticulate, crowded in a dense head or spike at the summit of a long, naked peduncle; calyx-tube persistent, with 4 broad petal-like spreading deciduous lobes; petals none; stamens 4–12; achene (commonly solitary) inclosed in the 4-angled dry and thickish calyx-tube.—About 35 species, natives of the North Temperate Zone. See Petunia.

SANSEVIERIA (after Raimond de Sangro, Prince of Sanseverio, born at Naples 1710. The spelling Sanseveria is not the earliest). Liliaceae. Bowstring Hemp. Herbaceous perennials, essentially tender foliage plants, although beautiful in flower, adapted to the coolhouse. They are grown for the stiff erect fls., which are usually variegated.

Rhizome short, thick, sometimes stoloniferous: lvs. in a basal rosette, this umbelliform, frequently elongated, rather flat or terete; scape simple, tall, stout; fls. greenish white, medium-sized or long, clustered in an often dense raceme; perianth-tube slender, sometimes very long; stamens 6; ovary free, 3-celled.—Trop. and S. Afr. and India. The most recent treatment is by N. E. Brown in Kew Bulletin, 1916, where 54 species are described. The genus is important in yielding fiber.

Sansevierias are easily propagated by division or they may be raised from leaf-cuttings about 3 inches long. These cuttings form roots in sandy soil after about one month, after which a long stolon-like bud is formed, which produces the new plant at some distance from the cutting. Sansevierias are well adapted to house decoration, since they require much sunlight. A rather heavy soil suits them best.

SANSEVIERIA (after Raimond de Sangro, Prince of Sanseverio, born at Naples 1710. The spelling Sanseveria is not the earliest). Liliaceae. Bowstring Hemp. Sansevierias are well adapted to house decoration, since they require much sunlight. A rather heavy soil suits them best.
SANTALUM (from the Persian Chandal which in turn is derived from the Sanscrit Chandana, the name of the tree). Santalaceae. Evergreen glabrous trees or shrubs. S. album, yields the sandalwood: lvs. opposite, rarely alternate, coriaceous: fls. axillar in or terminal, trichotomous, parceulate, dicous; perianth campanulate or ovoid, lobes 4, rarely 5, valvate with a tuft of hair on their face; stamens 5–9, sheathed between the lobes. The wood is white or citron-colored, sweet-scented when dry, and is esteemed in India as a perfume.

SANTOLINA (derivation of name doubtful). Often, but incorrectly spelled Sancotila. Compositae. Shrubs or rarely herbs, natives of Eu. and Asia, mostly in the Medit. region, sometimes grown in the open for ornament.

Leaves alternate, aromatic; margins tuberculose, dentate or pinnately lobed, often finely divided: fl.-heads yellow or rarely white, of disk-fls. only, many-flled; involucre campanulate, squarrose, indurate, appressed. About 8 species.

Santolina is valuable for its distinct foliage and is used in the South for specimen planting and in the North for summer bedding and borders. Cuttings for the latter purpose are usually taken in the spring from plants wanting in a frame but may be taken before frost in the fall. They are easily rooted in sand.

S. alpina, Linn., is Anthemis montana, Linn., which makes a pretty ground-cover and has yellow fls., but appears not to be in the trade. (G. 75, p. 220.) S. strobophylla, Wild. In erect stems, branches leafless: lvs. in 4 vertical ranks, toothed: involucres scales lanceolate. S. Eu. G. 30/25.

SANTIVALIA (after a noble Italian family). Compositae. Usually low, much-branched herbs grown for their attractive yellow flowers.

Leaves opposite, petiolate, mostly entire: heads of fls. small, solitary, with yellow or sometimes white rays; involucres short and broad, of dry or partly herbaceous bracts; receptacle from flat to subulate-conical, at least in fr.; its chaffy bracts concave or partly conduplicate: achenes all or only the outer ones thick-walled, those of the rays usually 3-angled, with the angles produced into rigid, spreading awns or horns, those of the disk often flat and winged.—About 4 species, natives of the S. W. U. S. and Mex. May be grown as an annual in the open, but if given protection it will sometimes flower the second year. Sanvitalias are of easy culture but prefer a light or sandy soil in full sunlight.

SAP (3071) SAP

SAP, a term applied to the juices of living plants. Sap is composed of water containing mineral salts absorbed from the soil, and organic substances chiefly constructed within the plant. The water pressure by which the sap is forced from the soil by the roots or other absorbing organs may contain potassium, sodium, magnesium, calcium, iron, and nitrates, phosphates, sulfates, and chlorides. The different processes and the different reactions that take place in separate tracts of tissue are responsible for the fact that the sap is not alike in composition throughout the body of the plant.

The mineral elements and their salts may be found in nearly all saps. The limits of this article do not permit the enumeration of the large number of organic substances which may be found in the sap of various species. The more important of such compounds may be grouped under the acids, sugars, or carbohydrates and proteins. Many plants are of economic importance because of the materials dissolved in the sap. The sap of the sugar maple, for example, contains over 3½ per cent of sugar, while the sugar-beet and sugar-cane have a sap in which the proportion is very much higher.

The popular expression of "ascent of sap" refers to the fact that water entering the living cells of the roots is forced into the woody tissues or non-living elements through which it passes upward to the leaves at a rate which may vary from a few inches to over a yard an hour. (See Transpiration.) The forces operative and the mechanism of the flow are not perfectly understood.

Among other facts of interest it may be mentioned that the sap-current may pass through dead sections of stem, although it is equally certain that the sap that takes place in living cells furnish at least a part of the motive power.

The flow of sap from the sugar maple and other trees in the early spring, before the soil has thawed and while it is yet too cold for the living matter of the plant to show any great activity, is not due to the bleeding pressure, but to the expansion of the gases and liquids in the trunk and branches of the tree due to the direct warming action of the sun's rays. During the day the bubbles of air in the wood-cells become heated and expand, driving the sap from the wood-cells into the auger-hole which has been bored into the tree. At night the trunk of the tree cools slowly and the flow ceases, to be begun again next day.

The exudation pressure by which water or sap is forced from the living cells is exhibited in the bleeding which ensues when stumps and branches are cut away. The pressure which produces bleeding is often called root-pressure, although it is exerted by any part of the plant. Bleeding is exhibited by a large number of trees at the beginning of the growing season, and is also especially noticeable in the vine, dahlia, castor-oil plant, calla, nicotiana, and corn.

The amount of bleeding exhibited by any plant may be found if the stem is cut and bent over in such a manner that the end is thrust into a tumbler or small vessel, which will serve to collect the escaping sap.

Interesting records of measurement of the amount of bleeding are available. A specimen of Petasites patellaris gave off over sixty-three pounds of water in twenty-four hours; an Agave americana yielded twelve and one-half pounds in twenty-four hours. The pulque of Mexico is the preparation of sap which collects in the center of the mature rosette of agave when a cavity is cut into it.

The range of concentration of sap as denoted by its osmotic properties varies widely. Cacti and other succulents have a sap which would set up a pressure of only three to twelve atmospheres. Indian sandal shrubs may have a sap which would set up a pressure of over 3,000 atmospheres.
hundred atmospheres. The concentration is greatest in mature leaves, and in the lila this may be from twelve to twenty-five atmospheres, while the roots of the same plant may not show more than four or six atmospheres. var. fistulosus, D. F. MacDougal.

**SAPINDUS** (Latin, soap and Indian, alluding to use of the fruit as soap in India). *Sapindaceae. Soapberry.* Trees or shrubs, sometimes somewhat climbing, of economic use and sometimes used as ornamentals.

Leaves alternate, without stipules, abruptly pinnately compound, in one to four pairs; the lfts. entire, rarely serrate: rachises or terminal or axillary: fls. polygamous, regular; sepal 4-5, in 2 rows; petals 4-5, naked or bearing 1 or 2 glabrous or villous scales and gland near the apex; stamens 8-10; berry fleshy or leathery: seeds frequently globose, with a horny testa and no aril, black or nearly so.—About 15 species, tropical regions of the world.

The fruit has an alkaline principle known as saponin which makes it useful for cleansing purposes. The fruit was much used in eastern countries before the introduction of soap and is still preferred for washing the hair and cleansing delicate fabrics like silk. The seeds of some species are used for making rosaries,buttons, and the like.

The soapberry trees in cultivation are evergreen or rarely deciduous trees with pinnate, rather large foliage and with terminal large panicles of small whitish flowers followed by berry-like globose orange-brown to black fruits. With the exception of *S. Drummondii* which has proved fairly hardy in sheltered positions as far north as Massachusetts, they can be grown in subtropical regions only, but *S. Mukorossi* is apparently somewhat harder than the rest. They are sometimes planted for ornament in the southern states and in southern California and some, particularly *S. Mukorossi* var. carinatus, may possibly be profitably planted for their fruits which are rich in saponin. They do well in rather dry and rocky soil. Propagation is by seeds which germinate readily and by hardwood cuttings in early spring.

A. Lfts. oblong-obovate, 4-9; rachis usually broadly winged: petals without scales.

**Sapindaria**, Linn. A small tree, to 30 ft., with rough grayish bark: lfts. oblong-lanceolate and acute to elliptic-ovate and somewhat obtuse, opposite or alternate, entire, glabrous, veiny and lucid above, tomentose beneath, 3-4 in. long; rachis usually winged; panicle 7-10 in. long; sepal round, petals ovate, hairy: fr. ¾-3¼ in. across, globose, keeled, orange-brown, translucent. Fls. in Nov.: fr. in spring. *S. Fla.*, W. India, and S. America. Cult. in N. Fla. and S. Calif. S.S. 2:74, 75.

AA. Lfts. acuminate, 7-19; rachis with narrow margin or margins: petals with 2 scales. b. Trees evergreen.

**marginatus**, Wildl. A tree reaching ultimately 60 ft. in height: lfts. very short-stalked or nearly sessile, 7-13, lance-oblong, acuminate, glabrous above, puber beneath and somewhat pubescent on the midrib, 2-5 in. long, the upper nearly opposite, the lower alternate; rachis narrowly margined or margins: fls. white, sometimes tinged with red, in pyramidal panicles; petals ciliate, ovate to ovate-lanceolate; filaments villos: fr. yellow, translucent, globose, keeled, ½ in. across. May, June. S.C. to Fla. S.S. 18:828.—Cult. for ornament in *S. Fla.*

**Mukorossi**, Gaertn. Tree, to 60 ft.: lfts. 8-13, stalked, the stalk ½-3 ½ in. long, oblong-obovate to oblong-lanceolate, oblique and cuneate at the base, glabrous, reticulate beneath, 3-6 in. long; rachis with narrow margins: panicles 2-8 in. long; sepal subovate to ovate, obtuse, petals ovate to ovate-lanceolate, acute, ciliate; filaments villos: fr. globose, yellow or orange-brown, about ¼ in. across, slightly keeled. China, cult. in Japan. S.I.F. 1:71. Var. carinatus, Radlk. (S. littlta, Trabat). Fr: more fleshy, strongly keeled.—According to Trabat this variety is cultivated in Algeria for its fr. which contains nearly 38 per cent of saponin; the trees come into bearing in 8–10 years and a tree may yield 60–120 pounds of berries every year.

**SAPIUM** (the Latin name used by Pliny for a resiniferous pine). *Euphorbiaceae. Tropical trees and shrubs cultivated for their economic products and sometimes for ornament.*

Glabrous: juice milky and poisonous: lvs. alternate or rarely opposite, simple, denticulate to entire; stipules small, 2 conspicuous glands at the apex of the petiole and on each of the acule-like bracts: fls. generally in terminal spikes, the pistillate singly below, the staminate 2-3-lobed, the lobes imbricate; stamens 2-3, filaments free: ovary 1-3-celled, 1 ovule in each cell; a 3-parted central column remaining after dehiscence of the capsule: seed without a caruncle.—Nearly 100 species, in the tropics of both hemispheres, chiefly in Amer. Two intro. species are now found wild in *S. Fla.* Related to *Sapindus, Hura*, and *Houmulanthus.*

In their native country a number of species of Sapium are utilized in many ways. They are chiefly important as a source of rubber. *S. Jenmanii* is the chief source of rubber in British Guiana, where it is found in the alluvial forests in humid situations. It does best in well-drained clayey peat. *S. verrum*, once common in Colombia, has been cut for the rubber until it is now rare, but does well under cultivation in higher altitudes, yielding ten to eighteen pounds of raw rubber to each tree. A number of other species are used for rubber in South America. *S. Pavonianum* yields a medium grade. It is easily grown but is scarcely in culture. *S. sebiferum* is cultivated, especially in China, for the wax of the seed-covering which is used for candles, soap, and cloth-dressing. The wood of this and other species is utilized. Some of the "jumping beans" are seeds of Sapium which contain insect larva. Sapum may be propagated by seeds or by cuttings. The best varieties are sometimes top-grafted on seedling stocks.

**Jenmanii**, Hom. A large tree; lvs. oblong-lanceolate, abruptly and obtusely acuminate; glands of the petiole short, sessile; lateral lfs. veins more curved than in the preceding species and the ovary 1-celled: style not persistent. British Guiana.
SAPODILLA

Achras Sapota, Linn., of the family Sapotaceae, generally considered one of the best indigenous fruits of the American tropics. The tree is commonly cultivated, as well as naturalized, on the Florida Keys, and the fruit (Fig. 3545) is offered in south Florida markets.

Botanically the sapodilla is closely related to the maneye sapote (Liane maneye), the tia (L. nervosa) and the star-apple (Chrysophyllum Cainito), fruits which are well known in various parts of tropical America. The tree is evergreen, stately, with a dense rounded or conical crown sometimes attaining a height of 50 to 30 feet, horizontal or drooping at the ends of the branchlets; the wood is hard and very durable, timbers in an excellent state of preservation having been found in the Mayan ruins of Yucatan. The bark contains a milky latex known commercially as chicle.

SAPODILLA 3073

which is secured by tapping the trunk, and is exported in considerable quantities from Mexico to the United States, where it forms the basis of chewing-gum. The leaves are borne upon slender petioles up to 1 inch long, the blades entire or emarginate, ovate-elliptic to elliptic-lanceolate in outline, rounded-cuneate at the base and commonly obtuse at the apex, 2 to 5 inches long, glabrous, of rich green color, the midrib prominent on short finely pubescent pedicels in the leaf-axils.

The sapodilla is the name applied in the United States to Achras Sapota, Linn., of the family Sapotaceae, generally considered one of the best indigenous fruits of the American tropics. The tree is evergreen, stately, with a dense rounded or conical crown sometimes attaining a height of 50 to 30 feet, horizontal or drooping at the ends of the branchlets; the wood is hard and very durable, timbers in an excellent state of preservation having been found in the Mayan ruins of Yucatan. The bark contains a milky latex known commercially as chicle.

The flavor of the sapodilla is difficult of description, likened to that of a pear by some writers, and with a peculiar character common to several sapotaceous fruits. Some of the early writers were enthusiastic in praising it, the Spanish historian, Oviedo, going so far as to call the sapodilla the best of all fruits. More recently Firminger, an Anglo-Indian horticulturist, wrote that "a more luscious, cool and agreeable fruit is not to be met with in this or perhaps any country in the world," while Descourtis says it is "melting, and has the sweet perfumes of honey, jasmin, and lily-of-the-valley." In Florida it is a general favorite, especially among residents of the Keys, and in numerous other parts of tropical America it assumes considerable importance among cultivated fruits.

The tree is considered by Pittier to be indigenous in Mexico south of the Isthmus of Tehuantepec, in Guatemala, and possibly in Salvador and northern Honduras, being especially abundant in the lowlands of Tabasco, Chiapas, and the western part of Yucatan, which are the principal centers of production in the southern part of the state. The common name is derived from the Nahual word zapotl or tzicozapotl, the latter meaning "gum zapotl," and surviving to the present day in the precise form chiezasapotl, by which the tree is commonly known in southern Mexico; zapotl was the name given by the Aztecs to all soft sweet fruits. In Spanish-speaking countries the sapodilla is frequently called nispero, which name properly belongs to the European medlar. In the British West Indies the tree is known as sapotilla; in Brazil one form of the fruit is called sapotl, another sapota. The German name for the tree is Breiteiphaben, the French sapotiller, and the Dutch mispelboom.

From its home in tropical America, the sapodilla has been carried around the globe, and though less commonly cultivated in the Orient than the papaya, it is grown in many regions, particularly in some parts of southern India, where, according to Macmillan, it thrives up to elevations of 3,000 feet, though in Ceylon it is seldom productive above 1,500 feet and succeeds best on the coast. In Ecuador its cultivation is said by Pittier to extend into the temperate belt at altitudes of more than 8,000 feet. Its culture in Florida is limited to the southern part of the state, approximately the section south of Palm Beach on the east coast and the Manatee River on the west. Mature trees have passed uninjured through temperatures of 28° F., according to Reasoner. A notable advantage of the tree for some parts of the West Indies is the fact that the branches are tough and not easily broken by hurricanes. In California it has not yet fruited, though in favored locations specimens have occasionally attained an age of several years without being injured by frost. Even in the tropics, however, the tree grows very slowly, and in California the cool winters greatly hinder its development. It seems probable that it may yet be fruiting in protected foothill regions, but its culture in most parts of southern California is not recommended. The soil best adapted to the sapodilla seems to be rich sandy loam, but it thrives almost equally well on light clay and on the shallow sandy soil, underlaid with soft limestone, which is found on the lower east coast of Florida. Even though grown under the most favorable conditions, the trees rarely come into bearing until six to eight years of age, if seedlings, and in some sections do not attain a greater ultimate height than 20 to 30 feet. They should not be set either on chalky or calcareous land, because of their close compact growth. As a general
employed, their judicious use will doubtless improve

fruit at especially desirable times of the year. From
such seedlings one should select the best for propa­
gation. After three or four weeks the stock may be
examined to see that the eyes are well developed.

incision and renders it difficult to do the
work properly. Waxed tape should be used for wrap­

ready to be set out in the open ground.

the sapodilla as they have with most of the other
tropical fruits, but experiments in Florida have shown
that it can readily be budded, using as stocks seedlings of the same
species.

Seeds, if kept dry, will retain their vitality for several
years, and are easily transported through the mails to
any distance. They should be planted in shallow flats of
light sandy soil, covering them to the depth of ½ inch. In warm weather germination takes place within
a month, and the young seedlings, after they have
made their second leaves, can be potted off and carried
along in pots for the first year or two, when they are
ready to be set out in the open ground. If to be budded,
they may be planted in nursery rows about 3 feet
apart, 18 inches apart in the row. In south Florida,
May has proved to be a favorable season for budding;

in strictly tropical regions the work can probably be
done at any time, provided the stock plants are in
active growth. Budwood should be chosen from young
branches which have begun to lose their greenish color and
assume a brownish tinge, and should be carefully
examined to see that the eyes are well developed.

Shield-budding is the method used, the details being
practically the same as with the mango; buds should be
chosen from young branches which have begun to lose their greenish color and
assume a brownish tinge, and should be carefully
examined to see that the eyes are well developed.

ready to be set out in the open ground. If to be budded,
they may be planted in nursery rows about 3 feet
apart, 18 inches apart in the row. In south Florida,
May has proved to be a favorable season for budding;

in strictly tropical regions the work can probably be
done at any time, provided the stock plants are in
active growth. Budwood should be chosen from young
branches which have begun to lose their greenish color and
assume a brownish tinge, and should be carefully
examined to see that the eyes are well developed.

Shield-budding is the method used, the details being
practically the same as with the mango; buds should be
chosen from young branches which have begun to lose their greenish color and
assume a brownish tinge, and should be carefully
examined to see that the eyes are well developed.

Seeds, if kept dry, will retain their vitality for several
years, and are easily transported through the mails to
any distance. They should be planted in shallow flats of
light sandy soil, covering them to the depth of ½ inch. In warm weather germination takes place within
a month, and the young seedlings, after they have
made their second leaves, can be potted off and carried
along in pots for the first year or two, when they are
ready to be set out in the open ground. If to be budded,
they may be planted in nursery rows about 3 feet
apart, 18 inches apart in the row. In south Florida,
May has proved to be a favorable season for budding;

SAPONARIA
BB. Fls. rose or white.
c. The plants not cespitose.
d. St. stout, erect.

**officinalis**, Linn. BOUNCING BET. Fig. 3546. Perennial: sts. 1½–2½ ft. high, leafy, simple, clustered, glabrous; lvs. mostly oblong-lanceolate, 3-nerved; fls. light pink (nearly white in shady situations), in compact, corymbose, paniculate cymes; calyx glabrous, the teeth triangularly acuminate; petal-lobes obovate, entire, notched at apex. July, Aug. Eu.

Var. *albo-plena*, Hort., is a double white-flowered form growing 2 ft. high, leafy, simple, clustered, glabrous; lvs. mostly oblong-lanceolate, 3-nerved; fls. described as white tinted rose by some, as deeper colored than the type by others, grows 1½ in. high. All summer and fall. Var. *caucasica flore-pleno*, Hort. (*S. caucasicajiorepleno*, Hort.), is said to have double reddish-purple fls. July–Sept.

**dd. St. slender, decumbent.**

Var. *spendidens*, Hort., has large fls. which are a more intense rose than the type. Var. *spendidissima*, Hort., has large deep rosy crimson fls. Var. versicolor, Hort., is a form in which the fls. are at first pure white later becoming rose. A cross between a white-flowering variety and var. *splendens*. R.H. 1913, p. 308.

**cc. The plants cespitose.**

d. **Lvs. obovate-elliptic.**

dd. Lvs. linear.

caspitosa, DC. Cespitose: sts. 2–3 in. high, nearly naked, fl.-bearing at the top: lvs. linear, glabrous, mostly radical, hardly dentulate: fls. rather umbellate, rose; calyx cylindrical, villous, deeply lobed, lobes acute; petals emarginate at the top, the blade very narrow. Pyrenees. G.C. II. 15:501.

**S. papillosa**, Hort. John Saul, is botanically unknown.—S. pulvinaris, Desvaux, (S. hianswith, Hort., S. Pulvillus, Boiss.). Densely cespitose-pulvinate; sts. low, 3–7-ft. lvs. small, linear, subcoriaceous; inf. hirsute; fls. bright rose. S. Sundermannii, Hort., closely resembles S. heliophila, but has rather larger fls. and more of them. June—S. Wettsteinianum, Hort., is closely allied to S. cespitosa, possibly only a form of it, but has pale purple fls. and a shorter calyx. Its habit is very compact and it is only 2–3 in. high.

F. Tracy Hubbard.
acute pubescent segments, and a four- or five-petaled greenish corolla, valvate in the bud, with small oblong-elliptic acutate concave petals; the stamens are as numerous as the petals and alternating with them, with short filaments and small oblong anthers; the ovary is superior, five-celled, bearing at its apex a three- to five-lobed sessile stigma.

The fruit, when of a choice variety, is as large as a good-sized orange, and somewhat resembles a quince in general appearance. The tender yellow or yellowish greenish flesh is as thick as thin, more or less smoother or scaly, surrounds the soft cream-colored pulp, of melting and delicate texture and pleasant but peculiar flavor, sweet and lacking any trace of acidity, with sometimes a touch of bitterness. The seeds, normally five in number, an inch long and half as wide, are oblong to elliptical in form, light yellow in color, reticulated on the surface; their number is frequently decreased by abortion to two or three. In the tropics the fruit ripens in July and August, in California usually not before October; it is picked when fully mature but while still hard, and must be laid away for a few days before it is mellow and ready for eating. Because of its thin skin and the delicate texture of the flesh it does not ship so readily as some other fruits, even while still carefully packed, it can be sent considerable distances. It is commonly used while fresh, and an over-indulgence in it is thought by the Mexicans to induce sleep, but it is doubtful whether there are grounds for this belief. The white sapote is popular among the Mexicans, especially in the region around Guadalajara, and is regularly found in the markets.

The hardness of the tree is attested by its behavior in southern Europe; it has fruited at La Mortola, and is cultivated in other points on the Riviera; it is also said to have fruited in the island of Jersey. In Mexico it flourishes up to altitudes of 7,000 feet, according to von Mueller.

Although introduced to California from Mexico about 1810, it has not yet become extensively cultivated in that state, and large specimens are rather rare. One of the oldest trees, thought to have been planted about a century ago, is growing on De la Guerra Street in Santa Barbara. Although uncared for amidst the most unfavorable surroundings it bears regularly; its fruits, however, are small and practically worthless. A number of trees of considerably lesser age—most of them planted about 1880—are in bearing in various parts of southern California, and while some produce small, inferior fruits others produce large ones of delicious flavor. After it comes into bearing the tree commonly produces regularly and abundantly. It has shown itself to be remarkably drought-resistant, though it naturally succeeds much better when irrigated in the dry season. It seems to prefer a well-drained sandy loam, but thrives on heavy clay if the drainage is good, and in south Florida has done well on shallow sandy soil underlaid with soft limestone. In this latter state it produces regularly and abundantly.

The terminal bud should be pinched though it can get along with little water if necessary. Stock plants should be selected from young, vigorously growing seedlings, with stems about \( \frac{3}{3} \) inch in diameter at the base. Budwood is taken from the ends of the branches, using fairly well-matured wood which has assumed the ash-gray color. The buds are cut about 1 1/2 inches long. In the spring, just as the bud begins to open, they may be unwrapped, and then re-wrapped loosely, leaving the bud exposed so that it may start into growth, at the same time lopping back the stock to a point 3 or 4 inches above the bud. In the tropics budding can probably be done at almost any season; in California spring and summer, when the stock plants are in most active growth, are the best times.

Three named varieties have been established in California—Harvey, Parroquia, and Gillespie. Of these Harvey is the largest and probably the best; the tree is very prolific, and individual fruits sometimes measure \( \frac{3}{2} \) inches in diameter. W. H. POTENOE.

**SAPROPHYTE** (Greek, rotten, and plant, i.e., living on dead organic matter). A dependent, or heterotrophic, plant (whether bacterium, fungus, or higher plant) subsisting upon the decay of dead organic materials. A holosaprophyte is a plant which lives exclusively on dead organic food. One which is only partially dependent on dead organic food and also feeds independently, as an autophyte, is appropriately called a partial saprophyte. The customary classification which includes under the term "saprophyte" all bacteria that do not subsist on living plants or animals no longer corresponds with facts. The integrity of the classification has been destroyed by the discovery of certain bacteria in the soil, as the nitrifying bacteria, which are able, even without sunlight, to appropriate the carbon dioxide of the atmosphere. Saprophytes intergrade with parasites on the one hand so closely and with the autophytes on the other that the distinction of them is often difficult. For example, it is supposed that the chestnut blight (Endothia parasitica) was originally saprophytic, but has recently assumed a virulent parasitic development. Among the fungi we class as saprophytes all plants which live upon a dead or decaying organic substratum. Such are the baker's yeast (Saccharomyces cerevisiae), the mushroom (Agaricus campestris), and the stinkhorn (Phallus impudicus). Most mushrooms and toadstools are saprophytes. Some of the flowering plants possessing ectotrophic mycorrhiza (Indian pipe, Monotropa uniflora) and endotrophic mycorrhiza (Neottia Nidus-avis, Corallorhiza invena, Epipogium aphyllum, snow-plant, Saracodes sanguineus and Thamn Aseroe) are also classified as saprophytes. A few algae are from young, or dead, or decaying organic substratum. For this reason trees propagated by some vegetative means should be planted. Shield-budding is successfully practised, the method being essentially the same as with the avocado. Stock plants should be selected from young, vigorously growing seedlings, with stems about \( \frac{3}{3} \) inch in diameter at the base. Budwood is taken from the ends of the branches, using fairly well-matured wood which has assumed the ash-gray color. The buds are cut about 1 1/2 inches long. In the spring, just as the bud begins to open, they may be unwrapped, and then re-wrapped loosely, leaving the bud exposed so that it may start into growth, at the same time lopping back the stock to a point 3 or 4 inches above the bud. In the tropics budding can probably be done at almost any season; in California spring and summer, when the stock plants are in most active growth, are the best times.

**SARACA** (from Sarac, the name of the genus in India). Imaginum. Unarmed trees (or tall climbing shrubs?), grown in the warmhouse. Leaves abruptly pinnate, the lfts. leathery, often few-paired; stipules small, caducous; fls. yellow, rose, or scarlet, racemose, the racemes in short very branched panicles which are often lateral; calyx-tube elongated, strongly incurred, 5-lobed; petals 4; stamens 4 to 10; ovaries 3-5-lobed, hairy; stigmas 3-5, free; ovary stipitate, ovules many; legume oblong or elongated, flat-compressed or turgd, leathery to somewhat woody, 2-valved.—About 6 species, Trop. Asia.
Indica, Linn. A medium-sized tree: lfts. 6-12, oblong or oblong-lanceolate, acute or obtuse, 3-9 in. long, entire, short-petioled: fls. orange-red, fragrant, collected in compact, roundish panicles which are shorter than the lvs.; stamens usually 6 or 7, inserted on the calyx and flowering at the summit of the calyx-tube; style long, curved; bracte red, appearing as a calyx: pod 4-10 in. long, 4-8-seeded; seeds oblong, compressed, 1½ in. long. Inda and Malay. BM. 3018 (as Jostea Asoca).

It has flowered well with greenhouse treatment at height of 4 ft. It is suitable for outdoor planting only in tropical regions. Intro. into S. Fla.

casinifora, Baker. A shrubby tree: lfts. 10-12, rigidly subcoriaceous, the upper oblanceolate-oblong, acute, 1 ft. or more long, the longer shorter, more oblong; corysts solitary or in pairs, nearly sessile, dense, 4-6 in. broad: fls. scarlet: stamens 7. India. Intro. into S. Fla.

F. Tracy Hubbard.

Sarcanthus (name from Greek words signifying flesh and flower, in allusion to the fleshy nature of the blossom). Orchidaceae. A small genus related to Vanda, and owing to the smallness of the lvs. seldom cult.; sepals and petals similar; labeldum firmly united with the base of the column, spurred, with 2 small lateral lobes on a longer corona and nodose lober folia and habit of vanda. Give plenty of water in the growing season. They should have basket cult., with fern-root, and a temperature of 65° to 85°. When at rest, give very little water and reduce the temperature to 55°. Cult. practically as for Vanda.

tereuliolus, Lindl. (Luisia tere, Lindl.) St. 1 ft. high, with cylindrical lvs. 2-4 in. long; raceme bearing 7-8 inconspicuous fls.; sepals and petals oblong, dull green, with red disk; labeldum slipper-shaped, white, lateral lobes edged with red. Sept. China. BM. 3371. S. sativus, Rolfe. Distinguished by its inflated spur, which is much longer than the seeds of the lps.; sepals and petals green, with 2 dark brown stripes; front lobe of lip light yellow, side lobes white. Annam.—S. robusta, O'Brien. Lvs. narrowly oblong, about 6 in. long, spike few-fl.; fls. cream to blush-white, marked with claret-purple. Bernsen. G.C. Ill. 83-25.

Heinrich Hasskberg.

Sarcocephalus (Greek, flesh and head, alluding to the fleshy heads of fruit). Rubiaceae. Shrub or trees sometimes climbing, suitable for warmhouse culture or hardy in the extreme southern United States.

Branches suberete or obtuse quadrangular; lvs. opposite, rarely in whorls of 3, subcoriaceous; heads terminal and axillary; fls. white, pink or yellow and flesh-colored, teeth 5-6 hairy; calyx narrowly funnel-shaped, rather fleshy, 5-lobed; anthers 5, subcissile; disk inconspicuous; ovary 2-celled; syncarpium fleshy.—About 30 species. S. sexangularis, Auct. A tree with long branches or often a shaggy shrub 10-25 ft. or more high; lvs. elliptical, short-cissile; fls. in terminal heads, white, pale pink or yellowish, fragrant; calyx-teeth furnished with alternating filiform-clavate appendages: fruiting head 2½-3½ in. in diam., deep red with brown granulated surface. Trop. Afr.—Edible, the peach or country fig of the natives of Sierra Leone. S. ovata, Elmer. Tree, 18 ft. high, with rigid branchlets; lvs. glabrous, leathery, ovate or elliptic, acute at the base, obtuse at the apex, 2½ in. ind. capitata, pedunculated; fls. red; calyx with ciliata, pellucid and deciduous appendages; corolla glabrous, nearly ½ in. long. Philippines. Said to be intro. into Calif.

Sarcochilus: Thrixpermum.

Sarcochilus (Greek, flesh-like, alluding to the fleshy fruit). Orchidaceae. A genus of parasitic orchids, of which the Indian-pipe or corpse-plant is an example. Few species are known in this family, and they are all local or rare. The snow-plant derives its popular name from its habit of shooting up and blossoming as soon as the snow melts away in the spring. They are handsome evergreen shrubs with ovate to lanceolate entire lustrous leaves, rather insignificant whitish flowers in axillary clusters and red or purple berry-like fruits. S. ruscifolia and S. Hookeriada var. humilis have proved hardy in sheltered positions at the Arnold Arboretum, while S. saligina is tender. They do not seem particular as to the soil and do best in partly shaded situations. Propagation is by seeds or by cuttings which root easily.

A. Lvs. distinctly 3-nerved, caudate-acuminate.

B. Lvs. obscurely veined.

ruscifolia, Stapf. Shrub, to 6 ft.: lvs. ovate to elliptic-ovate, acuminate, rounded or broadly cuneate at the base, dark green and lustrous above, 1½-2 in.; petioles ½-3 in. long; fls. in, usu­ally 4-fl. racemes: fr. subglobose, dark scarlet. Oct.—Feb. Cent. and W. China. Var. chinensis, Rehd. & Wilson (S. saligina var. chinensis, Franch.). Lvs. elliptic-ovate to elliptic-lanceolate, cuneate or broadly cuneate at the base, 1½-2½ in. long. W. China.

Alfred Reeder.

Sarcodes (Greek, flesh-like). Monotropaceae. S. saginata, Torr. (Fig. 3248), is the Snow-Plant of the Sierra Nevadas. It is a low and fleshy plant growing 3-12 in. high and entirely devoid of green lvs. It belongs to that strange family which comprises the fleshy and parasitic plants, of which the Indian-pipe or corpse-plant is an example. Few species are known in this family, and they are all local or rare. The snow-plant derives its popular name from its habit of shooting up and blossoming as soon as the snow melts away in the spring; these are handsome evergreen shrubs with ovate to lanceolate entire lustrous leaves, rather insignificant whitish flowers in axillary clusters and red or purple berry-like fruits. S. ruscifolia and S. Hookeriada var. humilis have proved hardy in sheltered positions at the Arnold Arboretum, while S. saligina is tender. They do not seem particular as to the soil and do best in partly shaded situations. Propagation is by seeds or by cuttings which root easily.

SARCODES

SARCORDIA (name refers to the fleshy corona).

Sarcoëdes (Dendrobium cymboïdium, Lindl. D. pendulum, Lodd.). Raceme few-flowered; lvs. pale yellow or straw-color, the lip yellow, suffused with rose or purple, with 2 lanceolate lateral lobes and a strongly curved, fleshy, obovate to oval, thin-lipped; calyx-lobes 5, obtuse, the middle one obovate; tinctorial, the outer lobes 5, obtuse, the middle one obovate; tepals rhombic, acute. Trop. Himalayas.

George V. Nase.

SARRACENIA

Sarcoëdes, Lindl. D. pendulum, Lodd.). Raceme few-flowered; lvs. pale yellow or straw-color, the lip yellow, suffused with rose or purple, with 2 lanceolate lateral lobes and a strongly curved, fleshy, obovate to oval, thin-lipped; calyx-lobes 5, obtuse, the middle one obovate; tinctorial, the outer lobes 5, obtuse, the middle one obovate; tepals rhombic, acute. Trop. Himalayas.

SARRACENIA (named after Mart. Sarmiento, a Spanish botanist). Euphorbiaceae. A glabrous shrub, creeping or clambering over trees and rocks, to be grown in a moist greenhouse; sts. slender; lvs. opposite, rather fleshy, entire or few-toothed: lvs. red, peduncled at the axes, solitary; calyx free, 5-parted, segments narrow; corolla-tube elongate, ventricose, limb slightly oblique, lobes 5, rounded, spreading; stamina 2, posterior perfect, 2 anterior staminodial; disk obsolete; ovary 5-loculed. —One species. Chile, S. repensa, Ruiz & Pav. Sts. slender; lvs. rather small, somewhat fleshy; lvs. scarlet, axillary and solitary; calyx 5-parted; corolla-lobes 5, rounded and spreading; stamina 2, posterior perfect, 2 anterior staminodial; ovary 5-loculed. —One species. Chile, S. repensa, Ruiz & Pav. Sts. slender; lvs. rather small, somewhat fleshy; lvs. scarlet, axillary and solitary; calyx 5-parted; corolla-lobes 5, rounded and spreading; stamina 2, posterior perfect, 2 anterior staminodial; ovary 5-loculed. —One species. Chile, S. repensa, Ruiz & Pav.

amongst fine hairs may occur. This area excretes a slightly viscous juice, which accumulates in the pitcher cavity, and which, as Mellichamp showed, readily wets and drowns any insect that falls into it. The lowest part of the pitcher in all species bears long delicate down-directed hairs that incline insects to move upward; and even the entire leaf may be of a dark crimson-purple hue, and correspondingly attractive. Minute honey-glands occur over the exterior, which forms therefore the "alluring surface." But these are specially abundant over the inner lid surface, where they are interspersed with down-directed hairs that incline insects to move on to the upper part of the tube. So this inner lid area has been termed the "attractive surface." The upper third to half of the tube is extremely smooth, and affords little foothold for insects, which often tumble from it into the pitcher cavity. So this has been called the "conducting surface." Beneath it in S. purpurea is a wide glandular surface that is absent in the other species, although in some of them glands scattered inches across, and in color from pale lemon-yellow, as in S. minor, to deep crimson, as in S. Drummondii and S. rubra. Each lasts from eight to twelve days. The five spreading sepals inside three small bracteoles are move or less petaloid; the petals are large pendent banners, the stamens are numerous and disperse an abundant pollen which early falls into the umbrelloid cavity of the style. The pistil consists of a five-celled ovary that is covered outside by crystalline nectar-secreting warts, and within bears many ovules; a style that expands above into a large umbilicate structure with five marginal notches, at the base of each of which is a minute dry peg-like stigma. The entire pistil after pollination matures in about three months into a many-seeded capsule. Cross-pollination seems always necessary for formation of good seeds. This act, as well as hybridization of distinct species, can readily be effected if pollen from one flower that has been wetted by nectar from its own ovary surface is placed on the dry stigma of a flower on another plant. All of the seven species cross readily with each other, alike in the wild state and under cultivation, if flowers mature about the same time. Thus at various localities in western Florida and in Alabama, where the tall handsome species S. flava, S. Drummondii, and S. Sledgei grow, the writer has found hybrids at times to be nearly as abundant as either parent. The numerous artificial hybrids between the species, that are themselves fertile and give rise to second hybrids in which the characters of at least three parents may be blended, also afford a means of hybridization. The seeds germinate readily in about four weeks if sown with chopped sphagnum moss on a moist sandy muck. After production of the linear cotyledons, each seedling plant forms pitched leaves that successively increase in size till good specific characters are shown by the second year.

The larvae of certain moths, flies, and beetles at times prey on the pitchers, while the rhizomes may be excavated and destroyed by still another type. Careful detection and destruction of the infested leaves or pieces of rhizome are recommended. Mosquitos also may breed in the liquid of the pitchers of S. purpurea. All of the species succeed well under cultivation if grown in pots filled with fine sandy muck, from which, while decaying, humic acid constituents are evolved. Alkaline waters are always detrimental. In this respect they require the same treatment as do other swamp or semi-swamp plants of the eastern states. They should also have a bright sunny southeastern exposure, should be kept near the glass if grown in greenhouses, and the pots should stand permanently in about an inch of water. All can endure a temperature that approaches the freezing-point in winter.

The writer has monographed the genus in Engler's "Pflanzenreich," Vol. 4, No. 110 (hft. 34, 1908). A useful synopsis, along with some helpful figures, was given by Masters in 1881 (G.C. II. 15, 16. 1881).

The sarracenias have always excited the interest of the curious, and many of the native haunts have been depleted. In his "New England's Rarities," 1672, Josselyn gives a picture (Fig. 3549) of what he calls the "Hollow Leaved Lavender," and the following account of the plant we now call Sarracenia purpurea: "It is a Plant that grows in salt Marshes overgrown with Moss, with one straight stalk about the bigness of an Oat straw, better than a Cubit high; upon the top standeth one fantastical Flower, the Leaves grow close from the root, in shape like a Tuska, hollow, tough, and always full of Water, the Root is made up of many small strings, growing only in the Moss, and not in the Earth, the whole Plant comes to its perfection in August, and then it has Leaves, Stalks, and Flower, as red as blood, excepting the Flower which hath some yellow admixt. I wonder where the knowledge of this Plant hath slept all this while, i. e. above Forty Years."
INDEX.

1. SPECIES.

A. Pitchers erect: fls. yellow or whitish yellow.

2. Siedgei, Macfar. (S. Gronovii var. alata and S. flavâ var. cespitosa of authors). Pitchers erect, 12-30 in. long, trumpet-shaped, green with purple veins above, or greenish purple through lid; lid vertical or often slightly incurved, ovate-cordate; wing as in last; fls. 1½-2½ in. wide; petals whitish yellow to yellow, often fading to white. Moist savanna lands of west side of Alabama and Mobile rivers to E. Texas, often covering wide areas of marshland.

—Very uniform in structure, but varying in color from green to dark red in the pitchers; often confused in the past with S. flavâ, which does not occupy the same area. Presently known growing with S. Drummondii in nature to form S. arcuata.

3. flavâ, Linn. Pitchers erect, 10-34 in. long, trumpet-shaped, with prominent longitudinal veins, yellow-green to green, often crimson throat or deep crimson throughout; lid ovate-oblong, slightly inflexed over mouth, with strong coral-like ribs; Savanna swamp from west side of Alabama and Mobile rivers to E. Texas, often covering wide areas of marshland.

—Very uniform in structure, but varying in color from green to dark red in the pitchers; often confused in the past with S. flavâ, which does not occupy the same area. Presently known growing with S. Drummondii in nature to form S. arcuata.

B. Pitchers spreading: fls. crimson to purple-red.

4. rubra, Walt. (S. Sweetii, DC. S. Gronovii var. rubra, Wood. S. minor, Sweet). Pitchers erect, in long, slender, enlarging upward, tubular above, green to purple-veined over upper part of tube and lid; lid ovate, slightly concave and inflexed over mouth; wing rather wide, nearly uniform, from middle to top of pitcher: fls. 1½-1⅔ in. wide, petals crimson, scent of sweet violets. Moist to dry savanna lands of the Carolinas, S. Ga. to W. Fla.; the most delicate and graceful species of the genus. B.M. 3515. L.B.C. 12:11. Var. arcuata, DC. Lid ovate, apex acuminate. All transitions occur between this and the type species.

AA. Pitchers erect to decumbent: fls. crimson to purple-red.

5. rubra, Walt. (S. Sweetii, DC. S. Gronovii var. rubra, Wood. S. minor, Sweet). Pitchers erect, in long, slender, enlarging upward, tubular above, green to purple-veined over upper part of tube and lid; lid ovate, slightly concave and inflexed over mouth; wing rather wide, nearly uniform, from middle to top of pitcher: fls. 1½-1⅔ in. wide, petals crimson, scent of sweet violets. Moist to dry savanna lands of the Carolinas, S. Ga. to W. Fla.; the most delicate and graceful species of the genus. B.M. 3515. L.B.C. 12:11. Var. arcuata, DC. Lid ovate, apex acuminate. All transitions occur between this and the type species.

B. Pitchers spreading: fls. crimson to purple-red.

6. purpurea, Linn. The common pitcher-plant of the N. and the one on which the genus was founded. Fig. 3551. Pitchers ascending, in rosettes of 3-6, 2-10 in. long, widest toward middle, narrow below and upward, green to dark purple; lid upright or slightly inclined outward with fine hair-like hairs over inner lid or attractive surface; wing broad, prominent; fls. 1½-1⅔ in. wide; sepals and petals greenish purple to purple. In wet sandy muck or by swamp margins from Labrador and Minn. to N. Fla and Ala.; flowering from fourth week in March to third week in March in N. Fls. to second week in Aug. in Lab. B.M. 849. L.B.C. 4:308. F.S. 10: 1076. G.C. II. 15:821. Mn. 1:81. G.L. 27:179.—Very variable in coloring from bright green in shady places to dark purple in sunny situations. According to Lod­ diges, writing in 1825, this species was “cultivated before the year 1640 by Tradescant, who was gardener
7. psittacina, Michx. (S. calceolata, Nutt. S. pulchra, Croom). Pithers procumbent in radial rosettes, 2–6 in. long, enlarging from base to hooded apex, green with dull purple and white veins or areoles to claret-purple throughout; apex of tube psittacoid, forming with fused lid an incurved margin to pitcher-oriifice; wing narrow to wide vertical in position: fls. 5½–13½ in. wide, greenish-purple to purple. Often abundant in pools of springs of Ga., N. Fla., and westward to La. F.S. 7:268, des.; 20:2063. F. G.C. II. 15:816. F. 1877, p. 254.—This species flourishes well under cult., when treated as a semi-aquatic, with that is its roots largely submerged in water.

II. NATURAL AND ARTIFICIAL HYBRIDS.

9. arcostis, Macfarl. (S. Slechtii × S. Drummondii). Pithers elongate-tubular, green below, purple-veined and areolate above and curved lid. Lid circular-cordate, margin somewhat undulate, with fine white hairs within: fls. 2–2½ in. wide, yellowish-purple.—This is the species wherever both parents occur near each other. It is specially abundant from near Mobile, Ala., westward for 50 miles. It is readily in cult. if grown like both parents, with the roots largely submerged in waters that have a humic acid reaction.

11. Cattabeli, Ell. A hybrid between S. flava and S. purpurea, that is common throughout the southern states. It was first described by John Ray fully 200 years ago from specimens sent to him from this country. The writer has noted as many as 117 specimens, going near Pensacola, Fla. It is only rare, and produces pitchers and flowers that are the most striking and beautiful of the genus.

13. Claytonii, Nichols. Origin and parentage unknown; it is thus described by Nicholson: "Pitchers beautifully colored vinous purple and red, veined to crimson.

16. crispita, André. A name of doubtful value, that seems to have been inadvertently used by different authors. Probably either Slechtii or a hybrid of S. flava with S. minor. The writer has gathered undoubted examples of the last-named cross near Summerville, S. C. Pitchers erect, green with whitish areolations above, lid broadly ovate, somewhat constructed over orifice: fls. bright yellow.

17. decora, Hort. A probable cross between S. psittacina and S. minor, and so of like or more recent parentage with S. formosa.

18. excelsa, Nichols. A probable hybrid between S. minor var. albicaulis and S. Drummondii.

19. exculta, Nichols. A hybrid of like parentage as S. Moorei, which see.

20. exornata, Nichols. Said to be a hybrid of S. purpurea with S. crista-poa.

21. Firchami, Hort. A beautiful hybrid said to be a cross between S. Drummondii and S. rubra, and which combines details of both parents in pitcher and fl. The writer has collected a single wild example near Milligan, Fla., where the former parent is common and the latter is sparse.

22. flambeau, Hort. A hybrid of doubtful origin and parentage, colored as described. Possibly a cross of S. purpurea with S. minor, and so of like origin as S. Smaragdiana.

24. illustrata, Nichols. Lvs. elongate-tubular, veins becoming deep greenward, lid cordate, slightly acuminate, with crimson veins. Between S. flava var. picta and the hybrid S. Stevensi, so with 3 parts of S. flava "blood" and 1 of S. purpurea.

25. Maddisoniana, Nichols. A hybrid with the same parentage as S. formosa, but in reversed relation. Pitchers ascending, short, with dull purple veins and whitewhish areoles upward, encased end of tube and fused lid richly white and purple-veined.

26. Mandallana, Hort. A natural hybrid with like parentage to S. Moorei. Widely and across areas from N. Cent. Fla. to the Alabama River. It is so widely to be found wherever both parents are common. A tall form, with crimson throat of S. flava var. Kupiana, and the crimson and white areolations of S. Drummondii. It grows well under cult. First sent out by Pitcher & Anda.

27. melanorrhida, Veitch. A cross between S. Stevensii var. purpurea, and S. purpurea, so with 1 part parentage of S. flava and 3 parts S. purpurea. Pitchers ascending, long, widening from base to mouth, lid erect or slightly incurved with undulate margin and crimson veins showing short hairs, top of pitcher and lid crimson-green with dark crimson himid veins, wings prominent, broadest in middle.

The artificial hybrids were sent out by Bull. The writer has got a few like plants growing wild near Bay Minette, Ala., where both parents are common.

29. Morelei, Mast. This, the first artificial hybrid produced, was raised by Mose of Glensie, as a cross of S. flava with S. Drummondii. Pitchers tall, erect, tubular, with strong veins, light green below, crimson-veined and faintly white-areolate above with usually rich crimson posterior throat area; lid crimson, and white-areolate with slightly undulate margin and humped hairs on areoles, as in S. Drummondii. Shape and coloring of S. S. Mandallana is a natural hybrid of similar parentage. G.C. III. 1: 722; des.; 16:44.

30. Patersonii, Hort. A hybrid raised by Patterson, orchidologist of Bridge of Allan, Scotland, and with parentage like No. 28.

32. Porphyroneilia, Hort. Probably a synonym of, and of like origin as S. purpurea.

33. Sanderi, Nichols. An artificial cross of S. Drummondii var. rubra with S. Cookiana of unknown parentage.

34. Sanderiana, Hort. A garden hybrid of S. Drummondii var. rubra and S. Fairchildii, distributed by Sande. Cult. at Kew, and of great beauty.

36. Sazanamiana, Nichols. A hybrid with the same parentage as S. Catesbiana and with S. purpurea.

39. S. minor. A beautiful but complex cross of S. Courtl (S. purpurea × S. psittacina) with S. melanorrhida, that is a hybrid of S. Stevensii (S. purpurea × S. flava) with S. purpurea. It more or less combines characters from all of the 3 species-parents, and is delicately colored pale green, white, and crimson.

40. Wilsoniana, Nichols. Of same hybrid origin as S. Stevensii and others.

41. Wringleyana, Veitch. Reputed to be a garden cross between S. psittacina and S. Drummondii or the converse.

J. M. M'CALLANNE.
Deciduous; lvs. alternate, entire or 3-lobed, slender-petioled; fls. dioxeous, rarely perfect, apetalous; calyx 6-parted; stamens 9, the 3 inner ones furnished at the base with 2 stalked, orange-colored glands; staminodes 3 or wanting; anthers opening with 4 valves; ovary superior, 1-loculed; fr. an oblong-ovoid, 1-seeded, dark blue drupe surrounded at the base by the thickened scarlet calyx. Two species, one in E. N. Amer. and one in China.

The sassafrases are handsome trees of pyramidal habit with rather large, entire or 3-lobed leaves and small yellow flowers in few-flowered racemes appearing in spring with the leaves and followed by ornamental dark blue fruits on red fleshy stalks. The native species is hardy North, while the Chinese, one which is still little known in cultivation, is somewhat tenderer. The American sassafras usually affords light lands, although it may grow in clay loams. It is a desirable tree for ornamental planting on account of its handsome light green foliage, which is interesting with its varying shapes and its orange-yellow or bright red color in autumn, and on account of its decorative bright-colored fruit. It prefers, at least in the North, a warm and sunny position. It is not easily transplanted when old on account of its long tap-roots. Propagation is by seeds soon as ripe; also by suckers, which are often freely produced, and by root-cuttings.

variifolium, Kunze (S. officinalis, Nees. S. Sassafras, Karst. Laurus Sassafras, Linn.). Figs. 3552 (winter tree), 3553. Tree, 30-60, or occasionally 90 ft. high; young branches bright green, pubescent; lvs. oval and entire, or 3-lobed almost to the middle, oblong, silky-pubescent when young, glabrous when mature. Fls. yellow, ½ in. across, glabrous inside, without stamnodes, in several-flowered racemes, umbellate when unfolding, afterward at the base of the young branchlets; stamine fls. without rudimentary pistil; staminodes wanting fls. 4-6; fls. milky, April, May. Maine to N. Mass. to S. C. and Ky.

SATUREIA (the old Latin name used by Pliny), also spelled Satureja. Syn., Calamintha. Lamiaceæ. Savory.

Hardy aromatic herbs and subshrubs, grown in borders for their flowers and also as pot-herbs. Leaves entire, narrow and small or toothed, or broad and larger: floral whors either axillary or in terminal spike-like racemes; calyx campanulate-tubular or tubular, rarely campanulate, 10-13-nerved, 5-toothed, sometimes 2-lipped; corolla-tube short or long, exserted, upper lip flat, entire or emarginate, lower lip expanded, 3-cleft, with flat lobes, the midlobe usually larger and emarginate; stamens 4: nectlets ovoid, smooth.—About 160 species in the warmer regions of both hemispheres.

A. Plants annual.

Ácinos, Scheele (Calamintha Ácinos, Clairv.). Annual, herbaceous, about 6 in. high; lvs. opposite, cut, base narrow, subsegmented, green on both sides; floral lvs. similar, exceeding the fls.: floral whors about 6-fl., distinct; calyx 3-4 lines long, deeply 3-4-nerved, hispid; corolla purple-blue, scarcely exceeding the calyx. Eu., Caucasus.—Escaped from cult. in N. Amer.

hortensis, Linn. (Calamintha hortîensis, Hort.). Summer Savory. Annual herb, pubescent; lvs. erect, about 6 in. high or a little more; lvs. oblong-linear, acute, base narrowed to a short petiole; floral lvs. similar, floral whors lady's somewhat 6-fl., in dense interrupted spikes; calyx sebaceous-hispid on the nerves; corolla sparsely pubescent outside, scarcely exceeding the calyx. Eu., and widely escaped from cult.

AA. Plants perennial.

b. Lvs. ovate, oblong-linear or spathulate.

montana, Linn. (Calamintha montâna, Lam. C. officinalis, Moench.). Winter Savory. Subshrub, glabrous or slightly sebaceous-pubescent: sts. woody at base; branches erect or ascending, 6-12 in. high; lvs. oblong-linear, acute or inferior spatulate or cuneate, obtuse; upper and floral lvs. narrower; floral whors many-fl., lacinately dissected, in a spike or raceme; calyx campanulate, 10-nerved or rarely obscurely 13-nerved; corolla white or purple. Eu., N. Af., and widely cult.

B. grandiflora, Scheele (S. grandiflora, Meech.). Herbaceous perennial: lvs. ovate, serrate: sts decumbent, branching from the base: lvs. in axillary whors, quite large, 1½ in. long, with a straight tube; upper lip flattened, purple. June, July.

F. TRACY HUBBARD.
SAUROPOUS (Greek for lizard foot). Euphorbiaceae.

Tropical shrubs rarely cult.: lvs. alternate, simple: fls. in axillary clusters, apetalous, sepals imbricate; no rudiment of a pistil in the staminate fls.; disk absent from the pistillate fls.; styles almost entire; ovules 2 in each of the 3 cells of the ovary: fr. more or less fleshy.—About 20 species of Trop. Asia and South Sea Isls. Related to Phyllanthus. S. albicans, Rümme, occurring in many varieties from Ceylon to the Philippines, has edible fr. and has been in cult. in Eu.

J. B. S. NORTON.

SAURURUS (Greek, lizard's tail, referring to the curve of the spike of fls.). Saururaceae. Lizard's Tail.

Perennial marsh herbs, suitable for the bog-garden.

Erect: lvs. heart-shaped, converging-ribbed, petioled, without distinct stipules; fls. of 3-4 carpels united at base and indehiscent; seed usually solitary.—Two species, one in N. Amer., the other in Asia.

crēnum, Linn. SAURURUS cernuus. (X3)

N. E. BR. Petiole up to 15 in. long, rose, the Begms. ovate or orbicular-ovate; stamine fls. from the pistillate fls.; styles almost entire; ovules 2 in each of the 3 cells of the ovary: fr. more or less fleshy.—About 20 species of Trop. Asia and South Sea Isls. Related to Phyllanthus. S. albicans, Rümme, occurring in many varieties from Ceylon to the Philippines, has edible fr. and has been in cult. in Eu.

J. B. S. NORTON.

SAUSSUREA (named after Theodor de Saussure, 1767-1845, or for his father, Horace Benoit de Saussure, 1717-1767). Compositae. Anther 3-4 mm. long, purple or pink, glabrous or tomentose herbs of various habit, some of the species adapted to the warmhouse, others to the coldframe.

Tuber undivided: lvs. few, on the lower part of the st., rarely many at the sides of the tall st.; fls. medium-sized or rather large, in often densely fl. spikes; bracts membranaceous or somewhat leaffy, sometimes imbricate in the young spike and often strongly reflexed, in a dwarf species overtopping the fls.; sepals free, rather similar to the petals; labellum erect, broad-coneave, galeate or cucullate undivided: caps erect, oblong, not beaked.—About 125 species, India, Mascarene Isls., Trop. and S. Afr. Most of the species, of which several are more or less commonly cult. abroad, succeed well in a coldframe, in a compost of turfy peat, fibry loam and sand with plenty of drainage. Prop. by division of roots, made as fresh growth is commencing.

crēnum, R. Br. One to 2 ft. high: st. stout: lvs. 2, radical, subcentral, ovate or orbicular-ovate: fls. many or rather few, with several ovate or spathaceous sheaths; spikes oblong, 3-8 in. long, dense, many-fl.; fls. large, pink or rose-colored; sepals and petals united at base, oval, spathaceous-oblong, obtuse, lateral sepals larger; petals elliptic-oblong; lip cucullate. S. Afr. B. M. 1512. G. C. III. 4:697. G. W. II. 2, pp. 349, 350.

crēnum, Don. St. 6-30 in. high, usually very sparsely haired: lvs. few, oblong to linear-oblong, 4-10 x 2-4 in., rather fleshy, sessile: spike 1-6 in. long, densely fl.; bracts oblong or lanceolate, much larger than the fls.: fls. fragrant, white to rose-pink; sepals linear-oblong, obtuse; petals rather narrower, lip superior, broadly ovate, mucronate and strongly reflexed on the back; blade 14-16 in. long, 3 in. wide below, about 1 in. wide from the middle to the apex, yellow within and with crowded oblong purple or black spots. Himalayas. B. M. 4465 and 2446, F. S. 13:1334 (both erroneously as S. gutatum).

S. gutatum, Schott. Petioles 3 ft. long; fl. segments 8-10 in. long, 4 in. wide, oval, lateral smaller; spathe-tube 3-4 in. long, purple on the back: blade 14-16 in. long, 3 in. wide below, about 1 in. wide from the middle to the apex, purple on the back, yellow within and with crowded oblong purple or black spots. Himalayas. J. F. 1:12. B. R. 1017 (as Arum venosum).

venéndum, Schott (S. similènsis, Schott.). Petioles spotted, 3½ ft. long; fl. segments 8-10 in. long, 4 in. wide, oval, lateral smaller; spathe-tube 3-4 in. long, purple on the back: blade 14-16 in. long, 3 in. wide below, about 1 in. wide from the middle to the apex, purple on the back, yellow within and with crowded oblong purple or black spots. Himalayas. B. M. 4465 and 2446, F. S. 13:1334 (both erroneously as S. gutatum).

S. bréviispica, N. E. Br. Petiole up to 15 in. long, rose, the Begms. of blade 5-6, 4-6 in. long, narrowly linear-lanceolate, caudate-acuminate; spadhe shortly stalked, the tube swollen, 1½ in. long, pale yellowish green, family rose-splotted, the limb narrow, convolute, twisted, arching. 4-6 in. long, pale greenish or rose-bright red at throat; spadix as long as spathe, slender, rose below, orange above. Himalayas. B. M. 7190.

JARED G. SMITH.

SAUSSUREA (named after Theodor de Saussure, 1767-1845, or for his father, Horace Benoit de Saussure, 1717-1767). Compositae. Anther 3-4 mm. long, purple or pink, glabrous or tomentose herbs of various habit, sometimes planted in the garden for ornament.
Leaves unarmed, alternate, entire, toothed, pinnatifid or pinnatisect: heads narrow or broad, sometimes crowded on the dilated top of a simple st., peduncled, or sessile, solitary, corymbose or panicled; fls. purple or bluish, all perfect and similar, tube slender, limb narrow, 5-cleft; involucre ovoid-oblong, globose or hemispheric, bracts not spinescent: achenes glabrous, oblong, 4-ribbed.—About 200 species, temperate regions of Eu., Asia, and N. Amer., mostly in the mountains. S. gossypiphora, Don. Perennial, densely long yellow or whitish matted woolly; st. 6–12 in. high, hollow, clavate, often 4 in. broad at top: lvs. sessile, linear, removably toothed or punctate-margined; heads very many, cylindric; involucre-bracts linear-oblong, shining: achenes narrowly obovoid. Himalayas and China. G.C. III. 51:85. S. leucodoma, Diels. Plant 4–9 in. high: lvs. basal, narrowly pinnate, upper almost linear, the blade being entirely sacrificed to the development of the abundant cottony tomentum in which practically the whole plant is smothered, the fl.-heads alone are free of it and form a compact mass 2–3 in. in diam. China. G.C. III. 51, suppl. Feb. 10. S. Velichkova, Drumm. & Hutchins. Herb, 2–3 ft. high, with about 2–5 leafy scapes from a tufted crown: fls. st.-rigid, flocose upward: lvs., the lowest, 10 x 2 in., oblong-linear, green above, loosely hairy below; the upper ovate-lanceolate; bracts bluish-pink or purplish; heads nearly ovoid, over 1 in.; florets deep purple. China. B.M. 3831. G.C. III. 50:88. F. Tracy Hubbard.

SAVES PRAGA. Rockfoil. Chiefly perennial herbs, but a few species are annual and a few others biennial, while some others are subshrubby; useful for border planting, rockeries, and alpine gardens, and much prized by fanciers, particularly abroad.

Plants usually with more or less developed caudicles which are either at the base or at the summit. Including Re- gina and Peliphiillum, genera which are maintained as distinct by Engler in his last treatment of the group. Saxifragaceae. Saxifraga. Rockfoil. (Latin, rock and to break; said by some to refer to the fact that many of the species grow in clefts of rock, by others to the supposition that certain spe- cies were once used for breaking stones. C. A. S. and P. C. A. are commonly clustered at the base and most often alternate on the stems, very variable in shape: infl. panicle, corymbose, racemose or solitary: fls. as a rule not large, white, yellow, red, pink, or purple; calyx either free or partly adnate to the base of the ovary, the tube short or elongated, 5-cleft or 5-parted; petals usually equal but occasionally decidedly unequal; stamens 10, rarely 5: fr. a 2-beaked, 2-celled caps. opening down or between the seeds, or sometimes 2 almost separate foli- cles; seeds numerous.—About 400 species from a horti- cultural viewpoint or approximately 250 botanically speaking. Temperate (principally alpine) and northern boreal regions, rare in Asia, very few in S. Amer. and lacking in Austral., S. Afr., and the Pacific Islands. In preparing the following treatment of the genus and in the arrangement of species, Engler, in Engler & Prantl's Pflanzenfamilien, has been followed with the exception above mentioned, while the specific delimitation is largely based on Engler's Monographie der Gattung Saxifraga, 1872, with cultural and other horticultural information drawn from Irving & Malby's Saxifrages. The true saxifrages, so-called (excluding Bergenia and Peliphiillum), have been separated into several genera at different times. The horticultural species men- tioned in this treatment which are native of N. Amer. have been divided among the following genera: Saxifraga, Muscari, Brachyscome, Micranthes, Spatialaria, Leptopis, Heterisia, Peliphiillum and Antaphylla. See Small in N. Amer. Fl., vol. 22, pt. 2, 1907.

Saxifrages are various in habit and stature, but they are mostly low and spreading with rosulate or tufted root-leaves. Most of the species in cultivation are grown as rock-garden plants, although the large-leaved members of the Megasea or Bergenia section are some- times used as border-plants. Owing to the small attrac- tion given to rock-garden and alpine cultivation in the handbooks, the saxifrages are little known to our horticulturists. Most of them are abundantly hardy as to frost, but are likely to suffer from the dryness and heat of the American summer. Partial shade in summer is essential for the best results with most of the species. In winter the stools should be given ample covering of leaves. The most useful kinds for this country are the species of the Megasea section. These are low plants of bold habit, and are admirably adapted for rockwork and for spring forcing under glass. Fig. 1819, Vol. III, shows a clump of these plants in the lower left-hand corner.

The alpine species are mostly dwarf plants with more or less persistent foliage. Many of them, as S. oppositifolia, make dense moss-like mats; others, of which S. Asson may be taken as a cultural type, produce a dense rosette of leaves at the surface of the ground, from which small plants arise. Amongst these species the saxifrages are very interesting because of the vari-colored or sil- very effect produced by natural incrustations of lime on the leaves, particularly on the leaf-edges. Give shade. Most saxifrages make stolons and offshoots freely, and by these the plants are easily propagated; they are also increased by division. Some make bulbs and multiply in this manner.

The number of species of saxifrage cultivated abroad in rockeries and alpine gardens is very large and there are many fanciers who have made very large collec-
f. foliage. Succeeds best in a rather sheltered spot.

ligulata, orbicular or obovate, 2-12 in. diam., base cordate, mar-

vory handsome species because of its purple scapes and

erect. June. Sikkim (India), 10,000-15,000 ft. B.M:

. 3.' purpurascens, Hook. f.

3. purpurascens

abundantly and is suitable for moist spots in rockwork or along streams. Some, possibly much, of the material cult. under this name is really Cymbalaria moschata, Boiss., which has not been frequently cult.

SAXIFRAGA

July. Eu. and in the Rocky Mts., S. Canada to Colo. and Utah.—A very common and widespread European species which has not been frequently cult.

Section V. Neprophylhum.

a. Basal lvs. cuneate or spatulate. 11. lactea
b. Basal lvs. cordate or reniform. 12. granulata

3556. Saxifraga Stracheyi, as the flowers are appearing in earliest spring. (×1½)

11. lactea, Turcz. Cespitose, 4-6 in. high; sts. erect, glandular-pubescent below, panicle above: lvs. light green, lower cuneate, 3-5-parted, lobes oblong, very obtuse, horizontal-spreading; upper 3-parted, lobes linear, obtuse: infl. axillary, with pedicels much longer than the fls., 2-fl., the terminal fl. exceeded by the lower; fls. white (milky white according to trade-lists); calyx-lobes ovate, obtuse, longer than the tube; petals obovate-cuneate, lightly 3-nerved, 3 times longer than the calyx-lobes. June. Siberia.—Probably not in general cult.

13. rivularis, Linn. Cespitose, the sts. ascending 1-3 in. high, more or less villous: basal lvs. with petioles 3-5 times longer than the blades, reniform, incise-lobed, lobes obtuse, petals with broad ciliate stipules; upper lvs. short-petioled, 3-lobed: infl. long, peduncles arising from the axils of the lower lvs., almost as long as the whole st.; fls. at the top short-pedicelled or sessile: fls. 1-5, white (often tinged purple), erect; calyx short-glandular-pilose or rather glabrous, tube hemispherical, lobes ovate, obtuse, shorter than the tube; petals obovate-oblong, twice as long as the calyx-lobes. July, Aug. Circumboreal, in N. Amer. to the White Mts. and in the Rocky Mts. to Mont.

Section VI. DACTYLOADES (MUSCAIUA).

a. Lower lvs. undivided or short 3-5-pointed; petals mostly small (see also S. moschata and S. globularia, which have some of the lvs. undivided).

b. Plants loosely cespitose, with indeterminate secondary shoots borne in the V-arios.
**SAXIFRAGA**

**aa.** Infl. a few-fl., panicle borne on a fl-st. about 1 in. high............. 14. tenella **bb.** Plants densely cespitose: scape 1-fl.d. or few-fl., paniculate............. 15. aphylla

Subsection HOLOPHYLLA...

14. tenella, Wulf. Lax, cespitose, 2-4 in. high, with foliose, prostrate or erect caulicles: sts. erect, slender, glabrous: lvs. yellow- or apple-green, shining, thin but rather stiff, lower and also caulescent, linear-subulate, cuspitate-aristate, margin setulose-ciliate or glabrous, glandulose-ciliate toward the base: infl. terminal, few-fl., panicules with slender pedicels longer than the fls.: fls. white or yellowish white; calyx-lobes triangular, acute, equaling the tube, glabrous; petals obovate-oblong, recurved above, 3-nerved, twice as long as the calyx-lobes. June, July. Mountains of Cent. Eu.

15. aphylla, Sternb. (S. leplophylIla, Froel.). Loosely cespitose, about 1 in. high with numerous sparingly foliate caulicles with rosettes at the top: sts. scarcely glandular or pubescent: lvs. light green, rather thin, entire or 3-5-crustate, the divisions ovate-lanceolate, obtuse: infl. almost leafless 1-fl., rarely 2-fl., glandular scapes: fls. light yellow; calyx-lobes ovate, acute; petals linear, acute, equaling the calyx-lobes. June, July. Mountains of Cent. Eu.

16. muscoides, All. Densely cespitose, 1-2 in. high, with short caulicles: sts. columnar, densely imbricate-foliose, ashy pilose: lvs. linear, rounded-obtuse, base attenuate, when dried 3-nerved, apex cuneate; infl. numerous, terminal, few-fl., racemes or more seldom several-fl., panicked with very short pedicels: fls. white or yellowish white (rarely citron-yellow or purple); calyx-lobes ovate, obtuse, petals rounded-obovate, very obtuse, smoothly emarginate, 3-nerved, twice as long as the calyx-lobes. July, Aug. High mountains from the Pyrenees to Austria. Gn. 76, p. 615.—Frequently confused with S. moschata and S. cespitosa. A strictly Alpine species forming a dense moss-like cushion, the uppermost lvs. of which are reddish toward the base and fresh green toward the apex and are rather fleshy. Suitable only for alpine-gardening. Var. folius-variegatus, Hort., is a form with yellow-and-white variegated lvs. Very likely this really is a variety of S. moschata.

17. androsacea, Linn. Cespitose, 1-3 in. high (possibly more), with the basal and lower lvs. aggregated and sessile: lvs. dark green, shiny, spatulate or obovate, cuneate, apex entire or 3-5-toothed, the teeth short and acute, the central twice longer than the lateral, when dry 5-11-nerved, margin ciliate, at the top glandulose-ciliate; cauline lvs. oblong-lanceolate: infl. numerous, almost naked, sparsely glandular, 1-3-fl., rarely 5-fl., scape: fls. small, clear white or greenish white; calyx-lobes ovate, obtuse, the base and margins glandular; petals obovate-oblong, 3-nerved, at the top emarginate, the uppermost portion reflexed, twice longer and broader than the calyx-lobes. June-Aug. Mountains of S. and Cent. Eu., also the Baikal region of Asia.
**SAXIFRAGA**

**Subsection AXILLIFLORAE.**

18. *ajugifolia*, Linn., also spelled *ajugaefolia*. Cespitose, about 3–6 in. high; st. decumbent, rooting; lvs. sparsely glandular-pilose, light green, rather thick and fleshy; orbiculate-digitate, 3–5-parted, attenuate to the flat petiole, lobes lanceolate, acute; infl. 1–3 slender, nearly simple, few-fl. scape arising from the axis of the lower lvs.; bracts linear, entire, acute; pedicels very short, puberulent; fls. rather small, whitish or clear milk-white; calyx-lobes ovate, acute; petals ovate-oblong, 3-nerved, very shortly clawed, twice longer than the calyx-lobes.

May–July. S. Eu.

19. *perdurans*, Kit. Cespitose, 1½–3 in. high; st. procumbent; lvs. rather thick, bright green, the lower surface striated purple at the nerves, those of the young shoots and the lower cauline similar, without glands, wedge-shaped, attenuate to the flat petiole, palmately 3–5-parted, lobes horizontal spreading, oblong, obtuse, muticous, faintly 3-nerved; refl. a solitary, axillary, sub-simple, few-fl. scape with a reddish base and one partially clasping fl.; bracts 3-parted or entire; fls. 1–6, cymose, white; calyx-lobes roundish; petals spreading, oblong, 3-nerved, more than twice as long as the calyx-lobes. June, July. Mountains of E. Cent. Eu.—Closely allied to *S. ajugifolia*.

**Subsection CERATOPHYLLAE.**

20. *geranioides*, Linn. (*S. palmata*, Hort., not Smith and others). Biennial or perennial, cespitose, 2–10 in. high, with numerous furtaceous subwoody, leafy caulicles; st. erect, somewhat pilose; lvs. bright green, lower rather pilose, suborbicular or reniform, palmately 3–9-divided with the lateral lobes bifid, lobes lanceolate-acute or 2–3-toothed, base of the ciliate petiole dilate; calyces cuneate-ovate with narrow lobes; infl. subcorymbose, many-fl., with pedicels shorter than the fls.; fls. white, campanulate; calyx-lobes erect, linear-lanceolate, acute; petals obovate-oblong, long-clawed, more than twice longer than the calyx-lobes. May–July. Mountains of Eu.—Best prop. by seed. A showy little ground-cover; plant suitable for terraces and the like.

21. *pedatifida*, Ehrh. (*S. cuspidata*, Schleich.). Cespitose, 2–8 in. high, with furtaceous, subwoody, leafy caulicles; st. erect, rather stiff, puberulent; lvs. fresh green, the lower with ovate and pectate-parted blades, many-nerved and borne on flat petioles which are longer than the blades, the lateral lobes of which are 3-lobed, the lobules linear, entire and more or less mucronate; the lvs. of the young shoots longer-petioled and with longer, narrower lobes; the cauline lvs. 3-lobed; bracts narrowly linear; infl. subcorymbose, the peduncles much overtopping the lvs., the pedicels and calyx glaucous, pilose; fls. 3–9 on a peduncle, campanulate, white; calyx-lobes erect, lanceolate, acute; petals obovate-oblong, 3-nerved, very shortly clawed, twice longer than the calyx-lobes. June. S. Eu.—Closely allied to *S. geranioides* but distinguished readily by the gradual narrowing of the blades, which are many-nerved into the petiole and also by the linear divisions of the lvs.

22. *Campsis*, Boiss. & Reut. (*S. Wallaca*, McNab. *S. Wallacæna*, Hort.). Fig. 3557. Perennial, loosely cespitose, 3–6 in. high, with slightly shrubby caulicles covered with old reflexed lvs.: fls. seta. erect, reddish, entirely glabrous; lvs. stiff, dark green, shiny, those of the young shoots and the lower ones incise-5-lobed, more than double the length of the strongly broadened, nerved petiole and having decidedly prominent nerves, the lateral lobes of the blade again 2-lobed or dentate with the teeth mucronate, the midlobe usually entire, linear and mucronate; calyces cuneate, attenuate to the petiole, more or less on one petiole; bracts spatulate, acute; infl. terminal, 6–10-fl., more or less congested corymbs or panicles; lvs. large, 3–4 in. across, subcampanulate, white; calyx-lobes oblong, acute; petals rounded-obovate, shortly clawed, 3-nerved. May–July. Spain. B.M. 6640. Gn. 35, p. 387; 75, p. 335. A.F. 4:493. G.M. 43:192; 55:276; 57:620. J.H. III. 70:250.—This species has been intro. into Amer. but never succeeded well owing, it is said, to the hot climate. An attractive little plant on account of its showy fls. which are occasionally used for cut-fls.

23. *canaliculata*, Boiss. & Reut. Lax, cespite, 6–8 in. high, with ascending caulicles which are covered below with old, rather remote lvs., and terminate in rosettes: fls. stam. numerous, erect, very glabrous; lvs. very stiff, quite dark green, strongly viscid below, with transversely broader blade which is 3-parted and is borne on a flat, deeply grooved petiole, midlobe of the blade entire, the lateral ones 2–3-parted, with the lobes bowed and mucronate at their apex; calyces 3-lobed; bracts linear, mucronate; infl. corymbose-paniculate: fls. white; calyx-lobes linear-lanceolate, mucronulate; petals obovate-oblong, attenuate to the claw, 3-nerved, twice as long as the calyx-lobes. July. Spain.—Allied to *S. Campsis* from which it differs in the more spreading divisions of the lvs. and the fact that the petioles are not broadened except at the base.

24. *trifurcata*, Schrad. Perennial, loosely cespite, 4–8 in. high, with slightly shrubby leafy caulicles covered with old reflexed lvs.: fls. stam. erect, glabrous; lvs. dark gray-green, viscid, twice as long as the petiole, palmately 3-parted, nerved, the lateral lobes of the blade sub-3-divided, the midlobe cuneate, 3-toothed, with the teeth mucronate; calyces lvs. few, shortersetated; bracts linear, acute; infl. 3-parted and is borne on a flat, deeply grooved petiole, midlobe of the blade entire, the lateral ones 2–3-parted, with the lobes bowed and mucronate at their apex; calyces lvs. 3-parted; bracts linear, mucronate; infl. corymbose-paniculate: fls. white; calyx-lobes linear-lanceolate, mucronulate; petals obovate-oblong, attenuate to the claw, 3-nerved, twice as long as the calyx-lobes. July. Spain.—Allied to *S. Campsis* from which it differs in the more spreading divisions of the lvs. and the fact that the petioles are not broadened except at the base.

25. *pedemontana*, All. Sparsely glandular-pubescent, cespite, 2–4 in. high, with densely leafy caulicles: lvs. bright green, those of the young shoots and the lower cauline, cuneate or obversely triangular; lower, truncate or oblique-oblong, obtuse to the petiole; lvs. 3-lobed; bracts narrowly linear; infl. subcorymbose, the peduncles much overtopping the lvs., the pedicels and calyx glaucous, pilose; fls. 3–9 on a peduncle, campanulate, white; calyx-lobes erect, lanceolate, acute; petals obovate-oblong, 3-nerved, 2 or 3 times longer than the calyx-lobes. June. S. Eu.—Closely allied to *S. geranioides* and distinguished readily by the gradual narrowing of the blades, which are many-nerved into the petiole and also by the linear divisions of the lvs.

26. *Campsis*, Boiss. & Reut. (*S. Wallaca*, McNab. *S. Wallacæna*, Hort.). Fig. 3557. Perennial, loosely cespite, 3–6 in. high, with slightly shrubby caulicles covered with old reflexed lvs.: fls. stam. erect, reddish, entirely glabrous; lvs. stiff, dark green, shiny, those of the young shoots and the lower ones incise-5-lobed, more than double the length of the strongly broadened, nerved petiole and having decidedly prominent nerves, the lateral lobes of the blade again 2-lobed or dentate with the teeth mucronate, the midlobe usually entire, linear and mucronate; calyces cuneate, attenuate to the petiole, more or less on one petiole; bracts spatulate, acute; infl. terminal, 6–10-fl., more or less congested corymbs or panicles; lvs. large, 3–4 in. across, subcampanulate, white; calyx-lobes oblong, acute; petals rounded-obovate, shortly clawed, 3-nerved. May–July. Spain. B.M. 6640. Gn. 35, p. 382; 75, p. 335. A.F. 4:493. G.M. 43:192; 55:276; 57:620. J.H. III. 70:250.—This species has been intro. into Amer. but never succeeded well owing, it is said, to the hot climate. An attractive little plant on account of its showy fls. which are occasionally used for cut-fls.
26. *conferta*, Coss. & Dur. densely cespitose, 1½-3 in. high, with numerous short, densely imbricate-foliate caulescences: fl.-sts. stiff, ascending, few-lvd., purplish below, densely glandular-pubescent above: lvs. those of the caulescences, subpatent; calyx-funnel spreading; all of them undivided, sessile, oblong- or lanceolate-linear, cuspitate-aristate, leathery, margin short-ciliate: infl. 3-9-fl., corymbose-racemose or paniculate: fls. white; calyx pubescent-glandular, the lobes ovate-triangular, mucronate; petals not known. June, July. Spain.—Rare and seldom cult.

27. *hypnoides*, Linn. (S. *hibernica*, Hort.). Perennial, loosely cespitose, 1½-8 in. high, with herbaceous loosely foliose caulescences which are frequently reddish-tinted: sts. erect, covered with very slender glandular lvs. light green, those of the caulescences rather thick, sparsely covered with slender hairs, when old rather glabrous, the subterminal blade is cut all the way to the base, 3-lobed, and is borne on a rather broad, flat, 1-nerved, cupulate scabrous petiole which is shorter than the blade, lobes of the blade linear-lanceolate, a little dilated at the middle, acute or mucronate, with the lateral lobes divaricate, often 2-lobed; upper lvs. of the young shoots 3-toothed, attenuate to the long petiole, the uppermost linear-lanceolate, oval and like the lvs. of the cauline linear-lanceolate, ciliate and acute or mucronate: infl. 3-7-fl. paniæces: fls. long-pedicelled, white, ½-in. diam.; calyx very densely glandulate, the lobes oblong-trianglar, mucronate; petals obovate, 3-nerved, longer than the calyx-lobes: fr. ovate-globose. May-July. Mountains of Eu., as far north as Great Britain and Ireland. G.C. III. 43:302.—Frequently confused with *S. cespitosa*, Linn., and *S. decipiens*, Ehrh., and this is the distinction of the 3 species is almost hopeless; confused. Botanically speaking very probably Hooper's *S. hypnoides* in his Students' Flora of the British Islands, ed. 3, p. 142, is correct in referring *S. cespitosa* and *S. decipiens* as varieties to this species, but horticulturally at least they are better retained as separate species. Var. *genuinera*, Hort. (S. *Kingii*, Hort., also spelled *Kingiana*), is a close-growing, compact form. Var. *purpurea*, Hort., is offered in the trade. Var. *rosa*, Hort., is offered in the trade. Var. *Whitlavia*, Hort. (S. *Whitlavia*, Hort.) is a form with closely packed foliage said to be suitable for edging. A variation of this is *S. gemmifera* 3090 SAXIFRAGA

28. *spathulata*, Desf., also spelled *spatulata*. Perennial, very densely cespitose, 2½-4 in. high, with short, prostrate, very densely imbricate-foliate caulescences: sts. slender, erect, few-lvd.; lower lvs. spathulate, ciliate, apex obtuse, rarely 3-toothed, 3-nerved; calyx linear: infl. 3-5-fl., corymbose-pedicelled with pedicels longer than the fls. and sparsely glandular as is the calyx: fls. white; calyx-lbs. ovate, very obtuse; petals obovate-oblong, twice as long as the calyx-lbs.: fr. subglobose. June, July. N. Afr.—It is doubtful whether this species is hardy in E. U. S. It forms very thick, close mats which are reddish green or brownish with the silver-gray buds of the axils of the leaves. Not very showy, as the pedicels are few-fld.

29. *globulifera*, Desf. Cespitose, about 3-4 in. high, with densely foliose, short caulescences: sts. prostrate, nearly glabrous or sparsely pilose, few-lvd.: lvs. bearing in their axils buds which are shorter than the lvs.; lvs. all nerved and borne on dilated rather flat petioles; the lowest spathulate-ciliate, 3-nerved; the other lvs. oblong-rounded or, if the lateral lobes are bident, 5-lobed, the midlobe oblong-lanceolate or, if all the lobes are tridentate, with the teeth rather acute; calyx lvs. oblong-linear, obtuse; bracteoles linear: infl. 3-5-fl., corymbose-pedicelled; pedicels twice or more longer than the fls.: fls. white; calyx short-pilose, the lobes ovate-triangular, obtuse; petals obovate, 3-nerved, more than twice the length of the calyx-lbs.: fr. subglobose. May, June. S. Spain and N. Afr.

30. *Maweana*, Baker. Cespitose, about 6 in. high, with copiously branched, slender purple caulescences which are glandular-pubescent: fl.-sts. erect from a decumbent base: lvs. 6-8 to a shoot, loosely disposed, coriaceous, ternate-palmately parted, the lobes with 5-6 oblong, subobtuse teeth; the pedioles spreading, the upper half narrowly winged, often 2-3 times longer than the blade: axillary buds copious and robust: infl. laxly corymbose, 4-9-fl., borne on densely puberulent peduncles: fls. white, large; calyx-lbs. ligulate-lanceolate, subulate, twice as long as the densely puberulent tube; petals obovate-ciliate. May. Morocco. G.C. 1871:1355.

Subsection *Cespitosa*.

31. *decipiens*, Ehrh. (*S. cespitosa*, Hort., not Linn.). Cespitose, about 3 in. high, the caulescences hirta, rarely subglabrous, rather long and leathery: sts. erect, few-lvd., smooth or at first glandular-piloset above: lvs. obovate-ciliate or spatulate, attenuate to the 1-nerved, flat petiole, apex either 3-pointed or 3-lobed, lateral lvs. 2- or 3-lobed even on the midlobe: fr. ovate-oblong; calyx-lobes 3-lobed: infl. loosely pedicelled, few-fl. (usually 3): fls. white; sepal oblong-lanceolate, subacute; petals obovate, 3-veined. May, June. Eu. L.B.C.16:1510. Gn. 78, p. 271.—Approaches *S. cespitosa*, Linn., from which it is most easily distinguished by the aculeate fl. lobes and subacute sepalas; also approaches *S. hypnoides*, from which it is readily told as that species has buds in the axils of the lvs. of the barren shoots, whereas *S. decipiens* has not. Very variable; some of the cult. forms are: Var. *Alba*, Hort., which has strong growth and white fls. Var. *Arkwrightii*, Hort. (S. *Arkwrightii*, Hort.). Rather tall-growing and free-flowering: the buds are suffused with a pale rose tint, but the fls. are pure white, flat, and large, ¾-1 in. across. G.C. III. 45:314. Var. *bathoniensis*, Hort. (S. *bathoniensis*, Hort. *S. muscoides* var. *bathoniensis*, Hort.). A rapid grower, 10-14 in. high, with stout branching sts. bearing large scarlet-crimson fls. Var. *bistolaris*, Hort. (S. *bistolaris*, Hort.) is probably a strain of red-fld. *S. muscoides* var. *muscoides* (S. *muscoides* var. *muscoides*, Hort.). Var. *Brullei*, Hort. (S. *Brullei*, Hort.), with neat cushions of *S. decipiens* var. *Brullei*. Var. *bagnata*, Hort. (S. *bagnata*, Hort.), a rapidly spreading, lax-flowering form, with medium-sized brilliant red or dark carmine-red fls. All of these forms are much prized by fanciers abroad.

Var. *hybrida*, Hort., is probably a strain of red-fl. *S. hybrida*. It is suggested by one author that they are the result of a cross between *S. decipiens* and *S. grandiflora*; one of the trade names of these variants is *S. decipiens* var. *hybrida* (S. *hybrida* grandiflora, Hort. (S. *hybrida* grandiflora, Hort.), with large rich crimson or bright red fls. *S. hybrida* grandiflora *Alba*, with neat cushions of deep green foliage, the flowers and fr. are described as deep clear rose, rich crimson and rich blackish crimson, ½-in. or more diam. G.C. III. 45:301. G. 30:393. Gn. 73, p. 264. J.H. III, 58:431. Var. *bathoniensis*, Hort. (S. *bathoniensis*, Hort. *S. muscoides* var. *bathoniensis*, Hort.). A rapid grower, 10-14 in. high, with stout branching sts. bearing large scarlet-crimson fls. Var. *bristolicrata*, Hort. (S. *bristolicrata*, Hort.) is said to be a remarkably effective variety with rich rose-red fls. Var. *hybrida*, Hort., which is said to be a remarkably effective variety with rich rose-red fls. G.M. 56:151. Var. *hybrida* splendens, Hort., with rosettes of moss-like foliage covered with medium-sized brilliant red or dark carmine-red fls. All of these forms are much prized by fanciers abroad.
Var. lutescens, Hort., is offered in the trade. Var. purpurea grandiflora, Hort., is a trade name for a form which is said to be more vigorous than previous races. It is said to form compact basal tufts, with bright red fls., fading to rose, nearly 1 in. diam. April. Var. sanguinea, Hort. (S. sanguinea superba, Hort., not S. sanguinea, Franch. S. muscoides var. sanguinea superba, Hort.). Habit neat and compact, growth rapid; fls. rich blood-red, well retained when old. Var. Stérbergii, Engl. (S. Stérbergii, Willd. S. hibernica, Haw., not Sternb. S. hirpinoides var. Stérbergii, Hort.). Lvs. ciliate, somewhat pedate; the midlobe entire, the lateral 2-parted, or the midlobe and also the lateral 3-parted; the divisions rather obtuse. Germany, Ireland, Norway, and Greenland. Var. villéa, Engl., is a form which is villous and canescent and has white fls.

32. cespitosa, Linn., more commonly spelled cespitosa (Muscari cespitosa, Haw.). Cespitose, 2–6 in. high, with subwoody columnar caudicles which are densely imbricate with persistent old lvs.; fl-sts. erect, those of the caudicles and shoots cuneate, borne on a large petiole which doubles the length of the blade, 3-parted (rarely 5), the lobes linear and obtuse: inf. terminal, 1–5-fld.; fl-sts. stoutish: fls. white; sepal oblong-deltoïd, obtuse; petals narrowly obovate or oblanceolate, obtuse; pedicels and calyx-lobes, rounded at the apex. June–Aug.

33. exarata, Vill. Fl. 3558. Cespitose, 3–6 in. high, with sublignous and also herbaceous caudicles which are rosulate at their tips: fl-sts. erect, few-flvd., densely glandular above; lvs. of the caudicles deep green, smooth, nearly glabrous, either cuneate, attenuate to the petiole, the ap. 3-toothed, or obvate-cuneate, attenuate to a petiole double the length of the blade, 3-parted (rarely 5), the lobes linear and obtuse: inf. terminal, 1–5-fld.; fl-sts. stoutish: fls. white; sepal oblong-deltoïd, obtuse; petals narrowly obovate or oblanceolate, obtuse, rounded at the apex. June–Aug.

34. obscura, Gren. & Godr. Cespitose, 3–8 in. high, with somewhat shrubby, elongated caudicles covered with old lvs.; fls. erect, slender, nearly naked, pilose: lvs., those of the shoots and the lower, pedate-divided, with lanceolate lobes, linear, longer- petioled, broadened at base. lateral lobes biffid or 2-toothed, teeth lanceolate, the midlobe 3-parted; caly whole lvs. 3–5-parted: inf. 5–15-fld., with pedicels shorter than the fls.: fls. white; calyx-lobes linear, subacute; petals oblong, not at all clawed, double the length of the calyx-lobes. July, Aug. Pyrenees.—A rare, little-known species.

35. mixta, Lapeyr. The whole plant glandular-pilose, densely cespitose, 2–3 in. high, with subwoody columnar caudicles which are densely imbricate with persistent old lvs.; fl-sts. erect: lvs. mostly light green, soft and more or less strongly nerved, those of the caudicles and shoots cuneate, borne on a large petiole which equals the blade in length, 3-lobed, the lobes horizontally spreading, obtuse or at other times the lobes 3-lobed, the lobules linear, obtuse; caly whole lvs. obovate-cuneate, 3-lobed; bracts oblong, obtuse: inf. corymbose-paniculate: fls. milk-white, not uncommonly purple-nerved; calyx-lobes ovate, obtuse; petals round-ovate, 3 times as long as the calyx-lobes. June–Aug. Pyrenees.—said to be an attractive little plant with a good habit, but the species proper appears not to have been cult. Var. hirta, Engl. (S. hirta, F. Schultz). About 2 in. high, differing from the type in the deep green, broadly ovate-cuneate lvs. which are 5–9-divided, the lobes being linear, short, and obtuse; in the few-fld., narrow panicle and also in having the white fls. veined with purple. May–July. Pyrenees.—The variety is more common in cult.

Subsection EXARATE.

36. moschata, Wulf. (S. muscoides, Hort., not All. S. moschoides var. moschata, Hort.). Cespitose, 1–5 in. high, the caudicles herbaceous or subligneous, foliose: lvs. smooth, nerves not prominent, glabrous or glandular-pilose; those of the caudicles linear, entire, obtuse or cuneate, 3–6, rarely 3-parted, lobes linear, obtuse, horizontally spreading; caly whole lvs. few, 3-lobed or entire; bracts linear, obtuse: inf. racemose or paniculate, 1–10-fld., borne on erect, few-flvd., subglabrous or glandular-pilose fl-sts.: fls. commonly yellowish but not uncommonly rose or dark purple, seldom almost white; calyx-lobes ovate, obtuse; petals spreading, oblong, obtuse, 3-nerved, slightly exceeding the calyx-lobes; fr. ovate-globose. May, June. Cent. and S. Eu. Gn. 76, p. 283 (as S. cespitosa).—Linnaeus included this under S. cespitosa and in consequence the two species have been commonly confused. There seems no doubt, however, that Linnaeus intended his cespitosa to apply to the Lapland form. S. moschata is readily separated from the true S. moschoides by the lobed lvs.; those of the latter are unlobed and linear. A very variable species; some of the varieties in cult. arc: var. Alliöni, Engl. (S. Alliöni, Caud., not Bau. S. muscoides var.
3092 SAXIFRAGA

SAXIFRAGA

Alliottii, Hort.). Laxly cephalo-ses, robust, 3-6 in. high:

Section VII. BORAPinLA (SPATHULARIA, MICRANTHES).

Robust habit and larger deeper colored lvs. A form of this more commonly cult., is known as superba Rhei, or with three crenatures. Var. Rhei, Hort., also spelled mossy hillocks covered in April and May with masses the lvs. rather thick, all entire, the apex rounded-obtuse or with three crenatures. Var. Rhei, Hort., also spelled mossy hillocks covered in April and May with masses of rather large rose-colored lvs. Grows about 6 in. high. A form of this, more commonly cult., is known as S. Rhei superba or S. muscosæ Rhei superba, and has a more robust habit and larger deeper colored lvs.

13. bryophora, Gray (SPATHULARIA bryophora, Small). Two to 8 in. high, slender: lvs. 1 in. or less long, basal rather far apart, roseulate at the top of the slender cucullules, oblong-elliptic to oblong-cuneate, obtuse, entire, ciliate: infl. solitary or tufted naked scape, paniculately hispid: lvs. short-pilose on both sides, the lvs. short-pilose on both sides, the apex acute, the teeth equal and acute; lower bracts linear-chalcate, narrowly dentate, upper ones nearly entire: infl. 1 or more scapes arising from the axis of the basal lvs. and branching panicle from the middle, with the branches more or less diffuse; pedicels slender: lvs. white, numerous and star-like; sepals lanceolate; petals unequal, the 3 larger ones with 2 light yellow spots at their coriaceous base, twice as long as the sepals: fr. ovate. June. Mountains of Va. to N. C. and Ga. L.B.C. 16:1698. B.M. 2559. B.B. 2:176; (ed. 2) 2:221 (as Hydastia petulosa).

38. davarica, Pall., also spelled dahirica (MICRANTHES davarica, Small). Three to 8 in. high, rhizome thick: lvs. basal, rather stiff, forming a rosette, sparsely covered with very short hairs, oblong-elliptic, obtuse, narrowly entire or with short teeth rounded at the apex, deeply and evenly dentate, teeth ovate, acute, blades cuneate-attenuate at the base to the petiole which is membranaceous sheathing at the base; bracts oblong-lanceolate, the lowest of the oblong-cuneate: infl. erect, naked scape, which are solitary or several together, and are covered with very slender ciliate, partly glandular hairs, many-fl.d. and corymbose-paniculate-branched from the middle; pedicels filiform: lvs. white, numerous; sepals yellow-green, ovate, rather acute, erect-spread and not reflexed in age: petals obvolute-oblong, scarcely twice as long as the sepals. E. Siberia and the islands of Bering Sea. — Much of the so-called American S. davarica and apparently more or less of the material cult. as S. dahirica is really S. Lyallii from which it differs in having the peduncles hairy instead of glabrous and many—instead of few-fl. smaller lfs. and other characters. Somewhat similar to S. virginiensis.

40. Lyallii, Engl. (S. dahirica, Lyall.). Micranthes Lyallii Small). Four to 15 in. high, rhizome slender: lvs. fresh green, obvolute ("labellate, varying to sub-orbicular or reniform-labellate"), cuneate, attenuate to a basally dilated petiole, equally serrate-dentate above, glabrous, almost nerveless: infl. 6-10-fi.d. loosely paniculate scapes which are naked, slender, erect, almost glabrous, with very slender, erect-spread, later erect pedicels which are purple almost glabrous: lfs. milk-white; calyx purple, the sepals ovate-triangular, reflexed; petals obvolute-rounded, slightly clawed, 1-nerved. Rocky Mt. region, Brit. Col., Alaska, and Bering Sea region. — Has been confused with S. davarica, Pall., which see.

41. micranthidifolia, Steud. (S. erosa, Pursh. Micranthes micranthidifolia, Small). Up to 3 ft. high: lvs. all basal, oblong or oblong-lanceolate, obtuse, attenuate to a flat petiole which is partly clasping at the base, crenate-dentate, sparingly and also very shortly pilose, margin short-ciliate: infl.paniculate, loosely fi.d. and elongated, borne on a tall softly pilose scape; pedicels filiform, densely covered with slender glandular hairs, viscid: lfs. numerous, white; sepals linear-lanceolate, obtuse, finally reflexed; petals ovate, obtuse, with a yellow blotch below the middle, slightly longer than the sepals. June. July. Cold mountain brooks and wet rocks, Pa. to N. C. and Tenn. B.B. 2:174; (ed. 2) 2:219. — Occasionally cult.

42. pennsylvanica, Linn. (MICRANTHES pennsylvanica, Haw.). SWAMP SAXIFRAGE. Tall and stout, up to 3 ft or more high, viscid pubescent: rhizome thick: lvs. ab
basal, sometimes almost 1 ft. long, oblongate or oblong-spatulate, attenuate to a little shorter that the base, obtuse, very shortly and also remotely dentate, margin short-ciliate: infl. 4-8-fld. cyymes in a large panicle at first clustered, borne on a naked erect scape which is few-or few-striate, shortly-pilose, toward the top glandulous-pilose: fls. numerous, small, greenish; calyx-lobes dotted, spreading, in fr. reflex; petals oblong-linear or linear-lanceolate, 1-nerved, a little longer and narrower than the calyx-lobes. June, July. Swamps and low meadows, Maine to Ont. and Minn., south to Mo. B.B. 2:173; (ed. 2) 2:219.—Recommended as a bog-plant.

43. integrifolia, Hook. (Microtheca integrifolia, Small). Whole plant glandular-pilose, viscid, very viscid above, 4–14 in. high: caudex short and somewhat woody, the st. always solitary: basal lvs. dark green, spiny below at the base, obtuse, very shortly and also remotely dentate, margin short-ciliate: infl. 4-8-fld.

44. nivalis, Linn. Two to 6 in. high: rhizome rather thick, short and simple but thick and hard, crowned with a tuft of lvs.: lvs. rather thick and leathery, roundish-ovate, generally abruptly narrowed to the petioles, obtuse, sharply crenate-serrate, upper surface dark green, under surface purple or red and often pubescent; bracts bristly-purple or red: infl. composed of cymules aggregated into one or more terminal conspicuously bracted heads and borne on erect solitary or clustered purple or purple-tinted scapes which are glandular-viscid especially above: fls. white, very short-pedicelled or sessile; sepals ovate or deltoid-ovate, obtuse, ciliate; petals oblong to elliptic, mostly obtuse, narrowed into petals 3-nerved, unequal, 4 smaller, lanceolate, very shortly and also remotely dentate; infl. 4-8-fld., crowded or loose panicle 50. sarmentosa, Linn. Which is borne on the solitary, erect or ascending naked scape: fls. white; not punctate; sepals ovate, obtuse, reflexed; petals oblong, obtuse, double the length of the sepals. Alaska to Alberta, south to Mont. and Calif.—Very similar to Micranthes but readily distinguished by the viscid-ovate lvs.

Section VIII. DIPTERA.

47. Mertensiiina, Bangard (Heterotia Mertensiana, Small). Perennial, 4–15 in. high, subumbellate: lvs. basal, in a rosette, subrounded, base cordate, incise-lobed, the lobes quadrate, 3-toothed with the teeth obtuse or acute; the petals long, slender, pilose and at the base with a long membranaceous sheath: infl. a loosely diffuse panicle with erect-spreadig glandular-pilose branches borne on a slender erect almost naked green scape: fls. white with very long pedicels; sepals ovate, obtuse, reflexed; petals oblong, obtuse, double the length of the sepals. Alaska to Alberta, south to Mont. and Calif.—Very similar to Micranthes but readily distinguished by the incise-ovate lvs.

48. cortusoflora, Sieb. & Zucc., also spelled corusafolía. From 6–12 in. high, not stoloniferous: lvs. basal, rather thick and fleshy, bright green, the lower part reddish, strigo-pilose, margin ciliate, roundish, 7-lobed, milky large, 3-lobed or 3-lobed, acuminate, base cordate; petals 3–4 times as long as the blade and broadened into a sheath ciliate with long rusty brown hairs: infl. laxly paniculate, terminal on an erect, strize, strigo-pilose scape; pedicels long, very slender, erect: fls. white; calyx-lobes lanceolate, acute; petals 3-nerved, unequal, 3 (generally) slightly longer than the calyx-lobes and ovate-lanceolate, the other 2 (sometimes 1–3) 8–10 times longer and quite entire, very long-attenuate to a claw. Oct. Japan. B.M. 6680. Var. média, Maxim. (S. médı́a, Makino). Lvs. thin-membranaceous, deeply lobed, with the lobes 3-lobulate and incise-dentate. Oct. Japan. G.C. III. 46:379.

49. Fortunée, Hook. (Bergenia Fortunée, Steink. Perennial, scoriae (if at all) sarmentose, up to 2 ft. : lvs. dark green, one-colored, basal, thick, strigo-pilose, rounded-reniform, nerves, somewhat 7-lobed, the lobes rounded, strongly and acutely laciniate-serrate; petals longer than the blade, double the length of the sepals; the blades of the calyx-teeth long, doubly ciliate-dentate: infl. loosely paniculate, borne on a stout, erect, strigo-pilose scape; the panicle-branches glandular, spreading, 4–7-fld.; pedicels nodding; fls. white; calyx-lobes ovate, rather obtuse, spreading; petals 1-nerved, unequal, 4 smaller, lanceolate, very entire or subentire, the fifth much longer, 3 or 4 times larger than the others, strongly serrate. June–Oct. Japan. B.M. 5377. G.L. 24:351. G.W. 74, p. 622; 78, p. 964. G.C. III. 46:26. G. 6:445. G.W. 14, p. 398. G.W. 24:759.—A very showy species which is not entirely hardy in England, requiring winter protection. Var. tricolor, Hort., is a form with the lvs. irregularly blotched with rose, white, and yellow. F.S. 21:2227, 2228.

50. sarmentăsa, Linn. (S. japonica, Hort. S. chinensis, Lour.). STRAWBERRY GERANIUM. In England known as MOTHER OF THOUSANDS, a name also applied to Linaria Cymbalaria. OLD MAN'S BEARD. Fig. 3569. Perennial, 9–24 in. high, stoloniferous, the stolons long and filiform: cauline and petal-leaf lvs. sometimes, but rarely, rather thick, strigo-pilose, reniform-rotundate, roundly rounded-ovate, nerved, doubly crenate-dentate with broad acute teeth, upper surface green veined white, lower surface
reddish; petioles twice as long as the blade, semi-terete: infl. loosely paniculate, borne on an erect, strigose-pilose scape, the panicle-branches glandulose, spreading, 4–7-fld.: fls. white, numerous; calyx short-glandu­lose, the lobes ovate, obtuse or acute, spreading; petals 1-­nerved, clawed, unequal, the 3 smaller ovate, acute, of these the two outer have a yellow spot, the middle one 2 scarlet spots, the other two 3–4 times larger and lanceolate-elliptic. May–Aug. Japan. B.M. 62. G.C. III. 7:257 (showing irri­tability of plant to light). Gn. 30, p. 363; 32, p. 37. R.H. 1876, p. 427. G. 25:365. Gn. W. 25:751.—An old-time greenhouse plant, and also one of the commonest window-garden subjects. Of easiest cult. Not quite hardy in England but frequently used in sheltered rock crevices and slightly protected. Var. tricolor, Sieb. (S. tricolor, Hort. & S. tricolor superba, Hort.), has lvs. hand­somely marked with creamy white and red vei­rargations. G.Z. 9:32. Less hardy than the type.

51. cucutaefornis, Lodg. Perennial. 3–6 in. high, stoloniferous, the stolons filiform, often branched and tangled in one another like the sts. of cucuta: lvs. basal, rather thick, plano-convex, both surfaces strigose­pilose, green, white-veined, sub­bilocular or ovate, nerved, coarsely toothed or undulate-acute. Teeth broadly acuminate, becoming obtusely with age; petals longer than or equaling the blade, rather large and thick; infl. laxly seud-paniculate from below the middle of the slender, ascending, strigose­pilose scape; the panicle-branches glandulose, erect-spreading, slender, 2–3-fld.: fls. white; calyx very short-glandul­lar, the lobes ovate, acute, spreading; petals 1-nerved, very short­clawed, lanceolate-elliptic, 3 of them smaller and often pink toward their base and with a yellow spot, the other 2 slightly or twice longer. June, July. Japan. L.B.C. 2:216. An excellent plant for cold damp locations as it is a native bog-grower. Var. grandiflora, Hort., is finer flowering than the type and has golden yellow fls. 1 in. across; more desirable than the type.

Section IX. Hircinus.

a. Petals obovate. ........................... 52. diversifolia

52. diversifolia, Wall. Early to 18 in. high, forming tufts of basal lvs.: sts. hirsute below and glandular (becoming glabrous with age) above, erect and foliose; lvs. polymorphous, the lower petiolated, ovate, obtuse or cordate-based, subacute, undulate, sparingly hirsute or glabrous; calyx mostly sessile, very entire, oblong-glandular; teeth broadly acuminate; infl. corymbose-racemose or paniculate, rarely few-fid.: fls. yellow, obscurely spotted, ½–⅔ in. across; sepals ovate, spreading, at length reflexed; petals obovate, short-clawed, 3-nerved with 4 glands at their base, exceeding the sepals. July–Sept. N. temperate, subarctic and alpine regions. B.B. 2:171; (ed. 2) 2:216. An excellent plant for cold damp locations as it is a native bog-grower. Var. grandiflora, Hort., is finer flowering than the type and has golden yellow fls. 1 in. across; more desirable than the type.

Section X. Trachyphyllum (Leptasea, Chondrosea).

a. Stolons or runners absent: the young shoots leafy and also floriferous.

b. Sts. with a basal rosette of lvs., but few-lvd. above. ........................... 55. chrysantha

c. Axils of the cauline lvs. with buds.

d. Peduncles glabrous: calyx-lobes ovate-triangular. ........................... 60. aspera

dd. Peduncles glandular: calyx-lobes lanceolate.

e. Lvs. linear-lanceolate, gray-green; margin ciliate or spinulose. ........................... 57. bronchialis

f. Lvs. lanceolate; under surface lineolate; margin ciliate, with white hairs. ........................... 58. gemmipara

g. Calyx of calyx lvs. without buds, the lowest, however, have more or less elongated leafy shoots.

h. Pedals oblong, 1-nerved: the cauline lvs. obovate. ........................... 59. aizoides

ii. Pedals oblong, 1-nerved: the cauline lvs. lanceolate. ........................... 60. cinerascens

AA. Stolons or runners present: the young shoots glabrous.

b. Fls. long-pedicelled. ........................... 61. Brunoniana

bb. Fls. almost sessile. ........................... 62. flagellaris

55. chrysantha, Gray (Leptasea chrysantha, Small). Dwarf empetaceous plant, 1–2 in. high, with creeping

3559. Saxifraga sarmentosa (×2). No. 50.
SAXIFRAGA

Saxifraga

SAXIFRAGA

shoots: lvs. mostly basal, in a rosette (a few cauline), imbricated, oblong-ovate, glabrous and fleshy: infl. 1-3-fld., terminal on filiform, glandular-pubescent peduncles: fls. large, yellow; calyx-lobes ovate or oblong-ovate, obtuse; petals oval to broadly obovate, much longer than the calyx-lobes. Mountains of Colo. and New Mex.—Has been offered by dealers in native plants.

56. *aspétra*, DC. More or less cespitose, 4-6 in. high, with prostrate, mostly dark purple caulicles: fls.-stems erect or ascending, remotely lvd.: lvs. pale green, shiny, lanceolate-linear, stipitate and ciliate, those of the caulicles bearing buds in the axis: infl. 1-fld., or few-fld., panicled, on glabrous peduncles: petals oblong, obtuse, abruptly attenuate toward the base: calyx-lobes oblong-triangular, obtuse, spreading: petals orange, 1-nerved, 1½ times as long as the calyx-lobes. June–Aug. Eu., Asia, arctic Amer., south to Gulf of St. Lawrence, mountains of N. Y., W. N. Y., and the Lake Superior region. B.B. 2: 171; (ed. 2) 2: 217. (The Rocky Mt. form has been segregated as *S. Van-Bruntia*, Small.)—Usually found in stony places where there is trickling water. Very easy to grow and may be divided almost any time. Var. *aurantia*, Hort., is a form with the fls. described as of “old-gold pusing off to a kind of coppery red.” Var. *atrubens*, Engl. (S. atrubens, Bt.). Lvs. stiffly spinulose-ciliolate: fls. rich crimson (Emmer says orange-red or cinnamon-colored). Cent. Eu.

57. *brounichias*, Linn. Dwarf, cespitose, 4–8 in. high: sts. ascending, densely foliace at the base; fls.-stems few-fld.: lvs. stiffish, almost leathery, gray-green, shiny, linear-lanceolate, margin ciliate or spinulose: infl. few or many-fld., paniculate, borne on erect-spreading glandulose pedicels: fls. yellowish white with orange-red dots; calyx-lobes oblong-lanceolate, rather obtuse, glabrous; petals oblong, 3-nerved, twice as long as the calyx-lobes. May, Asia and Alaska.—The material from the Cascade Mts. of Wash. to Alberta and southward along the Rocky Mts. to New Mex., which has been passed as *S. bronchialis*, has been separated under the name of *S. austromontana*, Wiegand (*S. bronchialis*, Pursh, not Linn. *Leptdsea austromontana*, Small). It differs from *S. bronchialis* in its more subulate, darker green lvs., more slender often purple sts., calyx-lobes, pedicels, smaller white petals with purple dots above and not clawed at the base. *S. austromontana* is probably not in cult.

58. *gemmipara*, Franch. Sts. erect from a long rhizome, 4–5 in. high, branched, the branches rising from pockets, pilose below; lvs. with buds; lanceolate, long-mucronate, entire, pale, shiny and lineolate on the under surface, both surfaces and the margin striosed with white hairs: infl. paniculate-corymbous, borne on a densely glandular fl.-st. which is naked above; pedicels bracteate at their base: fls. yellow to white; sepals lanceolate, glabrous or glandulose, scarcely or not spreading; petals oblong, obtuse, abruptly attenuate to a long claw, twice as long as the sepals. July–Sept. China.

59. *aizoides*, Linn. (Leptdsea aizoides, Haw.). Loosely cespitose, 2–6 in. high, with decumbent or ascending, foliace, glabrous or sparsely very short pilose caulicles which are branched from the base: lvs. green or reddish, the lower linear or linear-oblong, mucronate, flat below: lvs. above convex, glabrous or more or less glandulose: calyx-lobes oblong-ciliolate; the upper rather remote, smaller, oblong, rather obtuse, rarely ovate: infl. 1-fld., often many-fld., racemose, borne near the top of the st. on axillary peduncles: fls. yellow, more or less spotted with orange;

calyx-lobes oblong-triangular, obtuse, spreading; petals oblong, 1-nerved, 1½ times as long as the calyx-lobes. June–Aug. Eu., Asia, arctic Amer., south to Gulf of St. Lawrence, mountains of N. Y., W. N. Y., and the Lake Superior region. B.B. 2: 171; (ed. 2) 2: 217. (The Rocky Mt. form has been segregated as *S. Van-Bruntia*, Small.)—Usually found in stony places where there is trickling water. Very easy to grow and may be divided almost any time. Var. *aurantia*, Hort., is a form with the fls. described as of “old-gold pusing off to a kind of coppery red.” Var. *atrubens*, Engl. (S. atrubens, Bt.). Lvs. stiffly spinulose-ciliolate: fls. rich crimson (Emmer says orange-red or cinnamon-colored). Cent. Eu.

60. *cinerascens*, Engl. & Irmscher. Densely cespitose, 2–4 in. high, the caulicles prostrate, rosetulate: lvs. of the caulicles rather stiff, linear-lanceolate, margin carinauligous and lax-ciliolate or ciliolate-spinulose, apex tapering to a persistent awn, under surface shining, whitish; the cauline lvs. lanceolate, rather stiff, aristate, margin densely short, black glandular-pilose: infl. 1-fld., or 3-fld., which are often reddish their whole length and black glandular-pilose as are the pedicels: fls. golden yellow; sepals ovate, subacute, not reflexed; petals obvate, narrowed to a stipitate base, 3-nerved, the lateral nerves bifid. Sept. China.

61. *Brunoniana*, Wal. Fig. 3560. Lax, cespitose, 2–8 in. high, very glabrous, stoloniferous; the stolons wiry, filiform and reddish: sts. erect, slender: lvs. stiffish, light green, becoming gray in age, linear-lanceolate, cartilaginous-mucronate, setose-ciliolate; the lowest imbricate, erect and appressed; the upper few and smaller: infl. 1–4-fld. corymbs; the peduncles and pedicels glandulose; the latter 3 or 4 times longer than the fls.: fls. light yellow; calyx-lobes ovate, obtuse; petals oblong, obtuse, 3-nerved, 3–4 times longer than the calyx-lobes. July, Aug. Temperate Himalaya. B.M. 8189.— *Spatularia Brunoniana*, Small, is not this species but a variety of *S. lecanumifolia*. *S. Brunoniana* freely spreads by means of its runners and likes a moist spot. Not commonly in cult. in Amer. Var. *grandiflora*, Hort., is offered in the trade. Var. *mailed*, Eng. & Irmscher (S. majuscula, Hort.). Larger than the type: sts. 3–8 in. high: infl. composite, 3–9-fld.; the branches 1½–4 in. long. Sept., Oct. China.

62. *flagellaris*, Willd. (*Leptdsea flagellaris*, Small). Sts. simple, erect, 1–8 in. high, leafy, densely glandular-pilose: the plant stoloniferous, the stolons bearing a minute bud and roots at their apex: lvs. more or less minute, glandular-pilose, margin glandular-pilose or setose-ciliolate; the basal and lower lvs. close together, ovate-oblong; the upper lanceolate: infl. corymbose 1–10-fld.; the pedicels very short: fls. large, golden yellow; calyx divided beyond the middle or even to the base, the lobes oblong, obtuse, densely glandular-hirsute;
petioles 3-4 times longer than the blade and channelled above: infl. paniculate, the branches 3-6-fl., pedicels slender; fls. white; calyx-lobes oblong, obtuse; petals ovate-oblong, twice as long as the calyx-lobes, with a yellow spot on their base and occasionally with several small purple-red dots. May, June. Pyrenees, Ireland and said to occur in Newfoundland.—A species in common cult. abroad and very variable, by some considered as a variety of S. umbrosa. Var. crenata, Hort., (S. umbrosa var. crenata, Ser.) Lvs. crenate or crinate-dentate: fls. pink, unsuppcted. Pyrenees. Var. crenulfult, Hort., is said to resemble a refined form of S. umbrosa. Var. dentata, Eng!. (S. dentata, Link. S. hiirtuta, Linn. S. umbrosa var. hirtula, Hort. S. umbrosa var. deniata, Hort.). Lvs. rather glabrous or hirsute, orbicular, acute-serrate: fls. white with 1 yellow dot or even several purple dots on each petal (by some said to be unsuppcted).

Section XI. ROBERTSSONIA.

A. Lvs. of the rosette ovate or obovate-oblong, attenuate to a flat petiole.
B. Blades of lvs. very glabrous: panicle-branched 1-3-fl.

63. cuneifolia, Linn., sometimes misspelled cuncifolia. Laxly cepstose, 4-6 in. high, with slender sublignous caulicles: sts. slender, erect, short-glandular and naked: lvs. very glabrous, rather thick, the upper surface dark green and shiny, the lower paler and dull or violet, ovate or subrotund, very obtuse, cuneately attenuate to a long flat ciliate petiole, margin slightly cartilaginously repand-crenate: infl. a loose panicle with 1-3-fl. branches: fls. white; calyx-lobes oblong-triangular, very obtuse; petals oblong, 3-nerved with a yellow spot at the base (occasionally also spotted with purplish red dots). June, July. Mountains of Eu.—There is a form of this species which is grown as S. Buctklandi, Hort., which only differs in having 2 or 3 yellow spots on each petal.

Var. subintegra, Ser. (S. apennina, Bert. S. cuneifolia var. appennina, Koch. S. capillipes, Reichb.). Caulicles long, scantily lvd., forming a rosette at their tip: lvs. smaller, retuse, few-dentate or entire, petiole equaling the blade: sts. few-fl., simple panicle. Switzerland, Tyrol, Apennines, and Maritime Alps.

64. umbrosa, Linn. LONDON PRIDE. ST. PATRICK'S CABBAGE. Loosely cepstose, 6-12 in. high, with sublignous caulicles: sts. erect, naked: lvs. forming a dense rosette 6-12 in. across, rather thick, leathery, grey-green, dull shiny, lower surface tinged reddish or violet, oblong or obovate-oblong, sparsely hirsute, very obtuse, attenuate to the ciliate (rarely glabrous) petiole, margin cartilaginously repand-crenate: infl. a loose panicle with 3-6-fl., shortly glandulouss-hirsute branches: fls. white, varying pink; calyx-lobes oblong, obtuse; petals oblong-ovate, 3-nerved, with several red dots at their base and a yellow spot in the middle. June, July. Eu.—Very neat and attractive plant, frequent in European gardens, but rarely seen here. Var. acanthifolia, Hort., is offered in the trade. Var. bellidifolia, Hort., is offered in the trade. Var. cassinifolia, Hort., is offered in the trade. Var. crassiphylla, Hort., is offered in the trade. Var. erosa, Hort., is offered in the trade. Var. foliis-variegatis, Hort., a form with the lvs. variegated. Var. gracilis, Hort., is offered in the trade. Var. marmorata, Hort., is offered in the trade. Var. primuloides, Hort. (S. primuloides, Hort.), is described as follows: Wl. erect, 4-6 ft. high, but carries entire or partial shade. It forms masses of dark green rosettes of primula-like lvs., whence rise a host of slender sts. about 6 in. high, bearing little lfs. of a kind of rose-pink (lfs. also stated to be bright carmine-rose). Var. rotondifolia, Hort., is offered in the trade. Var. serratifolia, Don. (S. serrata, Sternb. S. serratifolia, Mackay.), is a form with erect, oblong lvs. whose margins are acutely serrate. Ireland. There is a form of this variety known as S. umbrosa serrata minor. Var. variegata, Hort., is a form with the lvs. variegated with white.

65. Géum, Linn. (Mèrinthes Géum, Small). Six to 12 in. high, with sublignous caulicles: sts. nearly naked, erect, glandular-hirsute: lvs. variable, reniform-cordate, margins cartilaginous, crenate, the crenations equal except toward the very top where they are shorter, both surfaces but especially the lower hirsute, petals ob-
12-14 in. diam. and very profusely fl.-sts. panicules which attain a length of 2 ft. and a diam. of 16 in. The fls. are white. G.C. III. 53:390 (as S. longifolia). Gn. 77, p. 298; 79, p. 30.

67. lingulata, Bell. Fig. 3561. One to 2 ft. high with ascending branched caudicles which are covered with appressed vestiges of lvs. and form a cespitose clump; sts. erect or ascending, usually glabrous or sometimes sparsely glandular-pilose, leafy; basal lvs. numerous and rosulate, subulate above, usually linear-spatulate and rather acute, somewhat ciliate, margin erose-crenulate and crustate with lime; cauline lvs. shorter, the margin cartilaginous and less crustate; infl. a thyrsoid panicle from the middle of the scape or above, the branches slender, corymbose-paniculate at their tip, 3-5-fl.d., very often secund: fls. small, white; calyx glabrous, the lobes ovate or oblong, very obtuse; petals obovate or obovate-oblong, attenuate toward the base, 3-nerved, 2-14 in. diam. and very profusely fl.-sts.: fls. white, 1/4-3/4 in. diam.; calyx red-brown, the lobes small, ovate, obtuse; petals obovate, apex rounded. June, July. M. Time Alps. Eu. B.M. 6988. G.C. III. 44:245; 51:174. Gn. 74, p. 326. Var. major, Hort., has much larger rosettes of lvs. and taller sprays of fls. It is suggested that it may be of hybrid origin. Var. minor, Hort. (S. Pilsgni, Correv.), has minute rosettes of silvery lvs. and much shorter sprays of fls. which are white.—Apparently some of the material grown as S. valdenas is referable to this.

70. crustata, Vest (S. inerudita, Vest). About 1-3 in. high with ascending branched caudicles which are covered with appressed vestiges of lvs. and form cespitose clumps up to 4 or 5 in. diam.: sts. ascending, densely glandular-pilose; basal lvs. light gray-green, the lower third pink, subulate, linear, obtuse, minutely crenulate with the crenatures very close together, crustate with lime, ciliate toward the base. Var. rheticus, Engl.; few, linear-lanceolate, serrate, glandular at base; infl. a scape, racemose from the middle or above, the branches 1-fl.-d. or paniculate 3-6-fl.; fls. yellowish white sometimes purple-dotted toward the center; calyx glabrous, the branches oblong-triangular with membranaceous margins; petals obovate, base scarcely attenuate, almost 3 times as long as the calyx-lobes. June. Tyrol.—Easy to grow and adapted to a shady location; scarcely known in Amer.

71. Hösti, Tausch (S. elatior, Mert. & Koch. S. Aizoon var. Hösti, Hort.). Cespitose, 6-18 in. high: sts. erect, rather stout and glandular-pilose; basal lvs. numerous, rosulate, rather erect, lingulate with an obverse apex and ciliate base, margin crenulate, the crenatures truncate; cauline lvs. longer and broader spatulate, more or less at the base but not so at the apex; margin narrowly crustate. Marine Alps. G. C. II. 15:109. Gn. 64, p. 61; 73, p. 55. Minor forms of this variety are cult., as S. lanatiscana eréctâ, having pure white fls., and S. lanatiscana supérba, having arching plumes of creamy white fls. larger than those of the variety proper.

65. catalunicâ, Boiss. & Reut. Densely cespitose, 1-2 ft. high: lvs. of the rosette, which grows to be 3 in. diam., erect-spreading, obovate-ligulate, rather obtuse, margin subentire and white-crustate, glabrous, subcartilaginous, base obtuse; the cauline lvs. few, obovate-oblong: infl. a slender-branched cymose panicle borne on an erect few-lvd. fl.-st. with erect bracteolate slender glandular-viscid pedicels, which are longer than the fls.: fls. white; sepals oblong, obtuse, glabrous, longer than the glabrous tube of the calyx; petals glabrous, glaucous, 3 times as long as the sepals. May, June. Spain. Gn. W. 25:125.—By some considered only a variety of S. lingulata.

69. cochleâris, Reichb. (S. lingulâta var. cochleâris, Engl.). Six to 9 in. high, densely cespitose, with short much-branched caudicles covered below with withered lvs.: lvs. densely rosulate, spreading, 1/4-1 in. long, linear at their base, toward the top spreading into a rounded or spatulate blade, glaucous, coriaceous, margin cartilaginous and crustate with lime; the cauline lvs. small, linear, acute, red-brown: infl. panicleate, erect and oenon, either thyrsoid or subcorymbose, borne on a strong grower and said to produce offsets very freely in this way spread rapidly. Var. rhötica, Engl., equals the type. G. C. III. 54:135. Var. Hostii, Hort. (S. Hostii, Hort.). Cespitose, 6-18 in. high: sts. erect, rather stout and glandular-pilose: basal lvs. numerous, rosulate, rather erect, lingulate with an obverse apex and ciliate base, margin crenulate, the crenatures truncate; cauline lvs. longer and broader spatulate, more or less at the base but not so at the apex; margin narrowly crustate. Maritime Alps. Eu. B.M. 6688. G.C. III. 44:245; 51:174. Gn. 74, p. 326. Var. minor, Hort., has minute rosettes of silvery lvs. and much shorter sprays of fls. which are white.—Apparently some of the material grown as S. valdenas is referable to this.

73. Altissima, Kerner (S. Hösti var. altissima, Hort.). Fig. 3558. Cespitose, 6-2 ft. high: sts. erect, rather stout, glandular-hirsute: lvs. thick, the basal spreading, broad, tongue-shaped, rather acute, base ciliate, margin serrate, serratures cartilaginous; cauline lvs. oblong-linear or oblong, obtuse, glandular-pilose: infl. a scape, paniculate above the branches, elongated, naked and densely glandular-pilose; the pedicels densely short-glandular: fls. white, often with numerous purple dots toward the center; calyx lobes ovate, obtuse, glandular-triangular; petals oblong or oblong-oblong, double the length of the calyx-lobes. May—Aug. Mountains of Cent. Eu.—A strong grower and said to produce offsets very freely and in this way spread rapidly, the branches about 10-fl.-d. and densely glandular-pilose; the pedicels densely short-glandular: fls. white, their base greenish and purple-ciliate toward the center; calyx lobes ovate, obtuse, cartilaginous; petals elliptic, 3-nerved, twice as long as the calyx-lobes. Tyrol.—Very closely allied to S. Hostii, possibly not specifically distinct. Little known in Amer. outside fanciers' collections.

72. Altitissa, Kerner (S. Hösti var. altissima, Hort.). Fig. 3558. Cespitose, 6-2 ft. high: sts. erect, rather stout, glandular-hirsute: lvs. thick, the basal spreading, broad, tongue-shaped, rather acute, base ciliate, margin serrate, serratures cartilaginous; cauline lvs. oblong-linear or oblong, obtuse, glandular-pilose: infl. a scape, paniculate above the branches, elongated, naked and densely glandular-pilose; the pedicels densely short-glandular: fls. white, their base greenish and purple-ciliate toward the center; calyx lobes ovate, obtuse, cartilaginous; petals elliptic, 3-nerved, twice as long as the calyx-lobes. Tyrol.—Very closely allied to S. Hostii, possibly not specifically distinct. Little known in Amer. outside fanciers' collections.
almost twice as long as the calyx-lobes: fr. globose. June, July. Alpine and rock plant of Eu. and As. Amer. from Greenland and Lab. to Sak., locally south to Nova Scotia, New Bruns., mountains of N. Vt., and Lake Superior. J. H. III. 69: 135.—A very variable alpine plant, much tufted and forming small dense rosettes. S. Pört. Stem from ground, golden yellow and is apparently only a minor variation of S. Aizoon. Var. ambigua, Hort., is offered in the trade. Var. atropurpurea, Hort., is said to have slender branching sts. and rose-purple fls. Var. baldensis, Hort., also spelled baldénsis (S. baldénsis, Hort.), is a form with close rosettes of medium size and rather flat white fls. with larger red spots than usual (fls. reported as sometimes pale pink). Balkan Mts. Var. balénsis, L. farrer, with ash-gray lvs., which are short, thick and markedly dentate; their apex rounded: the young shoots glossy, blood-crimson: the fls. white. Var. brevifolia, Hort., with white fls. is offered in the trade. Var. bulgarica, Hort., has rosy spotted fls. Var. callitrichoides (S. callitrichoides, Hort.), with white fls. must not be confused with S. callitrichoides, Greene (Microtheces callitrichoides, Small), a species of Section Boraphila, closely related to S. virginiensis which is probably not in cult. Var. Chuchillii, Hort., with pointed gray lvs. in stiff rosettes. Var. cultrata, Hort., is offered in the trade. Var. dubia, Hort., is offered. Var. erecta, Hort., is offered in the trade. Var. flavescens, Hort., is a free-growing decorative form with clear lemon-yellow fls. produced in good spikes. Not to be confused with S. flavescens, Hort. (S. medica) which is apparently source in cult. Var. intacta, Engl. (S. intacta, Willd.), has beautiful white, unsplotted fls. S. intacta major is the cultural name of a larger form of the species and produces numerous offsets. The above description is taken from Schott's original. Whether the plant offered is the same is undetermined. Probably a variation of S. Aizoon.

75. cartilaginea, Wild. (S. Kolenatiâna, Regel). Six to 9 in. high: st. sparingly glandulose, few-br. lvs.: fls. roseate, oblong or obovate, acute or acuminate; petals oblongelliptic, acute, the tube longer than the calyx-lobes. Asiatic, from Formosa to Ryukyus. G.C. III. 95. —A strong-growing form with prominently toothed lvs. Var. major, Koch, has oblong-linear lvs. which are not much broader at the base, the panicle composite, pyramidal, glandular-pilose all over, the branches paniculate from their middle, 5–15-fl.: fls. white, occasionally tinged rose; calyx-lobes longer than the glandular tube, oblong-acute; petals obovate-elliptic, 3–5-nerved, midnerve mostly obtuse, 2–3 times longer than the calyx-lobes. May–July. Caucasus region and Asia Minor.—S. Kolenatiâna has been kept distinct by some but seems to differ only in the slightly more acuminate fls. of the lvs. In gardens it is more common under this name. A somewhat larger form is known as S. Kolenatiâna major, Hort.

76. Cotyledon, Linn. Tufted, 6–24 in. high: st. erect: lvs. thick and fleshy, basal linguliform or obovate-linguliform, short-cylindrical; the bases softly fimbriate, the apex acute or acuminate, serrate, serratures cartilaginous, at the apex androstely acuminate; caulis lvs. linguliform-lanceolate, the lower part glandular-lanceolate, the upper serrulate; bracts linear, acute and glandular: infl. a scape, paniculate from the middle, 5–15-fl.: fls. white, occasional tinged rose; calyx-lobes longer than the glandular tube, oblong-acute; petals obovate-elliptic, 3–5-nerved, midnerve mostly obtuse, 2–3 times longer than the calyx-lobes. May–July. Mountains of Eu. G. 11: 209; 34: 781; 35: 541. G.W. 12, p. 471.—Easy to prop. as it makes a large number of side shoots which root quickly when potted. Var. pendula, Maxim. (S. pendula, Hort.), has small silver-marbled lvs. and white fls. Var. paradóxa, Hort., is a form with long bluish lvs., their margins with silvery serratures: fr. white. Eng. G. 74, p. 489. See S. paradóxa in suppl. list. var. pectinata, Hort. (S. pectinata, Hort., Nym. & Kotsch.), has narrow lvs. with blunt teeth and conspicuous silvery margins in the narrow rosettes: the fls. are small, of a nice white and spotted with red.

Var. récta, Ser., in part (S. récta, Lapeyr., in part. S. Aizoon) forma grêalis, Engl. S. carinallata, Schott, Nym. & Kotsch), has lvs. which are spatulate-slate shortly dilated toward the apex, narrowly and also deeply serrate: the sts. laxly paniculate from the middle and above; the branches 1–3-fl.: fls. white. Var. rôsea, Hort., is similar to the type, but has bright pink fls. Var. rosulâris, Hort. (S. rosulâris, Schlech.), has finely incurved rosettes and large sprays of white fls. Var. Stabiana, Hort. (S. Stabiana, Ten.), has large rosettes and sprays of creamy white fls. Not very distinct from the type. Var. Sturmiana, Schott, Nym. & Kotschis, is a good-sized form with flattish rosettes, probably referable to the type-form.

77. mutàta, Linn. Six to 12 in. high: rhizome thick, horizontal or oblique: st. ascending, foliose: basal lvs. almost twice as long as the calyx-lobes: fr. globose. June, July. Alpine and rock plant of Eu. and As. Amer. from Greenland and Lab. to Sak., locally south to Nova Scotia, New Bruns., mountains of N. Vt., and Lake Superior. J. H. III. 69: 135.—A very variable alpine plant, much tufted and forming small dense rosettes. S. Pört. Stem from ground, golden yellow and is almost twice as long as the calyx-lobes: fr. globose. June, July. Alpine and rock plant of Eu. and As. Amer. from Greenland and Lab. to Sak., locally south to Nova Scotia, New Bruns., mountains of N. Vt., and Lake Superior. J. H. III. 69: 135.—A very variable alpine plant, much tufted and forming small dense rosettes. S. Pört. Stem from ground, golden yellow and is apparently only a minor variation of S. Aizoon. Var. ambigua, Hort., is offered in the trade. Var. atropurpurea, Hort., is said to have slender branching sts. and rose-purple fls. Var. baldensis, Hort., also spelled baldénsis (S. baldénsis, Hort.), is a form with close rosettes of medium size and rather flat white fls. with larger red spots than usual (fls. reported as sometimes pale pink). Balkan Mts. Var. balénsis, L. farrer, with ash-gray lvs., which are short, thick and markedly dentate; their apex rounded: the young shoots glossy, blood-crimson: the fls. white. Var. brevifolia, Hort., with white fls. is offered in the trade. Var. bulgarica, Hort., has rosy spotted fls. Var. callitrichoides (S. callitrichoides, Hort.), with white fls. must not be confused with S. callitrichoides, Greene (Microtheces callitrichoides, Small), a species of Section Boraphila, closely related to S. virginiensis which is probably not in cult. Var. Chuchillii, Hort., with pointed gray lvs. in stiff rosettes. Var. cultrata, Hort., is offered in the trade. Var. dubia, Hort., is offered. Var. erecta, Hort., is offered in the trade. Var. flavescens, Hort., is a free-growing decorative form with clear lemon-yellow fls. produced in good spikes. Not to be confused with S. flavescens, Hort. (S. medica) which is apparently source in cult. Var. intacta, Engl. (S. intacta, Willd.), has beautiful white, unsplotted fls. S. intacta major is the cultural name of a larger form of the species and produces numerous offsets. The above description is taken from Schott's original. Whether the plant offered is the same is undetermined. Probably a variation of S. Aizoon.

75. cartilaginea, Wild. (S. Kolenatiâna, Regel). Six to 9 in. high: st. sparingly glandulose, few-br. lvs.: fls. roseate, oblong or obovate, acute or acuminate; petals oblong-elliptic, not clawed, obtuse, apex acute or acuminate; petals oblong-elliptic, not clawed, obtuse, apex rounded. Serbia.—Plants under this name are offered in English trade-lists, but the species is not included in any of the recent treatments of Saxifraga. The above description is taken from Schott's original. Whether the plant offered is the same is undetermined. Probably a variation of S. Aizoon.

76. Cotyledon, Linn. Tufted, 6–24 in. high: st. erect: lvs. thick and fleshy, basal linguliform or obovate-linguliform, short-cylindrical; the bases softly fimbriate, the apex acute or acuminate, serrate, serratures cartilaginous, at the apex androstely acuminate; caulis lvs. linguliform-lanceolate, the lower part glandular-lanceolate, the upper serrulate; bracts linear, acute and glandular: infl. a scape, paniculate from the middle, 5–15-fl.: fls. white, occasional tinged rose; calyx-lobes longer than the glandular tube, oblong-acute; petals obovate-elliptic, 3–5-nerved, midnerve mostly obtuse, 2–3 times longer than the calyx-lobes. May–July. Caucasus region and Asia Minor.—S. Kolenatiâna has been kept distinct by some but seems to differ only in the slightly more acuminate fls. of the lvs. In gardens it is more common under this name. A somewhat larger form is known as S. Kolenatiâna major, Hort.

77. mutàta, Linn. Six to 12 in. high: rhizome thick, horizontal or oblique: st. ascending, foliose: basal lvs.
lingulate, rosulate; margin cartilaginous, densely fimbriate below, entire or obliquely serrulate above with many little indistinct pits; cauline lvs. lingulate-spatulate, very obtuse: incl. racemously paniculate from the base or middle of the scape, this and the peduncles glandular-hirsute: fls. yellow, red-orange or copper-colored; calyx-lobes oblong-triangular, sparsely glandular-pilose or glabrous; petals linear-lanceolate, acute, 3-nerved, narrower than and twice the length of the calyx-lobes. July, Aug. Mountains of Cent. Eu. B.M. 351.—Suitable for rather heavy shade. The plant dies after flowering. Said to be biennial.

Section XIII. KARSCHIA.

1. Caudicle lvs. broader or as broad above the middle as below it.
   a. Petals as long as or slightly longer than the calyx-lobes: fls. reddish or purplish, keeled, blotched. (The following four species are very closely related.)
   b. Infl. spreading, branched.
      c. Lower lvs. spatulate-lingulate, the tip somewhat recurved .. 76. media
      d. Lower lvs. oblongo-lanceolate, the tip spreading .. 79. Stribrnyi
      e. Spatulate or nearly so.
         f. Rosette lvs. spatulate-lingulate, their apex rounded mucronate.80. Grisebachii
         g. Rosette lvs. linear-lanceolate, their apex acute or acutish .. 81. Friderici- [Augusti

78. media, Gouan (S. calycijlora, Lapeyr.). Cespitose, 2-3 in. high, with short densely foliate caulicles: fls. erect, leafy, densely glandular-pilose: basal lvs. imbricately, stiff, gray-green, reddish toward their base, the rosettes flattened-depressed, spatulate-lingulate, apex acute or obtuse, margin narrowly cartilaginous, ciliate below, 7-11 pits near the margin when old; cauline lvs. spatulate, cartilaginous, and densely glandular-hirsute on both surfaces except toward the tip which is mucronate and glabrous: incl. cymose-paniculate or racemose; peduncles and calyx purplish and densely glandular: fls. flesh-colored or purplish, at length dark blue; calyx-lobes ovate; petals erect, obvoate, about 3-5-nerved, scarcely longer than the calyx-lobes. June, July, Pyrenees. Gn. 78, p. 108.

79. Stribrnyi, Velen., also spelled Stribrnyi, Stribrnyi, and Stribrnyi (S. porophylia var. Stribrnyi, Velen.). Cespitose, 4-5 in. high, with short, densely foliate caulicles: fls. sts. erect, branched, sparsely leafy, spreading, glandular-pilose: lower lvs. rosalate, spreading, sessile, spatulate-oblancoate, apex submucronate, fleshy, above intramarginally pitted, carinate below, margin narrowly cartilaginous toward the base, sparingly ciliate; cauline lvs. oblongo-spulate, subacute, sometimes reddish toward the apex, margin below glandular-ocillate, both surfaces sparsely glandular-pilose: infl. cymose, branches spreading or slightly recurved up to 1½ in. long; the pedicels up to ½ in. long, spreading, glandular-pilose: fls. nodding, carmine, ½ in. diam.; calyx campanulate, reddish purple and densely glandular-pilose outside, the lobes subequal, oblong-ovate, apex rounded, glandular-pilose outside; petals subrect, broad-spulate, apex obtusely dentate, glabrous, about the same length as the calyx-lobes. Feb.-April. Bulgaria. B.M. 8504. G.C. III. 46:193. Gn. 73, p. 212. G.L. 24:366.—A hardy species with grayish foliage and open infl.

80. Grisebachii, Degen & Doerfl. (S. media var. montenegrina, Hort.). Fig. 3593. Cespitose, 4-6 in. high, with short, densely foliate caulicles: fls. sts. erect, leafy, densely spreading, glandular-pilose: lower lvs. imbricately spreading, sessile, spatulate-lingulate, apex rounded-mucronate, above numerous intramarginal small pits, below carinate, margin cartilaginous, slightly ciliate toward the base; cauline lvs. spreading, oblongo-spulate, reddish, the tip contracted into a green mucron, both surfaces densely glanduloid-pilose except the mucron: incl. racemose or subepicate; pedicels much shorter than the bracts: fls. purple or crimson; calyx reddish purple, densely glandular-pilose, the lobes unequal, oblongo-elliptic, apex rounded; petals erect, elliptico-lanceolate, ciliate below. March. Albania and Macedonia. B.M. 8308. G. 33:513. G.C. III. 33:123. G.M. 46:119. Gn. 83, p. 180; 72, p. 215; 77, p. 120; 79, p. 31. G.W. 12, p. 470. J.H. III. 46:207.—Hardy in England.
SAXIFRAGA

Cespitose, 2–6 in. high with short densely foliate caulicles: sts. erect, densely glandular: basal lvs. forming a flattened rosette, linear-lanceolate, acute or acutish, glabrous, flat, entire, often ciliate at the base, remotely pitted near the margin; cauine lvs. spatulate, glandular: inf. a spike-like rosette, dark purple; pedicels all about equal and shorter than the bracts: fls. violet-purple; petals ovate, acutish, oblate, obtuse; petals cuneate-spatulate, scarcely longer than the calyx-lobes. April. Dalmatia, Serbia, Greece, and N. E. Asia Minor. G. 35:761.—This species has been treated as *S. media* var. *Frederici-Augusti*, Engl., but differs from that species in the narrower lvs. and more spicate raceme. It has also been referred to *S. porophylla*, Bertol., as a synonym: the latter is said to have lingular basal lvs. with obtuse apex, and flesh-colored petals. The distinctions between *S. Frederici-Augusti* and *S. porophylla* seem to be very unsatisfactory. Much of the material cultivated as *S. Frederici-Augusti* is really *S. apiculata*.

82. **aretoides**, Lapey. Cespitose, about 2 in. high, with woody, densely imbricate-foliose caulicles: sts. short and leafy, glandular-hirsute: lower lvs. sulcate, weakly keeled, leathery and stiff; pedicels grey-green but violet at the base of the under surface, linear-lingular, apex rather obtuse, margin narrowly cartilaginous, the lower portion ciliate and near the margin are 7–9 pits noticed with age; cauline lvs. linear-lingular, glandular-hirsute and cartilaginous except the apical portion: inf. terminal, 1–3-fl., rarely cymose, 3–5-fl.; the pedicels and calyx glandular: fls. golden yellow, calyx-lobes ovate and acutish; petals broad-obovate, 5–7-nerved, more than twice as long as the calyx-lobes. April–July. Mountains of Eu. B.M. 5549.—Should be planted on a shady edge where it will obtain plenty of moisture. Little known in Amer. *Var. primulina*, Hort., grows about 1½ in. high; the peduncles are paler green than the type; the fls. are true primrose-yellow and the petals are usually well rounded and fairly well imbricated.

83. **Ferdinandi-Coburgi**, Kell. & Sunderm. Cespitose, about 2 in. high, with columnar foliose branched caulicles: sts. with 9–12 lvs., glandular-hairy as is the calyx and tinted red-brown: lower lvs. somewhat glaucous, up to 3½in. long, long narrow toward the top, margin fine-hairy below, apex thickened and incurred-pointed; cauline lvs. 9–12 in number: inf. close heads of 4–5 (or more) rich yellow fls.; petals ¾in. long, ½in. wide, strongly narrowed toward the base. March. April. Macedonia.

84. **scardica**, Griseb. (*S. scardica*, J. Wood). Cespitose, 3–4 in. high, with woody, densely foliate caulicles: sts. ascending and glandular-pilose: basal lvs. leathery, stiff, light gray-green, pale violet toward the base, oblong acute, spreading, upper surface concave, lower convex-carinate, lower margin indistinctly serrulate or ciliate, upper cartilaginous, entire, when old they are 4–15 pits near the margin; cauline lvs. few, lanceolate, acute, glandular-hirsute except the apical portion, cartilaginous and glandular-hirsute: inf. corymbose. 3–11-fl.: fls. white, ivory-white, or pale rose-red; calyx-lobes ovate, acutish; petals obvate-cuneate, 6-nerved, more than twice the length of the calyx-lobes. June–July. G. 65, p. 593; 69, p. 231. S. E. Eu.—Readily distinguished from *S. Rocheliana* by its keeled and more pointed lvs. The species itself is hard to grow and consequently is very rare in cultivation: the plant is very dwarf, and has the true *S. scardica*, Griseb. G. 34:199. *Var. obtusa*, Spreng., differs from the plant in which subsacute to obtuse lower lvs. with fewer pits, fl.-sts. 1–3-fl. and green, and the calyx-lobes obtuse and less pubescent.

March. Macedonia. B.M. 8058 (as *S. scardica*). G. 32:520.

85. **Rocheliana**, Sternb., also incorrectly spelled *Rochellaniana*. Very densely cespitose-cushioned, forming mats 8–12 in. diam., 2–3 in. high, with more or less elongated, densely imbricated, foliose, often columnar caulicles: lower lvs. stiff, shiny light gray-green above, violet below, densely aggregated, horizontally spreading, spatulate, obtuse, very smooth, flat above, rather convex below the base, ciliate, 7–9 pits near the margin noticeable when old; cauine lvs. few, obvate-spatulate, cartilaginous and glandular-pilose except the apical portion: inf. corymbose-paniculate, 3–9-fl., borne on an erect purple-red glandular-pilose fl.-st.; pedicels erect, these and calyx glandulose and pale green: fls. white; calyx-lobes ovate, obtuse, erect; petals obvate, clawed-attenuate, 7-nerved, thicker than the calyx-lobes. April–July. E. and S. E. Eu.—Flowers freely. *Var. corophylla*, Engl. (*S. corophylla*, Griseb., also spelled *corophyllum*). The lower lvs. smaller, less horizontally spreading, oblong, obtuse, fewer pitted: fls. ivory-white. Bosnia and N. Albania.

86. **marginata**, Sternb. Cespitose, about 3 in. high, with caulicles which are subnaked below or short-columnar, woolly and leafy: lower lvs. obvate-cuneate, obtuse, the base ciliate, the upper margin cartilaginous; cauline lvs. cartilaginous and glandular-pilose except the apical portion: inf. corymbose, 5–7-fl., borne on erect fl.-sts., these as well as the pedicels and calyx being black-glandular-pilose: fls. white; calyx-lobes oval-oblong, obtuse; petals obvate, attenuate at the base, 5–7-nerved, 3 times the length of the calyx-lobes. March–June. S. Italy. B.M. 6702. Gn. 77, p. 206; 79, p. 294. G.L. 18:117.—Suitable for sunny ledges and rocky crevices, but requires lime and good drainage. Some of the material cult. under this name may be *S. Borgii*.

87. **Boryi**, Boiss. & Heldr. (*S. marginata*, Bor. & Ch., not Sternb.). Cespitose-cushioned, about 1½ in. high, with densely imbricate-foliose caulicles which are elongated and columnar: lower lvs. obvate-spatulate, obtuse, glabrous, erect-spreadingsubcoriaceous, flat above and subcoriaceous below, margins ciliate at base or others entire, remotely pitted near the margin; cauine lvs. few, minute and glandulose: inf. corymbose, 3–5-fl., borne on glandular-fl.-sts.: fls. ivory-white; petals elliptic-spatulate, twice the length of the calyx-lobes. April–July. S. E. Eu.—Thrives in a sunny location. Closely allied to *S. marginata* but differs in having smaller lvs., acute calyx-lobes and shorter and narrower petals.

88. **lilacina**, Duthie. Cespitose, ⅓–1 in. high, with numerous very densely foliate, columnar caulicles: lvs. rosetulate, oblong, obtuse, recurved and thickened toward the apex, sparsely ciliate at the base, margin cartilaginous and incurved, 3–5-pitted toward the apex; cauine lvs. 1–2, alternate, erect, linear-oblong or spatulate, obtuse, glandular, half-clasping at base: inf. 1-fl., borne on glandular-pubescent fl.-st., which are linear: fls. about ⅓in. diam., pale or grayish line with a purple center; calyx ⅓in. long, glandular-pubescent, the lobes ovate-oblong, obtuse; petals ⅓in. long, obvate-rotund, ciliate on the base, the margins undulate. March, April. W. Himalayas. G.C. III. 35:250. Gn. 65, p. 290.—The plant is very dwarf, and is grayish green in color, though the fl-tips are dark green.

89. **squarrosa**, Sieber. Very densely cespitose, about 3 in. high, with wooly, subcylindrical caulicles which are very densely imbricate-leafy: lvs. of the caulicles on stiff, shining green stems, linear-lanceolate, erect, sitting at the apex, linear-lanceolate, obtuse, submurculate, very narrowly cartilaginous, at the base fimbriate, the back convex and obtusely carinate above, marked with 7 pits, erustate with line when young.
SAXIFRAGA

95. sancta, Griseb. Cespitose, about 2 in. high, with short, woody, imbricate-foliate caudicles: stts. erect, glandular: lower lvs. densely congested, gray-green, light violet on the under side, erect, recurved from the middle, spathulate-linear, obtuse, dorsally convex and obtusely carinate, 9-pitted near the margin, crustate with lime, fimbriate from the base to the middle; cauline lvs. spathulate, 5-pitted, glandular, 3-in. long, finely corymbose, 6-10-fl., borne on dark purple fl.-stts.: fls. white; calyx-lobes ovate, very obtuse, glandular; petals obvate, 3-5-pitted, almost 3 times as long as the calyx-lobes. June-Aug. Mountains of Eu. L.B.C. 5:426. Var. major, Don, has the sts. more robust, taller, and strongly villous: the rosettes somewhat noticeable when old; cauline lvs. linear-lanceolate with mucronulate, near the margin very slightly cartilaginous at their tips; petals obovate, 3-5-nerved, lateral nerves bowed or straight, almost 3 times as long as the calyx-lobes. June-Aug. Mountains of Cent. Eu. G. 1:198; 36:289. Var. elegans, Hort., is mentioned in connection with S. G. 36:289. Var. minor, Hort., is said to have diminutive white fls. Var. minima, Hort., is offered in the trade as a form with fine yellow scapes bearing solitary fls. which are larger than that of var. major. April, May. G. 47:164. Var. N. 54:213. Var. grandiflora, Hort., grows about 1½ in. diam. with crimped white petals. Feb. Austrian Alps. G. 1:211: 11: 21:23. G. 63, p. 75. Var. minima, Hort., is said to have diminutive white fls. Var. minor, Hort., is mentioned in connection with S. Paulina as one of the parents of that hybrid. Var. rosea, Hort., equals S. irvingii. Var. speciosa, Hort., has bright red scapes bearing solitary fls. which are rich red and later than the type; the petals are pure white, broad and almost round. Var. tridentata, Jenkins (var. tridentata, Hort.), is more tufted than var. major; the fl.-stts. more richly scarlet and the fls. less notched at the margins, the petals reflexed, white. Jan., Feb. Dolomites. G. 37:379.

96. Juniperifolia, Adams (S. juniperifolia, Bieb.). Cespiteose, about 2 in. high, the caudicles densely leafy: lvs. rigid, prickly, dark green, the lower imbricate, spreading, lanceolate, acuminate, stiffly mucronate, the entire margin ciliate-denticate, cartilaginous, 3-5 minute pitted when old) near the cartilaginous margin; cauline lvs. large, lanceolate, acuminate: inf. corymbose-paniculate, 1-3-fl., borne on erect sts., these as well as the peduncles and calyx densely slender glandular-pilose: fls. white; calyx-lobes oblong-triangular; petals broadly obvate, strongly cuneate-attenuate toward the base, many-nerved, 3 or 4 times as long as the calyx-lobes. April. S. Tyrol and N. Italy.

93. Vandelii, Steinh. About 2 in. high, the caudicles very closely imbricate-follose and also strongly congested: lvs. of the caudicles leathery, very stiff, light green, erect, lanceolate, acute, stiffly mucronate, 3-cornered, 5-7-pitted (noticeable when old) near the cartilaginous margin, fimbriate at the base, when young crustate with lime; cauline lvs. linear-lanceolate, glandular-pilose except the long-mucronate apex: inf. corymbose-paniculate, 3-7-20-fl., borne at the top of erect fl.-stts. and calyx covered with spreading, glandular hairs: fls. white with reddish veins; calyx-lobes ovate-lanceolate, acute; petals erect, ovate, strongly cuneate-attenuate toward the base, many-nerved, 3-4 times as long as the calyx-lobes. April-Aug. Tyrol. G. C. III. 44:71; 57:238. G. N. W. 25:458. - Best suited to rock-fissures as it has deep woody tap-roots; also requires lime.

92. Tombeanensis, Boiss. (S. diapensioides var. tombenensis, Hort.). One to 2 in. high, with numerous very densely foliose, columnar, erect, or ascending caudicles: lvs. of the caudicles imbricate, erect, recurved at their tip, ovate-lanceolate, subulate, 3-cornered, apex mucronate, 3-7-pitted (noticeable when old) near the cartilaginous margin, very thinly subulate, 5 minute pitted are noticeable when old; cauline lvs. linear-lanceolate with the exception of the apical part, narrowly cartilaginous-marginate, acute, glandular-pilose: inf. cymose-racemose, 1-3-fl., borne on erect sts., these as well as the peduncles and calyx densely slender glandular-pilose: fls. white; calyx-lobes oblong-triangular; petals broadly obvate, strongly cuneate-attenuate toward the base, many-nerved, 3 or 4 times as long as the calyx-lobes. April. S. Tyrol and N. Italy.
Austrian Alps. Var. speciosa, Farrer, has a stouter plant, about 2 in. high; lvs. opposite, rather remote, thick, fleshy, green or purple, lower obovate-rotund, upper obovate-spulate, apex rather obtuse, rarely acute, 1-pitted, sparsely piliate and also ciliate, dorsally subcarinate: fls. frequently in pairs, dark violet, deep purplish crimson or blackish blue; calyx broad-ovate, glandular-hirsute, lobes obvue obtuse, ciliate; petals lanceolate, 3-nerved, one-half longer than the calyx-lobes and narrower than them. April–July. Mountains of Eu.–Found wild in rocky debris watered by the melting snows. Seldom seen in cult.

99. retusa, Gouan. Cauliaces prostrate, much branched, the branches densely cespitose, only about 1½ in. high; fls. erect, 1-4-fid., glandular-hirsute or obtuse; lvs. opposite, stiff, dark green, gray-tipped, the infi. racemose or capitate, few-fid.; fls. small, yellow; calyx lanceolate, 3-nerved, lvae. rather obtuse, about 2½ in. high; lvs. opposite, rather remote, thick, fleshy, green or purple, lower obovate-rotund, upper obovate-spulate, apex rather obtuse, rarely acute, 1-pitted, sparsely piliate and also ciliate, dorsally subcarinate: fls. frequently in pairs, dark violet, deep purplish crimson or blackish blue; calyx broad-ovate, glandular-hirsute, lobes obvue obtuse, ciliate; petals lanceolate, 3-nerved, one-half longer than the calyx-lobes and narrower than them. April–July. Mountains of Eu.–Found wild in rocky debris watered by the melting snows. Seldom seen in cult.
**SAXIFRAGA**

**AA. BETWEEN SPECIES OF SECTION II.**

103. Vetteriana, Beauverd (S. hederaea × S. Hueteriana). Lvs. intermediate between the two parents: fls. sulfur-yellow or whitish, the shape of those of *S. Hederaea* and twice as large as those of *S. Hederaea*; the petals more elongated than those of the last-mentioned species. June. Switzerland.—A spontaneous hybrid which appeared in the alpine garden of the Hortus Boissierianus.

**AAA. BETWEEN SPECIES OF SECTIONS XI AND XII.**

105. Engleri, Huter (*S. Aizoon × S. cuneifolia*). Lvs. elongate, obovate-oval, the narrowed lower portion ciliate, margin indistinctly crenate and obscurely pitted: fl.-sts. about 4 in. high, glandular-hairy: infl. lady's 2–3-fld.: fls. very small. A garden hybrid.—Quite probably all of the material grown as *S. Engleri* is not the same as another form, "with beautiful, long, silvery lvs. in handsome rosettes bearing upward of 20 handsome plumes of white fls. to a height, some of them, of more than 1 ft."

106. Dr. Ramsey, Hort. (*S. longifolia × S. cochlearis*). Resembling the latter parent more, but both the spoon-shaped lvs., which take on a brilliant red tint in the fall, and the infl. of white fls. are larger than in *S. cochlearis*. The fls. are sprinkled with pink dots. A garden hybrid.

107. Splendens, Hort. (*S. longifolia × S. Cotyledon*). A showy plant about 1½ ft. high, with silvery rosettes more like the former parent and the looser infl. of the latter: fls. white. A garden hybrid.

108. Burnatii, Sundern. (*S. cochlearis × S. Aizoon*). Rather intermediate in character, but more nearly approaching the former parent in its fl.-rosettes and the infl. of large white fls. A natural hybrid found in the Maritime Alps.

109. Grandfieldii, Hort. Said to have been raised from *S. Aizoon* var. regulars, by some said to be more probably raised from *S. Aizoon* var. lutea. The lvs. are ligulate, about 1 in. long and ⅜ in. broad, encrustated and form a basal rosette: fls. pure white, unsotted and loosely arranged in stalks 15 in. high in spreading sprays. A garden hybrid of English origin. G. 30:673.

110. Gaudentii, Bruegg. (*S. Aizoon × S. Cotyledon*). Also spelled Gaudaudiana. Rosettes small and silver-gray; the fls. white. Supposed to be a spontaneous hybrid. Eu.

111. Macababina, Hort. (*S. Cotyledon × S. Hostii*, S. Hostii var. Macababina, Hort.). The rosettes of lvs. are intermediate in character, but the lvs. are much smaller than in *S. Cotyledon* and the plant is seldom more than 1 ft. high, more or less branched above: fls. numerous, white, heavily speckled with pink to purple dots, the spots largest in June. A garden hybrid. G. III. 20:968. J. H. III. 57:61.

**AAA. BETWEEN SPECIES OF SECTION XIII.**

112. ambigua, DC. (*S. media × S. aretioides*). About 2½ ft. high with redish or purplish glandular fl.-sts.: fls. linear, nearly obtuse and a little reflexed: fls. purple, red or coppery, with the petals a little longer than the calyx-lobes. Pyrenees. G. III. 54:183.—One of three native hybrids resulting from this cross. *S. ambigua* comes nearest to *S. media*, with red sepals and yellow petals; while *S. Lapereoisai*, Don, resembles *S. aretioides* more closely; its sepals are green and its petals yellow.

113. susanitaca, Hort. (*S. media × S. aretioides*). More nearly resembling *S. aretioides* but the rosettes are larger: fls. yellow. Very similar to *S. luteo-purpurea*, Laperey.

114. internedia, Hort. (*S. Griesebachii × S. Stibniyi*, *S. Griesebachii* var. internedia, Hort.). Nearer in character in all respects to the former, but more nearly approaching the latter: fls. tinged red and bearing a head of 2–3 fl.-sts. 5 in. high, glandular-hairy and terminated by a cluster of erect pink-tinted fls.; the shade deeper toward the base, fls. cylindrical in form with the petals never reflexed. Feb., March. A garden hybrid.

115. Eudoxiana, Kellerer (*S. Friderici-Augusti × S. perophylla*). Nearer the former parent in habit, about 3 in. high, the rosettes of lvs. 1½ in. diam.; lvs. long, narrow, and pointed, with the chalk-pits very evident: infl. nodding fracture borne on a red stem. With red leafy bracts which are tipped with green: fls. red, on short pedicles. A garden hybrid.—Does well in a crevice or on a ledge, but requires lime.

116. Kellerei, Sundern. (*S. Friderici-Augusti × probably a form of S. Bursarinae*). Inclined in habit to the former, with well-developed rosettes which are nearly 2 in. diam., but the lvs. are longer and narrower and are acutely pointed and pitted with white dots: fl.-sts. 5 in. high, glandular-hairy and terminated by a cluster of erect pink-tinted fls.; the shade deeper toward the base, fls. cylindrical in form with the petals never reflexed. Feb., March. A garden hybrid.

117. Eudoxiana, Kellerer (*S. Friderici-Augusti × S. sanceta*). An intermediate in character, growing like *S. sanceta*. The lvs. have the silvery appearance of the former parent and the length and pointedness of the latter: sts. tinged red and bearing a head of 2–3 deep orange-yellow fls. which are rather small. A garden hybrid raised at Sofia, Bulgaria.

118. apiculata, Engl. (*S. Rocheliana × S. sancta*, S. Friderici-Augusti, Hort., not Bias* S. luteo-purpurea Hort.*, not Laperey). Cespitose, forming a large dark green mat, with subligneous, very densely lvd. caulicules. fl.-sts. 2–3½ in. high, glandular-pilosus: basal lvs. linear-oblong, acutely cuspitate, slightly carinate, thick, with pitted margins; cauline lvs. subspatulate: infl. 5–9-fld., the latter: fls. tinged red and bearing a head of 2–3 deep orange-yellow fls. which are rather small. A garden hybrid raised at Sofia, Bulgaria.
later opening than the type. Var. pallida, Hort., a form said to have pale yellow lvs., is offered in the trade.

119. pingens, Sündern. (S. Rocheliana × S. juniperifolia). It is similar to the latter parent, with rather smaller rosettes of dark green, sharp-pointed lvs., but with the more compact habit of S. Rocheliana. Fls. fl.-sts. are about 1-2 in. high, glandular, to 3 in. in diameter, bearing several deep golden yellow lvs. which are larger and paler than those of S. juniperifolia. A garden hybrid.

120. Börstlin, Kellerer (S. marginata × S. Ferndinandi-Coburgi). It more closely resembles the latter parent. About 2-3 in. high with large rosettes of silvery lvs.; bracteate, glandular sts. each bearing 4 or 5 large yellow lvs. which are paler than S. Ferndinandi-Coburgi. A garden hybrid raised in Sofia, Bulgaria.—S. Kyriillii is another product of the same cross.

121. Kyriillii, Kellerer (S. marginata × S. Ferndinandi-Coburgi). Another product of the same cross as S. Börstlin but more closely resembling the former parent. The lvs. show the chalk-pits more distinctly; the petals are white, more the substance of S. marginata. March. A garden hybrid. Gn.W. 22:291.

122. Sündermannii, Hort. (S. marginata × S. Burseriana). A smaller plant than S. Obstini (a result of the reciprocal cross) and resembling the latter parent more closely. About 2-3 in. high, habit tufted and free-growing, the rosettes larger than in S. Obstini, 3/4 in. diam.: lvs. long, broadest at the base and tapering to a point as in S. Burseriana, upper surface channelled or concave and covered with a chalky deposit on the margins and apex: inf. 1- or 2-fl., borne on glands, the inff. and stronger growth that of the former but the infl. and stronger growth that of the latter parent: rosettes usually 1/2 in. diam.; lvs. awl-shaped, 3-cornered with cartilaginous margins and decidedly glaucous: fls. 1 1/2-2 in. high, tinged red, pubescent and covered with lvs.; fl-buds suffused with pink, but lvs. white, more the substance of S. Rocheliana and born 3-4 to a rosette. Feb., March. A garden hybrid. G. C. III. 49:229.—It is very like an enlarged S. Burseriana in general appearance though the foliage is intermediate and the lvs. resemble S. marginata. Another distinct form resulting from this cross is S. Sündermannii.

124. kestoniensis, Hort. Supposed to be a seedling of S. Burseriana, though by some said to resemble S. scarica var. obtusa more closely. It has very white lvs. which come very early and are starry. The fl.-sts. are bright red and about 3 in. high. Jan.—March. A garden hybrid.

Var. albâ, Hort. (S. Burseriana var. Böydii, Hort.). A plant which very little resembles S. Böydii and by some is taken as a hybrid (S. Rocheliana var. coriophyllâ × S. Burseriana). Lvs. subulate, arranged in small rosettes which form dense cushions: lvs. white, borne on scapes about 2 in. high, bearing a cyme of 3-4 fls. G. 71, p. 175; 72, p. 177. It resembles S. Burseriana in many respects but differs in having larger lvs. and more fls. to a scape. Var. késtoni, Hort., is offered in the trade, possibly the same as S. kestoniensis.

126. Faldonside, Boyd (S. Burseriana × S. aeticala. S. Leucodendron). Lvs. silvery: st. suffused with pink: fls. lemon-yellow, borne in 2's or 3's. A plant of beautiful form with full overlapping petals which are crimped at the edges; the small orange-colored glandular disk in the center of the fl. adds to its attractiveness. Feb., March. A garden hybrid. Gn.W. 22:291. The same cross as S. Böydii but freer growing and with larger fls. of a better form.

127. Salomónii, Sündern. (S. Burseriana × S. Rocheliana. S. salomónica, Hort.). The habit is more that of the former but the infl. and stronger growth that of the latter parent: rosettes usually 3/4 in. diam.: lvs. awl-shaped, 3-cornered with cartilaginous margins and deciduous glaucous: fls. 1 1/2-2 in. high, tinged red, pubescent and covered with lvs.; fl-buds suffused with pink, but lvs. white, more the substance of S. Rocheliana and born 3-4 to a rosette. Feb., March. A garden hybrid. Gn.W. 22:291.

128. Obristii, Sündern. (S. Burseriana × S. marginala). A robust plant, about 3-4 in. high, with rosettes about 3/4 in. diam.: sts. glandular and tinged red-brown: lvs. strap-shaped, acute, with 4 or 5 chalk-pits on their margins: fls. 2-4 to a rosette, large, almost 1 in. across; ivory-white; petals broad, rounded and overlapped as in S. marginala. March. A garden hybrid. G. C. III. 49:229.—It is very like an enlarged S. Burseriana in general appearance though the foliage is intermediate and the lvs. resemble S. marginala. Another distinct form resulting from this cross is S. Sündermannii.

130. Irwingii, Hort. (S. Burseriana var. macrantha × S. Frederici-Augusti, S. Burseriana var. elegans, Hort. S. Burseriana var. roseea, Hort.). This partakes more of the character of the former, with similar tufts of foliage and single lvs. The latter parent shows in the color of the fls. which are bluish-pink, deeper at the center. The fl-sts. are about 1 in. so high and the plant is very free-blooming. March. A spontaneous hybrid at Kew. G. C. III. 57:158. G. 73, p. 193; 79, p. 152. G. M. 58:149.—S. kevenis is another product of the same cross but more allied to S. Frederici-Augusti.

131. kevenis, Hort. (S. Burseriana var. macrantha × S. Frederici-Augusti). About 2-3 in. high with the lvs. of the latter parent but the cushioned habit of the former: sts. pale glandular-hairy; bracts red tipped with green; lvs. intermediate in shape; sepal red and glandular, while the petals are rose, much deeper colored toward their base. March. A garden hybrid. G. C. III. 51:247.

133. Paulina, Sündern. (S. Burseriana var. minor × S. Ferndinandi-Coburgi). Habit compact, nearer like that of the latter parent, about 2 in. high, with larger rosettes of glaucous foliage: sts. tinged with red and fls. pale yellow, about 3/4 in. diam. March. A garden hybrid.—Somewhat resembles S. Burseriana but the foliage is more glaucous and the rosettes are smaller. Var. compáctica, Hort., is said to have compact cushions
of dark green foliage and stout sprays of clear yellow
fls. resembling S. Bogdai.

134. Halgei, Sundern. (S. sacta x S. Ferdinandiana)
Curiously resembles the latter parent.
Its habit is very compact, its foliage is similar and glauc-
ous: fl-sts. 2-3 in. high, bracted, tinged red-brown
and glandular-hairy: fls. golden yellow, 4-5 to a st.,
clustered in heads. March, April. A garden hybrid.
Hort. 78, 1: 170.

135. Godseffiana, Hort., also known as S. Godseff
and S. L. S. Godseff (S. sacta x S. Elisabetha)
Habit of growth intermediate, foliage spiny and in close tufts:
fl-sts. 3-4 in. high, reddish and having reddish green-
tipped lvs. fls. an improvement on S. Elisabetha, being
deeper crimson and having better for fruit. A garden hybrid.

S. atrosaevia, Hort., is offered in the trade as a form growing 6 in.
high, with white fls. Probably belongs in Section Dactylodes.—S. Bogdai,
Bogdai, is offered in the trade and said to have white fls.—S. crassula, Hort.,
forms a hybrid in the trade as one of the easiest to grow, fls. white. Perhaps a misspelling of cori-
opus, the same plant as S. roburica. S. coriopus, is said to have
very slantly balsated foliage and pretty little panicles of white
fls. borne on sts. 4 in. high. It belongs to Section Eucosmica.—S. crassula
Hort., is offered in the trade as a form growing 6 in. high,
with white fls. Probably a form of S. Aizoon near var. para-
doxa, S. truncata. S. crassula Hort.,—S. elaeagni, Hort.,—S. elaeagni var.
major, S. gracilis, Hort., is offered in the trade as growing 6 in.
high, with white fls.—S. gracilis, Hort., forms cushions of rather pale
green, about 6 in. high, the growth being packed and somewhat
related at base of the stem more white and numerous. Probably belongs
in Section Dactylodes.—S. Hæferti, Hort., is offered in the trade.—S.
Hæfra Hort., not others.—S. Hæfra, Haw.,—S. hæfra, Haw.,—S. hæfra, Hort.,
not Don, is listed as belonging to the encrusted section and as having white fls.—S. incrustata, Don.
is a form of the plant Oettingen, seems to be the same as
S. incrustata, Hort.,—S. latifolia, Wimm.—S. Aizoon var. major.—S.

Var. pilifera, Hort.,—S. Eucosmica.—S. E. 38: 839.

S. mendax. Tr. 15: 113.

S. mendax var. gracilis, Hort.,—S. Eucosmica.—S. E. 38: 839.

S. mendax var. major, Hort.—S. Eucosmica.—S. E. 38: 839.

S. mendax var. minor, Hort.—S. Eucosmica.—S. E. 38: 839.

S. mendax var. major, Hort.—S. Eucosmica.—S. E. 38: 839.

S. mendax var. minor, Hort.—S. Eucosmica.—S. E. 38: 839.

S. mendax var. major, Hort.—S. Eucosmica.—S. E. 38: 839.

S. mendax var. minor, Hort.—S. Eucosmica.—S. E. 38: 839.

S. mendax var. major, Hort.—S. Eucosmica.—S. E. 38: 839.
3. *stellata*, Linn. An annual plant, hairy, simple or somewhat branched, 6-18 in. high: lvs. cut or somewhat lyrate, the terminal lobe large, obovate, dentate, the upper ones often pinnately parted; fls. blue, in long-peduncled heads; corolla 5-cleft, the lobes radiate. June and later. S. Eu.

4. *brachiatä*, Sibth. & Smith. An annual species about 1 ft. high: lower lvs. ovate-oblong, the upper pinnately cut, lyrate; the lower lobes deciduous, the terminal large, obovate, oblong: fls. light blue, purple, and later. Eu., Asia. Recent authors have kept this distinct as the type of the genus Calistemma where it becomes *C. brachiatum*, Boiss.

5. *ucranica*, Linn. (S. Wulfenii, Roem. & Schult.) Biennial or perennial: sts. erect, branched: lvs. pilose-pubescent with appressed white hairs; the lower pin-nately parted, segms. oblong or oblong-linear, entire or dentate; the upper often undivided: calyx-limb short-stipitate; corolla white or yellowish white, rarely rose or blue, lobes nearly entire or crenate; fruiting head spherical. Eu., Asia Minor, and Persia.

6. *Reuteriana*, Boiss. Annual: st. erect, branched: lower lvs. oblong-oblongate, entire; the other lvs. lyrate, lateral segms. on each side 1-2, short, lanceolate, terminal segm. much larger: involucre hirsute, involucre bracts in 2 rows, very unequal, shorter than the fls.: nana or Tom Thumb. This is the group listed in the trade as Tom Thumb. The forms of *S. atropurpurea* are among the most popular of flower-garden annuals. Seeds sown in the open ground in spring should give bloom in early summer and continue till frost. The composite-like heads are produced on long stalks, good for cutting.

S. *pumila*, Hort., also known horticulturally as *grandiflora minor*, is a smaller-growing group of plants, very much branched, of which the following forms are named in the trade: *S. minor aurea* flore-pleno, also known as *S. minor aurea* flore-pleno, which has bright yellow double fls.; *S. minor jolite-aurea* with yellow foliage, and *nana pumila*. Var. *pumila*, Hort., also known horticulturally as *grandiflora pumila*, is a dwarf group occurring in various colors; there is also a double form horticulturally known as *pumila flore-pleno*. This is the group listed in the trade as *S. atropurpurea*....
SCÁNDIX (Greek, to sting, in reference to the roughness of the fr.). UMBELLIFERÁ. Glabrous or pubescent annual herbs, one of them grown for foliage and bloom: lvs. pinnately decompound, the segms. small and narrow; umbels compound, few-rayed, or now and then simple (1-rayed); involucre none or 1-bracted; fls. white, polygamous; calyx-teeth minute or wanting; petals often unequal, oblong, cuneate or obovate: fr. oblong-linear, laterally compressed, long-beaked, primary ridges prominent, broad obtuse or filiform.—About 12 species natives of temperate or subtropical regions of the northern hemisphere.

Pécten-Venéris, Linn. Fig. 3565. A hardy garden annual 6-12 in. high, with finely cut lvs. and small white fls. in simple umbels. Et. —Little grown.

S. cerefoliúm, Linn. See Chervil.

SCAPHOSÉPALUM (Greek, boat and sepal, alluding to the form of the lower sepal). Orchidáceas. A genus separated from Masdevallia on the character of the lateral sepals, which are united into a boat-shaped organ. In habit the plants resemble masdevallias, except that the parts of the rhizome are longer, thus making the tufts less compact, and the racemes assume climbing habits, becoming very long and bearing fls. for months in succession. The dorsal sepal is free or partly connate with the petals and rather spreading, lateral broader than the dorsal; petals similar to the sepals; labellum articulate or continuous with the foot of the column, not divided or obscurely lobed; column rather long, 2-auredicated at the apex; pollinia 4.—About 15 species. Mex. to Brazil.

álba, Rolfe. Sts. fascicled, narrowly spine-shaped, 1½-2 in. long, 2-lvd.: lvs. linear, 1½-2½ in. long, minutely biobed at apex; fls. small, white, in fascicles of 3 or 4; sepals oblong; rather connivent; petals somewhat narrower; lip cuneate-oblong, nearly entire. Hab. (?).

S. Cogniauxiana, Wildem. A small species with narrow lvs. 2-4 in. long; fls. greenish yellow; sepals acute, petals subacute. Brazil.—S. sedólo, Lock. differs from S. volácea in having larger fls., with more spreading segms. and lateral lobes of the lip as large as the middle one. Guinea.—S. volácea, Lindl. Sts. terete, articulated, 2-3½ in. long, linear or linear-lanceolate; fls. violet, minute; lateral sepals twice as broad as the dorsal; lip white, filiform, cuneate. Guinea. B.M. 4071. B.H. 1903.

F. TRACY HUBBARD.

SCHLENÓSTOMA: Charántoma.

SCHAUÈRÍA (after J. C. Schauer, professor at Greifswald, 1818-1848). Acanthácceas. Erect half-shrubby herbs, of greenhouse cult., with entire lvs.; fls. yellow or red, in a terminal thyrse or spike; calyx 5-parted, segms. linear or setaceous; corolla-tube long, gradually broadened upward; limb 2-lipped, the upper lip interior narrow, entire or emarginate, erect, lower lip cut into 3 subequal, recurved segms.; stamens 2 each, with 2 parallel anthers, about as long as the upper lip; aborted stamens wanting; style filiform; ovary seated on a disk, 2-loculed, with 2 seeds in each locule.—About 8 species from Brazil. Closely related to Jacobinia, from which it differs by the equal parallel anther-cells. It is distinguished from Anisacanthus by its setaceous calyx-lobes, and from Fittonia by its habit.

flavicoma, N. E. Br. (Justicia flavicoma, Lindl. Justicia flava, Hort., not Kurz.). Fig. 3566. Half-shrubby plant, with erect, branched sts. up to 4 ft. high: lvs. opposite, petiolate, ovate to ovate-lanceolate, shining green, undulate; fls. light yellow, 1½ in. long, borne in erect, feathery panicles; calyx-
lobes long, subulate, glandular-haired, or glabrous, scattered, or several along the main leaf axis. The leaves may be simple, palmately compound, or digitately compound. The flowers are usually showed in the axils, stalked, the corolla 2-3 in. long, the tube inclined or drooping. A glabrous vine 6-18 ft. high:

**Schina**

**Schima** (said to be an Arabian name). *Ternstroemia*. Evergreen trees or shrubs, suitable for the greenhouse or hardy in the far South. Leaves various, mostly digitately compound, rarely simple and then usually mixed with compound lvs., very seldom double digitately compound: fls. in umbels, heads, or racemes, these mostly arranged racemously, seldom in whorls; calyx- limb weakly developed, obscurely and shortly toothed or almost lacking; petals 5 or more (15), mostly 5-6. Stamens as many as the petals: fr. globose to ovate or elongated, sulcate or angular. About 150 species in the tropical regions of the world. Para-
tropia Sieberiana, Bar.-Rodr., belongs to this genus. See under Para-
tropia. A glabrous vine 6-18 ft. high:

**Schinus** (Greek name for the mastic-tree, Pistacia Lentiscus; applied to this genus on account of the resino-
vous mastic-like juice of some species). *Asafoetida*. Resinous dioecious trees, one much planted in California.
Leaves alternate, pinnate; lfts. sessile, axillary: panicles terminal, bracteate: fls. small, white, with short, 5-lobed calyx, 5 "umbellated" petals, broad annular disk, and 10 stamens: fr. a globose drupe. —About 17 species, all S. American except one in the Hawaiian Isles, one in Jamaica, and one in St. Helena. Only two are cult.: they are semi-tropical and grown in the warm-house at the E. and in N. Eu., in the open at the S. and in Calif., as far north as the San Francisco Bay region. Schinus molle, the old generic name, is from Mulli, the Peruvian name of S. molle, and not, as sometimes supposed, Latin molle, soft, which would not be applicable in this case.

**Schinus Molle** is everywhere present in southern California, where it attains a height of 50 feet and soars itself. It was a great thing for this region in years past before the water systems had reached their present efficiency. Now the pepper-tree is under a ban, and justly so. Next to olive, the pepper-tree is most subject to black scale. Hence the pepper-trees, being large and numerous, have been indirectly a serious menace to the orchards of citrus fruits. Thousands of old trees, 2 to 3 feet in diameter, have been cut because of their proximity to orange orchards. Los Angeles boasts some magnificent avenues of them. *S. tomentosifolius* is but little known in this region, the tallest tree being only 15 feet as yet, but it is likely to be extensively planted in the near future. (Ernest Braunton.)

**Molle, Lind.** **PERUVIAN MASTIC-TREE, CALIFORNIA PERUVIAN-MASTIC-TREE.** Figs. 3567, 3568. Evergreen tree, 20 ft. and more, with rounded outline and graceful, pendulous branchlets when not trimmed: lvs. 9 in. or more long, glabrous, of many alternate, linear-lanceolate lfts. 1½–2 in. long; fls. in conical panicles, yellowish white; ripe berries black. W. S. Amer. B.M.7406.

**Schinus molle,** Linn., is now considered a subgenus of *Schinus.*
white, the total mass of green being less than the varie-
gation; petiole 3—4 1/2 in. long: blade 4-5 x 1 1/2-2 1/2 in.
nae was offered in 1853 by John Soal, Wash-

ngton, D. C.

Upper surface of blade ashy-striped.

Longispâtha, Bull. Lvs. ovate, base slightly cordate, apex acuminate, upper surface green with minute white dots, lower pale black-dotted; petiole about as long as blade. Borneo. Var. albo-maculata, Engler (S. cri-
spinata, Hook.).--S. rubriflora, Hook. & Thoms.

cc. The petiole about equaling the blade and verrucose.

asperâta, Engler. Caudex short: lvs. ovate or ovo-
vate, base cordate or only emarginate, apex acuminate, upper surface green with minute white dots, lower pale black-dotted; petiole about as long as blade. Borneo. Var. albo-maculata, Engler (S. cri-
spinata, Hook.).--S. rubriflora, Hook. & Thoms.

BBB. Blade ovate-oblong or its outline more or less triangu-
lar and cordate or rarely cordate-ovate, sometimes variegated in the same specimen.

c. Adult s-blades oblong-ovate, base distinctly cordate; blade ashy-maculata.

neoguineennis, N. E. Br. (S. neoguineennis, Engler.

S. variegtata, Hort., not Hook.). Lvs. ovate-cordate, bright green, irregularly blotched with pale yellowish green, the total mass of green being greater than the varie-
gation; blade 8—9 x 6—7 in. long, New Guinea. I.H. 27:380 (as Colocasia neoguineennis, the variegation being a bright cream-colored white).--S. variegtata, Hort.

cc. Adult s-blades t'fin, broadly ovate-cordate, white or palely ashy-maculata.

Picta, Schott. Lvs. ovate-cordate, the basal lobes short, but the sinus deep, dark green above, marked with lacertoid glaucous spots at the middle, on each side of the midrib, and between the nerves; petiole 8—10 in. long: blade 6—7 in. long. Java.

BBBB. Blade broadly ovate-cordate, slightly longer than broad, posterior lobes semi-ovate.

latifolia, Miq. (S. rugprtsis, Zoll. & Mor.). Caudex thick; above ground: lvs. ovate, acute, deeply cordate, 6—18 x 6—12 in., upper surface dull green, lower paler, posterior lobes semi-ovate, sinus acute; petiole usually longer than the blade. Java, Celebes, and the Philippine.

S. oblongoflora var. Catttii, Hort., is offered in the trade but is apparently not known botanically. (S. Roebelw, Fischer & Mand. 1895, p. 138. "Lvs. beautifully marked with silvery white in a broad leafy variegation. Only the center and edge of the lvs. are plain light green. The plant is compact, tree-growing, with falcate lvs. as enduring as those of a rubber tree. A fine house plant." This plant is imperfectly known. It is figured in Pitcher & Manda's catalogue for 1895:141 as S. picta and in V. 23:71 (1899) as S. crispata. The plant so pictured is distinct from any species described above. There is more white than green in the lvs., the entire blade and midrib portion being green. Some growers think it to be a sport of S. aspera var. albo-maculata.—S. Seemann, Hort. Bull. was addressed by his botanical name. (S. Niesy, var. Picta, P. Tracy Hubbard.)

SCHISMSUS (Greek, schisma, a cleft, referring to the 2-lobed lemma). Gramineae. Low annuals with short dense panicles of pale shining spikelets. Species 4, Medit. region and Afr. S. calcigenus, Coss., has recently been intro., but is of no horticultural importance.

A. S. Hitchcock.

SCHIZDRA (Greek, to split). Schizandra is a group of small ferns with twisted grass-like lvs. and sedge-like sporophylls formed of a cluster of closely com-
pacted pinnae, each with 2 rows of sporangia, which in common with the family are pear-shaped, with an apical ring, opening by a vertical fissure.

S. pulsiflora, Pursh. Our only native species, growing in sand at the edges of bogs, mainly in N. J. Lvs. 1 in. long, grass-like, twisted sporophylls 2-3 in. long, with the apex expanded and consisting of 6-8 closely com-
pacted divisions. Known locally as club-grass. The prothallus resembles the protomma of a moss, being filamentous rather than thalloid as in ordinary ferns.

L. M. Underwood.

SCHIZANDRA (Greek, schizhen, to cleave, and aner, andros, man, stamen, referring to the cleft or separate anther-cells). Including Sphenaneris and Magnolioduce. Ornamental vines grow chiefly for their handsome bright green foliage and the scarlet or orange-red berry-like fruits.

Deciduous twining shrubs: lvs. alternate, long-petioled, entire. Propagation is by seeds, by greenwood cuttings, in cuttings under glass, root-cuttings or layers, and also by suckers.

coccinea, Michx. High-climbing shrub: lvs. slender-petioled, ovate or oval, acuminate, entire or obscurely dentate, glabrous, 2-3 in. long: flowers white or red, berries scarlet or red, rarely black, berry-like fruits forming drooping racemes.

S. chinensis is hardy North, while the other Chinese species are somewhat tender; the native S. coccinea can be grown only South. They may be used for covering rocks, tress, shrubs, or fences, and seem to thrive most in partly shaded and somewhat moist places in a porous, sandy loam. To enjoy the very showy fruit which ripens at the end of August or in September, both sexes must be planted together, as most species are dioecious.

S. suiswai, F. L. H. Ev,., a cleft, referring to the cleft or separate anther-cells. Includes Sphenaneris and Magnolioduce. Ornamental vines grow chiefly for their handsome bright green foliage and the scarlet or orange-red berry-like fruits.

Deciduous twining shrubs: lvs. alternate, long-petioled, entire. Propagation is by seeds, by greenwood cuttings, in cuttings under glass, root-cuttings or layers, and also by suckers.

coccinea, Michx. High-climbing shrub: lvs. slender-
petioled, ovate or oval, acuminate, entire or obscurely dentate, glabrous, 2-3 in. long: flowers white or red, berries scarlet or red, rarely black, berry-like fruits forming drooping racemes.

S. chinensis is hardy North, while the other Chinese species are somewhat tender; the native S. coccinea can be grown only South. They may be used for covering rocks, tress, shrubs, or fences, and seem to thrive most in partly shaded and somewhat moist places in a porous, sandy loam. Deciduous twining shrubs: lvs. alternate, long-petioled, entire. Propagation is by seeds, by greenwood cuttings, in cuttings under glass, root-cuttings or layers, and also by suckers.
A monotypic genus, the species being S. elegans, Meissn. (S. Grahamii).Fig. 3569. The most variable of the species, with many horticultural forms distinguished by height of st. and color-markings of the fls. Typically 2 ft. high; lvs. 1–2-pinnatisect; the segms. entire, dentate or incised pinnatifid; fls. varying in depth of color, the lower lip usually violet or lilac; the upper paler, its middle section with a yellow blotch at its base and spotted with purple or violet. B.M. 2404; 2521. B.R. 725; 1902 (as var. pubescens, var. pubescens, G. W. 12:613. G.W. 3, p. 497.—The plant known horticulturally and in trade as S. grandiflorus, Hort., and variations, undoubtedly belongs to

Var. albus, Hort. (S. grandiflorus albus, Hort.), has fls. slightly larger than the type, offered in several forms in the trade. Var. niveus, Hort., has pure white fls. Var. compactus, Hort., is a compact form similar to var. niveus, and offered in several forms in the trade. Var. lilacinus, Hort., has lilac fls. Var. nana, Hort., is dwarfer than the type, offered in several colors in the trade. Var. papilionaceus, Hort. (S. grandiflorus papilionaceus, Hort.), has a purplish black blotch surrounded with yellow at the base of the middle segm. of the upper lip or with the typical yellow portion dotted with small dark purple spots. H.F. 1862:451. H.F. II. 2:294. Var. papilionaceus, Hort., has a central coloroglyph, what as var. oculatus, with the general color of the fl. marbled in various shades. Var. roseus, Hort., has rose-colored fls. Var. tigrinolus, Hort., is also cult.

F. TRACY HUBBARD.
purple, nearly 1 in. broad; fr. very hairy, producing seed freely by which the plant is readily prop. (or by cutting). Vera Cruz, Mex. G.C. III. 42:293. Gt. 62, p. 275. This species, although first described in 1839, has not been in cult. until since its rediscovery in 1901 at Jalapa by J. N. Rose. It is a very dainty plant, well worthy of ornamental cult. It is grown to some extent in Mexican gardens at an elevation of about 3,000 ft., where it does unusually well, growing apparently as well in shade as in the bright sunlight. The plant has been grown for a number of years in the N. Y. Botanical Garden, and when in full flower makes a most striking display. It forms a dense mat and is well suited for close carpet-bedding.

J. N. Rose.

**SCHIZOCÔDON** (Greek cut and bell, referring to the fringed corolla). *Diapensiae*. Glabrous herbs, with the caudex perennial and scale-bearing between lvs., suitable for outdoor planting; lvs. all radical, long-petioled, ovate-rotund, base cordate, crenulate-undulate, leathery and bestent; fls. few at the top of the stolons, racemose, subsecund, nodding, 1–2-bracted; calyx 5-parted, the segms. linear-oblone, striate-nerved; corolla funneliform, 5-lobe, the lobes truncate, fimbriate, and imbricate; stamens 5; ovary ovoid-globose, 3-angled.—Perhaps 4 species. Japan. S. **soldanelloides** is a pretty alpine plant or boreal with rosy fls. fringed like the well-known soldanellas of the Alps. It may be readily distinguished from Soldanella (which is a member of the primrose family) by the lvs. being toothed, and the stamens 4 instead of 5. The name “fringed soldanella” has been proposed for schizocodon, but all soldanellas are fringed. “Fringed galax” would be better, as galax is the nearest relative, schizocodon being, in fact, the Japanese representative of the American galax. The lvs. of schizocodon are sometimes more or less bronzy, like those of *galax*, but *soldanelloides*, obtuse; corolla deep rose in center passing into bluish or white at the edges; staminodes linear. Japan. B.M. 7316. Gn. 44:418. G.C. III. 13:415; 51:348. G.M. 36:206. J.H. III. 34:523; 44:347. V. 20:119.—This is probably the only species in the genus, as *S. vulgatus* Shortia and *S. uliginolus* is thought to be a variety of *S. soldanelloides*, with more variable lvs. and fls. ranging from red to white. Offered by many European dealers, and by one or two Americans; little known here.

F. TRACY HUBBARD.

**SCHIZÔLÖBIUM** (Greek, to cleave and pod, alluding to the manner of dehiscence). *Leguminossae*. Tall trees adapted to the warmhouse and planted outdoors in the extreme South: lvs. large, bipinnate; lfts. numerous, small; fls. in axillary racemes or in panicles at the ends of the branches; calyx-tube disk-bearing, oblique, turbinate, the segms. slightly unequal, reflexed; petals 5, clawed, ovate or rotundate, slightly unequal; stamens 10, free, ovary scarcely stipitate: legume compressed, obovate, 2-valved, 1-seeded.—One, possibly 2, species. Brazil and Panama.

**SCHIZÔPÉTALON** (Greek, cut and petals, alluding to the cut petals). *Cruciferae*. Half-hardy erect annual herbs used in border planting; lvs. alternate, sinuate, dentate or pinnatifid; fls. purple or white, in terminal, leafy-bracted racemes; sepals erect; petals clawed, pinnate-lobed, involute; silique narrowly linear, knotty; seeds many.—About 10 species. S. Amer. S. Walkeri, Sill. S. weak, assurgent: lower lvs. 4–5 in. long, sinuate-pinnatifid, elongate-oblong in outline, long-attenuate at base, secrably on both surfaces, distant; peduncles solitary, axillary, but collected at the top into a raceme; fls. white; calyx cylindrical; petals spreading, ovate, incise-pinnatifid. Chile. B.M. 2379. G. 24:240.

**SCHIZÔPHRAGMA** (Greek, schizein, to cleave, and phragma, wall; the inner layer of the wall of the valves is dehiscent by fleshy fibers). *Saxifragaceae*. Ornamental vines grown for their handsome bright green foliage and the showy clusters of white flowers. Shrubs climbing by aerial rootlets: lvs. opposite, long-petioled, dentate or entire; fls. in loose cymes; sepals and petals 4–5; stamens 10; free; ovary 4–5-loculed; marginal sterile fls. consist only of 1 large white sepal, terminating the branchlets of the inflo.: fr. a small, 10-ribbed caps.—One species in Japan and another in China, allied to Hydrangea and Decumaria. These are handsome woody vines with rather large bright green foliage and loose terminal cymes of small white flowers with large and showy sterile ones at the margin. They are well adapted for covering walls and trunks of trees and cling firmly by means of aerial rootlets. The Japanese species is hardy as far north as New York City, while the Chinese one is tenderer. They thrive best in rich, moderately moist soil and partial shade, but also do well in full sun if the soil is not too dry. Propagation is by seeds or hardwood cuttings under glass; also by layers.

**SCHIZÔPHRAGMA**.

**SCHIZÔPHRAGMA** (Greek, schizein, to cleave, and **phragma**, wall; the inner layer of the wall of the valves is dehiscent by fleshy fibers). *Saxifragaceae*. Ornamental vines grown for their handsome bright green foliage and the showy clusters of white flowers. Shrubs climbing by aerial rootlets: lvs. opposite, long-petioled, dentate or entire; fls. in loose cymes; sepals and petals 4–5; stamens 10; free; ovary 4–5-loculed; marginal sterile fls. consist only of 1 large white sepal, terminating the branchlets of the inflo.: fr. a small, 10-ribbed caps.—One species in Japan and another in China, allied to Hydrangea and Decumaria. These are handsome woody vines with rather large bright green foliage and loose terminal cymes of small white flowers with large and showy sterile ones at the margin. Burma, to Java and Timor. Intro. into timber is good, the bark is astringent and when mixed
subsequently: racemes axillary: fls. yellowish or green: flowers oblong, obtuse or short-acuminate, entire, sessile or corymbose.-Two species, Asia. S. trijuga, Willd. A large tree: lvs. paripinnate, 8-16 in. long; lfts. simple, lanceolate, complicate: fl.-heads in the spathe; bracts narrower than the spathe, green or somewhat scarious, 2-keeled; petals showy, red, the tube slender, the lobes equal, oblong or ovate; ovary 3-celled: capsules obvoid or oblong, the top truncate, 3-grooved, membranaceous.—Two species, S. Afr.

coccinea, Backh. & Harv. Crimson Flag. A winter-blooming tender plant: st. 1-2 ft. high, bearing 2-3 lvs.: basal lvs. 2-3, about 1½ ft. long; fls. bright red, about 2 in. across. B.M. 5422. F.S. 16:1637. G.L. 24:208. J.H. III. 48:589.—The following cultural notes are taken from Garden and Forest 9:156. The species blooms from Oct. to early Dec. and is useful (or cut-flowers at this season. It is perfectly hardy in England but of little use here except for indoor use. The roots should be planted out in rich soil in spring about 8 in. apart, and encouraged to make a strong growth. The plants may be placed in a cool greenhouse, where they will flower. After flowering they may be stored in a frame until the following spring, when the fleshy roots will need to be separated about 8 in. apart, and encouraged to make a strong growth. In the fall the plants may be lifted, potted and placed in a cool greenhouse, where they will flower.

SCHIZOSTYLOS (Greek, to cut, and style, alluding to the silifom segments of the style). fridacea. Greenhouse or half-hardy plants: stts. fascicled on the rachis. Leaves linear or slightly bullate-thickened at the base. Lvs. linear or narrow-ensiform: stamens 5-8; ovary 3-4-celled: flowers dry. (Schlumbergera.) Schizostylis for J. C. Schleicher, a Swiss botanist.

SCHIZOSTYLOS (Greek, fridacea. Greenhouse or half-hardy plants: stts. fascicled on the rachis. Leaves linear or slightly bullate-thickened at the base. Lvs. linear or narrow-ensiform: stamens 5-8; ovary 3-4-celled: flowers dry. (Schlumbergera.) Schizostylis for J. C. Schleicher, a Swiss botanist.

SCHIZOSTYLOS (Greek, fridacea. Greenhouse or half-hardy plants: stts. fascicled on the rachis. Leaves linear or slightly bullate-thickened at the base. Lvs. linear or narrow-ensiform: stamens 5-8; ovary 3-4-celled: flowers dry. (Schlumbergera.) Schizostylis for J. C. Schleicher, a Swiss botanist.

SCHIZOSTYLOS (Greek, fridacea. Greenhouse or half-hardy plants: stts. fascicled on the rachis. Leaves linear or slightly bullate-thickened at the base. Lvs. linear or narrow-ensiform: stamens 5-8; ovary 3-4-celled: flowers dry. (Schlumbergera.) Schizostylis for J. C. Schleicher, a Swiss botanist.

SCHOMBOLIELIA (compound from Schomburgka and Lelia). Orchidaceae. A generic name to designate the hybrids between Schomburgkia and Lelia. S. tibicinis = S. tibicinis x L. tenebrosa.

SCHOMBOLEIOCATLEYA (compound from the names Schomburgkia and Leiolcattleya). Orchidaceae. A name to comprise the hybrids between Schomburgkia and Leiolcattleya. S. schombromium = S. rosea x L. Lucya.

SCHOMBURGKIA (named for Dr. Schomburgk, naturalist and geographer, who explored British Guiana). Orchidaceae. Orchids with the habit of cattleyas or lalias, except that they are less compact.

Pseudobulbs long, fusiform, bearing several brown scales and 2-3 leathery lvs. at the summit; ft.-sts. from the top of the pseudobulbs, sometimes very long, bearing a terminal raceme or panicle of showy fls.: fls. like those of Lelia except that the sepals and petals are narrow and undulate and the labellum does not completely envelop the column; labellum always evidently 3-lobed. About 15 species, in Trop. Amer.

3571. Schomburgkia tibicinis. (X1/2)

Give schomburgkias plenty of heat and a light place near the glass, which should be slightly shaded during the hot summer months. Provide freely of water in the growing season. Rest them in a temperature of 55°. S. tibicinis and S. Lycens are to be classed amongst the showy easily grown orchids resembling lalias. (Wm. Mathews.)

tibicinis, Batem. (Epipendrum tibicinis, Batem.). Fig. 3571. Pseudobulbs 1-1 1/2 ft. long, tapering upward: lvs. 2-3, oblong, leathery: raceme 4-8 ft. high, bearing numerous fls. each 3 1/2 in. across; sepals and petals oblong, undulate, crisp; lateral lobes of the labellum large, cucullate, middle lobe small, emarginate; fis. deep pink, speckled with white on the outside, rich chocolate-red within; labellum white within, deep rose-color at the sides, with a short chocolate-red middle lobe. Summer. Honduras, Cuba G.C. III. 4:212; 7:651. Var. grandiflora, Lindl. Fls. larger and paler, with more yellow in the lip. B.R. 31:30. B.M. 4476.

F.S. 1:54.—S. tibicinis requires less compost than the other species.

Lyonsii, Lindl. Pseudobulbs about 1 ft. high, with 2-3 linear-oblong lvs., at the top: racemes erect, 9 in. long, bearing 12-25 fls., each subtended by a reflexed bract about 3 in. long; fls. 2 in. across; sepals and petals ovate to ovate-lanceolate, undulate, white with several rows of purple spots; labellum larger, recurved, acute, white, with a yellowish brown crisp margin; anther 2-horned. Aug. Jamaica. B.M. 5172. F.S. 20:2130. G.C. III. 26:203.

S. rosea, Lindl. Related to S. undulata. Bracts, peduncles and labellum light rose: sepals and petals oblong, undulate, narrower than the labellum; labellum with rotund lateral lobes and a smaller subrotund middle lobe, margin crisp. Colombia.

S. Lueddemannii, Prill. Fls. brown, with the lip and column purple, and the crest and anther yellow: sepals and petals linear-oblong, obdurate, manifestly undulate. 1 1/2-1 3/4 in. long, lip 3-lobed, 3 in. long, the middle lobe ovate-ovaricular, apicate, about 1 1/2 in. long, the edges incurved near apex. Venezuela. B.M. 8427.—X. Sanderae, Rolfe. Fls. rose-earmine; sepals lanceolate-oblong, 1 1/4 in. long; petals oblanceolate-oblong; lip obscurely 3-lobed, 1 1/2 in. long, the front lobe broadly rounded obtuse, crisped-undulate. Origin unknown. J. H. III. 51:383.—S. Thomtomaea, Reichb. f. Sepals and petals linear-oblong, 1 1/4 in. long, crescent-white passing to yellow at apex, the sepals undulate, the petals crisped; lip 3-lobed, the middle lobe obtuse, emarginate, much crisped, deep purple, with a yellow disk. Cayman IIs. B.M. 7815.—X. Willisi, Reichb. f. Resembling S. Lueddemannii. Lip with broad obdurate side lobes, and very acute front lobe, all brown at apex.

GEORGE V. NASH, †

SCHOMBURGKIOCATTLEYA (compound from Schomburgkia and Cattleya). Orchidaceae. A genus established to contain the hybrids between Schomburgkia and Cattleya. S. spiralis = S. tibicinis x C. Mossiae.

SCHOTIA (named for Richard Schot, companion of Jacquin during his travels in America, 1754-1759). Leguminosae. Small trees or unarmed shrubs, suitable for greenhouse-growing.

Leaves odd-pinnate; lfts. leathery, or small; stipules short; fls. red, showy, clustered in short panicles; bracts and bracteoles ovate or oblong, caduceous; calyx-tube disk-bearing, turbinate; short or long; the base long-attenuate, segms. 4, strongly imbricated; petals 5, slightly unequal, sub sessile, imbricated, either ovate or oblong or minute scale-like; stamens 10, free, or shortly con nate at the base; ovary stipitate; legume oblong or broad-linear. About 6 species. Subtrop. and S. Afr.

a. Fls. on rather long pedicels.

b. Petals longer than the calyx

speciosa, Jacq. A tree or shrub, about 10 ft. high; lvs. variable in form, which fact has led to much separa tion of this species into varieties and species; lfts. 8-32, linear, oblong, or ovobovate: fls. crimson, in terminal panicles. S. Afr. B.M. 1153 (as S. tamarnindifolia).—Intro. in S. Calif.

bb. Petals shorter than the calyx.

brachypetala, Sonn. A large shrub or small tree: lfts. 8-10, larger than in S. speciosa, ovobovate or obovate: panicles many-fl., axillary and terminal; calyx-tube conical, crimson; petals very small, linear, hidden by the calyx. S. Afr.—Cult. in S. Fla. and S. Calif.
SCHOTIA

AA. Fls. nearly sessile.

latifolia, Jacq. Becoming a tree 20-30 ft. high: lfts. 4-8, ovate-oblong or obovate, usually 1½-2¼ in. long, ½-1 in. wide; fls. rosy or flesh-colored, in much-branched panches; petals longer than the calyx. S. Afr.—Advertised in S. Calif. F. W. Barclay.

F. TRACY HUBBARD.†

SCHRANKIA (named after F. B. Schrank, a Bavarian botanist); also spelled Schranciea. Leguminosae. Perennial herbs or subshrubs, often prostrate, armed with recurved prickles. The species in common cult. is

an outdoor plant. Lvs. bipinnate, often sensitive, petiole without glands, frequently bristly between the pinnae; the lfts. small; stipules bristle-like; fls. in globose heads or cylindrical spikes, peduncles solitary or fascicled at the axils, rose or purplish, 5-4-merous, sessile, perfect or polygamous; calyx very minute; petals longer than the calyx. S. Calif. F. W. BARCLAY.

SCHUBERTIA grandiflora. (X3)

SCHUBERTIA (named after Gotthilf Heinrich von Schubert). Asclepiadaceae. Twining shrubs, occasionally grown in the greenhouse: lvs. large: fls. large, white, borne in loose umbels; sepals ovate, generally acute, alternating with single glands; corolla funneliform or salver-shaped, with a broad tube; crown upright, included: follicles thick and hairy.—About 6 species from S. Amer. S. grandiflora, Mart. & Zucco. Fig. 3572. Branches twining, straw-colored, covered with long red-brown hairs; lvs. coriaceous, obtuse, with long surfaces densely brown-pubescent; umbels few-fl.; pedicels long-hairy: fls. white; sepals ovate-acute; corolla large, tube gourd-shaped, glabrous inside, the lobes oval-longish, obtuse, erect, sparsely pale yellow pubescent. Brazil. G. 36:503; 37:351. Gt. 50:1492. G. F. 3:369 (adapted in Fig. 3572). G. 2:256. S. graveolens, Lindl. (Ardisia graveolens, Mast.), is a Brazilian climber, likely to be found in collections of greenhouse plants, smaller-fl. than the above. See also Physianthus. There may be confusion in the use of the names S. graveolens, S. grandiflora, and Physianthus auricomus.

SCIADOCALYX: Isoloma. The following species was not treated under Isoloma, see Vol. III, p. 1705.

Isoloma Warszewiczii, Hort. (Sciadocalyx Warszewiczii, Regel. Kôtleria Warszewiczii, Honst.). Perennial herb, 3-4 ft. high, with catkin-like stolons: st., petioles, lvs., and calyx villous-hirsute: lvs. opposite, long-petioled, oval or cordate, crenate: fls. in axillary umbels of 3-6 fls., bright yellow or yellowish green, red or brown-dotted; calyx adnate to ovary, 5-lobed, lobes almost horizontally spreading; corolla almost oblique at base, tube slightly inflected, limb 5-lobed, lobes rounded; ovary hirsute, surrounded by a glandular, 5-lobed ring. Columbia. B. M. 4843. Gt. 2:256.

SCIADOPHYLLUM (shade leaf, because of the umbrageous foliage). Araliaceae. As understood by Benthum & Hooker in Genera Plantarum, it is a genus of the American tropics, at that time with about 22 known species, differing from Schefflera, among other things, in the calyptrate or coherent rather than free petals and sometimes 4-merous fls. Harms, in Engler & Prantl’s Pflanzenfamilien, refers it to Schefflera, and under this name (p. 3108) are here described any species probably now in the trade.

SCIADOPITYS (Greek, skiás, skiaiados, umbrellas, and pitis, spruce, alluding to the position of the leaves). Pinaceae. Umbrella Pine. Ornamental tree grown for its handsome foliage and regular pyramidal habit.

Evergreen resinous tree; lvs. of two kinds; small and scale-like lvs. scattered on the shoot, but crowded at its end and bearing in their axils a whorl of 20-30 long linear flat lvs. furrowed on each side, more deeply beneath; these lvs. really consist each of 2 connate lvs. borne on undeveloped spurs like those of Pinus; they have been sometimes called cladodes, but are not true cladodes: fls. monocious; the staminate oval, consisting of spirally disposed 2-celled anthers and appearing in dense clusters at the ends of the shoots; the pistillate are solitary at the ends of the shoots and consist of numerous spirally arranged scales subtended by a small bract and bearing 7-9 ovals: cone oblong-ovate, woody, the bracts connate, with the broadly orbicular thick scales spreading at the margin; seeds oval, compressed, with narrow wing, marginate at the apex.—One species in Japan, with very strong and straight-grained, nearly white wood.

The umbrella pine is a very handsome tree of narrow
pyramidal habit, with linear, rather large, needle-like dark green and lustrous leaves in whorls and oval ovaries 3 to 4 inches long. It is hardy as far north as Portland, Maine, and is of rather slow growth. It thrives well in a moderately and constantly moist, loamy, and also in clayey soil; in dry soil or in soil which periodically becomes dry, it grows poorly. Propagation is by seeds and layers, and sparingly by cuttings of half-ripened wood in summer; but seedlings are to be preferred, as they grow more symmetrically and more vigorously.

**SCILLA** (the old Greek name used by Hippocrates: *I injure*, according to Miller, alluding to the poisonous bulb). **Lilium**. Scilla. *Witches'-Bluebell*. Perennial bulbous plants remarkable for easy culture, quick growth, and beautiful blue, rose, or white flowers, blooming early in the spring (some in the wild-garden, and although typically they have blue or blue-purple flowers, most, if not all, of the species in cultivation have white and red-purple forms. *S. sibirica* and *S. bifolia* are the earliest to flower, and of these forms the Taurian kinds are in advance. The form of *S. sibirica* known as *multiflora* is nearly past before the usual type begins to expand. There is also sometimes cultivated in the garden a beautiful white scilla, with hyacinth-like flowers, known to the trade as *S. amena*. But these white forms are mostly oddities; the effective ones are the blue-flowering kinds. Occasional hybrids between scillas and chionodoxas are met with (see page 749). *Chionooscilla Alleni* is the accepted name for a natural hybrid between *Chionodoxa Luciliae* and *Scilla bifolia*, first obtained by Mr. Allen, of England, in 1891.

None of the hardy squills requires special culture, and if planted where they can remain undisturbed for a score of years, they will be expected. If the soil is occasionally enriched by top-dressings of manure, the writer has grown them distributed in the grass of the lawn for a number of years with considerable success. The bulbs should be planted as early as possible in autumn. The varieties may be increased if taken after the foliage has matured. For the cool greenhouse or conservatory, many of the scillas are ideal subjects. For this culture, five or six bulbs may be put in a 5-inch pot and the vessel afterward transferred to a coldframe and covered until growth commences. Up to this period very little water will be required, but as the flower-cluster appears the quantity should be increased and the pots transferred to the greenhouse, giving them a position near the glass. The foliage matured, the bulbs may be shaken out of the soil and stored. More attention should be paid to the propagation of the scillas by commercial dealers, for these bulbs should become one of the features of the wild-garden in early spring.

The *Urginea Scilla*, sometimes called *Scilla maritima*, needs to be mentioned in this connection on account of its yielding a medicine for many centuries held in esteem. Almost everyone is familiar with sirup of squills, and has obtained relief from its use in severe colds. The scales of the bulb contain mucilage, sinistrin, sugar, and crystals of calcium oxalate (stated by botanists to ward off snails); the active principles are scilloperin, scillitoxin, and scillin (the latter producing numbness, vomiting, and the like). Scilla bulbs or roots should never be used unless under proper direction, as in their fresh state they are extremely acrid, and might prove dangerous.

The trade names are considerably confused. Many of the so-called horticultural species and races may be united as mere varieties of species that have been defined botanically. The following names are thought to include all those in the American trade, but other species are known to fanciers.

SCILLA

KEY TO THE SPECIES.

A. Shape of fls. campanulate: color blue, blue-lilac, rose-purple, white.
B. Pedicels short: bracts linear, in pairs: raceme many-fld.; fls. broadly campanulate; produced from April to June. 1. nongrata

2. puschkinioiides

3. hispanica

BBB. Pedicels long (1–1½ in.); scape equilateral, compact; fls. cylindric-campanulate; perianth usually blue but often becoming rose-purple; or white; pedicels 1–1½ in. long. May, Spain and Portugal. B.M. 1102. Gm. 78, p. 456; 79, p. 255.—Durly. Several varieties of it are in the trade under the specific name campanulata, viz., alba, white; albo-majus, large white; cárnea, flesh-colored; hyacinthoides, hyacinth-like; rósea, rose-colored. This species is worthy of wider acquaintance. The bulbs are cheap and easily obtained in autumn, and if planted then they are sure to bloom the following spring.

4. numida, Poir. (S. pareflora, Desf.). Bulb ovoid, 1–2 in. thick; lvs. 4–6, fleshy, herbaceous, linear, 6–8 in. long, 1½–3 lines broad, suberect or paired, ½–1 ft. high; racemes dense, 30–60-fld.; pedicels short, ascending, 3–5 lines long; bracts minute, linear, evanescent; perianth rose-purple, 1½ lines long; single ovule in each of the ovarian cells: caps. small, globose, drooping. Flowering in winter in its native home, Algeria.

5. chinensis, Benth. (Dormidria scilloides, Lindl.). CHINESE SQUILL. Lvs. 2 or 3, equaling or exceeding the scape, rather hard, acute, channeled; bulb small, ovate; scape erect, slender, or wand-like; raceme spicate, dense, elongated; pedicels short; bracts minute, linear, evanescent; perianth rose-purple, 1½ lines long; single ovule in each of the ovarian cells: caps. small, globose, drooping. Flowering in winter in its native home, Algeria.

6. autumnalis, Linn. AUTUMN SQUILL. STARRY HYACINTH. Lvs. 5 or 6, glabrous, ascending, lanceolate, ½–1 in. broad, subobtuse, convex at back: scape long: raceme equilateral, compact: fls. cylindric-campanulate; perianth usually blue but often becoming rose-purple; white; pedicels 1–1½ in. long. May, Spain and Portugal. B.M. 1102. Gm. 78, p. 456; 79, p. 255.—Durly. Several varieties of it are in the trade under the specific name campanulata, viz., alba, white; albo-majus, large white; cárnea, flesh-colored; hyacinthoides, hyacinth-like; rósea, rose-colored. This species is worthy of wider acquaintance. The bulbs are cheap and easily obtained in autumn, and if planted then they are sure to bloom the following spring.

7. peruviana, Linn. (S. cluisii, Hort. S. Clusii, Parl.). CURAN LILY, PERUVIAN JACINTH. HYACINTH OF PERU (once thought to be a Peruvian plant). Fig. 3375. Bulb large, ovate, tunicate: lvs. many, broad-linear, 6–12 in. long; margins ciliate with minute white

3375. Scilla peruviana in full bloom.—Also known as Scilla cluisii. (X34)
bristles, channeled; scape robust, terminated by a many-fld. conic broad and compact raceme of purple, lilac, reddish, or whitish fls.; fls. rotate; corolla persistent; anthers short. May, June. Region of Medit., not Peruv. B.M. 749. Gn. 27, p. 288. R.H. 1882, p. 508. — The hyacinth of Peru is not hardy in Mass. It propagates freely by offsets. It flowers all through May and June and forms a most attractive object in the herbaceous border or bed. S. peruviana, however, has one fault that may tell against it in the opinion of many cultivators — it never flowers two years in succession; it seems to need a whole year's rest after the effort of producing its large spike of fls.

8. monopólia, Link (S. monopólia, Plan. S. pú­nita, Broit.). Dwarf Squill. Lf. solitary, inclosing the base of the scape, 2 in. long, 1/2 in. broad, involute, ovate-acuminate, with a callous apex, glabrous; scape erect, slender, usually 5-20-fld.: pedicels long, ascending, springing from a small sheathing bract; perianth bright lilac, 1/2 in. across, open, spreading; filaments lilac-blue, dilated at base; anthers erect, blue. May. Spain, Portugal. B.M. 3023.—Hardy.

9. bifólia, Linn. Fig. 3376. Bulb tufted, oblong-oval; lvs. 2, seldom 3, curculate, 4-8 in. long, 1/2-1/2 in. broad; scape 2-5-fld., erbracteate; fls. stellately rotate; perianth blue, sometimes reddish or whitish; anthers blue, versatile. March. Eu. Asia Minor. B.M. 746.—Hardy. Several varieties of this exquisite little plant are in the trade: alba, white-fl.; rósea, pink-fl.; rubér-red-fl.; splendens, intense cobalt-blue fls. Cultivators would do well to obtain all the varieties possible; also as many bulbs of this beautiful species as they can afford. It is one of the most charming of hardy, early spring-flowering plants.

10. natalénsis, Planch. Bulb thick, large, ovoid, sub-globose; lvs. broadly lanceolate, glabrous, 9-12 in. long, 3-4 in. broad, ascending; scape erect, teetee, 1-11/2 ft. long; raceme dense, simple, elongated, open, many-fld. (50-100): bracts solitary, subulate; fls. pale blue, stel­late, rotate; pedicels long, pale blue. Natal. B.M. 3379. F.S. 10:1043.—Suitable for greenhouse cult. It is a graceful and elegant species, suitable for cult. in pots.

11. hyacinthoides, Linn. (S. pufúfora, Salisb.). HYACINTH SQUILL. Lvs. 10-12, spreading, 1-11/2 ft. long, 1/2-11/4 in. broad, narrowed at both ends, minute-eruaceous-denticulate on the margins; scape straight, long; racemes many-fl.; broad, open; pedicels long, 1-11/2 in.; bracts whitish, minute, persistent; perianth bluish lilac, open, campanulate. Aug. Medit. region. B.M. 1140.—Hardy. This species is noted for its extreme slyness in flowering. The bulbs are sometimes 2 in. diam., and produce a profusion of offsets. In Fish's Bulb Culture several varieties are mentioned:

12. sibírica, Andr. (S. aména var. præcoz, Don.). Siberian Squill. Fig. 3577. Lvs. 2-4, ascending, narrow, 4-6 in. long; scapes 1-6, 3-8 in. long; racemes 1-3-fld.; fls. rotate, horizontal or drooping, with short pedi­cels; perianth blue deep. March. Russia, Asia Minor. B.M. 1025. Gn. 11, p. 168. P.M. 14:100. L.B.C. 2:151.—Hardy. This plant ought always to have a little shelter. It forms attractive tufts and has a desirable habit for rock-gardens. Several trade forms exist, viz., alba, multifóra, pallidá; amnubla, dwarfer with brighter blue fls.

13. aména, Linn. SPAR HYACINTH. Fig. 3578. Lvs. 4-7, flaccid, ascending, glabrous, 6-9 in. long, 1/4-3/4 in. broad; scapes several, equaling the lvs.; racemes several-fld., 4-8, open; fls. distant, 1/2-3/4 in. diam., blue; pedicels ascending or spreading. March. Austria, Germany. B.M. 341. G. 37:293.—Hardy. It grows luxuriantly, several flowering sts. being found on the same plant.

14. itálica, Linn. ITALIAN SQUILL. Bulbs ovate, clustered together; lvs. radical, several, flaccid, spreading, lanceolate, acute, 4-8 in. long, 1/4-1/2 in. broad; scape solitary, slender, longer than the lvs.; raceme dense, many-fld.; pedicels filiform, spreading; bracts in pairs: fls. fragrant, smelling like lilac, pale blue; perianth rotate, blue; segments, puberulous at apex; filaments white; anthers sagittate, dark blue. March-May. B.M. 663. L.B.C. 15:1483.—Hardy. This plant has less brilliant fls. than either S. sibírica or S. bifólia, but abundantly compensates for the paleness of its blue by the fulness and the sweetness of its fragrance. It is also taller than either of the others.

15. japónica, Baker (Ornithogalum japonicum, Thunb. Barnardia japónica, Schult. l.). JAPANESE JACINTH. Bulb ovoid, 9-12 lines thick; lvs. 2-3, fleshy, herbaceous, 6-12 in. long, 4-16 lines broad, acute; scapes 1-3, strict, erect; raceome 20-60-fld.: pedicels ascending: bracts minute, linear, white; perianth 1 1/2 lines long, rose-purple; caps. turbinate, trisulcate, 3/2-3 lines long; ovules solitary in each ovarian locule. Japan. The dwarf sibírica or S. peruviana, it is also noted for its extreme slyness in flowering. The bulbs are sometimes 2 in. diam., and produce a profusion of offsets. In Fish's Bulb Culture several varieties are mentioned:
Use in aquatic gardens. The nomenclature of those in

ennials (except perhaps the last), suited for shallow

ft. Racemes at the base, 2-3-cleft; fr. an achene with bristles attached.

- Rhapludophora pertusa. Jared G. Smith.

is sometimes kept separately as Cubcuaria marantifolia. Not known in broad: raceme many-flowered: perianth-segments white outside with

spikelets which are solitary, clustered or umbellate; scales spirally arranged; perianth of bristles or none, only a few species are in cult., and these are all perennials (except perhaps the last), suited for shallow water or damp places. The larger are important for

plants inhabiting the whole globe. Flowers perfect, in

clusters, tall and stout, 2-4 ft. high, bluntly triangular: lvs. long, coarse and firm,

3-6 lines wide, spreading: involucere foliaceous: umbel sparingly compound; rays stiff, very unequal; spiklets ovoid-oblong, acutish, dark greenish brown, in dense heads of 5-25; scales oblong, cuspidate; perianth-bristles 6, downwardly barbed above; styles 3. E. U. S. in mud or damp soil.

Holoeschénus, Linn. Stiff and rush-like, from stout rootstocks: sts. clustered, slender, cylindrical, 1-3 ft. high: lvs. 1-2, basal, stiff, erect and narrow, furrowed: bracts several, the larger one appearing as a continuation of the st.; spiklets very numerous and small, closely packed in 1 to several globular, light brown heads, 3-5 lines in diam.; scales ovate, mucronate, ciliate; perianth-bristles none; styles 2-3-cleft. Eu., Asia.—The form in cult is var. variegatus, Hort., with sts. alternately banded with green and yellowish white. Damp or dry soil.

AA. Sts. with very short basal lvs. or none.

b. Rootstocks very stout, creeping: sts. scattered, 3-9 ft. high.

lacinistis, Vahl. Great Bulrush. Sts. terete, smooth, tall, stout, and flexible, 3-9 ft. high: lvs. reduced to a few basal sheaths: bracts very short, erect: umbel compound, flexuous: spikes in heads of 1-5, oblong-conical, pale brown, 2½-8 lines long; scales ovate-oblong, obtuse, rarely mucronate; perianth-bristles 4-6, downwardly barbed throughout; styles 2-3. In shallow quiet water, N. Amer., Eu., Asia.—A composite species probably consisting in Eu. and Amer. of several distinct forms, each of specific rank. Typical S. lacinistis is a 3-style form common in Eu., not found in Amer. S. Tuberosomontanus, Gmel., is a European 2-style form. The horticultural variety of the latter species, with alternate bands of green and yellowish white, is var. zebra, Hort. (Juncus zebra, Hort.). S. collistis, Vahl, and S. occidentalis, Chase, are 2-styled American species. S. heterochéfetus, Chase, is a 3-styled American form. The bulrush is very effective as a border plant in aquatic gardens.

SCILLA (Latin for squill). SQUILL. CYPERACEAE. A large group of rush-like or grass-like plants inhabiting the whole globe. Flowers perfect, in spikes which are solitary, clustered or umbellate; scales spirally arranged; perianth of bristles or none, not enlarged in fr., smooth or barbed, persistent; ovary 1-loculed, with 1 anatropous ovule; style not thickened at the base, 2-3-cleft: fr. an achene with bristles attached. Only a few species are in cult., and these are all perennials (except perhaps the last), suited for shallow water or damp places. The larger are important for use in aquatic gardens. The nomenclature of those in the trade has been very much confused.

a. Sts. leafy.

atróvirens, Muhl. Sts. clustered, tall and stout, 2-4 ft. high, bluntly triangular: lvs. long, coarse and firm,
**SCIRPUS**

*SCIRPUS,* Vahl (S. gracilis, Koch. *Isolépis gracilis*, Hort.). Fig. 3579. Sts. very slender or filiform, cernuous, erect or more often drooping; basal sheaths leafless or with a very short filiform blade; involucral bract subulate, about equaling the spikelet, the latter usually solitary, oblange-lanceolate, 1–3 lines long; scales oblong-ovate, obsolete, pale brown or whitish; bristles none; style 5. Achenes in greenhouse plants rarely maturing. Widely distributed, common in Texas and Mex., G: 21:614; 25:111.—Grows well in damp pots, the drooping stts. producing a very graceful effect. This plant is now considered under *Scirpus* by practically all authors. *S. cernua* is an older name than *S. gracilis.*

**SCLOCÁRAPUS** (Greek, *hard and fruit,* the achenes are inclosed in a hardened pales). Syn., *Gynómpsis,* in part. *Compositae.* Annual or perennial strigosse-pubescent herbs, suitable for outdoor planting in the *S.* sts. branching; lvs. alternate or the lower rarely all opposite, dentate or subartic: heads small or medium, at the ends of the branches, pedunculate, many-fl.: fls. yellow; the ray-fls. few to several, fertile; pappus wanting: achenes more or less 4-sided with a broad flat suture.—About 15 species. N. Amer., region of Texas and Mex., Trop. Afr., and Trop. Asia. *S. wiesneri,* Bentham & Hook. f. (Gynómpsis wiesneri,* Hook. *Gynómolda wiesneri,* Hort.). Annual, 1–2 ft. high, loosely branched; lvs. alternately, slender-petioled, deltoid- or rhombic-ovate, or the uppermost lanceolate, ears dentate, the strigose pubescence of the lower surface canescent; corollas orange. Texas and Mex. R.H. 1853:261. G.C. III. 28:165.

**SCRODOSMA**

*SCRODOSMA.* (Greek, *hard and nut or kernel,* the name of a centipede, the resemblance being found in the lines of linear sori on the backs of the lvs.). *Polyopodiaceae.* The name most common in the trade for the hart’s-tongue ferns (known as *Scolopendrium vulgaris*) and its varieties. See *Phyllitis.*

**SCOLÓMUS** (old Greek name used by Hesiod). *Compositae.* Three or four herbs, all natives of the Mediterranean region. *S. grandiflorus,* a perennial species, is rarely cultivated abroad for its flowers and *S. maculatus,* an annual species, for its variegated foliage.

*Scólymus hispanicus* (Fig. 3580) is the vegetable known as golden thistle or Spanish oyster plant. It makes a root very like salsify, except that it is much lighter colored and considerably longer. Its flavor is less pronounced than that of salsify, but when carefully cooked, it possesses a very agreeable quality which is somewhat intermediate between that of salsify and pursnip. It is adapted to all the methods of cooking employed for those vegetables. The particular value of the Spanish oyster plant, aside from affording a variety in the kitchen-garden, is its large size and productiveness as compared with salsify. The product may be nearly twice as great, for a given area, as for salsify. The seeds are much easier to handle and to sow than those of salsify. They are sown in March or April. The seeds, or rather achenes, are flat and yellowish, surrounded by a white scarious margin. The roots may be dug either in, fall or spring. The greatest fault of the Spanish oyster plant lies in the prickly character of the leaves, which makes the plant uncomfortable to handle. The roots are often 10 to 12 inches long and 1 inch thick. It is said that the leaves and stalks are eaten like cardoons by the people of Salamanca; also that the flowers are used to adulterate saffron. The *S. hispanicus,* Linn., is a biennial plant, native to S. Eu. The radical lvs. are very spiny, oblong, pinnatifid, dark green, marked with pale green spots. The plant grows 2–2½ ft. high, is much branched and bears bright yellow fl.-heads which are sessile and contain only 2 or 3 fls., all of which are ligulate. The heads are sessile, terminal, and axillary.

**SCOPOLIA** (nominated in honor of Joh. Ant. Scopolii, 1725–1788). *Solandraceae.* Erect slightly branched glabrous hardy perennial herbs for outdoor planting: lvs. membranous, entire: fls. lurid purple or greenish, veined, nodding, borne on solitary, glabrous pedicels; calyx broad-campanulate, membranaceous truncate or broadly 5-lobed; corolla campanulate, the limb folded, 5-angled or shortly and broadly 5-lobed; stamens 5; ovary conical, 2-celled almost to the apex: caps. included in the calyx.—About 5 species, of Texas, 1 in Himalaya, and the others in Japan and China. *S. carniolica,* Jacq. (Hyoscymus Scopolii, Linn.). About 1 ft. or more high: lvs. entire, petiolate, about 3 in. long, ovate or obovate-oblong, subcupulate: fls. solitary, axillary, umbellate: corolla lurid red, yellow, or green inside. Russia. B.M. 1126.—Somewhat used in medicine.

**SCORODÓSMA** (*Ferula*; supplementary list.)
**SCORPIUS** (Greek, scorpion and tall, alluding to the twisted form of the legume). *Leguminosae.* Nearly hardy stemless or decumbent herbs, adapted to the open border: lvs. simple, very entire, elongate, twisted and folded; stipules adnate to the petiole: fls. yellow, often few, solitary or umbelliferous, on axillary peduncles, nodding; calyx with the 2 upper lobes connate above; petals long-clawed, the standard suborbiculate, the wings oblique-obovate or oblong, the keel incurved, bearded-acuminat; stamens 4, perfect, didynamous: ovary sessile, many-ovuled: legume subterete, circinate-involute, sulcate-costate, the ribs often tuberculate or muricate, indehiscent.—About 6 species, S. Eu., N. Afr. to the Canary Isls., and W. Asia. Prop. by seed-sown in the open border in the spring. *S. vermiculata,* Linn. A trailing annual: lvs. tapering into the petioles: fls. solitary on the peduncles, the standard streaked with red: pod thick, glabrous, with the inner ribs almost obsolete, but the 10 outer ones bear crowded stipitate tubercles which are obtusely dilated at the apex. Medic. region. See the article *Worms.*

**SCORZONERA** (old French scorzon, serpent; *S. hispanicus* was used against snake-bites). *Compositae.* The vegetable known as scorzonera or black salsify is a plant with a long fleshy tap-root like that of salsify, but differing in having a black skin. The flesh, however, is cultivated and cooked like salsify, but being somewhat more difficult to raise it is rarer than that vegetable, although considered by many to be superior to it in flavor. The leaves may be used for salads. Scorzonera is a perennial plant, but it is treated in cultivation as an annual or biennial crop. Perennial herbs, or rarely annual, floccose, lanate or hisrate: lvs. sometimes entire and grass-like, or wider, sometimes more or less pinnately lobed or dissected: heads long-peduncled, yellow, the fls. all radiate: achenes glabrous or villous.—About 100 species, all natives of the Old World. Cult. same as salsify.

Botanically, also, Scorzonera is closely allied to salsify. The two vegetables are easily distinguished in root, leaf, flower, and seed. The leaves of Scorzonera are broader, the flowers are yellow (those of salsify being violet), and the seeds are white. Also, the involucral bracts of Scorzonera are in many series; of salsify, in one series.

**Scrophulariaceae.** Herbs or subshrubs, glabrous or hirsute, often fetid, sparingly grown in the hardy stemless or decumbent herbs, adapted to the twisted form of the legume. Section

**SCROPHULARIA** (Greek, scrophularia, A reputed remedy for scrofula). *Scrophulariaceae.* Figwort. Herbs or subshrubs, glabrous or hisrate, often fetid, sparingly grown in the herbaceous border.

Leaves opposite or the upper alternate, entire, incised, or dissected: cymes lax, in a terminal simple or somewhat branched thyrsus: fls. small, rarely rather large, greenish purple, purple, lurid or yellow: calyx deeply 4- or 5-cleft or 5-parted; corolla 4- or 5-lobed, short, 4 cleft, the apex one spreading; stamens 4, perfect, didynamous: caps. ovoid or subglobose.—About 150 species, Medit. region, Orient and N. Amer.

**SCUTELLARIA** (Latin, dish: referring to the form of the persistent calyx). *Labiatae.* Skullcap. Annual or perennial herbs, or decumbent or diffuse rarely tall and erect subshrubs or very rarely shrubs, suitable for outdoor planting.

Leaves opposite, frequently dentate, sometimes pinnatifid or entire; the floral lvs. similar or changed into bracts: fls. in opposite 2-fld. floral whorls or in some species a few at the top, sometimes disposed in all or the lower axis, sometimes in terminal racemes or spikes, blue, violet, scarlet, or yellow; calyx campanulate, 2-lipped; corolla-tube long-exserted, limb 2-lipped; stamens 4, ascending, all fertile, the anterior pair longer: nutlets subglobose or depressed.—About 140 species scattered over the world, mostly in the temperate regions and the mountains, a few in Trop. Afr., not known from S. Afr.

**SCUTELLARIA** (Greek, scutellum, shield). *Scutellaria.* Annual or perennial herbs, or decumbent or diffuse rarely tall and erect subshrubs or very rarely shrubs, suitable for outdoor planting.

Leaves opposite, frequently dentate, sometimes pinnatifid or entire; the floral lvs. similar or changed into bracts: fls. in opposite 2-fld. floral whorls or in some species a few at the top, sometimes disposed in all or the lower axis, sometimes in terminal racemes or spikes, blue, violet, scarlet, or yellow; calyx campanulate, 2-lipped; corolla-tube long-exserted, limb 2-lipped; stamens 4, ascending, all fertile, the anterior pair longer: nutlets subglobose or depressed.—About 140 species scattered over the world, mostly in the temperate regions and the mountains, a few in Trop. Afr., not known from S. Afr.

**SCUTELLARIA** (Latin, dish; referring to the form of the persistent calyx). *Labiatae.* Skullcap. Annual or perennial herbs, or decumbent or diffuse rarely tall and erect subshrubs or very rarely shrubs, suitable for outdoor planting.

Leaves opposite, frequently dentate, sometimes pinnatifid or entire; the floral lvs. similar or changed into bracts: fls. in opposite 2-fld. floral whorls or in some species a few at the top, sometimes disposed in all or the lower axis, sometimes in terminal racemes or spikes, blue, violet, scarlet, or yellow; calyx campanulate, 2-lipped; corolla-tube long-exserted, limb 2-lipped; stamens 4, ascending, all fertile, the anterior pair longer: nutlets subglobose or depressed.—About 140 species scattered over the world, mostly in the temperate regions and the mountains, a few in Trop. Afr., not known from S. Afr.

Afr., not known from S. Afr.
SCUTELLARIA

Section II. HETERANTHESIA.

All American species.

Section III. STACHYMACRIS.

A. **S. subsecisile or short-petioled, sub-sect., lanceolate or linear** .... 11. *bicalensis*

AA. **S. petioloed, crenate or serrate, ovate to suborbiculate**.

B. Base of the lvs. narrowed, blades usually ovate-oblong or oblong-lanceolate .... 5. *violeta*

CC. **Margins serrate** .... 9. *montana*

BB. **Base of at least some of the lvs. truncate or cordate** .... 6. *albida*

CC. **Margins entire** .... 10. *brevifolia*

DD. **Floral lvs. sessile or shorter than the calyx** .... 4. *indica*

EE. **Surface of the lvs. villous above and below** .... 5. *violacea*

FF. **Margins of the lvs. entire** .... 7. *pergernina*

DD. **Sts. erect, more than 1 ft. high** .... 6. *albida*

EE. **Surface of the lvs. hispidulous above, lvs. ovate** .... 5. *violacea*

FF. **Margins of the lvs. entire** .... 7. *pergernina*

GG. **Floral lvs. petiolate, equaling or exceeding the calyx** .... 8. *albida*

5. *violacea*, Heyne. Herb, 6-12 in. high: st. erect or ascending, pubescent: lvs. petioloed, crenate-ovate, 1-3 in. long, serrate, pubescent or glabrous beneath: racemes 4-5 in. long, lvs. subsimple: fls. opposite, secund; calyx pubescent; corolla bluish, white or violet. India and Ceylon. B.M. 8260. G.W. 14, p. 620.

6. **albida**, Linn. St. erect, branched: lvs. petioloed, ovate or ovate-lanceolate, crenate, base broad-cordate, scarcely rugose: racemes elongated, somewhat branched, villous: fls. opposite, secund; calyx villos; corolla creamy white. 4 times as long as the calyx. S. E. Eu. and Caucasus.

7. *pergernina*, Linn. Sts. procumbent: branches elongated, glabrous or pubescent near the ends: lvs. petioloed, ovate, obtuse, crenate, base rotund-truncate, pubescent:

---

Section IV. GALERICULARIA.

A. **Fls. red, bright in axillary and terminal racemes** .... 13. *mociniana*

AA. **Fls. yellow** .... 12. *angustifolia*

BB. **Infl. composed of axillary racemes** .... 10. *brevifolia*

CC. **Margins of the lvs. entire** .... 11. *bicalensis*

DD. **Margins of the lvs. entire** .... 12. *angustifolia*

EE. **Margins of the lvs. entire** .... 11. *bicalensis*

FF. **Margins of the lvs. entire** .... 12. *angustifolia*

GG. **Margins of the lvs. entire** .... 13. *galericulata*

8. *brevifolia*, Gray. A half-hardy, compact perennial, ½-1 ft. high: lvs. ovate or oblong-ovate, coarsely and sharply serrate, lowest subcordate, upper acute at both ends, petioloed: raceme simple, few-fld.: fls. opposite; corolla large, 1½-1½ in. long, blue. Mountains of Ga.

9. *brevifolia*, Gray. A half-hardy, compact perennial, ½-1 ft. high: lvs. ovate or oblong-ovate, coarsely and sharply serrate, lowest subcordate, upper acute at both ends, petioloed: raceme simple, few-fld.: fls. opposite; corolla large, 1½-1½ in. long, blue. Blooming season long; summer. Dry limestone banks, Texas.

Subsection ANGIUSTIFOLIA.

Section V. GALERICULARIA.

A. **Fls. red, irregularly arranged in axillary and terminal racemes** .... 18. *mociniana*

AA. **Fls. yellow** .... 17. *brevifolia*

BB. **Infl. composed of terminal or axillary fls.** .... 16. *angustifolia*

CC. **Margins of the lvs. entire** .... 15. *bicalensis*

DD. **Margins of the lvs. entire** .... 14. *brevifolia*

EE. **Margins of the lvs. entire** .... 13. *galericulata*

FF. **Margins of the lvs. entire** .... 12. *angustifolia*

GG. **Margins of the lvs. entire** .... 11. *bicalensis*

12. *angustifolia*, Pursh. A hardy perennial, about 6 in. high, with lvs. ½-1 in. long, narrowed at the base, and violet-blue fls. ½-1 in. long, with the corolla-tube slender. Moist ground, N. W. U. S.

15. *brittonii*, Porter. C glandular- or viscid-pubescent, branching from the base, 4-8 in. high: lvs. oblong or oval, sessile and entire or the lowest short-petioled and slightly crenulate: fls. solitary in the axis; corolla blue
SCUTELLARIA

(pale blue and white according to some). Wyo. and Colo., and probably W. Neb. B.B. (ed. 2) 3:108.—Allied to S. resupinata.

16. antirrhinoideae, Bentham. Resembles the larger-leaved forms of S. angustifolia, but has longer petals and the flowers oblong at base and also shorter and broader fls. 7-10 lines long. Shady ground, N. W. U. S.

Subsection Lasiophloae.

17. lateriflora, Linn. A hardy perennial, increasing by slender stolons, 1-2 ft. high; lvs. ovate to lanceolate, 1-3 in. long; racemes axillary or terminal, narrow, leafy bracted; fls. blue to nearly white. Moist soil throughout the U. S. B.B. (ed. 2) 3:100.

Subsection Pteridioideae.

G.W. 11, p. 127. G.Z. 13:2.—According to Gn. 10, p. 606, the plants are of easy cult. with warm greenhouse treatment and may be grown as bush specimens or in hanging pots with a single st., when they will flower at about 1 ft. in height. Cuttings are easily rooted.

S. nuwantiaca, Hort., is offered in the trade.—S. pulchella, Hort., not Bunge, belongs to Section III and is closely related to S. nuwantiaca var. japonica, but the plant has more slender twigs, somewhat smaller lvs. which are short sub-hairy on the upper surface and a lower raceme with somewhat darker blue fls. Hab. (?). Qt. 6:296.—S. splendens, Link, Klotzsch & Otto, belongs to Section II and has broader, obtuse or scarcely acuminate, create lvs., with the base cordate and both surfaces hirsute; raceme elongate; fls. sparse; corolla scarlet. Mex. B.M. 4290 (as S. cordifolia).

F. TRACY HUBBARD

SCUTICÂRIA (Latin, scutico, lash or whip). Orchidaceae. Orchids remarkable for their long whip-like leaves, which are channeled on one side.

No evident pseudobulbs formed, but each shoot terminating in a long, pendulous fl.: lvs. rather crowded on the short rhizome: fls. solitary or several, on short peduncles, in structure fls. resembling Maxillaria, but the plants are easily distinguished by the terete lvs.; sepals and petals similar, the lateral ones forming a mentum; labellum movable, 3-lobed, with large, erect, lateral lobes; pollinia on a transversely elongated stipe.—Two species from S. Amer.

These plants require a temperature similar to cattleya and laelia, but should be grown on blocks or in shallow baskets in a mixture of equal parts peat fiber and sphagnum. S. Steélii does best on a block, as the plant grows downward in an inverted position. The compost should be kept moist, particularly while the plants are in action. They are propagated by division. (R. M. Grey.)

Steélii, Lindl. Fig. 3581. Lvs. attain a length of 4 ft. as thick as a goose-quill; fls. on short scape; sepals and petals oblong, connivent, pale yellow, with chocolate blotches; labellum large, cream-colored, striped with brownish purple, at all seasons. British Guiana. B.M. 3573. B.R. 1886 (both as Maxillaria Steélii).

3581. Scuticaria Steélii.

Hádwenii, Flanch. Lvs. 1 1/2 ft. long; fls. with spreading sepals and petals oblong, sharply acuminate, yellowish green, blotched with brown; labellum obovate-ovulate, white with flesh-colored spots. Brazil. B.B. 4629. F.S. 7:731 (both as Bifrenaria Hadwesi). G.M. 41:558.

HEINRICH HASSELBERG.

SCYPHÁNTHUS (Greek, beaker and flower, alluding to the shape of the flower). Sympodium, Lobeliaceae. Climbing plants, half-hardy annual herbs for outdoor border planting: lvs. opposite, 2-3-pinnatisect: fls. axillary, sessile, yellow, calyx-tube linear-elongate, lobes 5, spreading, linear-spatulate; petals 5, acute, alternate, which are hooded, 3-lobed at the base have 2 cali; stamina very many, in 5 fascicles opposite the petals, staminodia 10, in pairs opposite the scales; ovary elongated, 1-celled: caps. linear, upright, longitudinally 3-valved.—One or 2 species, Chile.

elegans, Don (Grammaticopus volubilis, Freyn). Sta. herbaceous, climbing and twining, frequently branched; lvs. opposite, rough with minute deflexed hairs, the lower ones bipinnatisect, the upper ones smaller and only pinnatifid, all the segms. oblong, 1-2-nerved; petiole short, channeled; fls. really sessile but appearing peduncled from the elongated inferior ovary, terminal or axillary, yellow, calyx-tube very long and incorporated with the ovary, limb of 5 spreading, spathulate, leafy segms.; petals 5, forming a cup, obtuso-ovate, deeply succate below the middle. B.M. 5028. J.H. III. 44:272.

F. TRACY HUBBARD

SEAFORTHIA (Francis Lord Seaforth, patron of botany). Palmaceae. A genus of palms, founded by Robert Brown on an Australian species, usually considered as synonymous with Ptychosperma. The Seaforthia elegans of cultivation, however, is said to be Archontophoenix, mostly A. Cunninghamii and perhaps some of it A. Alexandri; the original species described by Brown as S. elegans becomes Ptychosperma elegans, Blume.

According to Dammer (G.C. III. 31, pp. 18-20) the true Ptychosperma elegans of Blume is met with but rarely in European gardens. What is cultivated under this name in most cases is either Archontophoenix Cunninghamii or A. Alexandri. These archontophoenixes "are decorative hardy palms, forming on the Riviera very fine high-stemmed specimens. In youth they form bold leaves, the blade almost leafy. After having made some four to six such leaves, each larger than the foregoing, there appears a fully pinnate leaf, much differing in mode of growth from Phoenix and all other pinnatisect-ovate palms." S. elegans, Hort., and Ptychosperma elegans, Hort., are apparently sometimes Archontophoenix Cunninghamii and sometimes A. Alexandri. The last is very like A. Cunninghamii, but, according to Dammer, differs in its segments, which are green only above while underneath they are ashy-glaucous or white; it is well figured in G.C. III. 31:19; also in B.M. 4961 as Seaforthia elegans, Blume (Seaforthia elegans, R. Br., not Hort.), with pinnules erosive rather than acuminate at apex, is figured in G.C. III. 31:21.

In a recent study, O. F. Cook separates the plant grown in California under the name of Seaforthia elegans into a new genus, Lorosaria, making the species L. amethystina; probably from Australia. He also retains the genus Seaforthia for S. elegans, R. Br.

SEA-KALE (Crambe maritima, Linn.) is a large-leaved, strong cruciferous perennial, the young shoots of which are eaten in the spring, usually after having been blanched. The plant is little known in North America, but it is worthy of general cultivation in the home-garden, for it supplies an esculent of good quality.
at a season when vegetables are scarce. Sea-kale demands a deep rich and rather moist soil, in order to give the best results and to maintain its vigor for a series of years. The plants are grown about as much as rhubarb; that is, they should stand from 3 to 4 feet apart each way. The culture and general requirements are much the same as for rhubarb. The young shoots are blanched as they grow, in early spring. The blanching is accomplished by heaping fine loose earth over the crown of the plant, into which the shoots grow, or by covering the plant with an inverted box or flower-pot so that the light is excluded from the growing shoots. These shoots are eaten before the leaves have begun to expand to any extent, whilst crisp and tender. The vegetable is prepared as is asparagus.

Sea-kale is propagated by root-cuttings, and also by seeds. Quicker results are secured from cuttings. If strong cuttings, 4 or 5 inches long, are taken in early spring and grown in good and rather moist soil, the plants may be strong enough for cutting the following spring; but it is usually better not to cut them until two years from starting. The cuttings may be placed where the plants are to stand permanently, or they may be grown in drills in a seed-bed. The latter plan is usually to be preferred, since it allows the plants to receive better care. Seeds give plants that are strong enough for cutting about the third year. The seeds are really fruits or pods, and each fruit may produce two or three plants. Usually the fruits are sown without shelling. The seedlings are raised in the seed-bed and transplanted when one year old to permanent quarters. On good soil, plants of sea-kale should maintain their vigor for five to eight years after they have come to cutting age. As soon as they begin to show signs of decline, new plants should be propagated. Although the plant is hardy in the northern states, it is always benefited by a liberal dressing of litter or manure in the fall. Plants may be forced in hotbeds or under the greenhouse benches, as recommended for rhubarb. Sea-kale has large glaucous cabbage-like leaves which make it a striking plant for ornament early in the season. It also throws up a strong cluster bearing many rather showy white flowers. However, the plant is rarely propagated for its ornamental value. For botanical description, see Vol. II, p. 873. L. H. B.

3582. Fruit of Secchiun edulis. (X 5/9)

Sea-kale demands a deep rich and rather moist soil, in order to give the best results and to maintain its vigor for a series of years. The plants are grown about as much as rhubarb; that is, they should stand from 3 to 4 feet apart each way. The culture and general requirements are much the same as for rhubarb. The young shoots are blanched as they grow, in early spring. The blanching is accomplished by heaping fine loose earth over the crown of the plant, into which the shoots grow, or by covering the plant with an inverted box or flower-pot so that the light is excluded from the growing shoots. These shoots are eaten before the leaves have begun to expand to any extent, whilst crisp and tender. The vegetable is prepared as is asparagus.

As soon as they begin to show signs of decline, new plants should be propagated. Although the plant is hardy in the northern states, it is always benefited by a liberal dressing of litter or manure in the fall. Plants may be forced in hotbeds or under the greenhouse benches, as recommended for rhubarb. Sea-kale has large glaucous cabbage-like leaves which make it a striking plant for ornament early in the season. It also throws up a strong cluster bearing many rather showy white flowers. However, the plant is rarely propagated for its ornamental value. For botanical description, see Vol. II, p. 873. L. H. B.

SEA-LAVENDER: Statices. S.-aion. Urpinia marinaria; also applied to Ornithogalom camusum and Setha serna. S. pink: Armeria.

SEBASTIANIA (from Antonio Sebastiani, a writer on Roman plants 100 years ago). Euphorbiaceae. Tropical shrubs scarcely in cult.: juice milky: lvs. alternate, small, usually entire: inf. usually terminal: lvs. of 2-3 sepals free or connate at the base, imbricate; stamens 1-5; ovules in each cell of the ovary; seed carunculate. About 75 very variable species, all tropical except S. hpiastrih, Muell. Arg. in swamps from the northern United States until the plants are cut down by frost. Plants should be 8 to 10 feet apart, and trained on an arbor or trellis. In

SECHIUM (probably from the Greek seko, "to fatten in a fold," because it was fed to hogs). Cucurbitaceae. A climbing sparsely hairy herb, with perennial tuberous roots, grown in tropical and subtropical regions for its large fruits, which somewhat resemble the summer squash in use and character.

Leaves membranaceous, 3-angled or oblong, cordate at the base; tendrils 2-5-branched, opposite the lvs.: fls. small, monoeious, axillary, the pistillate solitary, the staminate in small clusters; calyx-tube saucer-shaped, the limb 5-lobed; corolla rotate, deeply 5-parted, the segms. ovate-lanceolate; filaments and styles connate into a central column, of which the anthers appear as lobes, while the stigmas are closely set together, forming a small head; fr. pear-shaped or globose, fleshy, 1-seeded.—One species, indigenous in Mex. and Cent. Amer. and widely planted.

edible, Swartz (Chayota edulis, Jacq.). CHAYOTE. CHAYOTLI. CHOCHOTTES. CHOCHO, CHUCHE, or CHUCO. CHOKRO. CHAIOTA. CHUKI, CHUX. CUCURBITACEAE. PITTENILLA. Fig. 3582. Sta. herbaceous, annual, sometimes making a growth of 50 ft. in one season, if the

plant is grown on rich well-drained ground: large tuberous roots are formed the second season: lvs. 4-6 in. long, resembling those of the cucumber, deep green, somewhat rough, scarcely hairy; corolla greenish or cream-colored: fr. 3-8 in. long; seed single, flat, 1-2 in. long, attached at the upper end of the cavity. G.C. 1865: 61; III. 24:476; 28:450. The chayote is grown successfully in southern California and about New Orleans, where it is fairly common. In Florida it is not yet common, but its culture is being extended rapidly. It can probably be grown successfully in those parts of the South where the ground does not freeze in winter. The fruit is round to pear-shaped, smooth or corrugated, the surface sometimes covered with small soft spines. The color varies from nearly white to dark green, the flesh being firm, crisp, and more delicately flavored than the squash. The cooked fruit can be creamed, baked, or made into fritters, sauces, tarts, puddings, salads, or used like potatoes with other meats and vegetables. The young spring shoots, tender branches, and tuberous roots form palatable dishes, while the woody stems furnish a fine fiber, known in French by the name as "paille de chouchou." The fruits, vines, and tubers are excellent fodder for stock.

The entire fruit is planted in early spring, and the vine should come into fruit after the rainy season, remaining in fruit (in the southern United States) until the plant is cut down by frost. Plants should be 8 to 10 feet apart, and trained on an arbor or trellis. In
Florida and the Carolinas, a vine may yield fifty to one hundred or more fruits in a season. The fruit can be easily collected and stored for four to two months at moderate temperatures. In tropical and subtropical regions there are numerous varieties, differing somewhat in flavor and value.

Nathan Menderson.

Securinée (Latin, secund, hatchet, and negare, to refuse, alluding to the hard wood). Euphorbiaceae. Shrubs sometimes grown for the bright green foliage.

Deciduous: lvs. alternate, short-petioled, entire, stipulate: fls. dioecious or monoeccious, apetalous, axillary, the pistilate solitary or few, the staminate in fascicles; sepals 5; stamens usually 5, with a 5-lobed disk at the base; pistillate fls. with entire disk; ovary 3-lobed, or 3-2 lobed styles: fr. a 3-lobed dehiscent capsule, 3-6-seeded.—About 10 species in temperate and sub-tropical regions of S. and C. Amer., Asia, Alt., and S. Eu.

The species in cultivation are bushy round shrubs with slender wand-like branches, rather small bright green foliage, inconspicuous greenish white flowers in axillary clusters or solitary and with small subglobose greenish capsules. They have proved fairly hardy at the Arnold Arboretum, usually only the tips of the young branches being winter-killed, and do not seem particular as to the soil. Propagation is by seeds which are usually freely produced when the two sexes are present, and by greenwood cuttings under glass. Seeds can be shipped, and stored for two to four months at moderate temperatures but at least 50 to 100 seeds are required. This genus is a favorite for window-sills, balconies, and house-tops, especially in crowded cities.

Sedums are also general favorites in all forms of rock-gardening. They are much used for carpet-bedding, especially the kinds with mealy or glaucous foliage, and those with various metallic shades of purple. In the hardy border, these greenwood cuttings, like S. maximum and S. spectabile, are preferred, though many of the lower-growing kinds are suitable for edgings and any of the evergreen kinds are welcome in winter when the hardy border shows other brown or dead signs of life. As a rule, sedums like the sun, but a few of the species may help to solve the difficult problem of carpeting the ground underneath the trees where the soil is dry and shaded. Sedums are also favorites for baskets and vases, especially the kinds with mealy or glaucous foliage and minute leaves. For greenhouse decoration, S. spectabile is the favorite, as it is perhaps the showiest of the genus. It may be had in flower at any season of the year and, as a horticultural point of view, by M. T. Masters in Gardener's Chronicle for 1878. Masters' descriptions and treatment have been partially followed in the present revision. The variability of the fls. is very noticeable both in thickness and breadth, some being thick and terete, others flat and thin, though all of them tending toward fleshy. Some are quite linear and from that they range to nearly 1½ in. broad. The margin is also variable from entire to deeply dentate. The synonymy of the species is very uncertain; and in some groups, especially the Telephium group, the specific delimitation is very uncertain; in fact the whole genus needs monographic study. The present key is an attempt to differentiate the more prominent forms as they occur in horticulture and is based in part on horticultural and in part on herbarium specimens. It is unfortunately not altogether satisfactory but may prove of some value in separating the species.

Sedums are of the family Crassulaceae. As a rule, they prefer sandy soil, and are very averse to a wet position in winter. Some are useful plants for carpeting poor and sandy waste places where few other things will grow. The little-yellow-flowered plant with pulpy foliage that spreads in nearly every cemetery is Sedum acre. Sedums are also general favorites in all forms of rock-gardening. They are much used for carpet-bedding, especially the kinds with mealy or glaucous foliage, and those with various metallic shades of purple. In the hardy border, these greenwood cuttings, like S. maximum and S. spectabile, are preferred, though many of the lower-growing kinds are suitable for edgings and any of the evergreen kinds are welcome in winter when the hardy border shows other brown or dead signs of life. As a rule, sedums like the sun, but a few of the species may help to solve the difficult problem of carpeting the ground underneath the trees where the soil is dry and shaded. Sedums are also favorites for baskets and vases, especially the kinds with mealy or glaucous foliage and minute leaves. For greenhouse decoration, S. spectabile is the favorite, as it is perhaps the showiest of the genus. It may be had in flower at any season of the year and, as a horticultural point of view, by M. T. Masters in Gardener's Chronicle for 1878. Masters' descriptions and treatment have been partially followed in the present revision. The variability of the fls. is very noticeable both in thickness and breadth, some being thick and terete, others flat and thin, though all of them tending toward fleshy. Some are quite linear and from that they range to nearly 1½ in. broad. The margin is also variable from entire to deeply dentate. The synonymy of the species is very uncertain; and in some groups, especially the Telephium group, the specific delimitation is very uncertain; in fact the whole genus needs monographic study. The present key is an attempt to differentiate the more prominent forms as they occur in horticulture and is based in part on horticultural and in part on herbarium specimens. It is unfortunately not altogether satisfactory but may prove of some value in separating the species.

Sedum is a genus of succulent herbs, rarely shrubby, mostly hardy and perennial, useful for rockeries and one species, S. spectabile, a frequent showy border plant. See Succulentia, Vol. V, page 2072. Plants glabrous or glandular-pubescent, fleshy, erect or decumbent, sometimes cespitose or moss-like: lvs. very variable, opposite, alternate or whorled, entire or serrate: fls. cynone in a few axils and solitary, white, yellow, or rose, rarely rose. Herbs from a basal rosette of lvs. and dying to base after flowering: st.-lvs. alternate, mostly broad, fleshy: fls. dimcious or monccious, apetalous, axillary, solitary: petals 4-5-carpelled: fr. a 5-lobed dehiscent capsule, 5-6-seeded.—About 250 species, mostly natives of the temperate and cold regions of the northern hemisphere. The hardy sedums are monographed, from a horticultural point of view, by M. T. Masters in Gardener's Chronicle for 1878. Masters' descriptions and treatment have been partially followed in the present revision. The variability of the fls. is very noticeable both in thickness and breadth, some being thick and terete, others flat and thin, though all of them tending toward fleshy. KEY TO THE SPECIES.

A. Lvs. terete or subterete (that is, relatively thick as compared to breadth).
B. Fls. yellow (except a white-flowered variety of No. 1).

C. Lf.-blades broad as compared to length.

D. Petals without a dorsal awn.
E. Petals lanceolate.
F. Lvs. flat (that is, relatively thin as compared to breadth).

CC. Lf.-blades narrow as compared to length (usually linear).

D. Apex of lvs. blunt.
E. The lvs. papillose-pilose.
F. The lvs. pubescent or puberulent.

DD. Apex of lvs. acute or acuminate.
EE. Base of lvs. membranaceous and dilated, abruptly tapered to a much narrower upper part.
EE. Base of lvs. not distinctly dilated, not abruptly tapered to a much narrower upper part.

FF. Petals acute or acuminate.
GG. Sepals subulate.
HH. Lfs. round or reniform.

GG. Sepals obovate-lanceolate.
HH. Lfs. round or reniform.

GG. Sepals obovate.
HH. Lfs. round or reniform.

GG. Sepals ovate.
HH. Lfs. round or reniform.

GG. Sepals linear to lanceolate.
HH. Lfs. round or reniform.

GG. Sepals obtuse.
HH. Lfs. round or reniform.

GG. Sepals acuminate.
HH. Lfs. round or reniform.

GG. Sepals subulate.
HH. Lfs. round or reniform.

GG. Sepals linear.
HH. Lfs. round or reniform.

GG. Sepals subulate.
HH. Lfs. round or reniform.

GG. Sepals ovate-lanceolate.
HH. Lfs. round or reniform.

GG. Sepals obovate-lanceolate.

HH. Lfs. round or reniform.
SEDUM

1. acre, Linn. (S. neglectum, Ten.). Stonecrop. Wall Pepper. Love Ectangle. Fig. 3583. Perennial, glabrous, cespitose: branches creeping, branched, about 2 in. long; fl.-sts. 2–3 in. high; Ivs. minute, about \( \frac{1}{2} \) in. long, fleshy, ovate, crowded, glistening at base, sessile; fls. yellow, about \( \frac{1}{2} \) in. across, in 1-sided cymes, which have 2–5 forks; sepal\. lvs.-like; petals lanceolate. Eu., N. Afr., E. Asia, and naturalized in N. Amer. Gn. 27, p. 316 —This is the commonest native species in England and one of the commonest in cult. Thrives best in poor soil and is a good ledge-plant and is frequently used for covering rather arid spots which would otherwise be bare. The lvs. have an acrid taste. Var. album, Hort., is a white-fld. form. Var. aureum, Mast., has the lvs. and shoot-tips bright golden yellow in spring. The yellow tint is lost later in the summer, but the variety is never so robust as the green form. Excellent for spring bedding, to give a bit of color. Var. elegans, Mast., has the tips and young lvs. pale silvery. More delicate than var. aureum and not so effective. Var. hawaiiunum, Hort., is offered in the trade. Var. maurus, Mast., is larger and more robust than the type: lvs. in 7 rows, deltoid-ovoid, scarcely auricled at base: fls. \( \frac{3}{4} \) in. across, in a 2-parted cyme, with a central sessile fl; sepal\. linear-oblong. Morocco. Var. Maivehana, Hort., is said by the trade to be the same as var. hawaiiunum. Var. sexangulare, Hort., is offered in the trade; it probably is S. sexangulare.

2. Stbhillii, Solms. Perennial, trailing, much branched, puberulent: sts. green or pinkish; fl.-sts. 4–6 in. high: lvs. opposite or nearly so, sessile, nearly round in cross-section, ovoid or ellipsoid, \( \frac{1}{2} \)–\( \frac{3}{4} \) in. long; fls. yellow, 7–9 lines across, in few-branched terminal cymes, the branches of which are recurved; sepal\. puberulent, linear-oblong; petals lanceolate, with a short dorsal awn just below the apex. Mex.

3. multitipes, Coss. & Dur. Perennial, about 2–6 in. high, base subshubby, much branched: barren shoots flexuous or erect, bearing dense rosettes of lvs. at their tips; fl.-sts. usually taller, erect: lvs. \( \frac{3}{4} \)–\( \frac{4}{5} \) in. long, glaucous or pruinose, pinkish and papillos. linear or oblongate, subterete: fls. pale yellow, about \( \frac{3}{4} \) in. across, 5-merous, in many-branched, 2–6-fld., scorpion cymes; sepal\. linear-oblong; petals oblong-lanceolate; others pale yellow. Algeria. G.C. II. 10:717.

4. sexangulare, Linn. (S. acre var. sexangulare, Godr. S. boloniimse, Lois. S. forsteriunum, Reichb., not Smith. S. pulchellum, Hort., not Michx.). Perennial, glabrous: barren shoots ascending 2–3 in., branched; fl.-sts. 2–3 in. high, very slender: lvs. densely crowded in 6–7 rows, about 2 lines long, linear-cylindrical, slightly gibbous at base: fls. yellow, \( \frac{3}{5} \) in. across, in a 3–5-branched umbellate cyme, 1–3 in. diam.; sepal\. linear-oblong; petals lanceolate. Eu. The Linnean material properly differs very little from this, else the horticultural material (especially the European) may be distinct.

5. tenuifolium, Strobl. (S. amplexicaule, DC. Spermervum tenuifolium, Sibth. & Smith). Perennial, glabrous, evergreen: barren branches 2–4 in. long, slender, wing, ascending; fl.-sts. decumbent, ascending, about 6–9 in. high: lvs. of the barren shoots dilated and membranous at base, gradually tapering to a long awl-like point; of the fl.-sts. alternate, sessile, \( \frac{3}{4} \) in. long, terete, with a membranous auricle at base: fls. numerous, golden yellow, secund in 2-forked cymes, with a sessile fl. in the fork; sepal\. ovate, oblong, acute, united below into a cup-shaped tube; petals oblong-lanceolate, \( \frac{3}{4} \) in. long, keeled; filaments greenish, anthers yellow. Mediterr. region.—There are often 6–10 petals in this species.

6. stenopetalum, Pursh. Perennial, tufted, glabrous: sts. 3–6 in. high, erect from a decumbent base: lvs. crowded on the barren shoots, sessile, linear or lanceolate, \( \frac{3}{4} \) in. long, terete: fls. bright yellow, in much-branched scorpion cymes; sepal\. subulate; petals linear-lanceolate, acuminate. Alberta to S. D., Neb., New Mex., and Calif.

7. sarmentosum, Bunge. Perennial, glabrous: shoots slender and prostrate: lvs. crowded, opposite or whorled, \( \frac{3}{4} \)–\( \frac{3}{5} \) in. linear, terete or slightly flattened: fls. bright yellow, \( \frac{3}{4} \) in. across, numerous, in a flat-topped, umbellate, 3–5-forked cyme, with a solitary fl. in the forks: branches recurved, the fls. on the upper surface only,
Sedum

**3583. Stonescrop, or wall pepper. — Sedum acre.**

but it has been referred to *S. rupestre* and also to *S. graminatum*, a species which does not seem to be in cult. and it has also been treated as a variety of both these species. Var. _glanduliferum_, Hort., is offered in the trade.

9. _rupéstre_, Linn. Perennial, glaucous, reddening with age and drought: barren shoots numerous, creeping, 1–3 in. long; fl.-sts. ascending or erect, 6–12 in. high: lvs. ½ in. long, in numerous rows, linear, subulate, incurved, flattened above, forming dense conical rosettes which are ¾–1 in. diam., at the ends of the sterile shoots: fls. numerous, yellow, barely ½ in. across, 5–7-merous, in umbellate, 3–5-forked, ultimate hollow-topped cymes; sepals ovate, oblong; petals ovate, oblong; anthers yellow. W. Eu. Closely allied to and confused with _S. reflexum_. Var. _spirale_, Hort., is offered in the trade.

10. _reflexum_, Linn. (S. collinum, Willd.). Perennial, glabrous; fls. trailing; fl.-sts. erect, 8–10 in. high: lvs. in 6 or 7 rows, crowded on the barren shoots into a conical mass, but not forming so marked a rosette as in typical _S. rupestre_, ½–3 in. long, linear-subulate, reflexed, terete, gibbous at base: fls. 4–8-merous, yellow, ½ in. across, in a decurved, many-fld. umbellate cyme which is many-branched, with a fl. in each fork; sepals oblong-lanceolate; petals linear; anthers yellow. Eu. Also escaped in N. E. N. Amer. Var. _albescens_, Mast. (S. albescens, Haw. _S. glaucum_, Smith), is glaucous: lvs. rarely in rosettes: fls. ½ in. across, 6-merous. Eu. and N. Afr. Var. _crisatulum_, Mast. (S. montanum, Hort. _S. robustum_, Hort.), has the sts. fasciated so as to form a crest like a cock’s comb. Var. _viridescens_, Mast. (S. viridescens, Willd.), is similar to var. _albescens_, but has pale sulfur-yellow fls.—This species and its varieties are treated by some authorities as a part of _S. rupestre._

11. _anglicum_, Huds. Perennial, about 3 in. high, glabrous, evergreen: barren shoots trailing or erect, forming dense masses; fl.-sts. about 2 in. high: lvs. crowded, alternate, on the fl.-sts. somewhat opposite and less crowded, ½–¾ in. long, ovate or ovate-lanceolate, green, becoming red-tinted: fls. white or rosy tinted, about ½ in. across, in few-fld. dichotomous cymes; sepals ovate; petals lanceolate; anthers red, becoming black. W. Eu. _Gn. 79_, p. 366.—A good plant for the rockery, though rather difficult to grow.

12. _carnéum_, Linn.; also spelled _carréum_ (S. carnérne, Desf.). Fig. 3584. Annual, glabrous, or pilose in the inf.: flts. 2–3 in. high, branched from the base: lvs. tufted, ½ in. long, oblong, obtuse, pale green, spotted with red: fls. pale blue to rose-lilac, ¼ in. across, 5–7-merous, in a lax, many-fld. cyme, which is 1 in. diam.; sepal oblong; petals oblong; anthers reddish brown. Medit. region. B.M. 2224. B.R. 520. _Gn. 27_, p. 315.—Said to thrive in a sandy soil, and to be adapted to carpet-bedding.

13. _brevifíllum_, DC. Perennial, said to grow about 4 in. high, glaucous, tufted lvs. crowded in 4–6 rows, deciduous, ½ x ¼ in., oblong, very obtuse: fls. white or flesh-color, nearly sessile, ½ in. across, crowded in a 2–3-parted cyme, 5–7-merous; calyx-tube very short, segments linear-oblong, pink-tipped; petals lanceolate, acute, keeled; anthers purplish brown. Madeira.—Masters says that most of the material under this name is really _S. album._

14. _farinosum_, Lowe. Perennial, glaucously pruinose, glabrous: sts. tufted, creeping, much branched: lvs. crowded in 4–6 rows, deciduous, ½ × ¼ in., oblong, very obtuse: fls. white or flesh-color, nearly sessile, ½ in. across, in a decurved, many-fld. cyme, which is about 1 in. diam.; sepal oblong-lanceolate, white, with a pink midrib; petals oblong, with a pink midrib; anthers purple. France and Medit. region. —Closely related to _S. dasyphyllum_ of which some authorities have made it a variety. Rather tender and sensitive to root-moisture. _Var. album_, Hort., is said to have bronzy lvs. and to grow 6 in. high. _Var. Pottsiï_, Hort., is offered in the trade as a form with tiny round lvs., covered with white meal.

15. _dasyphyllum_, Linn. (S. glaucum, Lam.), 4. Perennial, about 2–4 in. high, glabrous: sts. tufted, slender, branching: lvs. crowded, sessile, spreading, oblong-acute or suborbicular, thick, studded with crystalline pimpls: fls. white to pinkish, about ½ in. across, in lax, few-fld., corymbose cymes; sepals oblong; petals lanceolate; anthers yellow. Eu. and N. Afr. —The material cult. under the name of _S. glaucum_ probably belongs here; see also _S. rupestre_ and _S. hispanicum_. Var. _glanduliferum_, Mars (S. cönicum, Duby), has minute gray-green lvs. which are more or less densely glandular-pubescent: fls. white. Corseca and N. Afr. B.M. 6027. There is a form of this offered in the trade under the name of _S. cönicum_ var. _grandiflorum_, Hort.

16. _potosinum_, Rose. Sts. low and weak, at first erect, but soon prostrate or at most ascending; fl.-sts. 2–4 in. high, slender: lvs. crowded, rhomboid-subspHERICAL, nearly terete, ½–½ in. long, obtuse, pale green, glabrous, papillose (?), slightly glaucous: fls. white or tinged pink, terminal and few; sepals linear; petals lanceolate, acuminate, widely spreading. Mex.—A rare species.
17. *pilosum*, Bieb. (S. *Reptili*, Hort., not Kuntze). Fig. 3385. Biennial, 2-3 in. high, glabrous-pubescent: st. leafy; lvs. \( \frac{3}{4} \)-\( \frac{3}{4} \) in. long, oblong or oblanceolate-oblong; radical densely rosulate; cauline alternate, rather close together: fls. rose-pink, clustered in a corymbose cyme, \( \frac{3}{4} \)-\( \frac{1}{2} \) in. diam.; calyx-sepals oblong; petals elliptic-lanceolate, narrowed to a broad claw; anthers reddish. Asia Minor. G. 37:25.—A good plant for rockeries. Some of the material grown in gardens as *S. pulchellum* and *A. anglicum* are really this species. Var. *album*, Hort., was offered in the trade. Var. *roseum*, Hort., is offered in the trade as a glaucous-lvd. form.

25. *albunum*, Linn. Perennial, about 4-6 in. high, glabrous, cespitose: barren sts. erect or creeping, rooting, olive-brown; fls.-sts. erect, pinkish: lvs. alternate, spreading, linear-oblong, about \( \frac{1}{2} \) in. long, obtuse: fls. pink, about \( \frac{1}{4} \) in. across, in corimbos-segments, broadly ovate to subrotund, obtuse; petals lanceolate; anthers reddish. Eu., Temp. Asia, and N. Afr. Gn. 27, p. 315. G. 57:469.—Some of the plants grown as *S. neglectum* probably belong to this species.

26. *Kirilowii*, Regel. Perennial, rhizome destitute of shoots of preceding years, green, glabrous: sts. up to \( \frac{1}{2} \) ft. high, slender: lvs. spreading, elongate-linear, 2-3 in. long, attenuate, more or less congested toward the base: fls. rose-pink, yellow, 5-merous, rather small, in a dense, many-fld., corymbose cyme, which is commonly leafy; sepalae and petals linear. Soongaria, China, and Turkestan.—Allied to *S. roseum*.

27. *roseum*, Scop. (*Rhodolola rosea*, Linn. *S. Rhodolola*, D. C.). Perennial, 4-8 in. high: rootstock thick, fleshy, exhaling a perfume. 3585. Sedum pilosum. (X\( \frac{1}{2} \))

29. *Woodwardii*, N. E. Br. Perennial, glabrous: st-s. erect, pinkish: lvs. alternate, lax, obovate or spatulate, sessile, \( \frac{3}{4} \)-\( \frac{1}{2} \) in. long, attenuate, more or less serrate toward the tip: fls. oblong, sessile or slightly peduncled, pinkish brown beneath; anthers pinkish. N. Italy and Corsica. L.B.C. 3:461.

33. *Sedum*, Linn. and Linn. (S. *glaucum*, Linn. and *S. Aizoon*, Brit.). Perennial, glabrous, 2 in. high, much branched, smooth: lvs. flat, fleshy, obovate or oblong, obscurely 1-crenated, slightly toothed at apex: fls. dioecious, greenish or reddish purple, in a terminal flat-topped, subglobose cyme, about \( \frac{1}{2} \) in. diam.; sepals 4, lanceolate or oblanceolate; petals 4, linear-oblong; stamens 4 in the male, lacking in the female fls. Eu., N. Amer. and Himalaya. Gn. 12:103 (as var. *lanatum*). B.B. (ed. 2) 2:207.—A neotrop.-growing species well adapted to the rockery. Var. *linifolium*, Hort., is offered in the trade.

37. *dendroideum*, Moq. & Sessé. Shrub, 4-12 in. high, much branched, smooth; lvs. flat, fleshy, obovate or spatulate, sessile, \( \frac{3}{4} \)-\( \frac{1}{2} \) in. long; fls. sessile or nearly so, bright yellow, in a panicle cyme, numerous; calyx-lobes ovate; petals lanceolate. Mex.

39. *Woodwardii*, N. E. Br. Perennial, glabrous: sts. simple, about \( \frac{1}{2} \) ft. high, green: lvs. alternate, lax, \( \frac{1}{2} \)-\( \frac{1}{2} \) in. long; oblong or lanceolate, irregularly and obtusely dentate above, green, flat; fls. yellow, sessile, about \( \frac{1}{2} \) in. across, in dichotomously branched, 2-5-parted, rather flat, rather lax cymes, which are \( \frac{1}{2} \)-\( \frac{1}{2} \) in. diam.; sepals linear-subulate; petals lanceolate. China.—*S. oregunum* Nutt. (Germánia oregéná, Brit.). Perennial, glabrous: fls.-sts. erect, simple, 3-6 in. high: lower lvs. about \( \frac{1}{2} \) in. long, all spicate-oenate, irregularly and obtusely dentate above, green, flat; fls. yellow, sessile, about \( \frac{1}{2} \) in. across, in dichotomously branched, 2-5-parted, rather flat, rather lax cymes, which are \( \frac{1}{2} \)-\( \frac{1}{2} \) in. diam.; sepals linear-subulate; petals lanceolate. Alaska to N. Calif.

31. *sphatulifolium*, Hook. Fig. 3386. Perennial with slender rootstocks, glaucous, ultimately reddish: barren shoots creeping or ascending, 3-4 in. long; fls.-sts.
SEDUM

3585. Sedum spathulifolium. (X½)

36. Sempervivum, Linn. Perennial, 1½-4 in. high, with rosettes of leaves. Leaves oblong, erect, ciliate, approximately 1½ in. long, ½ in. wide, slightly fleshy. Flowers in terminal or near-terminal panicles, usually 3-5 per panicle. Bracts oblong, ciliate, with 3-5 supernumerary bracts. Corolla yellow, with 4 petals, 6 stamens, and 2 carpels. fruit a capsule, containing many seeds. Seeds small, black, and flat. Propagation by offsets from the base. Hardy in most climates, suitable for rock gardens and dry walls. 

37. Sedum album, Linn. Perennial, 1½-2 ft. high, with rosettes of leaves. Leaves lanceolate, with a white margin, ½-1 in. long, ½-1 in. wide, and slightly fleshy. Flowers in terminal panicles, usually 3-5 per panicle. Bracts oblong, ciliate, with 3-5 supernumerary bracts. Corolla yellow, with 4 petals, 6 stamens, and 2 carpels. fruit a capsule, containing many seeds. Seeds small, black, and flat. Propagation by offsets from the base. Hardy in most climates, suitable for rock gardens and dry walls. 

38. Middendorffianum, Maxim.; also spelled Middendorffii. Perennial, 1½-4 ft. high, with rosettes of leaves. Leaves oblong, erect, ciliate, approximately 1½ in. long, ½ in. wide, slightly fleshy. Flowers in terminal or near-terminal panicles, usually 3-5 per panicle. Bracts oblong, ciliate, with 3-5 supernumerary bracts. Corolla yellow, with 4 petals, 6 stamens, and 2 carpels. fruit a capsule, containing many seeds. Seeds small, black, and flat. Propagation by offsets from the base. Hardy in most climates, suitable for rock gardens and dry walls. 

41. Maximoviczii, Regel. Perennial, 1½-4 ft. high, with rosettes of leaves. Leaves oblong, erect, ciliate, approximately 1½ in. long, ½ in. wide, slightly fleshy. Flowers in terminal or near-terminal panicles, usually 3-5 per panicle. Bracts oblong, ciliate, with 3-5 supernumerary bracts. Corolla yellow, with 4 petals, 6 stamens, and 2 carpels. fruit a capsule, containing many seeds. Seeds small, black, and flat. Propagation by offsets from the base. Hardy in most climates, suitable for rock gardens and dry walls. 

42. kamtschaticum, Fisch. & Mey. Perennial, 1½-4 ft. high, with rosettes of leaves. Leaves oblong, erect, ciliate, approximately 1½ in. long, ½ in. wide, slightly fleshy. Flowers in terminal or near-terminal panicles, usually 3-5 per panicle. Bracts oblong, ciliate, with 3-5 supernumerary bracts. Corolla yellow, with 4 petals, 6 stamens, and 2 carpels. fruit a capsule, containing many seeds. Seeds small, black, and flat. Propagation by offsets from the base. Hardy in most climates, suitable for rock gardens and dry walls. 

43. Albidon, Linn. Perennial, 1½-4 ft. high, with rosettes of leaves. Leaves oblong, erect, ciliate, approximately 1½ in. long, ½ in. wide, slightly fleshy. Flowers in terminal or near-terminal panicles, usually 3-5 per panicle. Bracts oblong, ciliate, with 3-5 supernumerary bracts. Corolla yellow, with 4 petals, 6 stamens, and 2 carpels. fruit a capsule, containing many seeds. Seeds small, black, and flat. Propagation by offsets from the base. Hardy in most climates, suitable for rock gardens and dry walls.
variegatum, for rockeries and borders. Var. variegatum, Hort., occurs in many forms. A fine border plant, Turcz.

44. sempervivoides, Fisch. (S. Sempervivum, Ledeb.). Biennial, pubescent, 2–8 in. high: basal lvs. in a rosette of 40–50, oblong-cordate, pubescent and ciliate, about 1 x 8 in., cauline clasping, greenish red, oblong, acute;

45. oppositifolium, Sims. Perennial, trailing pubescent: fl-stems, erect, 6 in. high: lvs. opposite, deciduous, 1/2 x 3/4 in., obvate-spatulate, dentate-lobulate or crenate, slightly puberulent: fls. white, 1/2–3/4 in. across, in a terminal dichotomous cyme; sepals lanceolate; petals oblong-lanceolate; anthers orange according to Masters. Caspian and B.M. 1809 (authors shown as yellow).—Closely allied to S. stoloniferum, but the lvs. are brighter green and more regularly decussate.

46. populinum, Pall. Subshrub, with fibrous roots, glabrous: lvs. 6–10 in. high, greenish or purplish, slender, branched: lvs. alternate, distant, 1 1/2 x 1 in., petiolate, ovate, acute, base cordate, coarsely and irregularly toothed; petiole 1/4 in. long: fls. numerous, nearly 1/2 in. across, white or pinkish, in terminal, much-branched, corymbose cymes; sepals lanceolate; petals lanceolate; anthers pinkish, 1-nerved; carpels rose pink. Japan. B.M. 1809.—Very useful for rockeries and borders. Var. variegatum, Hort., not Wats. Var. variegatum, Hort., has white variegated lvs. LH.

47. Sieboldi, Sweet. Fig. 558. Subshrubby, 6–8 in. high, glaucous: branches terete, slender, purplish, erect, afterwad decurred: lvs. in whorls of 5, sessile or nearly so, suborbicular, sinuate, about 3/4 in. diameter, bluish green, margins pinkish, base cuneate: fls. pink, 1/2 in. across, numerous, in much-branched umbellate cymes; sepals ovate-acute; petals lanceolate; anthers pinkish. Japan. B.M. 5588. G. 31:831.—Very useful for rockeries and borders. Var. variegatum, Hort., not Hort. ex W. Mill.), has sts. erect, 2 to 3 x 1 in., oblong-obovate, denate; lower wedge-shaped at base; upper somewhat rounded: fls. numerous, pink, red-spotted or sometimes pure white, in dense terminal and lateral, pedunculate cymes; sepals lanceolate; petals lanceolate, 2–2 1/2 in. long, somewhat recurved. Cent. Eu. to Siberia and N. W. Asia. Gn. 27, p. 316.—Var. haematodes, Mast. (S. atropurpureum, Hort., not Turez. S. maximum var. atropurpureum, Hort. S. macrophyllum var. atropurpureum, Hort.), has sts. erect, glabrous, 1 1/2–2 1/2 ft. high; lvs. opposite, oblong-ovate, glaucous or dark purple; petals whitish, rose-pink. G.C. II. 10:337. Var. purpureum, Hort. (S. macrophyllum var. purpureum, Hort.), is a purple-lvd. form questionably different from the preceding variety. Var. variegatum, Hort., has been offered in the trade as a form with green-and-gold foliage. Var. versicolor, Van Houtte (S. Rodigasi, Hort.), is a form with pink lvs. and lvs. heavily variegated with white, their margins pink. F.S. 16:1669.

49. spectabile, Bor. (S. Faberla, Hort., not Koch). SHOWY SEDUM. Fig. 3588. Perennial, robust and glaucous: sts. 18–24 in.: lvs. opposite, deciduous or in whors of 3, 3 x 2 in., flat, scarcely petiolated, ovate or spatulate, entire or obscurely sinuate-dentate: fls. numerous, 1/2 in. across, pink, in large flat-topped, inversely pyramidal, leafy and umbellate cymes; sepals whitish, linear-lanceolate; petals slightly concave; anthers orange. Japan(?). Gn. 27, p. 315. I.H. 8:271. Gt. 21:709.—The fls. are said to vary from rose to purple and perhaps to white. This is the showiest of the sedums and is an excellent border and garden plant. It is said to thrive best in stony clay and not to do so well in lighter soils. Var. album, Hort., a white-flld. form is offered in the trade. Var. atropurpureum, Hort., is a form with rosy crim: fls. Var. purpureum, Hort., is offered in the trade. Var. roseum, Hort., is offered in the trade. Var. rubrum, Hort., is a form with crimson fls. There is also a form with variegated lvs.

50. alboroseum, Baker (S. erythrostictum, Mast., not Mor. S. japonicum, Hort., not Siebold. S. macrophyllum, Hort., not Hort. Vilm.). Perennial, glaucous: sts. several, ascending, about 1 1/2 ft. high, glabrous: lvs. up to 2 1/2 x 1 1/4 in., alternate in 4 ranks, slightly convex below, oblong-spatulate, upper margin incurved: fls. greenish white, in a dense corymbose cyme, 3–4 in. diam.; sepals deltoid; petals lanceolate; anthers pinkish: carpels rose pink. Japan. Gt. 21:709.—A fine plant for the border or rockery. Var. variegatum, Hubb. (S. erythrostictum var. variegatum, Mast. S. japonicum var. variegatum, Hort. ex W. Mill.), has the lvs. irregularly blotched yellow in the center. Gt. 21:709.

51. telephioides, Michx. Perennial, glabrous: lvs. 6–10 in. high: lvs. scattered, 2 x 1 in., oblong or obovate, nearly entire or sparingly toothed, base cuneate: fls. numerous, flesh-colored, in small, dense, compound cymes, 1 1/4 in. diam.; sepals lanceolate, petals lanceolate, falcate, hooded at the tip. S. Pa. to W. N. Y., to S. Ind., N. C., and Ga.—Not common in cult.

52. Telephium, Linun. ORNINE. LIVE-FOREVER. Fig. 5588. Perennial: sts. erect, 12–18 in. high: lvs. scattered, rarely opposite, 2–3 x 1–1 1/4 in., oblong-obovate, denate; lower wedge-shaped at base; upper somewhat rounded: fls. numerous, pink, red-spotted or sometimes pure white, in dense terminal and lateral, pedunculate cymes; sepals lanceolate; petals lanceolate, 2 1/2 in. long, somewhat recurved. Cent. Eu. to Siberia and naturalized in N. America. The American material may be another species which it is almost impossible to distinguish horticulturally, namely S. purpureum, Tausch., and which is referred to S. Telephium by many authors.) Var. Bördei, Mill. (Anacampseros Bördei, Jord. & Fourn. S. Bördei, Hort. S. Anacampseros var. Bördei, Hort.), has reddish sts.: lvs. distinctly petiolated, oblong, tapering at base: fls. pink, in

3527. Sedum Sieboldii.

3537. Showy sedum.—Sedum specia-
3589. Live-forever.—Sedum Telephium. (X5)

55. ternatum, Michx. Fig. 3590. Perennial by root-stocks, glabrous, tufted: barren shoots 6-8 in. long, prostrate and creeping; fl.-sts. erect: lvs. ½in. long, in whorls of 3, flat, oblong, to suborbicular spatulate, crowded in rosettes at end of the barren shoots; those of the fl.-sts. clustered, oblong, acute; fls. white, ½in. across, 4-merous, in 1-sided, leafy, terminal, 5-6-parted cymes; sepals oblong; petals oblong, acutė; anthers red. N. Y. and N. J. to Ga., Ind., Mich., and Tenn. B.M. 1977. B.R. 142. G.M. 57:340.

56. primuloides, Franch. Rhizome thick; branches of st. short and fastigiatēly clustered; lvs. clustered in a terminal rosette, densely papillose, more or less long-petiolate, broad-spatulate, 5-10 lines including the petiole, entire: peduncles 1-fl., short: sepals narrowly lanceolate; petals white, broadly ovate, about ½in. long. China. G.M. 57:212.—Apparently rare in cult.

57. cyaneum, Rudolph. Perennial, 2-3 in. high, glaucous, lilac above; st. solitary or congested: lvs. opposite, few, entire, glabrous; radical oblong or oblong-oblong, somewhat rosulate; caune line oblong or oblong-linear: fls. purplish pink, about ¼in. across, in a simple or compound corymbose cyme; sepals lanceolate; petals ovate-oblong. Siberia. Gt. 27:972.

58. stoloniferum, Gmel. (S. ibérieum, Stev. S. spuriuh, Bieb.). Perennial: barley shoots trailing, glabrous, rooting at the nodes; fl.-sts. ascending, 6 in. high; reddish; lvs. opposite, ¼–½ in. long, spatulate or obvate-cuneate, coarsely toothed above, short-petioled: fls. numerous, ½–¾ in. across, pink or white, in terminal umbellate cymes, 2 in. diam.; sepals linear-oblong; petals lanceolate; anthers reddish, speckled. Asia Minor and Persia, also escaped in N. Maine and Newfoundland. B.M. 2370. Gn. 27, p. 315. R.H. 1891, p. 523.—S. spurium, Bieb., is maintained as a species by some authorities, but there seem to be no good characters by which to distinguish it. A showy species, common in European gardens and well adapted to rockeries. Var. cocineum, Hort. (S. spuriu var. coccineum, Hort.), is offered, in the trade.—The following trade names also appear: S. spuriu var. albus, Hort., S. spuriu var. roseum, Hort., S. spuriu var. rubrum, Hort., and S. spuriu var. splendens, Hort.

59. Névi, Gray. Perennial, cepitose, tufted, glabrous: barren shoots prostrate; fl.-sts. erect, 2-5 in. high; lvs. of barren shoots crowded in terminal rosettes, ½ x ¾ in., alternate, obvate-spataulate, tapering to a short petiole, auricled at the base, sprinkled with pink dots; those of the fl.-sts. scattered, alternate, similar, but appressed: fls. numerous, white, nearly ½ in. across, in forked cymes whose branches are 1-1½ in. long and recurved; sepals greenish, oblong; petals lanceolate; anthers brownish purple. Mountains of Va. to Ala. and Ill., but hardy as far north as Mass. B.B. (ed. 2) 2:210.

60. reithum, Hemsl. Shrubby, glabrous: branches thick and fleshy; lvs. alternate, small, about ½ in. long, oblong-oval or obvate-spataulate, sessile, flat, fleshy, usually rebose: lvs. white, subsessile, in a few-fl. cyme; sepals linear-oblong; petals oblong, acute, keeled on the back. Mex.

61. Cepaea, Linn.; also spelled cepaie. Annual, 10-12 in. high, glabrous: st. tufted, simple or loosely branched: lvs. alternate, ½–½ x ¾ in., oblong-spataulate, narrowed to the petiole; caune line opposite, whorled or scattered, narrower: fls. white, ½–¾ in. across, in a loose many-fl. paniculate cyme which has purple-spotted, spreading branches; calyx-tube very short, sepals lanceolate; petals lanceolate, with pink mid­nerves and often a few pinkish spots; anthers purplish. W. and S. Eu.—Cult. specimens are sometimes said to be pink-fld.

62. Anacampseros, Linn. (S. ronundilórum, Lam.). Perennial, glaucous, evergreen: branches terete, rooting at the nodes; fl.-sts. erect, reddish, about 6-8 in. high; lvs. alternate, orbicular or obvate-obturate, cor­date, auricled, margins redish; fls. numerous, pale
SEEDS AND SEEDAGE. A seed is a ripened embryo, and its integuments and storage tissues resulting from fertilization in the flower. Seedage is a term used to include all knowledge respecting the propagation of plants by means of seeds or spores. The word was first used, so far as the writer is aware, in 1887. It is equivalent to the French semis, and is comparable with the words graftage, layerage, and cutage. See Spores.

In general literature and common speech, a seed is that part of the plant which is the outcome of flower-fertilization and which is used for propagating the species. In the technical or botanical sense, however, the seed is the ripened ovule. The seed contains an embryo, which is a minia
ture plant. The embryo has one or more leaves (cotyledons), a bud or growing-point (plumule) and a short descending axis (caulicle). From the caulicle or stemlet, the radicle or root develops. This embryo is a minute dormant plant. Each embryo is the result of a distinct process of fertilization in which the pollen of the same or another flower has taken part. The ovule is contained in the ovary. The ripened ovary is the seed-case or pericarp. The pericarp, with the parts that are amalgamated with it, is known technically as the fruit. In many cases there is only one seed in the fruit; and the seed and its case may adhere and form practically one body. Many of the so-called seeds of horticulturists are really fruits containing one or few seeds. Such are the seeds of beets, lettuce, and sea-kale. The winged seeds of elms, hop-tree (Fig. 3391), and ashes are really fruits containing a single seed. Acorns, walnuts, butternuts, and chestnuts are also fruits; so are grains of corn, wheat, and the “seeds” of strawberry. The keys of maple are double fruits, with two seeds (Fig. 3356). Petals and sepals are also true seeds, the fruit part being the pod in which they are borne. Seeds of apples and pears are also true seeds, the fruit being the fleshy part that surrounds them.

Germination is the unfolding and the growing of the dormant or embryo plant. The first visible stage in germination is the swelling of the seed. Thereafter the integument is ruptured, and the caulicle appears. When the caulicle protrudes, the seed has sprouted; and this fact is taken as an indication that the seed is viable (Fig. 3593). Germination is not complete, however, until the young plant has made vital connection with the soil, has developed green assimilative organs and is able to support itself (Fig. 3334). See, also, Figs. 3580 and 3290. Seeds that have sufficient life to sprout may still be too weak to carry the process to complete germination. The ideal test for the viability of seeds is to plant a few in soil in conditions that simulate as nearly as possible those in which they are finally to be planted. This test eliminates the seeds which are very weak and are not able to grow under ordinary
conditions and to push themselves through the soil. The sprouting test made in a specially prepared device, in which all conditions are regulated to a nicety, may be of the greatest value for purposes of scientific study and investigation and for the making of comparative tests between various samples, and the greater the sprouting test, the greater the germinating power; but one must not expect that the actual germination will always be as great as the percentage of sprouting. The test for sprouting shows only which seeds are alive. In many cases, the differences in results between the sprouting test in a specially prepared device and the germination tests in well-prepared soil in the open may be as great as 50 per cent. Viability varies with seasons and other conditions. While it is true as a general statement that the older the seed the less the viability, yet the reverse may be true within narrow limits. Sometimes lettuce and melons that germinate only 50 per cent in December germinate 70 to 80 per cent in April. For a discussion of technical methods of seed-testing, see Vol. II, “Cyclopedia of American Agriculture,” and other works.

In order that seeds shall germinate, they must be supplied with moisture and suitable temperature. The requisite temperature and moisture vary with the different kinds of seeds, and these factors are to be determined only by experience. Seeds may be planted in any medium that supplies these requisite conditions. Although seeds are ordinarily planted in the ground, such practice is not necessary to germination. They may be planted in coconut fiber, moss, or other medium. However, the ground may supply the requisites for germination, and it also supplies plant-food for the young plantlet when it begins to shift for itself; and, furthermore, the plants are in the position in which it is desired they shall grow. In the case of many seeds, germination is more rapid and certain when the seeds are sown in coconut fiber or other medium, for the conditions may be more uniform. As soon as germination is fairly complete, the plants are transplanted to the soil.

The depth at which seeds shall be sown depends on many conditions. Out-of-doors they are planted deeper than in the house, in order to insure a uniform supply of moisture. A depth equal to twice the diameter of the seed is an old gardeners’ rule. This applies well to the sowing of most seeds under glass when the soil is well prepared and is kept moist, but in the open ground three to four times this depth is usual. Seeds are placed near the building, where it can be visited frequently and where water may be applied as needed. If the bed is to be used late in the season when the soil is naturally dry, it is well to cover it the previous spring or fall with a coating of not too rich manure. This retains the moisture, and the leaching from the manure adds plant-food to the soil, thereby enabling the young plants to secure an early start. When the seeds are to be sown, the manure is removed and the surface is then in perfect condition. In the handling of young plants in seed-beds, one must take pains that the plants are not too thick and that they do not suffer for light, else they may become “drawn” and be practically worthless. In greenhouses and hotbeds, it is well to handle common vegetables and flower seeds in gardeners’ flats (Fig. 3597). These flats are easily handled, and the soil is so shallow that it can be kept in uniform conditions of temperature and moisture. The seeds of some of the finer and rarer kinds of ornamentals to please is required the special treatment. These treatments are usually specified in the articles devoted to those plants. Details of the handling of very delicate seeds are well discussed in the article on Orchids; see the article Palm and others, and the discussion of propagation of conifers, page 360, Vol. I.

As a rule, seeds germinate best when they are fresh, the best results being obtained when opened only a year old. Some seeds, however, of which those of melon, papaw, and cucumbers are examples, retain their vitality unimpaired for a number of years, and gardeners do not ask for recent stock. Seeds of corn-salad should be a year old to germinate well. Very bony seeds, as of haws and viburnums, often do not germinate until the second year. In the meantime, however, they should be kept moist. Seeds of most fruit and forest trees should be kept moist and cool, otherwise they lose vitality; yet if kept too moist, and particularly too close and warm, development of young plants will suffer. Nuts and hard seeds of hardy plants usually benefit by being buried in sand and allowed to freeze. The freezing and the moisture soften and split the integuments. Sometimes the seeds are placed between alternate layers of sand or sawdust: such practice is known technically as stratification.

L. H. B.

Seed-breeding may be considered from at least two very distinct viewpoints: first, the origination and development of new and improved varieties, either through selection or cross-breeding; and second, the development and raising of truer purer stocks of strains of proved value. See Breeding of Plants, Vol. I.

The first, as a rule, seems the most attractive in the sense of promoting knowledge and experience, but the growing of better and purer strains of the sorts which have proved best suited to one's local conditions and individual requirements is of far greater practical value. An important consideration of success in raising new varieties is the widest obtainable knowledge not only of the varietal forms of the species generally grown, but of the many stocks which at different times and in different locations have been found to be of so little practical value that they have never come into general cultivation. A second requisite is familiarity with the growing habits of the plant, and those of similar species, and the dexterity which can come only through practice in the crossing of the flowers and securing good growth and development of the fruits. There should also be developed a capacity for a quick judgment as to the probable correlation between conspicuous variations with others less discernible by the eye but which may affect the cultural value. Last, the development of new varieties of real value can come only through the practice of almost infinite patience which makes one content to throw into the dump thousands upon thousands of plants, many of which had seemed most promising, and to be satisfied if after years of labor one
CIV. Seed-growing in California.—Above, drying and turning lettuce stalks on the sheets. Below, cutting onion heads.
The second, and perhaps the most important branch of seed-breeding, is the raising of purer strains of stocks of proved value. An illustration of the need of work in this direction can be drawn from a recent trial planting of garden beets in which it was found that practically every root grown from 2-rod plantings of each of 214 samples of seed purchased under distinct varietal names from the most reputable seedsmen of America and Europe could be grouped into not over twenty distinct forms, and the roots so thrown together show as little variation as the crop from any one of the twenty most uniform samples in the trial. Often the only difference between two lots sold under different names would be in the proportion of the roots of each lot that conformed to the same varietal form. It is thought that seed-stocks of most species of garden vegetables would show similar variation, though possibly not to the same degree, and this is not so generally due to carelessness in growing or handling as to the want of adherence on the part of the seed-grower to clear-cut ideals of varietal form. Every plant grown from seed has a certain definite and changeless character which was inherent in the seed from which it was grown and is made up of a balanced sum of different tendencies, potentialities, and limitation of development inherited in different and varying degrees from each of its ancestors for an indefinite number of generations, plus more or less influence from climatic and other conditions effecting the development of the seed-producing plant. Generally the influence of the immediate parent is the dominant one, but not infrequently a characteristic of an ancestor which has been transmitted unexpressed for many generations appears in such strength as to change the whole character of the plant.

Under these conditions, a necessary preparation for the growing of better stocks is the formation of a very clear and comprehensive conception of the exact varietal character of the stock to be grown, and a rigid adherence to that ideal in the selection of seeding plants from year to year, never giving way to the ever-present temptation to use some superlative individual which differs in any respect from the original ideal of the stock. A most important aid, if not a requisite, for such persistence is the writing out and placing on file for frequent reference the fullest practical description of the exact varietal character of the sort. With this in hand, a few plants which come as near as possible to that ideal are selected, and the seed of each saved separately. The next season samples of each of these lots are planted in a preliminary trial. As they develop, and with the written description of the desired form in hand, they are carefully compared and the lots which most uniformly adhere to the described form are selected. The next season the reserved seed of the lots which seemed the best in the preliminary trial are planted in blocks as far as possible from each other, or any plants of the species, and the seed raised used for larger plantation for use as stock seed, in the meantime starting another selection from individual plants to take the place of the first, as it deteriorates. An illustration will show the value of careful selection and the necessity for constant renewal of even the purest of stocks. A very carefully bred strain of a variety of watermelon was used to plant a 20-acre field grown for seed. When about three-fourths of the fruit was ripe, several hours were spent in looking over the field for “off” stock and less than fifty fruits were found which should be removed. Fully 75 per cent of the fruits were so near alike that they could not be distinguished from each other. Seed from this field was used for planting seed crops and it was so good that little attention was paid to the stock; as a result, some years later, a crop grown in the same vicinity from seed of the same strain, but several generations removed, instead of less than fifty “off” fruits on 20 acres, had fully 75 per cent of the fruits more or less distinctly “off” and less than 20 per cent were as uniformly ideal of the variety as were 99 per cent of those of the first crop.

What might be termed commercial seed-growing has developed very rapidly in America in the past ten years, and there has not only been an increase in quantity, but an improvement in the varietal quality of the seed grown. Seed dealers having secured, sometimes at great cost, desirable stocks, enter into contracts with farmers located in sections where soil and climate are most favorable for the development of the best qualities of the sort and the securing of a full crop of the seed, to plant a given area and deliver to them the entire seed product. This the farmer does, often with little regard to selection, only taking the requisite pains to guard against contamination and mixture with other crops.

The United States Census of 1910 gives the total valuation of the vegetable- and flower-seed crop grown in the United States in 1909 at $1,411,013 (see page 3136), but it is thought that the amount actually produced was much larger, seed-dealers and -growers generally being inclined to depreciate the extent and profit of the business in order to lessen competition. Since then the amount grown and listed has increased materially, an estimate by a very experienced dealer of the area devoted to vegetable-seed crops in 1915 being as follows:

<table>

</table>
This is the estimated area contracted for by growers especially for seed, but in the case of many crops, such as melons and peas, the amount of seed grown is greatly increased by crops which were originally planted with the intention of selling them as green vegetables, but which because of market conditions are allowed to ripen and are harvested and sold as seed.

WILL W. TRACY.

The seed trade of America.

The history of the seed business in colonial times is largely one of importation from Holland and England, when small hucksters carried a few boxes of popular seeds with an assortment of drygoods, foodstuffs, or hardware. Corn, barley, peas, onions, fruits, and vegetables, necessary in fact for direct use, first claimed the attention of the colonists. Toward the end of the eighteenth century we begin to find references to the growing of stock seeds, in the newspapers of the day are a number of advertisements of shopkeepers who dealt in seeds. Agricultural seeds were an article of commerce as early as 1747 (Pieters), clover, onions, beans, peas, carrots, cabbage and cauliflower, and others, being raised for seed in the colonies at that time, though chiefly imported. At that time Boston did most of the business. Among the earliest advertisers of seeds for sale were Nathaniel Bird, 1763, a book-dealer of Newport, R. I.; Gideon Wells, "On the Point," 1774; Samuel Hall, a dealer in farm goods in New York in 1776; William Davison of New York in 1768, while in Philadelphia, in 1772, we find one Pela­tiah Webster advertising clover and duck-grass seed; James Loughead, "colly-flower" seed in 1775, while David Reid kept a general assortment.

It was not until the opening of the nineteenth century that America began to find that seeds could be grown here as profitably as they could be imported. Grant Thorburn, in New York, and David Landreth, of Philadelphia, seem to have been the largest dealers at that time. Tho­rburn's was perhaps the first business of importance devoted entirely to stock seeds, although this honor is disputed by the descendants of David Landreth. Thorburn, in his autobiography, says that he began his business by buying out the stock of one George Ingles for $15, Ingles agreeing to give up the market and to devote himself to the raising of seeds for Thorburn. This is but one of many small beginnings from which has grown a trade which now amounts to many millions; and this relation between seedsmen and growers is largely typical of relations which have obtained in the trade ever since.

With the development of the railway and the postal service the business grew rapidly, new land was found suitable for different varieties of seed, and a letter could carry to the countryman the garden seeds for his yearly consumption. There is probably no trade which has been more widely benefited by cheap postage and improved mail facilities, but of late years the distribution by Congressmen has tended to negative this benefit. The originally beneficent distribution of free seeds to pioneers and needy settlers was a form of agricultural encouragement against which there could be no criticism, but it has degenerated into an abuse, which because of market conditions are allowed to ripen and are harvested and sold as seed.

The statistics of imports of seeds were kept before 1873. Clover and grass seeds, especially timothy, have always taken the lead in the seed export trade, and until recent years garden seeds have not been a considerable factor in the total values. In 1826 some 10,000 bushels of clover seed were exported to England within a few months. How long this trade had existed we do not know. From 1855 to 1864 there is no record of any seeds exported except clover, but the value of exports increased from $13,570 in 1855 to $2,185,706 in 1853, the war apparently having no effect on the trade. The total value of the clover seed exported during this period aggregated $5,383,063. In the ten years ending with 1880, clover seed was not separately entered except in the last year, but the total exports of seeds amounted during that period to $20,739,277. The aggregate was increased by more than $3,000,000 before the end of 1890. From 1891 to 1898 there has been a slight reduction in the average annual value of seed exports and also in the amount of clover and timothy seed sent abroad. The value of "flower and vegetable seeds" reported in the Thirteenth Census (for 1899) is $1,411,013 as against $226,019 for 1899, an increase of above 70 per cent. Aside from this the statistics of imports and exports of seeds have been taken as given in the Yearbook of the Department of Agriculture.

The following table will give as close an estimate as can be made of the present annual cost of the chief staple garden seeds handled in America:

Probable invoice cost of imported garden seeds, $2,000,000
SEEDS AND SEEDAGE

The seeds usually offered by seedsmen in their catalogues, or in the seed-stores throughout the country, are secured from various parts of the world, and the seedsmen who sells seed at retail to the planter directs seldom grows his own seed, although some of the larger firms now grow seed-farms to grow certain specialties, and most of them conduct trial and experimental grounds.

The wholesale seed business is divided into two branches, so-called small-dealers, who buy from the farmers such things as grass seeds, clover seeds, and farm seeds used for planting large areas; the other line is the general seed-dealer who carries a limited stock of grass seeds, clover seeds, and the like, and specializes on vegetable seeds and flower seeds. He is usually not a grower of seed, but buys from seed-growers who specialize on a few things.

A large part of the vegetable and flower seed used in America is imported from England, France, Germany, Holland, and Denmark, especially such things as beans and mangels, cabbage and cauliflower, turnip and rutabaga, and the small flower seeds. In Germany, the seed-growers usually own or lease their own seed-farms, while in other countries, especially France, much of the production is conducted under the subcontracting plan, the grower keeping an agent in a certain locality and letting out small contracts with the farmers. The finer vegetable seeds and flower seeds, as well as the larger horticultural lines, are grown in this way.

In America, the smaller vegetable seeds and sweet peas are grown principally in California, where the growers own or lease their own seed-farms, and practically all of their capital is invested in the seed business. What are considered the "smaller vegetable seed-farms" and "California specialties" are carrot, endive, leek, lettuce, onion, parsnip, parsley, radish, salify, and flowering sweet peas. The preeminent California specialties are lettuce, onion, and sweet pea seed. There are no less than 5,000 acres, principally in the coast counties of central California, devoted to these three things. Pole beans, culinary peas, and some vine seeds are also produced in central California. These are grown on the subcontracting plan, much as in other places. Peas are now grown largely in Utah, Idaho, and Montana, as well as in Wisconsin, Michigan, and northern New York. Sweet corn and vine seeds are grown largely in Nebraska, northern Ohio, New York and New England. Watermelon seed is grown largely in the South; also okra. The best cabbage seed is produced in Long Island and to some extent in the country near Puget Sound in Washington. Pepper and eggplant, and some tomato seeds, are grown in New Jersey, and tomato seed is also grown in Michigan and California. Various other items are grown in greater or less quantities in various sections, such as beet and parsnip in New England, radish in Michigan, turnip in Pennsylvania, but the main sources of supply of these last-named articles are the European countries previously mentioned.

Seed-growers who subcontract their crops, usually operate large farms for the production of their stock seeds, where they do their selecting and developing, and where they grow the seeds which they send out to the farmers who produce crops from their stock. Such crops as are subcontracted are "rogued" and inspected throughout the season by the grower's agent. Seed-growing, as it affects vegetable and flower seeds, is conducted more or less scientifically and represents a very high state of intense farming, perhaps the highest known out-of-doors.

Seeds must be produced in regions where they can be grown not only profitably on account of climatic conditions, but also with abundant labor, where the quality can be maintained. Climates with a cold winter are usually required for biennial crops, such as carrot, beet, onion; when grown in California, the strains must be often renewed. Certain other crops require a dry summer climate, such as lettuce and sweet peas; other kinds require a moist or wet summer climate, as cabbage and cauliflower.

Many seed-growers now specialize on one or two lines, and there are large growers who raise nothing but tomatoes; others who grow only sweet corn; others who grow only field corn; and others who grow only sweet corn, others field corn, and others confine themselves to watermelon. Owing to the frequency of crop failures in seed production, as in other farm crops, the grower contracts with at least two sources of supply and usually both are separated.

Commission box assortments comprise one of the major branches of seed distribution, and one firm has nearly 150,000 customers to whom is consigned these assortments. Many of the larger horticultural lines also carry small lots of staple seeds in bags to sell in bulk and are therefore seed merchants in a small way. They usually rely for their base of supply on the seed-houses who consign them the box.

Dealers in garden seeds are also large dealers in flowering bulbs, such as hyacinths, tulips, narcissi, crocuses, and the like. These are chiefly imported from Holland, south of France, Italy, and Japan.

The trade is divided into the main branches of garden and flower seeds and bulbs, and agricultural products. The latter is practically a business by itself, devoted to such seeds as grass-gra_s, timothy, clover, red-top and alfalfa, some of which are exported or imported as the exigencies of the season's product demand. Flower seeds are subjected to no import duties, while on garden seeds there is a tariff figured on a specific basis. It is a moot point whether this tariff at the present time operates to the advantage of the trade, the principal seedsmen generally of the opinion that it tends to stimulate over-production in this country.

The main business of the country is in the hands of about 150 firms, but practically every grocerman in country towns and villages carries a stock during the spring season. This man, however, deals as a rule with the larger houses, and constitutes the principal class of middlemen for retail trade.

The seed-growing and merchandizing industry is represented by the American Seed Trade Association.

C. C. Mosse & Co.

SEEMANNIA (named for Berthold Seemann, 1825-1871). Gesneriaceae. Strigose-pubescent perennial herbs with rhizomes, suitable for the warmhouse: stes. stout, simple; lvs. verticillate in 3's or 4's, very short-petioled, frequently canescent below; the upper oval, pointed, acute; flowers solitary in axils: fls. red-purple; calyx-tube turbinate, adnate, lobes 5, narrow; corolla-tube bent downward, broadly and obliquely subcampanulate, the limb with 5 short, erect-spreading lobes; disk annular, undulate and not divided; ovary almost entirely inferior: caps. nearly inferior.—Two species, S. Amer. S. silvestrica, Hanst. (S. ternifolia, Regel). Plant 3-4 ft. high: lvs. 3-4 in a whorl, very shortly petioled; fls. calyx with 5 narrow lobes; corolla short-glabrous at base. Winter. Peru. Cult. 4, p. 182.

SELAGINELLA (diminutive of Latin Selago, old name of a club moss). Selaginellaceae. Club Moss. A large group of mostly tropical plants with small scale-like leaves and of diverse habit, ranging from minute prostrate annuals to erect or even climbing perennials.
Easily recognized by the production of two kinds of spores—powdery microspores from which the male prothallus arises and larger microspores produced 4 in a sporangium just within the axil of the terminal lvs. of the st. which often form a 4-angled spike. In all our cult. species the lvs. are in 4 ranks, the 2 upper smaller and pressed against the st., giving it a flattened appearance. Selaginellas are graceful fern-like greenhouse plants, often known to gardeners as lycopodiums. The botany of the genus is in an uncertain state, both as to nomenclature, and the limits of species. They are plants of the Pteridophyta or fern allies.

Selaginellas are favorite plants in every good conservatory, being greatly admired for their feathery moss-like foliage. They have various shades of green, and some of them are remarkable for metallic and iridescent tints, especially bronze and bluish colors, the latter being very unusual among plants in general. S. Willdenovii is a very choice large-growing species of the bronze and blue class. Another is S. ucutata, often called "rainbow moss." Selaginellas are often grown for their own sake as specimen plants, but they are also very commonly used as edging for greenhouse beds, for covering unsightly spots under the benches, and for hiding the surface soil of large tubs, orchid pots, and the like. (See Fig. 3598.) They are also delightful subjects for table decoration when grown in pans or jardimieres. For this purpose a well-grown selaginella should be a dense compact mass of fluffy and feathery green, not a weak thin straggling plant, as compared in Figs. 3599 and 3600. Selaginellas are also employed in bouquets of flowers, fronds being used for "green" instead of asparagus or fern. Occasionally a fancier of the more difficult species grows a large specimen in a Wardian case for exhibition. In general, selaginellas are of easy culture. As a rule they prefer shade and moisture and are somewhat tender in foliage compared with some of the commonest of commercial ferns. S. denticulata, S. Kraussiana, S. Martensii, and some other

commercial favorites may be rapidly propagated without any preliminary treatment in the cutting-bench. Cuttings of these species about an inch and a half long may be inserted directly into small pots of light sandy soil, placed in a shady position. Sylinge them lightly three or four times a day for a week, at the end of which time they will take root. They will soon grow into salable plants. The popular S. Emmelianana, which is generally considered by florists a variety of S. cuspidata, requires different treatment. It is much slower and sometimes requires about nine months from the making of cuttings until the young plants are ready for potting. Fill regular fern-boxes with fern soil, adding one part in five of sand, and press firmly. Choose mature fronds of the S. Emmelianana, cut them into pieces half an inch long, scatter thinly over surface of soil, and put just enough finely screened soil on top of the cuttings to attach some small portion of them to the soil. Water thoroughly, cover with glass, and place in a temperature of 70° F. In this condition they will soon form roots and little plants at almost every joint. When sufficiently large they should be separated and transplanted singly an inch apart into boxes, where they may be left until large enough to be potted. The following list of selaginellas for special and general purposes is not designed to be complete, but merely suggestive. For commercial purposes, S. denticulata, S. Kraussiana, S. Martensii, and S. Emmelianana; for carpeting the soil, S. denticulata; for table decoration, S. Emmelianana and S. Martensii, for cutting, the commercial kinds; for veranda-boxes, S. Braunii; for bronze and blue colors, S. Willdenovii and S. ucutata; for specimen plants and exhibitions, S. Braunii, S. Lyallii, S. viticulosa, S. Wallischii, and S. Willdenovii. Also the following, which are generally considered more difficult subjects: S. atroviolacea, S. hamatodes, and S. molliceps; for curiosity, S. serpens and S. lepidophylla. The curiosities of the genus call for special mention. S. serpens is remarkable for its changes of color during the day. In the morning the foliage is bright green; during the day it gradually becomes paler as though bleached by the light; toward night it resumes its lively green hue again. For S. lepidophylla, see Resurrection Plants. The following species also deserve a few running notes: S. Braunii is an old favorite which is often incorrectly labelled S. Willdenovii in collections. Its branches, or "foliage" in the popular sense, are exceptionally tough and wiry for the genus. Variegated forms appear in S. Martensii, S. Kraussiana, and S. involvens, the last-named species being prolific in singular form. It is better adapted for use as a pot-plant than for mINGling in a fernery, because of its strong-growing erect fern-like habit. The branchlets are thrown up from creeping stems and do not root readily, so that this species is usually propagated by division or spores. (W. H. Taplin and N. N. Bruckner.)

KEY TO THE SPECIES.

A. Lvs. all similar, many-ranked: 1. rupestris

AA. Lvs. 4-ranked, of two sorts, forming an upper and a lower plane: mostly hothouse exotics.

B. Foliation of the spikes uniform. C. Main st. elongate, usually rooting throughout. D. Plants perennial: lvs. firm. E. Sta. continuous, l. c., without joints.

S. Emmelianana.
SELAGINELLA

Med. region throughout.—Trade names are vars. aërea and follis variegatus.

3. *sérpen*s, Spring. Sts. 6–9 in. long, trailing, bright green, copiously branched: lvs. of lower plane crowded, oblong, spreading, ciliate at the rounded base; lvs. of upper plane obliquely oblong, acute. W. Indies.—Long in cult.

5. *uncináta*, Spring (*Lycopodium césium* and *Selagi­nella césia*, Hort.). Sts. 1–2 ft. long, extending in a somewhat naked tip beyond the branches, doubly grooved above, with short, alternate branches: lvs. thin, blue-green, with a distinct midrib, slightly more produced on the upper side; lvs. of upper plane cupulate, much imbricated. China.—In 1885 John Saul offered "S. césia arborea" with the remark that *S. césia* was a synonym thereof.

6. *plumós*a, Baker. Sts. 6–12 in. long, flat above, often forked near the base: lvs. of lower plane close, bright green, much more produced on upper side of midrib, ciliate on both sides at base; lvs. of upper plane half as long, ovate, much imbricated. India, Ceylon, China, Malay Isls.

7. *conína*, Spring (*S. serruláta*, Spring). Sts. 1 ft. or more long, copiously pinnately branched, with more or less fan-shaped compound branches: lvs. of lower plane crowded, bright green, glossy, much dilated and rigidly ciliate on the upper side at base; lvs. of upper plane one-third as long, long-cupulate, much imbricated. Mascarene Isls.—Var. *follis variegátis*, Hort., is cult.

8. *stoloniféra*, Spring. Sts. 1 ft. or more long, with a more or less naked tip, angled above and below, with short, compound branches: lvs. of lower plane closely set, rigid, acute, short-ciliate and minutely auricled at base. W. Indies.

9. *Kraussínia*, A. Br. Sts. 6–12 in. long, flat on the back, rounded on the face, copiously pinnate, with compound branches: lvs. of upper plane spaced on the branches and main st. acute, slightly imbricated over the st.; lvs. of upper plane obliquely ovate, acute. Afr., Madeira.—*S. Brownii*, Hort., is a dwarf form from the Azores. Vars. aërea and variegátis are American trade names.

10. *Cunnínghamii*, Baker. Sts. copiously pinnate, the lower branches compound: lvs. of lower plane ovate or oblong, cordate and very unequal-sided at base, much imbricated over the st.; lvs. of upper plane distinctly cupulate. Brazil.—Similar to preceding, but with longer lvs.

11. *brasilienís*, A. Br. Sts. copiously pinnate, the lower slightly compound: lvs. of lower plane mostly spaced, acute, cordate at base, ciliate and imbricated over the st.; lvs. of upper plane half as long, cupulate. Brazil.—Similar to preceding, but with shorter lvs.

12. *áspus*, Spring. Sts. 1–4 ft. long, angled above, with short, simple or forked branches: lvs. of lower plane pale green, serrulate but not ciliate, cordate on the upper side; lvs. of the upper plane ovate. Canada to Texas.—*Lycopodium densum*, cult. at the Harvard Botanic Garden, is said to belong here.

---

1. *rupéstris*, Spring. A small, rock-loving perennial, with branching sts. 4–5 in. long, many-ranked lvs. ending in a white aavn, and square, 4-angled spikes. Native of the eastern half of the U. S., but replaced by many allied species in the Rocky Mts. and on the Pacific coast. The writer has separated 6 of these and Dr. Hieronymus, at Berlin, has also characterized 10 others.

2. *denticuláta*, Link. Fig. 3398. Sts. less than 6 in. long, matted: lvs. of the lower plane slightly spaced, denticate, cordate on the upper side at base and imbricated over the st.; lvs. of upper plane cuspidate.
15. californica, Spring. Sts. 4-6 in. long, 4-angled, copiously pinnate: lvs. of lower plane ovate, minutely cuspidate, denticulate on the upper side at the base; lvs. of the upper plane very small, ovate-oblong. Said to come from Low. Calif. but not known at Kew and doubtfully in cult. in this country.

16. Martensi, Spring. Fig. 3599. Sts. 6-12 in. long, flat or rounded below, angled above: lvs. of lower plane oblong-lanceolate, serrulate but not ciliate, slightly incurved over the st. at base; lvs. of upper plane obliquely oblong, cuspidate. Mex.—Exists under many varieties in cult.

17. rubella, Moore. Sts. 1 ft. long, somewhat erect in habit, reddish brown, with 2 grooves on the upper face: lvs. of lower plane dark green, becoming reddish with age, obtuse or obscurely cuspidate, ciliate and incurved over the st. at the upper side of base; lvs. of upper plane ovate-cuspidate. Native country not known.—Has been in cult. since 1870. Var. variegata, Hort., is cult.

18. Pühlerti, Hort. Veitch. Sts. densely tufted, slender, suberect, 2-3 in. long, 3-4 times dichotomously forked: lvs. of lower plane spaced, subobtuse, obtuse, bright green; lvs. of upper plane nearly as long, but ovate and acute. Azores.

19. involvens, Spring. Sts. densely tufted, 2-6 in. long, deltoid, branched nearly to the base: lvs. of lower plane crowded, ovate, with a distinct cusp, bright green, thick, rigid, serrulate on both margins; lvs. of upper plane nearly as long, ovate-lanceolate, cuspidate. Japan to India and the Philippines.

20. lepidophylla, Spring. Resurrection Plant. Sts. 2-4 in. long, densely tufted, spreading in a close spiral so as to form a flatish expanse, curling closely into a ball when quite dry: lvs. of lower plane oblong, obtuse, minutely ciliate, green on the face, paler below; lvs. of upper plane nearly as long, obliquely ovate, obtuse. Texas and Mex. to Peru.—Often sold dry under the name of "resurrection plant" (which see), as the absorption of water will cause the ball with a dull upper face of the sts. long after the plant is dead.

21. cuspidata, Link. Sts. densely tufted, 6 in. or more long, branched nearly to the base, with copiously compound branches: lvs. of lower plane obliquely ovate, cuspidate, dilated and ciliated on the upper side at the base, pale green edged with white; lvs. of upper plane nearly as long, obliquely ovate, cuspidate. Cuba and Mex. to Venezuela.—A plant occurring under the horticultural name Lycopodium cordifolium has the st. a foot or more long and simple in its lower part, and doubtless represents a distinct species.

22. Emmeliâna, Hort. Fig. 3600. Sts. 6-12 in. high, the primary branches ascending, bipinnate: lvs. of lower plane close, obliquely ovate, those of the branchlets narrower and minutely spinulose; lvs. of upper plane raised above those of the lower one-half as large, spinulose-serrate, short-cuspidate. S. Amer.?(.)—Named for Th. Emmel, a German gardener. Var. aërea is a yellow form. This species and its variety are most commonly seen in the American trade. They require a constant supply of moisture. If allowed to dry, the tips of the fronds turn brown and do not recover.

23. Wällichii, Spring. Sts. 2-3 ft. long, with lanceolate branches and simple crowded branchlets: lvs. of lower plane crowded, smaller toward the end of the pinnules; lvs. of upper plane one-fourth as long, cuspidate: spikes ½-1 in. long. India and the E. Indies.—Highly ornamental.

24. Victòria, Moore. Sts. 3-4 ft. long, with lanceolate-deltoid, caduâte branches, with the lower branchlets forked or slightly pinnate: lvs. of lower plane crowded, a line long, truncate at base and obscurely petiolate; lvs. of upper plane one-fourth as long, short-cuspidate: spikes 1½-2 in. long. Borneo and Fiji Isls.

25. gràdilis, Moore. Sts. 2-3 ft. long, somewhat roughened, with lanceolate branches and simple branchlets: lvs. of lower plane ovate-falcate, adnate to st. on lower side at base; lvs. of upper plane ovate-lanceolate, cuspidate. Polynesia.

26. Lôbbi, Moore (S. cöptâta, Hort.). Sts. 3-4 ft. long, with lanceolate-deltoid branches and contiguous simple or forked branchlets: lvs. of lower plane oblong-lanceolate, acute, bright green, truncate at base; lvs. of upper plane one-third as long, obliquely ovate, cuspidate. Borneo and Sumatra.

27. Wildeânovii, Baker. Sts. reaching a length of many feet, with spreading deltoid branches and much compound branchlets, the ultimate short and contiguous: lvs. of lower plane crowded, ovate or oblong, fringed with blue, obscurely petiolate; lvs. of upper plane one-third as long, obliquely oblong, not cuspidate. India and the E. Indies.

29. viticulûsa, Klotsch. Sts. with deltoid 2-3-pinnate branches: lvs. of lower plane ascending, acute, short-ciliated and much imbricated over the st.; lvs. of upper plane one-third as long, obliquely ovate, cuspidate. S. Amer.

30. caûlécens, Spring (S. amëna, Hort.). Sts. stiff, erect, the short final branchlets curling when dry: lvs. of lower plane crowded, ovate, falcate, bright green; lvs. of upper plane one-third to one-fourth as long, cuspidate. Japan, China, and E. Indies. Var. argenteâta, Hort., is advertised.

32. flâbelâtâ, Spring. Sts. erect, deltoid, decompound, with contiguous final branchlets: lvs. of lower plane obliquely ovate, acute, broadly rounded and ciliate at the base; lvs. of upper plane obliquely oblong, cuspidate. Widely distributed in tropical regions.—One of the forms of this is cult. as S. crûsæ, Hort.

33. Vögeliîi, Spring (S. africâna, A. Br. S. Perséliî, Spring). Sts. decompound above, the lower pinna deltoid, petiolate, 3-4-pinnate: lvs. of lower plane lanceolate, ascending, often revolute on both edges, truncate at base; lvs. of upper plane minute, strongly cuspidate. Afr.

34. Liâlliî, Spring. Sts. deltoid above, the lower pinna bipinnate, the final divisions ½-1 in. long, ½-2
35. erythrops, Spring. Sts. under a foot long, deltoid and decumbent above, the lower pinna 3-pinnate, the ultimate divisions ½–1 sin. wide: lvs. of lower plane oblong-lanceolate, acute; lvs. of upper plane minute, acute. Madagascarn.

36. hematodes, Spring (S. Alcina, Spring). Sts. 1–2 ft. long, the deltoid pinnae 3–4-pinnate, the ultimate divisions ½–1 sin. wide: lvs. of lower plane ascending, oblong-lanceolate, acute, dilated on upper side at base, not ciliatc; lvs. of upper plane minute, cuspitate. Venezuela to Peru.

37. geniculata, Spring (S. elongata, Kl.). Sts. 2–3 ft. long, decumbent, with lower pinna 3-pinnate, the divisions ascending and pinnately arranged: lvs. of lower plane ovate, acute: lvs. of upper plane one-third as long, ovate-lanceolate. Costa Rica to Peru.

38. cordifolia, Spring (S. cordata, Kl.). Sts. trailing, a foot long, with short branches often ending in whip-like tips: lvs. of lower plane acute, pale green, ciliated on the upper edge, dilated and subcordate: lvs. of upper plane ovate-lanceolate, cuspitate. W. Indies.

39. molliceps, Spring (S. rubricaulis, A. Br.). Sts. erect, 6–9 in. long, bisulate above, much compound: lvs. of lower plane oblong-lanceolate, dark green, very unequal-sided, serrulate on the upper edge: lvs. of upper plane one-half to one-third as long, ovate or ovate-lanceolate, cuspitate. Afr.

The following American trade names can not be satisfactorily accounted for as species: S. occidentalis is said to be one of the most important commercial species cultivated in Amer.—S. circinata is cult. at Harvard Botanic Garden.—S. Lagenaria was intro. from Columbia and probably belongs to species already described from that country. It is said to be a very light green plant and a strong grower, whereas S. Pitcheriaca is of dwarf habit and with and under surface of fons red and upper surface dark green.—S. Mandibula is a recent intro. by W. A. Manda which can not be satisfactorily placed.—S. paradoxa. Offered by John Saul, 1893.—S. Pitcheriaca. Consult S. Lagenaria. Colombia.—S. ruibrutina and S. triangularis were offered by Saul in 1885.—S. uniflora. Once cult. by Pitcher & Manda, of the United States Nurseries.

F. TRACY HUBBARD.

SELENIA (probably from the Greek moon; said to refer to the round seeds). Crucefura. Small annual herbs sparingly grown in gardens: lvs. pinnatifid: racemes terminal, leafy: lvs. yellow; sepals spreading, colored, subequal; petal erect: silique stipitate, oval berry much compressed; seeds many, acut,d at the base, valves reticulate.—Three species, N. Amer.

aurea, Nutt., is a hardy annual of the mustard family, a native of the U. S. from Ark. and Texas to the base of the Rockies. It is not known to be cult. in Amer., but it seems to be one of the prettiest of our few native ornamental crucifers. It has small yellow fls. about 3½ sin. across, each of the 4 petals having a central band of red. It is also interesting for its finely cut foliage and its flat pods through which the seeds may be vaguely seen, as in the case of lunaria, or "honesty." It grows about 9 in. high. B. M. 6607.

SELENICEREUS (moon goddess and cactus). Cactaceae. Cacti with slender trailing hanging or climbing sts., more or less epiphytic: ribs several, usually low, with closely set areoles bearing small short or acicular spines: fls. large, nocturnal, fragrant; ovary and fr. covered with clusters of small spines often accompanied by long hairs. More than 20 species are known. This genus contains a number of easily grown species which are great favorites in cult. on account of the great size and beauty of the fls. Some of the species are reported to possess medicinal properties. These plants have been referred to Cereus.

A. Fl.-tube and ovary without long hairs.

B. Spines on sts. acicular.

vagans, Brit. & Rose (Cereus vagans, Brandeg.). Sts. slender, numerous, clambering over rocks in the wild state, but in cult. ascending: ribs low: spines rather short, yellowish: fls. 6 in. long; tube, including throat, about 4 in. long, slightly curved, brownish, with small scattered bracts bearing in their axis clusters of 5–8 acicular spines; throat narrow, 2 in. long; sepals linear, the outer ones brownish, the inner ones greenish white, 2¼ in. long; petals white, obovate, 2½ in. long with a short acuminate tip, the margins, especially above, undulate or toothed; ovary covered with acicular spines. West coast of Mex.

Bb. Spines on sts. not acicular.

spinulosus, Brit. & Rose (Cereus spinulosus, DC.). Slender climbing vine, 10–14 ft. long: ribs usually 5, not very conspicuous in age: spines about 8, very short, usually dark: fls. 4½–5 in. long, white, with a pink tinge; ovary and fl.-tube bearded with small clusters of acicular spines but no long hairs. Common in N. E. Mex. and S. E. Texas, but not found in the W. Indies. Blühenden Kakteen, pl. 53.

AA. Fl.-tube and ovary bearing long hairs among the spines.

Bb. Spines of the sts. acicular.

c. Color of spines white.

Donkeleri, Brit. & Rose (Cereus Donkeleri, Salm-Dyck). A slender epiphytic plant, much branched, clinging to the bark of trees by aerial roots, commonly in company with orchids: branches long, slender, nearly terete, about ¾ in. diam. with 6–8 low, almost inconspicuous ribs; spines 10–15, very short, snow-white, closely appressed to the st. Brazil.

c. Color of spines brownish.

grandiflorus, Brit. & Rose (Cereus grandiflorus, Mill.). Creeping or clambering vines: sts. stout, often 1 in. diam., bluish green; ribs 7 or 8, spines acicular, yellowish brown or brownish: fls. very large, fragrant, 6–8 in. long. Jamaica, but said also to be native of Mex., which is doubtless wrong. B. M. 3381.—A number of species resembling S. grandiflorus in a general way, but specifically distinct, are often to be found under this name in collections; they need further study. This species is used in the manufacture of a heart-tonic.
SELENICEREUS

bb. Spines of the sts. not acicular.
c. Sts. blue-green.

c. Sts. deep green.
d. Spines on ribs relatively low and few.

MacDonaldia, Brit. & Otto (Cereus MacDonaldiae, Hook.). Clambering vines of rapid growth, freely branching; branches deep green; the ribs rather low, obtuse, somewhat interrupted: spines 1 or 2, short, porrect, dark: fls. very large, 14 in. long, white. Horduras, probably, but some recent writers claim it came originally from Argentina, glabrous, 107, Cact. Journ. 2: 135.—One of the largest-flowered species of the cactus family and one of the best of the night-blooming kind.

SELENOPHYLLUM. For the species included in this genus in "Cyclopedia of American Horticulture," see Pharmagnumedit. The true Selendophyllums (or Selendopodium) are few and seen not to be in cult.

SELENOCYPRIPEDIUM (compounded from SELINUM (Greek name for parsley). SELF-HEAL: SELF-STERILITY OF FRUITS: SELIGUEA, S. (personal name, from Selligue, naturalist and mechanician). Polypodaceae. A group of ferns referred to Diels (Engler & Prantl, Die Naturlichen Pflanzenfamilien) to Polypondium. Only P. Féei, Mett. (Selliguea Féei, Bory, Gymnogramma Féei, Hook.), appears to be listed. It is described by Schneider as a small stover species of the Malay Isls., Java, and Borneo; a frount's entire, from a creeping rhizome, the barren ones 3-4 in. long and 2 in. or less broad, the fertile ones narrower and longer-stalked.

SEMELE (named for the mother of Bacchus). SEMELE, Linn. f. MARKING-NUT TREE. A moderately sized deciduous tree with large, oblong or obovate-oblong lvs. 8-24 in. long by 5-10 in. wide: fls. greenish white, ½ in. across, nearly sessile, in stout branching panicles about the same length as the lvs.: drupe 1 in. long, smooth, black. India.—The black acid juice of the nut is used for printing cotton cloth. Cult. in S. Fla.

SEMINICA (named for the mother of Bacchus). Liliaceae. CLAMMING BUTCHER'S BROOM. A warhouse plant, hardy outside in the extreme N. and S. of this country, and branched, high-climbing over trees attaining a height of 50-60 ft., cladodia fl-like, alternate or few, solitary at the axils of flesuous-membranaceous scales, ovate-lanceolate, acuminate, leathery: fls. small, yellow, fasciared, the fasciules on the margins of the cladodia, poriath persistent, tube very short, tubinate, almost hemispherical; crown none; ovary sessile or stalked; calyx 5-lobed; corolla oblique, 5-lobed, segments imbricated and deciduous; petals 5, spreading, somewhat unequal; disk annular and rather broad; stamens 5; ovary superior, sessile, 1-3-celled: nut or drupe reniform.—About 30 species, Trop. Asia and Austral.

Selenium, Linn. f. MARKING-NUF TREE. A moderately sized deciduous tree with large, oblong or obovate-oblong lvs. 8-24 in. long by 5-10 in. wide: fls. greenish white, ½ in. across, nearly sessile, in stout branching panicles about the same length as the lvs.: drupe 1 in. long, smooth, black. India.—The black acid juice of the nut is used for printing cotton cloth. Cult. in S. Fla.

SEMELE (named for the mother of Bacchus). Liliaceae. CLAMMING BUTCHER'S BROOM. A warhouse plant, hardy outside in the extreme N. and S. of this country, and branched, high-climbing over trees attaining a height of 50-60 ft., cladodia fl-like, alternate or few, solitary at the axils of flesuous-membranaceous scales, ovate-lanceolate, acuminate, leathery: fls. small, yellow, fasciared, the fasciules on the margins of the cladodia, poriath persistent, tube very short, tubinate, almost hemispherical; crown none; ovary sessile or stalked; calyx 5-lobed; corolla oblique, 5-lobed, segments imbricated and deciduous; petals 5, spreading, somewhat unequal; disk annular and rather broad; stamens 5; ovary superior, sessile, 1-3-celled: nut or drupe reniform.—About 30 species, Trop. Asia and Austral.

Selenium, Linn. f. MARKING-NUF TREE. A moderately sized deciduous tree with large, oblong or obovate-oblong lvs. 8-24 in. long by 5-10 in. wide: fls. greenish white, ½ in. across, nearly sessile, in stout branching panicles about the same length as the lvs.: drupe 1 in. long, smooth, black. India.—The black acid juice of the nut is used for printing cotton cloth. Cult. in S. Fla.

SELENOPIPEDIUM (named for Natale Sellier, a French engraver who worked for Cavanilles). Goodeniodaceae. Two creeping and rooting perennial herbs of Austral. and New Zeal. and one of them extending to Chile: plant creeping and rooting perennial herbs of Austral. and New Zeal., often in tens of thousands, the cladodia and the filaments free instead of grown into leaf-like organs which have the form and function of lvs. but not the morphology. Some members of this genus are probably not regularly in cult., but the roots of one of them are used in Europe and in the United States in the preparation of a fertilizer. The plants are probably not regularly in cult., but the roots of one of them are used in Europe and in the United States in the preparation of a fertilizer.
SEMELE

Gn. 72, p. 432. G.M. 31:477, 479; 37:261.—The members which have the position of lvs. are minute scales, in the axil of which are borne the cladophylla, the latter being 9-4 in. long. It is grown in the open in S. Calif. and is said to look like a tropical smilax and to have dark green tropical foliage likely to be mistaken for some of the Indian climbing palms.

F. TRACY HUBBARD.

SEMIBEGONIIELLA is a recent genus of the Begoniaceae, differing from Begonia in having a tubular male flower (Syngeneum has a tubular female flower), apparently not in cult. S. Sodiroi, C. DC. from Ecuador was described, and the genus founded, in 1908.

Leaves alternate, thick-fleshy, often revolute: cymes panicked, usually densely: fls. white, rose, green, yellow, or purple; calyx 6- to many-cleft or -parted, rarely 5-cleft; petals 6 to many, free or connate at the base, oblong or lanceolate; stamens double as many as the petals, rarely the same number, free; ovary with as many carpels as petals, rarely the same number, free; ovary with as many carpels as petals, free or the base or up to the middle immersed in the calyx-tube: fr. many-seeded follicles.—About 65 species, widely scattered in the mountains of the Old World. The genus was monographed (horticulturally) by J. G. Baker in Gardener’s Chronicle for 1879, and his treatment has been followed here to some extent with the addition of several species and slight modifications to meet more recent knowledge of the genus. Sempervivum is closely related to Sedum, but the floral parts are multiples of 6 or some larger number, while the floral parts of Sedum are in 5’s. The genus is a difficult one for the botanist, and the specific limits are very uncertain and unsatisfactory, no two authors agreeing. The key will undoubtedly prove faulty, but is an attempt to simplify the determination of the species.

Sempervivums are mostly hardy perennials and stemless, and increase by rosettes (Fig. 3602) which are sent out from the parent plant, thereby suggesting the easiest culture and are quickly multiplied by means of the offsets or rosettes. They may be used alone for the commonest, are the prettiest of them all, by reason of the webs that cover the young rosettes. These coverings are made by the plants themselves and are incidental to development, but in some species are not strongly developed and in all the group are less noticeable in the old rosettes.

SEMPERVIVUM

The species, which grows on the roofs of houses in Europe, is S. tectorum. In the case of S. soboliferum the young rosettes are attached to the parent plant by a more slender thread than usual and more easily detach themselves and roll about. The spider-web species, of which S. arachnoideum is the commonest, are the prettiest of them all, by reason of the webs that cover the young rosettes.

SEMPERVIVUM

THEORY

AA. Plants with secondary rosettes on offsets or seossile.

D. Fls. usually 6-merous; not widely spreading at maturity.
E. The fla. small; petals not fimbriated on the margin and keel
D. Segma. of calyx linear-oblong; petals linear-oblong
E. Segma. of calyx lanceolate; petals lanceolate
C. The fls. large; petals fimbriated on the margin and keel
D. New rosettes rolled up into round balls
E. Lvs. obovate-cuneate
D. New rosettes not rolled up into round balls
E. Lvs. oblong-cuneate
B. Fls. usually 12-merous (9-14, merous); widely expanded at maturity.

C. Color of fls. yellow or yellowish
D. Surface of lvs. glabrous
E. The lvs. obovate-cuneate
D. Surface of lvs. more or less hairy
E. Blade of lvs. ensiform, linguiform
D. Blade of lvs. obtuse to rounded
E. Blade of lvs. more or less obovate-cuneate
C. Segms. of calyx oblong
D. Petals linear-lanceolate, acute externally
E. Petals lanceolate, acuminate
D. Petals lanceolate, obtuse externally
E. Petals lanceolate, acute externally
C. Color of fls. reddish or purplish
D. Inner lvs. of rosette with their tips connected by fine hairs like a spider’s web
D. (The following 5 species are very closely related.)
SEMPERVIVUM

E. Rosette lvs. glabrous or merely puberulent at a apex.
F. Calyz-segms. lanceolate-linear, acute; cauline lvs. lanceolate-linear... 18. hetero-trichum
FF. Calyz-segms. linear, obtuse; cauline lvs. oblongate to oblong... 19. Moggridgei
EE. Rosette lvs. more or less hairy.
F. Segms. of calyz linear, ... 20. arachnoideum
FF. Segms. of calyz ovate to lanceolate.
G. Cauline lvs. lanceolate; rosette lvs. oblong-obovate. 21. Doellianum
GG. Cauline and rosette lvs. lingulate. ... 22. Laggeri
PP. Inner lvs. of rosettes not connected by fine hairs like a spider’s web.
E. Tips of lvs. with tuft of hairs. 23. Hausmannii
F. Lvs. ovate-oblongate. 24. Brotanum
G. Lfs. ovate or obovate. 25. assimile
H. Lvs. elliptical. ... 26. Laggeri
HH. Lvs. echiiate. 27. pumilum
II. Lvs. lanceolate. 28. montanum
JJ. Lvs. cuneate. 29. flagelliforme
TT. Surface of lvs. of the rosettes pubescent.
G. Stamens two-thirds as long as petals.
H. Barren rosettes not more than 1 in. diam. 27. pumilum
HH. Barren rosettes more than 1 in. diam. 28. montanum
II. Fls. numerous, mauve or red-brown. ... 29. flagelliforme
JJ. Fls. less (4-5), bright red. 30. fimbristatum
EE. Tips of lvs. without tuft of hairs.
F. Surface of lvs. of the rosettes pubescent.
G. Setae lvs. distinct. Fls. rose-red. 31. Pomellii
GG. Setae lvs. indistinct. Fls. bright red. 32. assimile
HH. Stamens half as long as petals.
II. Barren rosettes not more than 1 in. diam. 33. Lamottei
JJ. Fls. rose-red. 34. Pomellii
TT. Lvs. ovate or obovate. 35. Funckii
HH. Lvs. obtuse or acuminate. 36. glaucum
II. Lvs. pale green but not glaucous.
E. Cauline lvs. green-dipped; petals rose... 37. Verloti
EE. Cauline lvs. claret-dipped; petals white-marbled... 38. atlanticum
TT. Red-brown tip of rosette lvs. distinct.
I. The cauline lvs. red and green throughout. 39. triste
II. The cauline lvs. partly green.

SEMPERVIVUM

I. Rosette lvs. glabrous.
K. Outer lvs. of rosette 1½-2 in.; fls. about 3-4 in. across. 40. Greenii
KK. Outer lvs. of rosette 1½-2 in.; fls. about 4 in. acros... 41. calcarum
LL. Rosette lvs. not glaucous. (The following species are frequently kept distinct but no distinguishing key characters can be detected from the descriptions.)

1. pociuliforme, Berger & DeWild. St. simple, erect, more or less elongated: basal lvs. in a rosette, oblong-lanceolate, cuneate at the apex, serratulate, otherwise glabrous; cauline lvs. obovate-spatulate; fls. 5-merous, in a glabrous panicle; calyx glabrous, segments lanceolate-triangular subacute; petals lanceolate, acute. Canary IsIs. (7).

2. canariense, Linn. Subshrub: st. short, thick; lvs. in a flattened rosette, obvate-spatulate, mucronate, acuminate; petals in a petiole, villous; cauline lvs. obovate-rotundate; fls. 7-9-merous, pale yellow or white, in a lax thyrsoid elongated panicle; calyx very villous, segments ovate-lanceolate; petals linear, acute. Canary IsIs.

3. arboreum, Linn. St. arborescent, with terete branches; rosettes concave; lvs. spreading, obovate-spatulate, obtuse, mucronate, base cuneate, rather glabrous; fls. golden yellow in a many-flowered leafy panicle; calyx-segments ovate, rather acute; petals spreading, 10-12, elliptic. Medit. region.

4. chrysanthum, Hochst. Subshrub, 1-3 ft. high; st. thick; lvs. pectinate-ciliate, on barren shoots rosetulate, roundish ovate; cauline lvs. obvate-oblong, rounded above, apiculate; fls. about 8-merous, yellow, or white(?), in a thyrsoid corymb; calyx-segments short-triangular; petals linear-lanceolate. Abyssinia.--Closely allied to S. arboreum and possibly not distinct from it.

5. tabulatum, Hornem. Shrub; st. erect-branched; lvs. oblong-spatulate, base attenuate, flat, ciliate, gathered at the tips of the branches in a flat rosette; peduncles minutely glandular; petals linear-lanceolate, very pale sulfur. Canary IsIs.

6. spathulatum, Bornem. (S. barbatum, C. Smith. Aëonium barbatum, Webb & Berth.). Shrubby; st. stout; branches horizontal near the st., then arched and erect; rosettes flat, not dense; lvs. of the rosettes oblong-spatulate, acute, margin papillose, both surfaces with linear, red-brown markings; calyx lvs. linear-lanceolate, acuminate; fls. 8-10-merous, in rather open panicles, the fls. on the upper side of the branches; calyx-segments deltoid; petals oblong-lanceolate, acute. Canary IsIs.--Some of the material grown under this name is certainly not the species above described, but probably a form of S. tectorum.

7. Heufellii, Schott (S. petersii, Griseb. & Schenk). Barren-rosette 1½-2 in. diam., the young rosettes not pedunculated; lvs. 30-40 to a rosette, obovate-cuneate, distinctly cuspitate, glabrous, lower part pale green, upper third or even half tinted bright red-brown, margin crowded, stiff, white-ciliate, outer lvs. 3½-1 x 3½ in.
Sempervivum
culine lvs. close, red-brown, lanceolate, 3/4–1 in. long; fl.-st. including the infl. 6–8 in. high, densely short / puberulent, yellow-green, pale strigillose, pale purple, lance-ovate-cuneate, in a dense panicule 21/2–3 in. diam.; calyx-teeth linear-oblong, finely glandular-pubescent on the back and red-brown when old; petals 3/4 in. long, linear-oblong, obtuse, with 3 small cilia; keeled and finely glandular outside. Transylvania, Austria, and Greece in the mountains. Of the latest in flower.

8. Regia-Mamillia, Hedr. & Sart. Rosettes about 3 in. diam., the new ones sessile; lvs. 100 or more to a rosette, obovate-cuneate, distinctly cuspidate, all bright yellow, petalless in the upper half, greenish at the base, glabrous, margin ciliate, outer lvs. 1–11/2 x 1/2–3/4 in.; calyx lvs. crowded, lanceolate, brown, slightly pubescent: fl.-st. including infl. 6 in. high, densely pubescent; fls. 6–7-merous, pale yellow, in a dense many-fl. corymbose panicle; calyx finely glandular-pubescent, segms. lanceolate; petals lingulate, obtuse, obscurely tricuspidate, densely glandular externally. Mountains of Greece.

9. S. soboliferum, Sims (S. globiferum, Linn. as to synonymy with many other authors, not Linn. as to plant cited). Hen-and-Chickens. Houseleek. Barren rosettes globose, 1–11/2 in. diam., the copious new rosettes sessile and attached to the parent only by a slender thread and easily becoming detached from it and rolling about: lvs. 60–80 to a rosette, obovate-cuneate, obscurely cuspidate, pale light green, glabrous, margin minutely ciliate, outer ones tinted with red-brown especially on their back, 1/2–3/4 x 1/2–3/4 in.; calyx lvs. very densely crowded, ovate-lanceolate, acute: fl.-st. including infl. 6–9 in. high, very robust, finely pubescent: fls. 6–7-merous, pale yellow, in a short, dense, many-fl. panicle, which is 3–4 in. diam.; calyx-segms. lanceolate, nearly glabrous on the back, margins strongly ciliate, mostly 1–11/2 in. long; obtuse, tricuspidate, margins conspicuously fimbriate. Mountains of Austria. B.M. 1457.—Unless the young rosettes are thinned out the plants are not so apt to flower.

10. Arenarium, Koch. (S. Nebræcii, Schott, Nym. & Kotschy). Rosettes globular, deciduous: lvs. 60–80 to a rosette, oblancoate, acute, bright green, glabrous, outer lvs. slightly tinted red-brown on the back, 1/2–3/4 in. long; calyx lvs. ovate-lanceolate: fls.-st. including the infl. 6–9 in. high, crowded, leafy and finely glandular-hairy, puberulent at the apex above, glabrous beneath, glaucous; petals linear-lanceolate, acute, about 1/2 x 1/2–3/4 in.; tip reddish: fl.-st. slender, glabrous-hairy: fls. 12–merous, pale greenish yellow, striped red; calyx-segms. oblong; petals narrowly linear-lanceolate, acute. Tyrol.—Probably a hybrid; S. montanum x S. Wulfenii.

11. Sempervivum, Linn. (part, excl. synonymy: S. rubenicium, Koch). Rosette 1–11/2 in. across, rather flattened, the young ones globular, borne on scaled peduncules which are rather stout and about 11/2–3 in. long: lvs. obvate-cuneate to elliptical, grey-green, ciliate; calyx lvs. oblong, acute, about 1/2 x 1/2–3/4 in.; tip often red-brown: fl.-st. about 1 ft. high, including infl., densely short-hairy: fls. pale yellow, 12–14-merous, about 1–11/2 in. across; calyx-segms. lanceolate, acute; petals linear-lanceolate, acute, externally glandular-hairy and green-striate, margins glandular-ciliate. Russia in Eu.—As Koch points out in Flora 18, part 1, 1200, t. 1 (1835), the synonymy given by Linnaeus undoubtedly refers to S. soboliferum, a 6-merous species, but that the one plant Linnaeus cites and his "Habitat in Rutenia par. Gretili" undoubtedly refers to the 12-merous plant which Besser knew under the name S. globiferum and which he, Besser, sent to Koch in 1834.

12. Grandiflorum, Haw. (S. globiferum, Sims, not Linn.). Rosettes about 11/2 in. diam., the new ones on decumbent peduncules 1–2 in. long, which have small lvs.: lvs. about 40 to a rosette, obovate-cuneate, obscurely cuspidate, pale green, pubescent, only the tip obscurely red-brown tinted, outer lvs. 11/4–1 x 3/4–11/2 in.; calyx lvs. crowded, lanceolate, 1–11/2 in. long; fls.-st. including infl. 3–8 in. high, densely pubescent: fls. 12–14-merous, 1/2–11/2 in. across, pale yellow, sub sessile in a dense paniculate head; calyx pubescent, segms. lanceolate; petals lanceolate, acuminate, back glandular. Hab. (?). B.M. 307; D. Linn. 211. Rare in cult.

13. Lithophyllum, Schott. Rosettes 1–11/2 in. diam.: fls. 3–6 in. high, puberulent pubescent: lvs. of the rosette spatulate-linear, apex acute, with a tuft of hairs and also long web-hairs connecting the fl-tips, puberulent at the apex above, glabrous beneath, glaucous; calyx lvs. lanceolate-linear, puberulent on both sides: infl. puberulent; fls. 9–12-merous, rose, in a racemose panicle; calyx-segms. lanceolate-linear, acute; petals lanceolate, acuminate, ciliate, apex barbate. S. Eu.—Closely allied to S. Dodecanum and S. arachnoideum.

14. Moggridgei, De Smet. Rosettes 2 in. diam.: lvs. about 100 to a rosette, 3/4 in. long, elongate-cuneate or oblancoate, green, glabrous, margins minutely ciliate,
tips acute and hairy tufted; cauline lvs., the lower oblong-lanceolate, ⅓ in. long, tips bearded, pale green, tips reddish, the upper more oblong: cyme 3-4 times forked: fls. 10-12-merous, ½ in. diam.; calyx glandular-pubescent, segments linear, glabrous; petals in Raceme, acuminate, apiculate. S. Eu. B.M. 6610.—Allied to S. arachnoideum.

24. Pömeli, Lamotte; also misspelled Poemelia. Barren rosette 1½-1¼ in. diam., the new ones nearly sessile: lvs. 50-60 in. a rosette, oblong-lanceolate, with a distinct cusp, a few hairs on both surfaces, the cusp furnished with an inflexed tuft of hairs, outer lvs. ⅓-1 x ¼ in., tinged with red; calyln lvs. much imbricated, lanceolate, hairy, the lower 1-1½ in long: fl.-st. including inf. 6-10 in. high, densely pilose: fls. 10-12-merous, about 1 in. across, rose-red, in a panicle 3-4 in. diam., its simple branches 6-12-fld.; calyx densely pilose, segments linear-lanceolate, glandular; petals linear-lanceolate. France.

25. fimbriatum, Schnittsp. & Lethm. Barren rosette 1½-1¾ in. diam., the new rosettes nearly sessile: lvs. 50-60 to a rosette, oblong-lanceolate, obliquely ciliate, pale glaucous green, not red-tipped, margin short-ciliolate, surface minutely pubescent, outer lvs. ⅓-1 in. long: fl.-st. including the infl. about 6 in. high: fls. 12-merous, about ¾ in across, pale rose; calyx-segments lanceolate; petals linear. Transylvania.

26. assimilis, Schott. Rosettes of barren lvs. 1½-2 in. diam., the new ones nearly sessile: lvs. 60-80 to a rosette, oblong-cuneate, cuspidate, pale glaucous green, not red-tipped, margin short-ciliolate, surface minutely pubescent, outer lvs. ⅓-1 in. long: fl.-st. including the infl. about 6 in. high: fls. 12-merous, about ¾ in across, pale rose; calyx-segments lanceolate; petals linear. Transylvania.

27. pumilum, Bieb. (S. anatimum, Hort.). Barren rosette at most 1 in. diam., the compact new rosettes shortly peduncled: lvs. 30-40 to a rosette, oblong-cuneate, glabrous, brownish-purple, in a dense head, all sessile or sub-sessile; calyx very hairy, segments lanceolate; petals acuminate, very hairy outside. Caucasus.

28. montanum, Linn. Barren rosette 1¼-1¾ in. diam., the few new rosettes on red pilose peduncles 1½-1¼ in. long: lvs. closely packed, 60-80 to a rosette, oblong-cuneate-cuneate, cuspidate, green up to the tip, both surfaces slightly pilose, outer lvs. ⅓-1 x ¼ in.; calyln lvs. lanceolate, hairy all over, tinged red-brown, the lowest ½-⅔ in long: fl.-st. including infl. not more than 3-4 in. high; fls. few (4-8), about 12-merous, 1 in. across, bright mauve-purple, in a dense head, all sessile or sub-sessile; calyx very hairy, segments lanceolate; petals linear. Switzerland.

29. flagellifomx, Fisch. Barren rosette 1½-1¾ in. diam., with the new rosettes on long spreading peduncles and the small lvs. not aggregated into a dense erect head: lvs. 40-50 to a rosette, oblong-cuneate, obliquely ciliolate-tufted, upper surface minutely downy, pale green without a tint of red-brown at the tip, margin ciliolate, outer lvs. ⅓-1 x ¼ in.; calyln lvs. imbricated, lanceolate.
hairy, lowest about 1 in. long; fl.-st. 3--4 in. high including the infl.: fls. about 12-merous, about 1 in. across, bright red, about 8 in. high, in a dense head, sessile, or nearly so; calyx densely pilose, segms. lanceolate; petals linear, acuminate, densely glandular-pilose outside. Siberia (?).

30. **Schnittsnahi**, Lagg. (S. Fänkli, Lej.). Rosette medium-sized, open, the young ones on straight peduncles ½--1 in. long: lvs. of rosette ovate-lanceolate, with a short hair point, glabrous, margin white-lanceolate, dark green, tip red-brown, keeled beneath; calyces lanceolate: fl.-st. erect, furrowed, at top slightly winged, white-hairy; fls. brown-rose, later rose, more than 6-merous; petals broadly lanceolate. Switzerland.

33. **Lamottei**, Bor. Barren rosettes 3--4 in. diam., the copious young rosettes sessile: lvs. ovovate-cuneate, cuspidate, glabrous, margin cilia stiff, outer lvs. 1½--2 in. long and densely rosulate at their tip: fl.-st. including the infi.: fls. more than 1 ft. high, densely glandular-pilosae; fls. 12--16-merous, ½--1 in. across, rose-red, in a panicle 5 x 3--4 in.; calyx densely pilose; petals somewhat keeled. Cent. Eu.—The synonymy is much involved and by some authorities *S. Comotti* is said to be a hybrid, *S. accuminatum* and *S. Schottii* synonymous and distinct, and *S. Schlehanii* also distinct, but the differences seem extremely weak.

37. **Verlöffii**, Lamotte. Barren rosettes 1½--2 in. diam., the new ones nearly sessile: lvs. about 50 to a rosette, oblongate-cuneate, cuspidate, glabrous, pale green, faintly glaucous, only the very tip tinged with red-brown, margin stiff-ciliate, outer lvs. ½--1 × ½--1½ in.; calyces lvs. oblong-lanceolate, red-tinted, lowest 1--2 in. long: fl.-st. including the infl. 6--12 in. high, densely pilose, at least above: fls. 12--14-merous, about 1 in. across, pale or bright red, in a short compact panicle, 2--3 in. diam.; calyx densely pilose to glandular-pilosae, segments lanceolate; petals somewhat keeled. Cent. Eu.—The synonymy is much involved and by some authorities *S. Comotti* is said to be a hybrid, *S. accuminatum* and *S. Schottii* synonymous and distinct, and *S. Schlehanii* also distinct, but the differences seem extremely weak.

38. **atlanticum**, Baker (S. tectorum var. atlanticum, Ball). Barren rosettes 2--3 in. diam., the young rosettes nearly sessile: lvs. oblongate-cuneate, cuspidate, pale green, glabrous when mature, hardly at all tipped with red-brown, outer lvs. 1½--1½ in. long, ½ in. broad above the middle; calyces lvs. oblong-lanceolate, noticeably claret-red-tipped; fls.-st. including infl. nearly 1 ft. high: fls. 12-merous, pale red, 1 in. across, in a short panicle, 3--4 in. diam.; calyx densely pilose; petals linear, acuminate. Morocco. B.M. 6055.
about 1/4 in. across, pale red, in a panicle 1 1/2-2 in. diam.; calyx densely pilose; petals densely ciliated. Habitat unknown.

41. calcareaum, Jord. (S. californicum, Hort.). Barren rosettes about 2 in. diam., young ones nearly sessile; lvs. oblanceolate-cuneate, cuspidate, very glaucous, with a very distinct red-brown tip, glabrous, outer lvs. 1-1 1/4 x 1/4 in.; cauline lvs. densely imbricated, oblanceolate-obovate, 1-1 1/4 in. long; fl.-st. less than 1/2 ft, high, including the fls.: fls. 10-12-merous, 3/4 in. across, pale red in a panicle 3-4 in. long, with 8-12 simple scorpoid branches; calyx densely pilose, segms. lanceolate; petals greenish down the back, densely calyculate. France on the calcareous alps of Dauphiné.

42. arvenense, Leq. & Lamotte. Barren rosette 1 1/2-2 1/2 in. diam., copiously stoloniferous; lvs. about same number as in S. teectorum, oblanceolate-cuneate, cuspidate, bright pale green, glabrous, tips of lvs. with a distinct red-brown blotch 1/2-3/4 in., long, outer lvs. 1 3/4-2 1/2 in. long; fl.-st. including infl. 6-8 in. high, densely pilose; fls. pale pink, in a panicle 2-3 in. long and broad, the lower fls. distinctly pedicelled; calyx-segms. lanceolate; petals linear. France.

43. Bougnatitum, Bail. & Gren. Barren rosettes 2-3 in. diam.; lvs. of rossets obovate-oblong lanceolate, cuspidate, glabrous, green, red-tinted; cauline lvs. oblone to lanceolate, acuminate, sparingly pilose beneath; fls. purple-reddish in a panicle, star-like, expanded; petals 12, linear-lanceolate, glabrous, linearly oblanceolate, glabrous, the lower fls. distinctly pedicelled; calyx-segms. lanceolate, petals densely glandular-ciliate. Eu.—Botanically probably a variant of S. arvenense.

44. alpinum, Griebl. & Schenk. Rosettes 2-3 in. diam.; lvs. of rossets obovate-oblong lanceolate, cuspidate, bright pale green, red-tinted; cauline lvs. oblone to lanceolate, acuminate, sparingly pilose beneath; fls. purple-reddish in a panicle, star-like, expanded; petals 12, linear-lanceolate, glabrous, linearly oblanceolate, glabrous, the lower fls. distinctly pedicelled; calyx-segms. lanceolate, petals densely glandular-ciliate. Eu.—Botanically probably a variant of S. arvenense, though referred by some authorities to S. montanum.

45. Boissieri, Hort. Barren rosette very dense, 2-2 1/2 in. diam., composed of about 100 lvs.; new rosettes washed with purple; fls. red.—S. chrysanthum, DC. Crab.

46. alpinum, Griebl. & Schenk. Rosettes 2-3 in. diam.; lvs. of rossets obovate-oblong lanceolate, cuspidate, bright pale green, red-tinted; cauline lvs. oblone to lanceolate, acuminate, sparingly pilose beneath; fls. purple-reddish in a panicle, star-like, expanded; petals 12, linear-lanceolate, glabrous, linearly oblanceolate, glabrous, the lower fls. distinctly pedicelled; calyx-segms. lanceolate, petals densely glandular-ciliate. Eu.—Botanically probably a variant of S. arvenense, though referred by some authorities to S. montanum.

47. S. affinis, Lamotte, is offered in the trade as having dark green rosettes marked with rose; fls. red. Eu. The botanical description is not available and the species is not treated in recent European floras.

48. alpinum, Griseb. & Schenk. Rosettes 2-3 in. diam.; lvs. of rossets obovate-oblong lanceolate, cuspidate, bright pale green, red-tinted; cauline lvs. oblone to lanceolate, acuminate, sparingly pilose beneath; fls. purple-reddish in a panicle, star-like, expanded; petals 12, linear-lanceolate, glabrous, linearly oblanceolate, glabrous, the lower fls. distinctly pedicelled; calyx-segms. lanceolate, petals densely glandular-ciliate. Eu.—Botanically probably a variant of S. arvenense, though referred by some authorities to S. montanum.

49. S. alpinum, Griseb. & Schenk. Rosettes 2-3 in. diam.; lvs. of rossets obovate-oblong lanceolate, cuspidate, bright pale green, red-tinted; cauline lvs. oblone to lanceolate, acuminate, sparingly pilose beneath; fls. purple-reddish in a panicle, star-like, expanded; petals 12, linear-lanceolate, glabrous, linearly oblanceolate, glabrous, the lower fls. distinctly pedicelled; calyx-segms. lanceolate, petals densely glandular-ciliate. Eu.—Botanically probably a variant of S. arvenense, though referred by some authorities to S. montanum.

50. S. affinis, Lamotte, is offered in the trade as having dark green rosettes marked with rose; fls. red. Eu. The botanical description is not available and the species is not treated in recent European floras.

51. S. arvense, Lamotte, is offered in the trade as having dark green rosettes marked with rose; fls. red. Eu. The botanical description is not available and the species is not treated in recent European floras.

52. S. alpinum, Griseb. & Schenk. Rosettes 2-3 in. diam.; lvs. of rossets obovate-oblong lanceolate, cuspidate, bright pale green, red-tinted; cauline lvs. oblone to lanceolate, acuminate, sparingly pilose beneath; fls. purple-reddish in a panicle, star-like, expanded; petals 12, linear-lanceolate, glabrous, linearly oblanceolate, glabrous, the lower fls. distinctly pedicelled; calyx-segms. lanceolate, petals densely glandular-ciliate. Eu.—Botanically probably a variant of S. arvenense, though referred by some authorities to S. montanum.
the senecios are yellow-rayed. Of the vast number of species, very few have gained prominence in horticulture.

To Senecio belong the genera known as Jacobea, Kleinia, and Cineraria. The latter is a Senecio, although the florist's cineraria is described under that name in Vol. I of this work. Bentham & Hooker refer to Senecio the genus Callisia, which is kept distinct by American botanists. Hoffman (in Engler & Prantl's Pflanzenfamilien) refers the garden genus Emilia to Senecio, but keeps Ligularia (including Farfugium) and Cineraria (not the florist's cineraria) distinct. See Emilia; also Ligularia.

If the greenwood cineraria (which is technically a Senecio as understood by Bentham & Hooker) is omitted, the most popular species are S. micranthos or German ivy, S. elegans or purple ragwort, S. pulcher, and S. Cineraria, one of the plants commonly known as dusty miller, and one of them, Artemisia Sierriana, is sometimes confounded with Senecio Cineraria. Most other species are of very minor importance to the horticulturist. Several species are found in the European trade, and of the sixty or more species native to the United States and Canada, about a half dozen have been offered by dealers in native plants, but they are practically unknown horticulturally. Most of the species are wholly herbaceous, but in South Africa, Australia, Central and South America many species are shrubby. Some species are even arborescent; others are climbers. In South Africa and the Canaries is a small series of plants that has been separated as Kleinia, distinguished mostly by their habit, being for the most part, leafy shrubs or herbs, with terete or angular stems and whitish or pale yellow rayless flowers. Species of this group are sometimes seen in collections of succulents. S. vulgaris, Linn., from Europe, is a common annual weed in various parts of this country. Since senecios afford both greenhouse and hardy border plants, it is impossible to give general cultural directions. The species are not difficult to manage, however, and most of them propagate readily by means of greenwood cuttings and seeds and by the hardy species, the hardy species may be divided. Most of the tender species require greenhouse conditions. However, the most popular species are

(Kleinia) Anteuphorbium, Schz. Bip., is sometimes seen in collections, although it is not known to be in the American trade. It is a glabrous shrub 3–4 ft. high, with woolly sts. constricted at the joints, small, erect, woolly, entire Ivs. that are deciduous on the st., and solitary cymose yellow-flowered heads (with rose tinge) an inch long. B. M. 6099. According to J. D. Hooker, this plant “is one of the oldest Cape plants in cult. having, according to Dodoens, been brought to Eu. in 1570, and cult. in England in Gerard’s garden in 1596. The name Anteuphorbium was given because of its being a reputed antidote against the acrid poison of the Cape Euphorbia.” The names Kleinia spinulosa, K. pendula, and K. suspensa have appeared in the American trade, but they are unidentifiable.

2. radicans, Schz. Bip. (Cacalia radicans, Linn. f. Kleinia radicans, Huds.). Fig. 3603. Sts. prostrate, readily rooting from the nodes; Ivs. woolly, cylindrical, straight or somewhat curved, 1 in. or less in length, ½ in. thick, acute, narrowed at the base into a short petiole; peduncle terminal, bearing a single rayless head. S. Afr.—A desirable plant for the rockery; it grows freely among cacti and other flaxlike plants.

3. mikanoides, Otto (S. seddens, DC.). German Ivy. Fig. 3604. Slender and glabrous, tall-twinning; Ivs. ovate or deltoid-ovate in outline, mostly with a deep basal sinus, sharply 5–7-angled or angle-lobed; heads small, discoid, yellow, in close clusters on axillary and terminal branches; bracts of the involucre shorter than the disk-fls. S. Afr. G. 35:343.—Very common conservatory and window-garden plant, easily prop. by cuttings.

4. seddens, Buch.-Ham., not DC. A hardy plant with woody climbing sts. reaching a height of several feet; branches slightly hisrate; Ivs. short-petiolate, elliptic-lanceolate in general outline, undivided or bearing two or more divisions at the base of the blade, triangular-dentate, grayish green and finely pubescent on both surfaces; infl. a terminal panicle; heads radiate, rayed, yellow. China. R. H. 1909, p. 407.—Intro. by de Villorin, Verrières-le-Buisson, France.

5. macroglossus, DC. Cape Ivy. An herbaceous glabrous climbing perennial: Ivs. petiolate, deltoid-hastate, 1-½ in. long and broad, usually with 2 salient acuminate basal lobes, entire or subdentate, cordate to almost truncate at the base; flowering branches 1-3-headed: heads radiate with 8–12 yellow rays; disk-fls. 40–50: achenes glabrous. S. Afr. G. 26:20.—A coolhouse climber.

6. auriculatissimus, Brit. A perfectly glabrous climbing perennial, freely branching with disparately spreading branches; Ivs. petiolate, transversely oblong to subreniform, 2–3 in. broad, coarsely crenate-dentate, bright green above, paler beneath; petioles 1–2 in. long, slender, channelled above, sharply dilated at the base into 2 broad auricles completely clasping the st.: heads radiate, about 1 in. diam., disposed in loose terminal corymbose cyme; ray-fls. about 13, rays yellow: achenes 5-ribbed, puberulent along the ribs. Brit. Cent. Afr. G. C. III. 27:133, descr. B. M. 7237.—On account of the peculiar foliage and bright yellow fls. it is a striking plant and very worthy of more general cult.

7. elegans, Linn. (S. purpureus, Hort. Jacobaea elegans, Moench). Purple Ragwort. Annual, viscid-pubescent, erect or diffuse, 1–2 ft. high; Ivs. various, mostly oblong in outline, pinnate, lobed or toothed, the sinusae chiefly broad and rounded, clasping at the base. Heads in loose corymbs, the rays purple; disk-fls. yellow. S. Afr. B. M. 238. Var. erectus, Harv. St. slender but erect: Ivs. pinnate or 2-pinnatifid.—S. elegans is an old garden plant. A common form of it has double fls. Var. albiflos, Hort., has white fls.

8. pälcher, Hook. & Arn. Robust, 2–4 ft. high, white-cobwebby; st. simple or nearly so and scarcely leafy; Ivs. oblong-lanceolate, 1–10 in. thick, shallow-lobed and crenate-toothed; heads 2–3 in. across, with many long, red-purple rays and a yellow disk. Uruguay and Argentina. B. M. 5059. R. H. 1877, p. 94; 1896, p. 329. Gn. 49, p. 122. G. M. 40:745. G. 31: p. 489, desc.—A very bold species, with striking erect habit and large fls. in summer. Perennial, although it has been described as annual. In protected places and well-drained soils, it is hardy in S. New England.

9. grandiflorus, Berg. (S. venustus, Ait.). An herbaceous perennial 4–5 ft. high: st. simple or sparingly branched, virgate, strigate, glabrous or nearly so, rather leafy except toward the infl.: Ivs. sessile, pinnately parted into linear divisions with revolute margins, glabrous or sparingly pilose; numbers numerous, radiate, strongly calyculate, disposed in a loose nearly naked corymbose cyme; rays purple; disk-fls. yellow: achenes strigate, glabrous or puberulent in the furrows. S. Afr. B. R. 901. Var. albidos, Harv. (S. dlbidos, Mey.). Both ray- and disk-fls. pale or whitish.

10. Dicia, Linn. Erect, 3–4 ft. high: radical Ivs. oval-oblong or oblongate, 6–15 in. long, dentate, glabrous and glaucous, gradually narrowed into a winged petiole; st.-lvs. oblong-lanceolate, sessile and somewhat deciduous: heads yellow, with 5 or 6 rays. Eu.—Hardy perennial.

11. macrophyllus, Bieb. (Jacobaea macrophilla, Mey.). A stout herbaceous perennial, 3–4 ft. high, glabrous or nearly so: lower lvs. oblong-oblong or oblongate, 6–18 in. long, 1–4 in. broad, gradually narrowed into a winged petiole, pale green, not glaucous; upper st.-lvs. sessile, semi-amplexicaule and somewhat deciduous on the st.: heads radiate, disposed in a terminal compound corymbose cyme. Eu.—Closely related to the preceding. Not infrequent in European gardens and occasionally offered in trade catalogues.—Not the same as Ligularia macrophylla, DC.; see supplementary list.
12. Doronicum, Linn. Leopard's Bane. A hardy, 
herbaceous perennial, floccose-tomentulose to glabrous; 
Ivs. thickish, ovate to lanceolate, 2-7 in. long, 3/4-1 1/2 in. 
broad, the lower usually rather coarsely dentate and 
narrowed into a winged petiole, the upper much reduced, 
sessile and entire: heads few, large, including the bright 
yellow or orange-colored 
ray-fls. 1-2 1/2 in. diam.; 
bracts of the involucre as 
well as the bracteoles 
atent, black-tipped: 
achenes striate, glabrous. 
S. Eu.—Frequently 
offered by European deal-
ers, but seldom grown in 
American gardens.

13. Idgens, Richards. An herbaceous peren-

tial, floccose-woolly when 
young but becoming 
early nearly or quite glabrous: 
st. practically naked 
above: Ivs. oblong-obo-

vate to lanceolate, 1 1/2-8 in. long, 1/2-1 in. broad, 
estiately denticulate, the 
lower narrowed into a 
winged petiole: heads 
radially few, radate, 
including the yellow rays 
1/2-1 1/2 in. diam.: 
bracts of the involucre as 
well as the subtending bracteoles 
acute, black-tipped: 
achenes striate, glabrous.

simple, erect, 8 in. to 3 ft. high, 
striate, glabrous or 
more or less 
crisp-hirsute; upper st. Ivs. much reduced, sessile: heads 
up to 2 ft. in length: infl. a 
terminal several- to 
many-headed corym-
bose cyme; involucre as 
well as the petiole 3-8 in. long, 
Y/3-2 in. broad, 
tomentulose in the fl.-axils, 
the lowermost Ivs. becoming 
dilated below into an 
auricle partially clasping the st.; 
the base into 2 large auricles partially clasping the st.; 
the typical form with rays.

15. saxfragoides, Hook. f. A perennial herb from a 
stout rootstock: st. about 
1 ft. high, branched, covered 
at the base with a long silky-woolly tomentum and 
clothed above with white hairs 
intermixed with purple setae: 
radical Ivs. petiolate, oblong-
eliptic to nearly orbicular, 3-5 in. long, 1/2-1 in. broad, 
denticulate, appressed-villosus, setose 
along the margins of the 
petiole 2-6 in. long, 
two-thirds to nearly 
or quite as broad, crenate 
and more or less 
tinged with purple 
beneath, glabrous or 
ocasionally slightly tomentulose; rays of the involucre 
1/2-10 in. long; st. 
Ivs. variable, petiolate to 
sessile and amplexicaul, 
lyrate to pinnate, 
reduced toward the infl. 
some times to linear 
bracts: infl. a terminal several- 
to many-headed corysthy 
cyme; heads 1/2-3 in. high, 
radiate; involucre cam-
ulate, glabrous or occasionally 
slightly tomentulose; bracts of the involucre 13-21, linear, acute; 
ray-fls. 8-12, rays yellow; disk-fls. numerous: 
achenes glabrous. Lab. to Ga., west to 
N. D. and Ark. B.B. 
3:544.—Frequently grown in American gardens.

16. Bolandier, Gray. A slender 
herbaceous perennial: st. 
ascending or erect from 
creeping rootstock, 6-20 in. 
high: radical and lower st.-Ivs. 
undivided and 
crenately lobate-dentate to pinnately 
narrowed into oblong-obovate 
to almost rotund divisions, glabrous above, 
usually pubescent beneath, including the petiole 2-6 in. long, 1/2- 
1 1/2 in. broad; heads few, radate, disposed in a corysthy 
cyme; involucre of about 13 bracts, commonly 
tawny-pubescent; ray-fls. 5-8, rays yellow; disk-fls. 
25-40: achenes glabrous. Calif. and Ore., near the 
coast.

17. aureus, Linn. Golden 
Ragwort. Fig. 3605. An herbaceous perennial: st. 
1-2 ft. high, glabrous or not infrequently 
tomentulose in the fl.-axils, 
along the margins of the 
petioles, and in the infl.: 
lower Ivs. petiolate, 
undivided and rotund-ovate, 
somewhat triangular-ovate 
and dilated below into an 
auricle partially clasping the st.; 
the lowermost Ivs. becoming 
dilated below into an 
auricle partially clasping the st.; 
the base into 2 large auricles partially clasping the st.; 
the lowermost Ivs. becoming 2 ft. in length: infl. a 
many-headed corysthy 
cyme; heads 1/2-3 in. high, 
radiate; involucre cam-
ulate, glabrous or occasionally 
slightly tomentulose; bracts of the involucre 13-21, linear, acute; 
ray-fls. 8-12, rays yellow; disk-fls. numerous: 
achenes glabrous. W. China. G.C. III. 40:43, 
desc.—Originally intro. by 
Veitch & Sons, and more re-
cently by E. H. Wilson, who 
has traveled in China.

18. Paberi, Hemsl. A stout coarse herb, glabrous or 
glabrescent; st. several, 4-8 ft. high, strato-angled, 
hollow: Ivs. pinnatifid, coarsely dentate, expanding at 
the base into 2 large auricles partially clasping the st.; 
the lowermost Ivs. becoming 2 ft. in length: infl. a 
many-headed corysthy 
cyme 6-8 in. diam.; heads 
radiate with 3-5 deep yellow rays; disk-fls. 8-15, yellow. 
W. China. G.C. III. 40:43, 
desc.—Frequently grown in American gardens.

19. tanguticus, Maxim. (S. Hentzi, Hemsl.). A tall stout 
herbaceous perennial, glabrous or 
nearly so; st. 6-7 ft. high, 
branching above, leafy: Ivs. 
broadly ovate or deltoid in 
general outline, 5-7 in. long, 
and broad, pinnately divided 
into lanceolate coarsely and 
remotely toothed divisions, dark 
green above, paler beneath; 
achenes the lower Ivs. long 
and dilated below into an 
ampullaceous base: heads very 
numericous, radiate, disposed in 
a terminal pyramidal panicle; 
ray-fls. 3 or 4, rays yellow; 
disk-fls. 3 or 4, corolla-l�es 
revolute. W. China. B.M. 
7912. Gn. 64, p. 287.—A con-
spicuous and attractive species; flowers in Sept. and Oct. Frequently offered by American dealers.

20. **Jacobaea**, Linn. TANSY ROCKET. STINKING WISHES. An erect biennial or perennial herb: st. 1-3 ft. high, leafy; basal lvs. petiolate, sublyrate; st.-Ivs. sessile, 1\(\frac{3}{4}\)-6 in. long, 3\(\frac{1}{4}-2\) in. broad, 2-3-pinnatisect; heads numerous, radiate with yellow rays. Eu. Naturalized in N. E. Amer. along the coast.—Occasionally cult. in gardens.

21. **uniflorus**, All. A low herbageous perennial, densely white-tomentose throughout: st. 2-5 in. high, usually terminated by a solitary head: lvs. mostly radical, spatulate to oblong, entire to incised-dentate, 1-2 in. long, 3\(\frac{1}{2} \) in. or less broad: heads radiate; rays yellow. S. Eu.—An alpine plant, occasionally grown in Amer. and desirable for the rockery.

22. **fastigiatus**, Nutt. An herbageous perennial, floccose-tomentose throughout, somewhat glabrate: st. 1-2 ft. high: lower lvs. narrowly oblong-oblancoate, including the long slender petiole 3-6 in. long, 3\(\frac{1}{2} \) in. or less broad, entire or nearly so, usually with revolute margins; upper st.-Ivs. much reduced: heads radiate; commonly several in a terminal corymbose cyme; ray-fls. about 8, rays yellow. Idaho, Ore., and Wash.—Intro. by Franceschi, Santa Barbara.

23. **Pâmeri**, Gray. S."*alpina*, about 3 ft. high, branching, densely white-tomentose throughout: lvs. oblong-oblancoate, 1\(\frac{3}{4}\)-4 in. long, 3\(\frac{1}{2}-1 \) in. broad, entire to slightly sinuate-dentate, narrowed below into a more or less winged petiole: heads about 3\(\frac{1}{2} \) in. high, radiate, disposed in terminal subcorymbose cymes: ray-fls. 12-18, rays yellow. Guadalupe Isl., Low Calif.—Intro. by Franceschi, Santa Barbara.

24. **Gréyi**, Hook. f. A small spreading shrub 1\(\frac{3}{4}-3 \) ft. or more high: branches, under surface of lvs., and petioles densely covered with a soft white tomentum: lvs. oblong or oblong-obovate, 1\(\frac{3}{4}-3\) in. long, obtuse, entire, nearly glabrous on the upper surface: heads radiate, disposed in large terminal corymbose cymes; ray-fls. 12-15, rays yellow. Guadalupa Isl., Low. Calif.—Intro. by Franceschi, Santa Barbara.

25. **Cinerária**, DC. (Cinerária maritíma, Linn. *Senecio acañthifolius*, Hort.). Figs. 3606, 3607. Perennial. 2-6 ft. or less tall, branching from the base, very white-woolly throughout: lvs. pinnatifid, with oblong and obtuse segments; usually densely radiate; 1\(\frac{1}{4}-1\) in. high, disposed in small, compact cymes. F.M. 1872: 22. *Var. candidissimus*, Hort., has very white foliage. Var. *auro-marginatus*, Hort., has lvs. bordered with orange-yellow.—S. *Cinerária* is an old-fashioned garden plant, sometimes known as "dusty miller," and at the present time it is much used in American gardens for ribbon-ends and margins; the commoner "dusty miller" is *Lychnis Coronaria*, and still another one is *Artemisia Stelleriana*.

26. **Douglasii**, DC. Fig. 2608. A tufted perennial, white-tomentose throughout to essentially glabrous: sts. 1-3 ft. high, distinctly woody below, leafy: lvs. undivided and linear or narrowly linear-lanceolate to pinnatifid with few to several linear-attenuate divisions; infl. a terminal open corymbose cyme; heads about 3\(\frac{1}{2} \) in. high, radiate; involucres compound, composed usually of 21 bracts subtended by numerous attenuate bracteoles; ray-fls. commonly 18, rays yellow; disk-fls. 50-70: achenes pubescent. S. Utah to Arik., west to Calif., and northern Lower Calif.—First collected in Calif. by Douglas in 1833.

27. **magníficus**, F. Muell. A tall stout undershrub, glabrous and glaucous; st. sparingly branched, terete, leafy: lvs. thickish, sessile, oblong-lanceolate or oblancoate, 2-6 in. long, coarsely remotely and saliently dentate: heads relatively few, radiate, disposed in terminal corymbose cymes; ray-fls. 8-12, rays golden yellow; disk-fls. numerous. Austral. B.M. 7808.—Intro. by J. H. Maiden in 1899 and brought to flower at Kew in Oct., 1900.

28. **Kirki**, Hook. f. (S. glástifolius, Hook. f. *Solidago arboréscens*, A. Cunn.). An erect stoutly branching shrub, 7-15 ft. high; glabrous throughout: lvs. variable, narrowly oblancoate to oblong-obovate, 2-5 in. long, 3\(\frac{1}{2}-2 \) in. broad, entire or sinuate-dentate, narrowed into a slender petiole or cuneate at the base: heads numerous, large, radiate, disposed in a terminal compound corymbose cyme; ray-fls. 10-12, rays 3\(\frac{1}{4}-1 \) in. long, white: disk-fls. yellow. New Zealand. B.M. 8524.—The white rays and yellow disk-fls., and the profuseness of bloom, render this species a very unusual member of its genus; it should prove an interesting plant in horticulture.

29. **grandifíliús**, Less. (S. Ghiésbriechti, Regel). A leafy shrub, 9-15 ft. high; glabrous throughout: lvs. variegated, oblong-oblong-obovate, 6-18 in. long, one-half to two-thirds as broad, acute, sinuate-dentate and remotely callous-denticulate, dark green and glabrous or nearly so above, somewhat toway-tomentulose beneath, cordate to rounded at the base; petals stout, 1\(\frac{1}{4}-5 \) in. long: infl. a terminal many-headed subcorymbose cyme; heads radiate; ray-fls. about 5, rays yellow; disk-fls. about 10: achenes glabrous. S. Mex. Gt. 9: 2986. J. H. III. 60: 318.—An attractive leafy winter-flowering shrub.

30. **Prainíanus**, Berger. Shrub, about 3 ft. high; lvs. long-petiolate, ovate-deltoid, or suborbicular, 5-7 in. long, palely 7-9-lobed, cordate at the base, somewhat hirsut above, pubescent on the prominent nerves beneath: infl. a terminal much-branched drooping panicle; heads rayless. S. Mex. G.C. III. 50, p. 82 (whence the above description, and from which the plant would seem to be a Cacalia).—Said to be a very ornamental plant resembling the following species.

31. **Petasítis**, DC. (Cinerária Petasítis, Sims). VELVET GROUNDSEL. CALIFORNIA VELVET GROUNDSEL. A robust perennial 3-8 ft. high, somewhat hirsute-velutinous on the younger parts: lvs. petiolate, broadly ovate or sub-ovibar, 2-7 in. broad, cordate to subtruncate at the
3610. Senecio cruentus var. Webberianus, one of the early forms of the garden cineraria.

suborbicular, ½-1¼ in. broad, 5-7 lobed, araneous-tomentose in the young stages above but soon glabrate, densely and permanently white-tomentose beneath: heads radiate, most solitary on an elongated nearly naked peduncle; ray-fls. about 13, rays purple. Teneriffe. B.M. 53 (as Cineraria lanata). G.C. III. 50:333.-First brought into cult. about 1793.

33. cruentus, DC. (Cineraria cruenta, Mass.). Short-stemmed perennial, floccose-woolly; lvs. large, cordinate to ovate to cordate-triangular, angled or undulate and sinuate-toothed, rather long-stalked; fls. purple-red. Canary Is. B.M. 406.-The supposed parent of the florists' cinerarias (Fig. 3609) for discussion of which see p. 771, Vol. II. According to The Garden, March 1, 1890, it was in 1777 that the type of the florists' cineraria was first intro. from the Canary Is. by Mason. Whether the present highly improved races of cinerarias are direct descendants of S. cruenta or the result of hybridization is not now determined. The garden or modified race began to develop very early. Fig. 3610 is Cineraria Webberiana, Paxt. (Senecio cruenta var. Webberianus, Hort.), copied from The Garden, which "was raised in the spring of 1841 by Mr. Smithers, gardener to Mr. R. Williams, and has bright green leaves and boldly coloured flowers—a form that would give delight in these days." It is said that the first double cineraria is thought to have been Mrs. Thomas Lloyd, certificated in March, 1880.

Several species which have been described under the genus Senecio, some being of rather recent intro., seem to the writer to be more satisfactorily treated under the genus Ligulana. Among those appearing to be of considerable importance from a horticultural standpoint are the following: Ligulana clavata, Maxim. (Senecio clavorum, Maxim.). A robust herbaceous perennial, 4 ft. high, at first white-tomentose, later radiate, lvs. long-petiolate, glabrate; heads large, many-fl., radiate with orange-yellow rays; disk-fls. dark brown. Japan and China. B.M. 51:756. (Senecio clavata, Maxim. Gardeners Mag. and Sept.—Ligulana macrophylla, DC. (Cineraria macrophylla, Ledeb. —Senecio Ledebouri, Sch. B. 22, p. 160. Vol. IV.—Senecio Puri, Turrill. St. erect, radiate, densely tomentose; disk-fls. dark brown, crowned: lvs. long-petiolate, reniform, about 9 in. long, 15 in. broad, deeply cordate, coarsely toothed, glabrous on both surfaces: infl. many-camelled: lvs. many, 12 in. or more long, 2½ in. wide at the base; heads radiate; rays-fls. 1-5, rays yellow; disk-fls. 5-6. China. B.M. 8472.—Ligulana Veitchiana, Greenm. comb. nov. (Senecio Veitchianus, Hemsl. G.C. III. 38:212. 1905). A very stout perennial herb with simple flowering st. 3-6 ft. high; radical lvs. 15-16 in. long, 10-11 in. broad, sharply dentate; heads very numerous, about 2½ in. diam.; ray-fls. 10-12, rays yellow. China. G.M. 50:741.—Ligulana Weit­teniana, Greenm. comb. nov. (Senecio Weitmannianus, Hemsl. G.C. III. 38:212. 1905). Giant Groundsel. A robust herbaceous perennial with a flowering st. 3-5½ ft. high; radical lvs. long-petiolate, the blade reniform-cordate, 10-30 in. broad, sharply dentate; infl. an elongated columnar-like spike, branched at the base; heads very numerous, radiate, about 1 in. in diam.; rays-fls. 8-12, rays yellow. China. G. 34:113. G.C. III. 42:201. Thus and the preceding one are desirable plants for ditch-borders and bog-gardens.

J. M. GREENMAN.

SENNA: Cassia. S. Bladder: Coluteae.

SENSITIVE FERN: Onoclea sensibilis. S. Plant: Mimosa pudica.

SEQUEL (after Sennych, otherwise George Guest, a Cherokee half-breed of Georgia, about 1770-1847, originator of the Cherokee alphabet). Pinacea. Bro TREES OF CALIFORNIA. REDWOOD. Tall massive often gigantic forest trees, grown as ornamental evergreens in Europe, in California, and to a limited extent in the eastern states; of chief interest because of their great age and large size. S. gigantea is the most massive of all trees, although exceeded in girth by several others, notably the African baobab. S. sempervirens holds the record as the tallest tree in the world, at least so far as actual measurements have been made, one specimen in Humboldt County, California, measuring 340 feet, according to Sargent. Greater heights assigned to species of Eucalyptus were erroneous (see note under E. regnans, p. 1157).

Large trees with thick red fibrous and deeply grooved bark: heartwood dark red, soft, durable, straight-grained; sapwood thin and nearly white: lvs. persistent, 1-⅕ in. wide at the base; heads to 3½ ft. high, with trunk: stamens bearing 2-5 pollen-sacs; pistillate catkins terminal, composed of many spirally arranged stamens bearing 2-5 pollen-sacs; pistillate catkins terminal, composed of many spirally arranged scales, each with 4-7 ovules at base; cone woody, persistent, the divergent scales widened at summit which is rhomboid, wrinkled, and with a depressed center; seeds flattened; coryledons 2.

semper'virens, Endl. CALIFORNIA REDWOOD. Fig. 3611 (adapted from Amer. Forestry xx:323). Tree 100 to 340 ft. high, with trunk: 10-25 ft. in diam. and often clear of limbs for 100 ft. in mass: great gigantic trees, the narrow crown with horizontal or downward-sweeping branches: lvs. linear, mostly ½-1 in. long, 1½-4½ in. wide, spreading in flat sprays, or the upper lvs. and those on main st. of the branches only 1-5 in. long and awl-shaped; cone oval, ⅓-½ in. long, ½-3½ in. broad, maturing the first autumn; scales 14-26; seeds elliptic, narrowly margined, 2 lines long. Conifer to northern and central Coast Range of Calif. on slopes exposed to sea winds. G. 13, p. 172. G.W. 13, p. 531; 14, p. 511.—Reproduces by seeds and by stump-sprouts, the latter numerous and remarkably persistent, often producing mercantable lumber. Var. glac'ea, Hort. Foliage with a decidedly bluish cast.
The two great sequoias of California have a place of their own in science, history, and literature. Haenke, the botanist of the Malaspina expedition of 1791, first collected *S. sempervirens*, the coast redwood of California. Four years later Menzies, of the Vancouver expedition, secured specimens near Santa Cruz. Lambert published it in 1824 as *Taxodium sempervirens*. Douglas referred it to the same group, but in 1847 Endlicher created the separate genus Sequoia.

Two living sequoias, *S. sempervirens* and *S. gigantea*, are all that remain of many species that flourished in Tertiary times over a large part of the northern hemisphere. More than forty fossil species have been discovered, but there is still much confusion in regard to the botany of the extinct kinds. They have been found, however, from Italy north to Spitzbergen, and across northern Asia. Several now extinct species, such as *S. aquistiloba*, *S. Heerii*, and *S. Lanosorpa*, grew in California and Oregon in Miocene times. Asa Gray and others have told the story of the rise and fall of this great family of conifers, which was once as abundant as any tree-group in the world, but was cut off, swept away, destroyed by the glacial age, and survived only in parts of California.

The coast redwood, or *S. sempervirens*, seems to be a descendant of the fossil *S. Langsdorfi*; *S. gigantea* appears related to the fossil *S. Sternbergii*. The famous petrified forest of Arizona was a species of Sequoia, according to the United States Geological Survey. These Arizonian giants which grew millions of years ago, went down under a permanent ocean, were covered with sandstone, and rose again with the present continent. In like manner vast periods of time lie between the present forest and its ancient representatives. The value and interest of these wonderful trees are greatly increased by reason of their botanical and historical importance.

At the present time the coast redwood occupies only a narrow belt of country near the Pacific Ocean, nor is it continuous even there; the giant redwood, or California big tree, exists only in a few small and isolated groves, scattered over less than 60 square miles in all, extending along the western side of the Sierra Nevada range. Compared with the enormous territory once occupied by now extinct species of sequoia, the modern representatives of this ancient and honorable family are reduced to a very small area.

The first-known of the sequoias, and much the more valuable species, economically speaking, was *S. sempervirens*, the coast redwood of California. This is one of the most important timber trees of the world, and its forests, comparatively limited in area, have yielded and are still yielding, the most easily obtained, the most valuable and profitable fencing and building lumber of the Pacific coast. The reproductive powers of the tree are enormous; no other known conifer so persistently sprouts from the stump, so rapidly makes new forests, or so well resists fire. But it does not surpass any of their ancient representatives.

The climate where the redwood thrives is comparatively equable, marked by fogs and cool summer winds from the southwest. The tree delights in rich sheltered mountain valleys and fertile slopes, in dripping fogs and in heavy winter rains. Going east from the ocean, in the redwood region, one suddenly comes to the top of a ridge, to overlook oaks and pines, and at once reaches the plainly marked edge of the *S. sempervirens* forest.

While *S. sempervirens* is sometimes called second in size among the giant conifers of the Pacific coast, the tallest tree yet authentically measured is 340 feet high, exceeding in height the tallest living tree of the Sierra
The most famous of the sequoias and certainly the most widely known of all living conifers is the grand
treetop of the Sierra, \( \text{S. gigantea} \). It is probably the largest tree on earth, and it is the most noble and impressive of trees. The
interest attached to this sequoia is therefore distinctly international, and an immense body of literature has
gathered about it.

Jepson, in his "Silvics of California," 1910, lists thirty-one
known groves of big trees in the California Sierras,
containing 80,499 trees. While private owners control
much of these areas, still a large part is in the National

Forests and Parks, where, under protection, the safety of the tree is assured and reproduction is excellent. In
the Fresno grove, for example (Sierra National Forest),
thousands of young trees are now growing. The low vitality of the seeds of \( \text{S. gigantea} \) long a matter of complaint among nurserymen, appears to be less
marked than formerly, and nearly all the groves show young trees.

The measurements of standing trees and the age-
estimate made in the last decade have materially altered former conclusions. Sudworth has published
an excellent table of measurements in the Calaveras Grove, and Jepson has supplemented them with measures-
ments elsewhere. Sudworth measured thirty trees which were from 9 to 19½ feet in diameter 6 feet above the ground, and from 237 to 325 feet high.
Former measurements were generally taken at the
surface of the ground and hence were most misleading.
A tree in Giant Forest, on the Kaweah, for example, as
measured in circumference at the surface of the ground 72 feet, but at 11 feet, where the bulge ceased,
and the true shaft began, was but 57½ feet in cir-
cumference. The famous Boole tree, in Fresno County,
girths 109½ feet at the surface, and 77 feet at 10 feet
from the ground.

The problem of the age of the sequoia has long
occupied the attention of students; popular literature
has revealed extravagant statements on this subject,
so that many persons believe that trees now standing
were in existence before the pyramids were built. As
regards the coast redwood, so many trees have been cut and the rings counted that its age is now well
known; this species lives from 400 to 1,300 years, or
may possibly reach 1,500 years in a few cases. In
respect to the Sierra redwoods, \( \text{S. gigantea} \), the heavy
logging done in recent years on private lands has
enabled foresters to make careful age-determination.
They find that mature trees range from 400 to 1,500
years. It remains to determine the resisting powers of
mature trees. A few old fallen trees have been found
whose rings showed ages of 2,200 to 2,300 years. John
Muir estimated a partly burned tree at 4,000 years, but
this is open to discussion.

The economic value of the coast redwood is so high
that every principle of wise conservation requires more
careful management of private forests, more complete
reproduction and the reforesting of cut-over areas.
Little attention has yet been paid to the by-products
from the present waste which technical chemists are able to make profitable. This is also true of the *S. gigantea* when lumbered on private lands; the beauty and durability of the timber, and the value of its possible by-products make care in reforesting eminently desirable. Pencil manufacturers are beginning to use the wood of selected trees of *S. gigantea*. The rapidity of growth of both sequoias when young, and when favorably situated, is so great that the forestry of the future is likely to extend rather than diminish these forests.

CHARLES HOWARD SHINN.

SERÂPIAS (ancient name of an orchid, derived from Serapis, an Egyptian divinity). *Orchidaceae*. Terrestrial herbs with the habit of Orchis: sepals connivent in the form of a helmet; petals included, small; labellum not spurred, with erect lateral lobes and a larger undivided, middle lobe; pollinia with a common viscid disk; rostellum laterally compressed; column short. The following species are known from the Medit. region.

The keeps the plants partially dry during winter months. Give plenty of water when in vigorous growth. Pot in leaf-mold, loam, and sand. Always use the genus *Serapias* as formerly understood and known to horticulturists. With the recent use of this name for the Cephalanthera-Epipactis group, however, the following species are thrown in the genus *Serapias*.

**S. lingua**, Linn. St. erect, up to 1 ft. high, bearing several narrow, acute lvs.: sepals lanceolate, greenish or purplish labellum much longer; lateral lobes rounded, erect, middle lobe obtlong-lanceolate, acuminate, smooth, red. Medit. region. B.M. 5868, B. G.C. III. 48:482.

**S. rigidus**, Linn. St. erect, up to 1 ft. high, bearing several narrow, acute lvs.: sepals lanceolate, greenish or purplish labellum much longer; lateral lobes rounded, erect, middle lobe obtlong-lanceolate, acuminate, smooth, red. Medit. region. B.M. 5868, B. G.C. III. 48:482.

**S. lingua**, Linn. St. erect, up to 1 ft. high, bearing several narrow, acute lvs.: sepals lanceolate, greenish or purplish labellum much longer; lateral lobes rounded, erect, middle lobe obtlong-lanceolate, acuminate, smooth, red. Medit. region. B.M. 5868, B. G.C. III. 48:482.

**S. lingua**, Linn. St. erect, up to 1 ft. high, bearing several narrow, acute lvs.: sepals lanceolate, greenish or purplish labellum much longer; lateral lobes rounded, erect, middle lobe obtlong-lanceolate, acuminate, smooth, red. Medit. region. B.M. 5868, B. G.C. III. 48:482.

**S. lingua**, Linn. St. erect, up to 1 ft. high, bearing several narrow, acute lvs.: sepals lanceolate, greenish or purplish labellum much longer; lateral lobes rounded, erect, middle lobe obtlong-lanceolate, acuminate, smooth, red. Medit. region. B.M. 5868, B. G.C. III. 48:482.

**S. lingua**, Linn. St. erect, up to 1 ft. high, bearing several narrow, acute lvs.: sepals lanceolate, greenish or purplish labellum much longer; lateral lobes rounded, erect, middle lobe obtlong-lanceolate, acuminate, smooth, red. Medit. region. B.M. 5868, B. G.C. III. 48:482.

**S. lingua**, Linn. St. erect, up to 1 ft. high, bearing several narrow, acute lvs.: sepals lanceolate, greenish or purplish labellum much longer; lateral lobes rounded, erect, middle lobe obtlong-lanceolate, acuminate, smooth, red. Medit. region. B.M. 5868, B. G.C. III. 48:482.

**S. lingua**, Linn. St. erect, up to 1 ft. high, bearing several narrow, acute lvs.: sepals lanceolate, greenish or purplish labellum much longer; lateral lobes rounded, erect, middle lobe obtlong-lanceolate, acuminate, smooth, red. Medit. region. B.M. 5868, B. G.C. III. 48:482.
SERRADELLA is an annual leguminous plant, valuable as a fodder crop on dry, and sandy sterile soils. See Ortnithopus.

SERRÁTULA (from serrae, alluding to the roughly toothed leaf-margins). *Compositae.* A horticulturally unimportant group of composites consisting of about 30 species of herbaceous thistle-like perennials grown for their purple or violet fls.: stala, simple or branched; lvs. alternate, dentate, or much cut into sharp but usually unarmed segms., green both sides or sometimes pale and canescent beneath: infl. of a single pedunculate head or, as in the following, of a lax corymb; heads equal-fl., the involucral bracts in many series, narrowly acuminated at the apex, but not as in many thistles, spiny; fls. purple, but not very showy. Cult. in open border, but perhaps not in Amer. outside botanic garden collections. Eu., N. Afr., to China and Japan.

Tinctoria, Linn. A much-branched, freely flowering perennial, about 2-3 ft. tall: lvs. very variable, usually deeply pinnately cleft or divided and generally lanceolate in outline; the upper sometimes undivided and petioled, the basal usually divided and nearly sessile; fls. in a dense corymbiform infl. or thin, frequently spine-crowned, Eu. July and Sept. Eu., N. Afr., Middle East. *S. atriplicifolia,* Bent. & Hook. Of vigorous growth; lvs. large, heart-shaped; heads globular, attaining height of 5 ft.: fls. purple. Cent. China. N. TAYLOR.

*SÉSAMUM* (Greek name taken by Hippocrates from the Arabic). *Pedaliaceae.* Herbs, erect or prostrate, securvus or rarely glabrous, suitable for the warmhouse, and for the open in the S.: lowest lvs. opposite, the upper and almost all alternate, petiolate, entire, incised-dentate, 3-cleft or pedately cut: fls. pale or violet, solitary in the axis; calyx rather small, 5-parted; corolla glaucescent beneath: stigma 2-celled; cap. oblong or ovoid. —About 20 species, Trop. and S. Afr., E. Asia. The only species of importance is *S. indicum,* which has been extensively cult. in the tropics from ancient times. The seeds are sold in Amer. under the name of benne. They yield about half their weight of oil-of-sesame (known also as benne-, ginelli-, or teel-oil), which is odorless and does not easily become rancid. This oil is universally used for the manufacture of soap and adulteration of olive-oil. Also cult. in northern states as a medicinal herb, the mucilaginous lvs. being used in diuretic and diarrhoeal of children. Of several *S. sesami,* the Old World, of perhaps 50-60 species, sometimes mentioned in horticultural literature as acceptable border plants. 5-cleft and branched, with lvs. compound or 2-3-pinnate, and compound umbels of white fls., the involucres of few or many bracts or sometimes wanting; the fls.: calyx-5-parted, style surpassing the calyx tube; petals notched; styles very short; fr. nearly terebinthaceous, ovate or oblong. *S. ladanotis,* Koch, of wide distribution in Eu., is perhaps most likely to appear as a cult. plant: perennial, 1-2 ft., erect and stout, glabrous or pubescent, with many projecting rays, and many-bracted involucres and involucels.

*SÉSÉLI* (old Greek name for an umbelliferous plant). *Umbelliferae.* MEADOW SAXIFRAGE. Perennial and biennial herbs in the temperate and cold regions of the Old World, of perhaps 50-60 species, sometimes mentioned in horticultural literature as acceptable border plants. 5-cleft and branched, with lvs. compound or 2-3-pinnate, and compound umbels of white fls., the involucres of few or many bracts or sometimes wanting; the fls.: calyx-teeth either prominent or minute; petals notched; styles very short; fr. nearly terebinthaceous, ovate or oblong. *S. ladanotis,* Koch, of wide distribution in Eu., is perhaps most likely to appear as a cult. plant: perennial, 1-2 ft., erect and stout, glabrous or slightly pubescent; lvs. bipinnate, the lfts. ovate and sessile, umbel rounded, with many pubescent rays, and many-bracted involucres and involucels.

*SÉSUVIUM* (derivation unknown). *Aizoaceae.* Erect or prostrate, branched, succulent herbs or subshrubs, adapted to the warmest of climates: lvs. very variable, which is expressed from the seeds is in large doses a laxative.

Indicum, Linn. (S. orientale, Linn.). Plant 1-2 ft. high: lvs. variable, 3-5 in. long, oblong or lanceolate, the lower often 3-lobed or parted: corolla pale rose or white, 1 in. long, tubular, 5-cleft, the 2 lobes of the upper lip shorter. July. Tropics. B.M. 1688.—White- and blackseeded varieties have been known for at least two centuries. Runs wild in the extreme S. WILHELM MILLER.

SÉSÍNÁ (from Sasan, the Arabian name of *S. acrylica*). *Symn. Daubentonia, Oedtidiurn. Leguminosae.* Herbs or shrubs, sometimes arborescent, but short-lived, suitable for the warm- and coolhouse, and for outdoor planting in the far South. Leaves abruptly pinnate; lfts. many-paired, very entire; stipels minute or none: racemes axillary, lax; fls. yellow, red-purple, variegated, or white, slender-pedicelled; calyx broad, tube truncate, toothed or subequally lobed; standard orbiculate or ovate, spreading or reflex, wings falcate-oblong, keel incurved, obtuse or obtusely acuminate, with long claws; stamens free from the standard; ovary often stipitate: legume linear or rarely oblong, compressed, 4-angled or 4-winged. About 30 species, widely distributed in the warmer regions of both hemispheres.
Several species are annual weeds, such as Yellow Fox-tail (S. glauca, Beauv.) with oblong yellow spikes, and 5 or more bristles below each spikelet, and Green Fox-tail (S. viridis, Beauv.), with somewhat pointed green spikes and 1-3 bristles below each spikelet. Many American botanists use the name Chlochloa instead of Setaria. (Dept. Agric., Div. Agrost., Bull. 21, is devoted to this genus.) The setarias are scarcely horticultural subjects, being primarily forage plants; but they are so widespread in cult. and the forms are so confused that a somewhat full discussion of them may be inserted here.

### a. Plant perennial.

macrostachya, HBK. (S. Alopecurus, Fisch. S. alopecoides var. nigra, of the trade). An erect or ascending perennial: spike slender, tapering at apex; bristles 1 or sometimes 2, 1½-1 in. long; spikelets ½ in. long; first glume one-third to one-half, second two-thirds to three-fourths as long as the equal sterile lemma and fr.; first glume inflated at the base of the spikelet. Texas to S. Amer.

#### bb. Plants annual.

mâgna, Griseb. A coarse stout native, resembling common millet: spike ± in. thick, as much as a foot long, tapering above and below; bristles 1-3, scarcely ½ in. long; spikelets ½ in. long, elliptical, first glume one-third as long as second glume and sterile lemma, equaling the spikelet; fertile lemma smooth. Marshes of Gulf States as far north as Md.

îdâlica, Beauv. Common Millet of the U. S. (but not of Eu., this being Panicum miliaceum); also called German Millet and Hungarian Grass. Cm. 3-5 ft. high: spike yellow or purple, compound, more or less glomerate; bristles 1-3, often shorter than the spikelet. Thought to have been derived from S. viridis. Gn. 12, p. 69.—The cult. of millet dates from prehistoric times. At present it is raised extensively in parts of Asia as a food-plant. In the U. S. it is raised for fodder. The "Japanese millets" belong to S. italica, while the "Japanese barnyard millets" are Echinochloa Crussgalli or E. frumentacea.

The forms of S. italica may be distinguished from S. viridis by the articulation of the fruit (fertile floret), or what is commercially known as the seed. In the former species the fruit at maturity disarticulates above the glumes and falls away free from them. In S. viridis the fruit falls away surrounded by the glumes. The variegated forms have been classified by Hubbard (Amer. Journ. Bot. 2: 187, 1915) as follows:

#### a. Fr. yellowish to straw or light brown. (Stramineo-fructa.)

b. Bristles green.

c. Panicle more or less open-lobulate.

Subsp. stamneofructa, Hubb. Bristles noticeably longer than spikelets: a large plant with heads 4-12 in. long, and as much as 2 in. wide, usually strongly lobed. This is one of the forms cult. as German millet. Forma brevistata, Hubb. Bristles shorter than the spikelets or barely exceeding them. Cult. as Golden Wonder millet.

cc. Panicle dense or slightly lobulate at base.

Subvar. germânica, Hubb. Bristles noticeably longer than spikelets: head usually 2-3 in. long; ½ in. broad. One of the forms cult. as common millet.

#### bb. Bristles purple.

c. Panicle more or less lobulate.

cc. Panicle dense or slightly lobulate at base.

Subvar. Mêtzgeri, Hubb. Bristles noticeably longer than spikelets. Cult. as common millet, a common form. Sometimes called Hungarian grass, a name that should apply to var. atra (see below).

#### bbb. Bristles brown.

#### a. Fr. reddish or orange. (Rufrofructa.)

#### aaa. Fr. blackish, brownish black or purplish black with pale yellowish straw lines intermingled, these sometimes predominating. (Nigrofructa.)

Subsp. nigrofructa, Hubb. The common form cult. in U. S. is var. atra with small dense heads, with purple-brown bristles. Commonly cult. as Hungarian grass.

Many other varieties are cult. in the Old World.

### SEVERINA (named for M. A. Severino, a Neapolitan). Rudaceae, tribe Citrea. Small woody plants distantly related to the orange.

Spiny shrubs or small trees with short and stiff branches: spines single, at one side of the bud in the axis of the lvs.: lvs. simple, cotyledonously veined, borne on short apetrous petioles: fls. 5-merous, occurring 2 or 3 together in the axis of the lvs.; petals small, white; stamens 10, free; ovary 2-celled, with 1 ovule in each cell: fr. a small nearly globose berry, black when mature.—Only one species is known, usually called Atalantia buzzûfîla, native to S. China and Formosa, see Swingle, in Journ. Wash. Acad. Sci., Vol. 6, No. 19, 1916.

buzzûfîla, Ten. (Citrus buzzûfîla, Poir. Limonia buzzûfîla, Roxb. Scleroûgya buzzûfîla, Benth. Atalantia buzzûfîla, Oliver). A spiny shrub or dwarf tree native to S. China. intro. into cult. in Eu. late in the 18th or early in the 19th century and often considered by botanists to belong to the genus Atalantia, from which it differs widely in the character of the fr. which is a black berry, the ovary walls becoming succulent as the fr. ripens: lvs. simple, obovate-oblong, very obtuse or emarginate, ½ in. long, having numerous fine veins; spines solitary: fls. axillary, in fascicles or solitary, emarginate; stamens 10, free: fr. a true berry, becoming more or less fleshy at maturity, turning black, 2 (or sometimes 3) -celled, each cell containing a single seed, cells not filled with gum or pulp vesicles; seedlings with subterranean cotyledons, first lvs. very small, spirally arranged. lil. Seemann, Bot. Voy. Herald, pl. 81; Penzig, Studi bot. sugli agrumi, Atl., pl. 11, figs. 6–17; Swingle in Journ. Wash. Acad. Sci., Vol. 6, No. 19, 1916.—This plant, which has lvs. resembling the box (Buxus sempervirens) is common in S. China, in Hongkong, and occurs also in Formosa. It is grown in botanic gardens and Eu. and has been intro. in this country. It is erroneously listed by some nursery firms as Trachys monophylia. It is sometimes used as a hedge-plant in La. and other Gulf States, and is well adapted for this purpose, as it does not grow to large size and has very spiny forms that can be prop. from cuttings. It is being tested by the Dept. Agric. as a stock for the cult. citrus frr., as it is able to thrive in soils too salty to permit citrus to grow.

WALTER T. SWINGLE.

### SEYMÈRIA (named in honor of Henry Seymer, an English naturalist). Sérophulariaceae. Erect branched annual or perennial, mostly hardy herbs, used for bedding on account of their fls.: lvs. mostly opposite, incised-discinate or dissected, the uppermost floral ones reduced.
to entire bracts: fls. in interrupted racemes or spicate, j the pedicels solitary and without bracts, yellow; calyx campanulate, with 5 narrow, entire or dentate lobes; corolla-tube short and broad, rarely exerted, the throat broad; 5-lobed, the lobes broad or oblong, spreading; stamens, 4, subequal: caps. globose at base, the apex frequently compressed, acuminate or beaked.—Ten species. Amer., Texas, and from Madagascar. Seeds are sown in a well-drained bed of rather light rich soil. S. pectinata, Pursh. About 1 ft. high, minutely scabrous-pubescent or glabrate; lvs. pinnately parted into rather few short- or oblong-linear divisions or the upper incisedly few-toothed or entire; calyx-lobes linear; corolla hairy outside. N. C. to Fla. and Ala., perhaps to Texas. S. teretifolia, Pursh. About 2-4 ft. high, very slender; lvs. copiously 1-2-pinnately parted: fls. on filiform pedicels; calyx-lobes setaceous; corolla very deeply cleft, the lobes oblong. N. C. to Fla. and Texas.

SHAD-BUSH: Amelanchier.

SHADDOCK. A name used in the West Indies and Florida for the forms of the pummelo, Citrus grandis, supposed to have been introduced from India into the West Indies sometime in the seventeenth century by a Captain Shaddock. The shaddocks are large usually pear-shaped fruits with a thick peel and have a firm pulp of rather poor flavor. The leaves have very broad, winged pedicels and the twigs are usually more or less hairy, especially when young. Shaddocks were formerly grown in Florida but have been superseded by the grapefruit (see page 1391, Vol. III) as the latter finds more favor in American markets. Pummelos, very like shaddocks, are still grown in India, China, and the East generally. (see page 2857, Vol. V).

SHAGBARK: Hickory.

SHALLOT is Allium ascalonicum, Linn., native of Syria. It is grown chiefly for the small oblong-pointed gray bulbs (into which the parent bulb separates after harvesting in summer), which are used in cookery for flavoring; the leaves are sometimes eaten in a green state. The bulbs are of mild flavor. Shallots are little known in North America. They are grown as garlics (see Garlic), the bulbs or cloves being separated and planted too thickly in any good rich soil. Each bulb produces several, all cohering by the base. The mature bulbs are 2 inches or less long and only about half that in diameter. The leaves are small, terete, and hollow. The plant is hardy. The bulbs will keep several months or even a year. Small onions are sometimes sold as shallots.

L. H. B.

SHAMROCK. Half the world is sure that shamrock is the wood-sorrel, Oxalis Acetosella. The other half is equally certain that the true shamrock is white clover, Trifolium repens. In the time of Spenser’s “Faerie Queene,” shamrock was said to be good to eat. This applies to the former plant, but not to the latter. Moreover, according to Sowerby, the wood-sorrel is in perfection on Saint Patrick’s Day, while white clover is not. The wood-sorrel is sent in great quantities from Ireland to London for Saint Patrick’s Day. On the other hand, it is said that clover is the plant most commonly used in Ireland. Half a dozen other plants have their followers; and these are all plants with three leaflets. Nevertheless there are those who deny that Saint Patrick used the shamrock as a symbol of the trinity. These declare that the water-cress is the true shamrock. The question will always remain an open one. See Dyer’s “Folk-Lore of Plants.”

WILHELM MILLER.

SHAMROCK, INDIAN: A name found in some English books for the Trillium. S.佩: Parochetus communis.

SEYMERIA

SHEPHERDIA (named for John Shepherd, an English botanist). Elaegnaceae. Shrubs, or small trees with scaly fruits, two of which are in cultivation, one for its striking appearance, the second for its edible fruit.

Leaves opposite, petiolate, oblong and entire: fls. small, ducious, in very short spikes or racemes, opposite to small bracts along the rachis, male spikes many-fld., female 2-fld. in the axils of lvs. or on the rachis at leafless nodes; calyx of male fls. 4-parted, of female fls. urm-shaped, 4-leaf; stamens in male fl. 8, alternating with 8 lobes of a thick disk; ovary becoming a nut or achene and invested by the filaments and corolla, forming a drupe-like fr.—Three species. N. Amer. The genus Shepherdia was founded by Nuttall in 1818. Rafinesque’s Lep驾驭rgyi, 1817, is equivalent, and the species have been placed under this name; it is not accepted under the International Rules. In S. argentea, the buf­falo berry, the fl. is edible when made into jellies and conserves, and is much prized in the upper plains region for household uses. The shepherdias are hardy plants, withstanding extremes of cold and drought. They are easy culture, and grow readily from stratified seeds. For ornamental planting, they are prized for bold positions in front of shrubbery masses, where their gray or white colors afford excellent contrasts. S. canadensis, particularly well adapted for planting on dry rocky sterile banks, where most bushes find great difficulty in secur­ing a foothold. S. argentea succeeds better in the upper Mississippi Valley than in the eastern states. Staminate and pistillate plants of it have different forms of buds.

AA. Lvs. green above.

canadensis, Nutt. (Lep驾驭rgyi canadensis, Greene). Spreading twiggy bush 3-6 or even 8 ft. tall, the young branches brown-scyrouf: lvs. ovate, oval, or elliptic, rather thick, green above but rusty beneath: fls. yellowish, in short clusters at the nodes: fl. small (½in. or less long), oval, red or yellow, insipid. Along streams and on lake-banks, Newfoundland to Brit. Col. and in the northern tier of states, and southward toward the mountains in Utah.—The yellow-fruited form has been distinguished as S. zanthochez, Rehder.

AA. Lvs. silvery above.

argentea, Nutt. (L. argentea, Greene). BUFFALO BERRY. Fig. 680, Vol. I. Upright shrub, or sometimes almost tree-form, reaching 18 ft. tall, thorny, the young growth silvery-tomentose sometimes somewhat scaly-bracted, with scaly lvs. or oblong-lanceolate, silvery on both sides: fls. yellowish, in dense small fascicles at the nodes: fl. gloular or ovoid, about ½in. long, red or yellow, acid, edible. Kansas to Minn., west and north. See Buffalo Berry.

S. rotundifolia, Pursh, from Utah, is a silvery tomentose and scaly evergreen bush: lvs. round-oval or ovate, mostly somewhat cordate, short-petiolate: fls. stalked in the axis of the lvs., the staminate mostly in 3’s and the pistillate solitary: fl. gloular, scarly, ripening in July.

L. H. B.

SHIRWOODIA: Shortsia.

SHÓRTYA (named for Dr. Charles W. Short, a botanist of Kentucky). Diapensiacéae. Two scaly-leaved herbs, with the habit of galax.

Rootstocks creeping: lvs. evergreen, round-cordate: fl. solitary on a slender leafless stalk, the calyx with scaly bracts, the corolla bell-shaped and obtusely 5-lobed; stamens 8, the filaments adnate to the corolla, alternating with 5 scale-like staminodia; pistil 3-angled and 3-loculed; style filiform and stigma 3-lobed: fl. a globular capsule. From this, Schizocodon is distinguished by linear-elongated staminodia and fringed corolla. Allied genera mentioned in this Cyclopaedia are Galax, Pyxidanthera, and Schizocodon. Diapensia has two alpine and boreal species, one in the Himalayas and the other in N. Eu. and N. Amer. Berneuxia, the remaining genus, has a single species in Tibet, not in the American trade. Shortsia californica of seedsmen
SHORTIA

1-fld., bracted near the top: fls. inclined or adducting, white, 1 in. across, the obduct lobes undulate. Mountains of N. C. B. M. 7082. G. C. II. 15:596; III. 3:397; 17:453. G. 34:521; 36:121; 37:309. Gn. 38:204: 67, p. 286; 71, p. 73. Fig. 3613. Lvs. all radical, long-petioled, the blades orbicular or broadly ovate-ovibaric, often slightly cordate, at the apex obtuse or even retuse, the margin repand-serrate: peduncles slender, 3-8 in. tall.

SIBIRJEA

(named for the habitat of the plant, Siberia). Rosaceae. Low and depressed perennials, hairy and rare in cult., sometimes used in alpine gardens: lvs. 3-foliolate, alternate; stipules prominent: fls. cyme, yellow, small; calyx flatish, 5-cleft and with 5 bractlets; petals 5, linear-oblong, minute; stamens 5, alternating with the petals. About 5 species, natives of the colder parts of the North Temperate Zone. Reduced by Bentham and Hooker to a section of Potentilla, but separated by most authorities.

procumbens, Linn. Lfts. 3, wedge-shaped, 3-toothed at the apex: petals yellow. Ranges from the arctic regions to the summits of the White Mts. and in the Rockies comes as far south as Utah. It is also found in arctic and alpine Eu. and Asia. B. B. 2:217.—This plant is recommended by some persons, but is not known to be advertised for sale in Amer.

F. TRACY HUBBARD.

SIBBÁLDA (named for Robert Sibbald, Scotch naturalist). Rosaceae. Low and depressed perennials, hairy and rare in cult., sometimes used in alpine gardens: lvs. 3-foliolate, alternate; stipules prominent: fls. cyme, yellow, small; calyx flatish, 5-cleft and with 5 bractlets; petals 5, linear-oblong, minute; stamens 5, alternating with the petals. About 5 species, natives of the colder parts of the North Temperate Zone. Reduced by Bentham and Hooker to a section of Potentilla, but separated by most authorities.

procumbens, Linn. Lfts. 3, wedge-shaped, 3-toothed at the apex: petals yellow. Ranges from the arctic regions to the summits of the White Mts. and in the Rockies comes as far south as Utah. It is also found in arctic and alpine Eu. and Asia. B. B. 2:217.—This plant is recommended by some persons, but is not known to be advertised for sale in Amer.

F. TRACY HUBBARD.

SIBIRJEA (named for the habitat of the plant, Siberia). Rosaceae. subfam. Spiraeae. Two shrubs from N. E. Asia and W. China closely allied to Spiraea, but differing in the narrow entire lvs., the polygamous-paniculate fls. disposed in panicled racemes and in the 2-seeded carpels, and in the long-petiolate leaves. S. lewisii is a deciduous upright shrub with rather stout branches, with alternate, entire, generally oblong lvs. and with small short-stalked white fls. in spike-like racemes crowded into terminal panicles. It possesses no particular ornamental qualities and is rarely cult.: hardy N. The hardiness of the recently intro. S. tomentosa has not been sufficiently tested. Prop. is by seeds sown in spring or by layers. S. leavigata, Maxim. (S. galacifolia, Schneid., Spiraea leavigata, Linn.). Shrub, 5 ft. high, with stout upright branches: lvs. cuneate-oblong, bluish green, glabrous, 1½-3½ in. long: fls. polygamous, greenish white, in terminal panicles, 3-5 in. long, those of the staminate plant somewhat showier. May. Siberia. G. C. III. 31:337; 43:220, 221. G. 36:803. Gn. 67, p. 192; 71, p. 310; 72, p. 292. F. S. R. 3, p. 247.—Offered by importers of Japanese plants, but little known horticulturally. S. grandiflora, Hort., has larger fls. than the type, being as much as 1½ in. across. G. 32:253. Gn. 74, p. 164; 78, p. 177. G. M. 53:205.

L. H. B.
SIBTHORPIA (named in honor of John Sibthorp; 1758-1796). Scrophulariaceae. Hardy or greenhouse perennials, often rooting at the nodes, grown mostly for the flowers.

Leaves alternate or fasicled, peltioted, orbicular-reniform, crenate-serrate or inciso-pinnatifid; pedicles axillary, solitary or fasicled; fls. yellow, yellowish rose or purplish; corolla campanulate, 4-5-lobed, the lobes equal or unequal; corolla-tube short or very short, rotate, limb spreading; anthers sagittate: caps. membranaceous, compressed, loculicidally dehiscent, the valves splitting to the middle.—About 7 species, Eu., Trop. and N. and S. Amer., mountainous of India and S. Amer.

SIBERIA, Linn. A hardy trailing perennial with very slender sts.: lvs. orbicular, less than \( \frac{1}{6} \) in. across, 7-9-lobed; fls. small, on rather stalk pedicel, the 2 upper lobes of the corolla yellowish, the 3 lower pink. Deep woods, Eu. Var. variegata, Hort., a form with bright golden green foliage, is cult. abroad.

SIBERICA, Linn. Tender trailing greenhouse perennial; lvs. much crested: peduncles frequently fascicled, 2 in. long: fls. yellow, 5-8-parted; stems slightly shorter than the corolla. June. Mauritius. B.M. 218 (as Disandra prostrata).

SICANA (Peruvian name). Cucurbiteae. Annual slender subglaabrous tall-climbing vines, used out-of-doors in the S. for ornament; lvs. palmately 5-9-lobed, very graceful and shiny; tendrils 3-5-cleft, the branches adhering at the tip: fls. rather large, yellow, monococious, all solitary; calyx-tube short-campanulate, 5-lobed, the lobes ovate-lanceolate, recurved; corolla inflated-campanulate, 5-lobed above the middle, the lobes broad-ovate; stems 3 in the male fl.: fr. large, fleshy, many-seeded, fragrant and edible.—Three species, S. rhombifolia, Naudin, the CURUBA and PEPINO ANGULO; one species, S. odorifera, Naudin, the PEPINO PERRIGENA (as Disandra prostrata).

S. angulatus, Linn. Bum Cucumber. Annual climbing herb: lvs. very broadly rhombic-ovate, more or less shallow, 5-angled or lobed, pinnately veined; the lobes rather broad-detolled, the midlobe abruptly and narrowly acuminate, the lateral lobes apiculate, base somewhat halberd-shaped with a rounded rather narrow sinus; the petiole slender and glabrate-rose. S. Maine and W. Que. to Fla. and west to Minn., E. Kansas, and Texas.—Used on account of its rapid growth for screening walls, lattice-work, and the like.

SIDA (from the old Greek name for Nymphula alba; given without explanation by Linnaeus). Malvaceae. Herbs or shrubs with the indumentum frequently soft or tomentose, adapted to the warm- or coolhouse or some of them hardy; one species, S. rhombifolia, now cultivated in India for its fiber.

Leaves simple or lobed, usually serrate or dentate: fls. sessile or pedunculate, solitary or glomerate, axillary or in terminal racemose spikes or heads, various colored and sometimes showy, often small, yellow or white; calyx 5-toothed or 5-cleft; staminal column divided at the top into numerous filaments; carpels 3 or more, when ripe separating from the axis, generally 2-awned at the summit; seed 1 to a carpel and pendulous.—About 120 species, widely distributed in Afr., Asia, Austral., and N. and S. Amer.

Sida angulata, Linn. Scrophulent Herbs or shrubs of various colors. B.B. 2:420. Cult. same as for hollyhocks; prop. by seed. Index Kewensis refers the above species to Sida dioica, Linn., but according to Gray's Synoptical Flora of North America the two species belong to separate genera, the fls. of the first being hermaphrodite, of the second dioecious. Nymphula dioica is a strong-growing perennial 5-9 ft. high, with large radical lvs. often 1 ft. across and 9-11-cleft, the segms. cut into lanceolate serrate lobes; fls. dioecious, white, smaller than in Sida Nymphula. For pictures of the two plants, see B.B. 2:420. 422.

AA. Lvs. ovate to cuneate or lanceolate.

S. angulata, Linn. Bum Cucumber. Annual climbing herb: lvs. very broadly rhombic-ovate, more or less shallow, 5-angled or lobed, pinnately veined; the lobes rather broad-detolled, the midlobe abruptly and narrowly acuminate, the lateral lobes apiculate, base somewhat halberd-shaped with a rounded rather narrow sinus; the petiole slender and glabrate-rose. S. Maine and W. Que. to Fla. and west to Minn., E. Kansas, and Texas.—Used on account of its rapid growth for screening walls, lattice-work, and the like.

S. rhombifolia, Linn. Shrubby or subshrubby lvs. very variable, rhomboid-lanceolate to lanceolate, lower surface usually paler or even hoary: fls. axillary, solitary, pale yellow, rarely white, the petals blotched with red at the base. Tropics and subtropics of both hemispheres.—Yields a good fiber, and its cult. for this purpose has recently been encouraged in India. Probably of little value for ornament.
SIDALCEA (compound of Sida and Aloe, related genera). Malvaceae. Some of the sidalceas are annuals, but those in cultivation are hardy perennials, being recommended for the herbaceous border.

Leaves palmately cleft or parted, stipular: fls. often showy, pink, purple, or white, in terminal racemes or spikes, mostly without bracts or involucres beneath; stamens united into groups in a double series: carpels 5-9, reniform, separating at maturity.—About 30 species, natives of W. N. Amer. For monograph, see Gray, Syn. Fl. N. Amer., vol. 1, p. 302. Of easy cult. Prop. by seeds or division.

SIDERATIS (Greek, iron; the plants were supposed to have a healing power for wounds caused by iron. Discordes also used the name for other plants credited with the same ability). Labiatae. Herbs, subshrubs or shrubs frequently lanate or softly pilose, mostly hardy or half-hardy but some of them coolhouse plants: lvs. from more or less creeping root-stocks, the sts. more or less branching or shrubs frequently lanate or softly pilose, mostly hardy or half-hardy but some of them coolhouse plants: lvs. entire or toothed, the floral ones reduced to bracts or similar to the lower cauline: fls. in axillary clusters of 6 to many fls. or in interrupted or dense spikes, small, often yellowish; calyx tubular, 5-10-nerved, with 5 erect somewhat spiny teeth, or rarely muticous; corolla-tube included, bell-shaped; stamens attached to the tube at the base of the corolla; nutlets ovoid, smooth, without reticulations. Of easy cult. Prop. by seeds or division.

SIDEROXYLON (Greek, iron; the plants were supposed to have a healing power for wounds caused by iron. Discordes also used the name for other plants credited with the same ability). Labiatae. Herbs, subshrubs or shrubs frequently lanate or softly pilose, mostly hardy or half-hardy but some of them coolhouse plants: lvs. entire or toothed, the floral ones reduced to bracts or similar to the lower cauline: fls. in axillary clusters of 6 to many fls. or in interrupted or dense spikes, small, often yellowish; calyx tubular, 5-10-nerved, with 5 erect somewhat spiny teeth, or rarely muticous; corolla-tube included, bell-shaped; stamens attached to the tube at the base of the corolla; nutlets ovoid, smooth, without reticulations. Of easy cult. Prop. by seeds or division.

-down, to about 1½ ft. high, with thick oblong-lanceolate or spatulate lvs., the lower ones crenulate, densely white-pilose, Caucus region and Asia Minor. F. TRACY HUBBARD.

SIDEROXYLON (Greek, iron; the plants were supposed to have a healing power for wounds caused by iron. Discordes also used the name for other plants credited with the same ability). Labiatae. Herbs, subshrubs or shrubs frequently lanate or softly pilose, mostly hardy or half-hardy but some of them coolhouse plants: lvs. entire or toothed, the floral ones reduced to bracts or similar to the lower cauline: fls. in axillary clusters of 6 to many fls. or in interrupted or dense spikes, small, often yellowish; calyx tubular, 5-10-nerved, with 5 erect somewhat spiny teeth, or rarely muticous; corolla-tube included, bell-shaped; stamens attached to the tube at the base of the corolla; nutlets ovoid, smooth, without reticulations. Of easy cult. Prop. by seeds or division.
in. long, and small yellow fls.: fr. about 3½ in. through
W. Indies; cult. in S. Calif.—said to yield a sort of
chewing-gum. Wood useful in furniture-making.

F. W. BARCLAY.

SIEVEKINGIA (named for Dr. Sieveking). Orchi-
deeae. Pseudobulbous orchids suitable for the
greenhouse; of secondary importance.
Pseudobulbs usually clustered, 1-nd.: fl. usually
petioled; labelabum immobile, angled with the column,
venticose, either simple or triradiate at the apex.
About 3 species, natives of Cent. and S. Amer. Allied
to Lucena.

Reichenbachiana, Hook. f. Pseudobulbs clustered, 1
in. long, ovoid or obpyriform, blotched with blood-red
when old: fl. single, 4½-5 in. long, petioled, elliptic-lan-
ceolate, acuminate at both ends, dark green, strongly
5-ribbed: fls. about 6 in a pendulous corymb, about 1½
in. across; sepals subequal, ovate, pale straw-colored;
petals linear, acute, golden yellow, they and the lip
margined with long floccose golden hairs; lip spread
broadly, the lateral-ovate, s. dissinate, golden
yellow, blotched with blood-red, midlobe small,
linear, lacerate. Ecuador. B.M. 7576.

SULIVIS, Rechb. f. Pseudobulbs pyriform, approxi-
mate to: fls. perfect, small, diaphanous; peri-
and sepals spreading upward; petals 3 free, the
dorsal keeled, the lateral almost straight forward
and symmetrical; petals 2, rather similar to the sepalas;
labelabum free, inserted at the base of the S-bent rather
broad synostemium, somewhat mobile; column broad,
thin, much shorter than the labiate, the lip
compressed, ovate-oblong, apex l-lvd., base 2-3-lvd.;
long-clawed, 2-keeled; column elongated, very narrow;
not described and the scape including the fl. is only
2 in. high: pseudobulb ovoid or ovoid-oblong,
apex 1-lvd., base 4-lvd.: Ils. linear, subobtuse, or
minutely denticulate, base conduplicate: lapes lateral,
slower, few-fl.: sepals and petals straw-colored with
purple band at base of dorsal sepal and the petals
light yellow with a shiny orange-yellow crest; sepals
oblong spreading; petals subacute, oblong; labelabum
sessile, deltoid-rendiculatum, undulate. Peru.

F. TRACY HUBBARD.

SILÈNE (Greek name of one of Bacchus’ companions
described as covered with snow, also connected with
siônor, salvia; referring to the stickiness of the stem
and calyx of some species). Including Heliospàrma
Campion. Erect, cespitose, decumbent or diffusely
spreading, herbaceous or perennial herbs, some of
them tender and grown in the greenhouses, others hardy
and planted outdoors for their ornamental effect; often
excellent plants for the rock-garden.

Leaves opposite, entire: fls. solitary or variously
simple, white, through pink to rose and purple; calyx
5-toothed, 10- to many-nerved, naked at the base; pet-
als mostly crowned with a scale at the base of the blade;
stamens 10; styles 3, rarely 4: pod 1-seeded, sometimes
3-seeded.—Over 400 species described, widely scattered
over the world. There is a monograph of Silene, with a
key, in the Journal of the Linnean Society, vol. 32
(1896), by F. N. Williams, with 390 good species.
Williams refers the common S. virínas and S. pennyl-
vanica as well as the European S. alpístris to the genus
Melandrium, characterized by a strictly uncel lúcular
caps. with no trace of septation at the base. Only a
few of the known species are in cult.

Silenes are of easy culture. They mostly bloom in
summer and a few continue well into autumn. By
good management the season of bloom may be con-
tinued through spring and summer. Toward this end
the seeds of the common annual kinds should be sown
in early autumn, instead of spring. As a rule, the common
kinds prefer an sandy loam and full sunlight, but the
rock-garden kinds require special treatment, and other
suggestions for cultivation are given after the specific
descriptions. The most popular kinds are the pink and
rose annuals, S. Armeria and S. pendula: the peren-
nuals the most popular among the white-flowered kinds
are S. maritima and S. alpestris, while S. virínas, S. pen-
nyvanica and S. Schaffa are amongst the most popular
kinds with colored flowers. A good horticultural review
of the kinds in cultivation is found in The Garden, vol.
11, pp. 10-13 (1877).

KEY TO THE SPECIES.

A. Duration annual or biennial.
   B. Plants glabrous, although viscid above in No. 1.
   C. All except the lowest lvs. ovate or ovate-lanceolate from a subcordate, clasping base...
   D. All except the lowest lvs. oblong or oblong-lanceolate from a conuate base...

BB. Plants pubescent or tomentose.
   C. Stts. simple, usually fascicled, finally pendulous, and at least above.
   D. Fls. seashore, white...

AA. Duration perennial.
B. Height 1 ft. or more (Nos. 8, 12, 17, and 18 are usually less than 1 ft.; No. 9 is placed here with uncertainty as its height is not definitely stated).
C. Nerves of the calyx 20.
D. Stts. erect: base of lvs. cordate...

BB. Height 2-10 in. (Nos. 8, 12, and 18 occasionally reach 1 ft.; No. 17 is often 1 ft. or more high; No. 3 may belong here but is probably taller than 1 ft.).
C. Nerves of the calyx 20.
D. Plant not cespitose...

BB. Height 2-10 in. (Nos. 8, 12, and 18 occasionally reach 1 ft.; No. 17 is often 1 ft. or more high; No. 3 may belong here but is probably taller than 1 ft.).
C. Nerves of the calyx 20.
D. Plants glabrous.
E. Lvs. linear-oblong...
F. Lvs. lanceolate-spatulate...

DD. Plants pubescent or at least puberulent or pruinose-seaborous.
E. The lvs. in whorls of 4 (the uppermost and lowest sometimes opposite)...
F. The lvs. not in whorls of 4.
G. Blades linear or narrowly lanceolate or oblanceolate.
H. Stts. more or less deciduous or peniculate at the base.
I. Fls. solitary on the peduncles...
J. Fls. mostly in 3-fld. cymes.

II. Calyx oblong or oblate: fls. white or pink...
III. Calyx long-cylindrical, pink, peniculated; fls. bright Carmine...

GG. Stts. erect.
H. Fls. erect...
I. Fortunei var.
J. Fls. nodding...
K. Blades broader, usually ovate or oblate, sometimes broadly lanceolate or oblanceolate.
L. Stts. more or less decumbent or pendunculate.
M. Infl. leafy and borne in the forks of the branches...
N. Infl. not leafy, usually at least partly terminal...
O. Petals obcordate: fls. white or pink...

II. Petals 4-lobed: fls. scarlet...
III. Lvs. linear-oblong...

GO. Stts. erect, usually stout.
H. Fls. crimson or scarlet...
I. Lvs. thin, spathulate or oblanceolate; apex blunt or abruptly acute...
J. Virginica...
K. Lvs. thick, acute-lanceolate; apex acute or acuminate...

HH. Fls. white, greenish white, or bright green.
I. The fls. erect: lvs. tomentose...
J. The fls. nodding: lvs. pubescent but not tomentose...
K. Base of calyx gradually attenuate to the pedicel...
L. Base of calyx truncate and ambilicate...

LL. Height 2-10 in. (Nos. 8, 12, and 18 occasionally reach 1 ft.; No. 17 is often 1 ft. or more high; No. 3 may belong here but is probably taller than 1 ft.).
C. Nerves of the calyx 20.
D. Plant not cespitose...

DD. Plants cespitose.
E. Lvs. linear: plant dwarf, 2-4 in. high...
F. Lvs. lanceolate or oblong-lanceolate: plant 2-8 in. high...

GG. Stts. erect, usually stout.
H. Fls. nodding...
I. Fls. in panicles.
J. Color of fls. white...
K. Color of fls. cardinal-red...
L. Fls. 2-lobed or 2-cleft...
M. Petals 2-lobed or 2-cleft...

GG. Stts. erect.
H. Fls. erect...
I. Fortunei var.
J. Fls. nodding...
K. Blades broader, usually ovate or oblate, sometimes broadly lanceolate or oblanceolate.
L. Stts. more or less decumbent or pendunculate.
M. Infl. leafy and borne in the forks of the branches...
N. Infl. not leafy, usually at least partly terminal...
O. Petals obcordate: fls. white or pink...

II. Petals 4-lobed: fls. scarlet...
III. Lvs. linear-oblong...

GO. Stts. erect, usually stout.
H. Fls. crimson or scarlet...
I. Lvs. thin, spathulate or oblanceolate; apex blunt or abruptly acute...
J. Virginica...
K. Lvs. thick, acute-lanceolate; apex acute or acuminate...

HH. Fls. white, greenish white, or bright green.
I. The fls. erect: lvs. tomentose...
J. The fls. nodding: lvs. pubescent but not tomentose...
K. Base of calyx gradually attenuate to the pedicel...
L. Base of calyx truncate and ambilicate...

LL. Height 2-10 in. (Nos. 8, 12, and 18 occasionally reach 1 ft.; No. 17 is often 1 ft. or more high; No. 3 may belong here but is probably taller than 1 ft.).
C. Nerves of the calyx 20.
D. Plant not cespitose...

DD. Plants cespitose.
E. Lvs. linear: plant dwarf, 2-4 in. high...
F. Lvs. lanceolate or oblong-lanceolate: plant 2-8 in. high...

GG. Stts. erect, usually stout.
H. Fls. nodding...
I. Fls. in panicles.
J. Color of fls. white...
K. Color of fls. cardinal-red...
L. Fls. 2-lobed or 2-cleft...

GG. Stts. erect.
H. Fls. erect...
I. Fortunei var.
J. Fls. nodding...
K. Blades broader, usually ovate or oblate, sometimes broadly lanceolate or oblanceolate.
L. Stts. more or less decumbent or pendunculate.
M. Infl. leafy and borne in the forks of the branches...
N. Infl. not leafy, usually at least partly terminal...
O. Petals obcordate: fls. white or pink...

II. Petals 4-lobed: fls. scarlet...
III. Lvs. linear-oblong...

GO. Stts. erect, usually stout.
H. Fls. crimson or scarlet...
I. Lvs. thin, spathulate or oblanceolate; apex blunt or abruptly acute...
J. Virginica...
K. Lvs. thick, acute-lanceolate; apex acute or acuminate...

HH. Fls. white, greenish white, or bright green.
I. The fls. erect: lvs. tomentose...
J. The fls. nodding: lvs. pubescent but not tomentose...
K. Base of calyx gradually attenuate to the pedicel...
L. Base of calyx truncate and ambilicate...

LL. Height 2-10 in. (Nos. 8, 12, and 18 occasionally reach 1 ft.; No. 17 is often 1 ft. or more high; No. 3 may belong here but is probably taller than 1 ft.).
C. Nerves of the calyx 20.
D. Plant not cespitose...

DD. Plants cespitose.
E. Lvs. linear: plant dwarf, 2-4 in. high...
F. Lvs. lanceolate or oblong-lanceolate: plant 2-8 in. high...

GG. Stts. erect, usually stout.
H. Fls. nodding...
I. Fls. in panicles.
J. Color of fls. white...
K. Color of fls. cardinal-red...
L. Fls. 2-lobed or 2-cleft...

GG. Stts. erect.
H. Fls. erect...
I. Fortunei var.
J. Fls. nodding...
K. Blades broader, usually ovate or oblate, sometimes broadly lanceolate or oblanceolate.
L. Stts. more or less decumbent or pendunculate.
M. Infl. leafy and borne in the forks of the branches...
N. Infl. not leafy, usually at least partly terminal...
O. Petals obcordate: fls. white or pink...

II. Petals 4-lobed: fls. scarlet...
III. Lvs. linear-oblong...

GO. Stts. erect, usually stout.
H. Fls. crimson or scarlet...
I. Lvs. thin, spathulate or oblanceolate; apex blunt or abruptly acute...
J. Virginica...
K. Lvs. thick, acute-lanceolate; apex acute or acuminate...

HH. Fls. white, greenish white, or bright green.
I. The fls. erect: lvs. tomentose...
J. The fls. nodding: lvs. pubescent but not tomentose...
K. Base of calyx gradually attenuate to the pedicel...
L. Base of calyx truncate and ambilicate...

LL. Height 2-10 in. (Nos. 8, 12, and 18 occasionally reach 1 ft.; No. 17 is often 1 ft. or more high; No. 3 may belong here but is probably taller than 1 ft.).
C. Nerves of the calyx 20.

3617. Silene pendula. (×½)

1. Armæria, Linn. Sweet William Catchfly. Fig. 3616. Annual, glabrous, viscid above: sts. 1–1½ ft. high, erect, simple or slightly branched: lowest lvs. spatulate, the others ovate or ovate-lanceolate, from a subscapose, clasping base: fIs. pink or rose, in dense cymes, corymb-like, often dichotomous; calyx 10-nerved, cylindrical, clavate in fr.; petals obovate-cuneate, subretuse at base: caps. oblong. July—Sept. S. Eu. B.B. (ed. 2) 2:66. Var. alba, Hort., is a white-flowered form.

2. compacta, Fisch. Biennial, glabrous, glaucous-cent: sts. about 1½ ft. high, stout, simple or slightly short-branched above: lowest lvs. spatulate-lanceolate, the others oblong or oblong-lanceolate from a connate base: fIs. pink, crowded in dense, sessile heads, with the uppermost lvs. involucrate; calyx clavate; petals obovate, entire: caps. oblong. July. E. Eu., Asia Minor. L.B.C. 17:1638.—Most of the material cult. under this name is S. pendula var. compacta.

3. viscosa, Pers. Biennial, somewhat tomentose, very viscid: sts. stout, leafy, simple: lvs. somewhat undulate, radical oblong; cauleine lanceolate, acute: fIs. white, in short-peduncled, opposite cymes, forming a long verticillate raceme; calyx very viscid, long-cylindrical, 10-nerved, in fr. clavate; petals deeply 2-parted into ovate-oblong segms.: caps. oblong. June—Aug. E. Eu., N. Asia. Var. plena, Hort., is said to grow 1 ft. high and to have bright rose double fIs.—Use basal cuttings.

4. dichóta, Ehrh. Annual or biennial, minutely pubescent: sts. strictly dichotomous: lower lvs. spatulate, the others lanceolate, acuminate: peduncles very short, racemes in pairs, corymbose-fl.: fIs. white, sessile; calyx 10-nerved, the nerves green, more or less hissute, oblong-cylindrical; petals 2-parted to the middle or more, the segms. obvolute-oblong: caps. oblong. Eu., also intro. in N. Amer. and extensively escaped. B.B. (ed. 2) 2:67.

5. pêndula, Linn. (S. græca, Hort., not Boiss. S. rosæ, Hort.). Fig. 3617. Annual, crisp-pubescent: sts. 6–10 in. high, decumbent at base, dichotomously branched above: lvs. oblong-spatulate to lanceolate; floral lvs. oblong-lanceolate: fIs. flesh-colored or rosy, in lax racemes, finally pendulous; calyx hissute, reddish, 10-nerved, somewhat inflated after anthesis; petals large, ovate or 2-parted: caps. ovate. May—Aug. Mediterr. region. B.M. 114.—A variable species whose varieties seem to be nomenclatorially in confusion as the same form appears to bear several names; some of the forms offered in the trade are: Var. alba, Hort., is a white-flowered form. Var. Bonnetti, Hort. (S. Bonnetti, Hort.), has brownish red sts. and lvs.: fIs. shiny purple-red or dark purple. Var. carnea, Hort., is a compact, growing strain rather than a true variety; occurring in several color variations and both single and double.

6. fimbriata, Sims. Perennial, about 2 ft. high, pubescent: sts. erect, leafy and sometimes branched from the axils: lvs. large, ovate, base more or less cordate, margin undulate; the upper lvs. lanceolate, all dark green: infl. ovate-campanulate, teeth short-triangular; petals cuneate at base, obtuse above, deeply many-cut and fringed. Caucasus. B.M. 908.

S. maritima, With. Perennial, caespitose, gray-green, 8–16 in. high: sts. numerous, the barren shoots procumbent, the flowering ascending: lvs. lanceolate or ovate-lanceolate, margin cartilaginous or crenate: fIs. white, 1 or few to a st., but numerous, paniculate; calyx 20-nerved, inflated after anthesis; petals somewhat cleft and with 2 small scales at the base. June—Aug. Eu., N. Afr. Gn. 57, p. 372. G. M. 52:273.—The seaside form is said to be more glaucous than the mountain form. Allied to S. latifolia, but fewer and larger-flowered. Var. plena, Hort. (S. maritima var. flore-
Silene virginica. (X 1/2)

In second racemose panicles; peduncles opposite, 1-3-fl.; calyx subcalvate, obscurely 10-ribiate, glabrous; petals 2-cut, the segment, oblong-linear, obtuse: caps. elliptical. E. Eu., W. Asia.

10. Asterias, Griseb.; also misspelled Asteris. Perennial, glabrous, 3-4 ft. high: sts. tall, simple, rather viscid: lvs. lanceolate-spatulate, 4-5 in. long, obtuse, base attenuate; the uppermost oblong, elliptic-lanceolate: lvs. purple, subsessile, in a many-fl., capitate cyme; calyx membranaceous, reddish, oblong-cylindrical; petals oblong, entire: caps. oblong. Macedonia and Roumania. Var. grandiflora, Hort., is about 3 ft. high and has the crimson-scarlet lvs. in globose heads, Balkan Mts.

11. stellata, Ait. STARBY CAMPION. Perennial, 2-3 ft. high: sts. erect, branched, pubescent: lvs. in whorls of 4 (the uppermost and lowest sometimes opposite), ovate-lanceolate, acuminate, 2-3 in. long: lvs. white, nodding, in an open panicle; calyx campylanulate, pubescent, inflated; petals laminately cleft, unappendaged.
ovate-elliptic, more or less narrowed at base, acuminate, rarely obtuse: fls. scarlet, large, 1 in. or more across, scuruted; calyx funnelform-clavate; petals 4-lobed, commonly with 2 broad ones flanked by 2 narrower ones. caps. ovoid, concealed until dehiscence by the rather broad calyx. Coast Range, Ore. to N. and Cent. Calif.—Doubtful whether in cult.

20. \textit{virginica}, Linn. \textit{Fire Pink}. Fig. 3618. Perennial, 1-2 ft. high, viscid-pubescent: sts. striate, single, simple: lvs. spatulate or ob lanceolate, the lower narrow ed to ciliate-fringed petiole, the upper sessile: fls. very large, 1 in. or more across, crimson or scarlet, loosely cymose, commonly nodding or reflexed after anthesis; calyx clavate or oblong; petals broadly lanceolate, 2 (rarely 4) -toothed at the apex. Open woods and rocky hills, N. Y. to Minn., south to Ga. and Ark. B.M. 3342. Gn. 22, p. 375. G. 8:417. B.B. (ed. 2) 2:64.

22. \textit{gigantèa}, Linn. Perennial, 3-4 ft. high: sts. tall, stout, 4-angled below, viscid-pubescent: lvs. tomentose, the radical densely rosulate, thick, obovate, mucronate; the floral lvs. minute, linear-lanceolate; panicle long, racemelike, with the cymes densely many-flowered, remotely whorled and the uppermost sessile: fls. white; calyx hairy, obconical, 10-nerved; petals 2-parted into oblong segments. : caps. large, ovate. E. Medit. region.

23. \textit{viridiflora}, Linn. Perennial, 1-2 ft. high: sts. simple or branched above, soft-pubescent, very viscid above: lvs. petiolate, ovate-oblong, acute: fls. greenish white, in loose, elongated panicles, few, nodding; calyx glabrous, 10-nerved; petals 2-parted above the middle into linear-oblong segments: caps. oblong. S. Eu.

24. \textit{melifera}, Boiss. & Reut. Perennial, cespitose, 1½-2½ ft. high: sts. erect, stout, very short-puberulent below, very viscid above: lvs. acute, pubescent, the lower and rosette lvs. oval or spatulate-lanceolate, attenuate to a long petiole; the upper lanceolate or linear: fls. small, bright green, in long lax cymose panicles, rather small; petals obovate, green-striate; claws obtuse, the limb deeply 2-lobed, cuneate: caps. ovate-conic. Spain, Portugal, and Algeria.

26. \textit{pumilio}, Wulf. Dwarf perennial: sts. a few inches high, cespitose, glandular, linear, obtuse, ciliate: fls. solitary, rose, ½ in. across, on slender pedicels; calyx fainly 20-nerved, oblong-campanulate, pubescent, somewhat inflated after anthesis, green or violaceous green; petals undivided or notched: caps. ovate-cylindrical. June. Austrian Alps.—A rare and choice plant. Niven says it has hard woody roots which are easily damaged in transit, and therefore those who wish the species should secure seeds.

27. \textit{Lerchenfieldiana}, Baunig. Low cespitose perennial, glabrous and glaucous: sts. decumbent ascending: lvs. rosulate below, lanceolate above, attenuate, ciliate: fls. solitary, rose, ½ in. across, on slender pedicels; calyx fainly 20-nerved, oblong-campanulate, pubescent, somewhat inflated after anthesis, green or violaceous green; petals undivided or notched: caps. ovate-cylindrical. June. Austrian Alps.—A rare and choice plant. Niven says it has hard woody roots which are easily damaged in transit, and therefore those who wish the species should secure seeds.

29. \textit{dianthifolia}, J. Gay. Perennial, densely cespitose, 4-6 in. high, glabrous: sts. erect, 1 (rarely 2) -flowered: lvs. ciliate at the broadened base, maroon, the lower congested, the upper shorter; calyx reddish-nerved, short obconic-cylindrical, teeth ovate; petals 2-parted above the middle into linear-oblong segments: caps. ovate. Asia Minor.

31. \textit{alpestris}, Jacq. Perennial, 4-6 in. high, cespitose, more or less viscid above: sts. dichotomous: lvs. mostly radical, lanceolate-linear, rather obtuse: fls. white, rather large, shining, in corymbose panicles; calyx short, campanulate-clavate, not inflated, 10-nerved; petals obovate, 4 -lobed at the apex, and with 2 teeth at the base of each petal. May-Aug. Mountains of E. Eu. Gn. 63, p. 251.—It forms a dense mass of underground stems and is easily prop. by division or seeds. Var. \textit{grandiflora}, Hort., is a large-flowered form offered in the trade. G.C. III. 55:442. Var. \textit{Richentreichii}, Hort., is offered in the trade as a smaller form, about 6 in. high.

32. \textit{Saxifraga}, Linn. (S. \textit{petrae}, Waldst. & Kit., not Adams). Perennial, somewhat shrubby, densely cespitose, bright green: sts. numerous, 3-10 in. high, ascending, filiform, glabrous or scabrous-puberulent, viscid above: lvs. linear or linear-lanceolate, acute, glabrous or scabrous-puberulent, margin serrulate-ciliate: fls. whitish, very often solitary or in 2-3-flowered cymes, erect on very long pedicels; calyx tubular-clavate glabrous, 10 -staminate, staminal green or reddish, puberulent; petals 2 -parted, the lobes obovate: caps. ovoid-oblong. Eu. and Asia Minor. L.B.C. 5:454.
33. \textit{odonopetalà}, Fenzl. Perennial, densely pubescent: sts. 4–6 in. long, leafy, subsimple, glandular-villous above: lvs. lanceolate or linear-lanceolate, 1-nerved, acute or somewhat obtuse; fls. cyamo, 1–7-fld., white; calyx pubescent, rather viscid, whitish, coapmate; petals 2-lobed: caps. ovate. Asia Minor and Syria.

34. \textit{Elfbæthæa}, Jan. Perennial, 4–6 in. high: sts. tufted, erect or ascending, viscid-pubescent: lvs. narrowly lanceolate, acute, the lower 2–3 in. long, gradually becoming smaller upward; panicle terminal; fls. bright rose-violet, 1½ in. across, cylindric at first cylindrical, at length oval and bladdery, pale dull green, veined and margined purple; petals 2-lobed, white-clawed, blade cuneate-filament, margin crenate-dentate. Italy. B.M. 5400. G. 8: 412.

35. \textit{cilíata}, Pourr. Perennial, 3–6 in. high, pubescent, cespitose from a woody rhizome: sts. slender, simple, or slightly branched, nearly naked: lvs. of the rosette and lower st. linear-lanceolate or linear, the upper shortened and gradually narrowed from a broadened base: fls. in a few-fld. cyme, pedicelled, white or ivory-white; calyx ciliate, short-pubescent, green-, red-brown, or purplish striate; petals 2-lobed. Eu.

36. \textit{répens}, Patrin. Perennial, 8–10 in. high, with a long repent root: sts. several, erect, simple or branched, more or less searbo-pubescent: lvs. narrowly oblong on or below, glabrous, somewhat viscid above: lower lvs. oblongate-spatulate, acute, ciliate on the ribs and margin; upper lvs. linear, acute: fls. white, racemose-pincinate on opposite, axillary, 1–5-fld. peduncles: calyx cylindrical-clavate, inflated, 10-lobate, pubescent-villous; petals 2-cut, the segments oblong, obtuse, the claw glabrous. Russia, E. Siberia, Caucasus, China and Japan, and in N. Alaska.

37. \textit{Reichenbachii}, Vis.; also spelled \textit{Reichenbachiana} in the trade. Perennial, miniature, shrub-like, tufted: sts. somewhat woody at base, puberulent below, glabrous, somewhat viscid above: lower lvs. oblongate-spatulate, acute, ciliate on the ribs and margin; upper lvs. linear, acute: fls. white, racemose-pincinate, nodding; peduncles usually 1-fld.: calyx linear-clavate, 10-nerved, pubescent: petals 2-cut, the segments oblong, obtuse, the claw glabrous. E. Siberia, Caucasus, China and Japan, and in N. Alaska.

38. \textit{rupéstris}, Linn. Perennial, 2–8 in. high, loosely cespitose, glabrous: sts. numerous, erect from a branched base, 1½–2 in. high: lvs. lanceolate, acute, the lower attenuate at base: fls. flesh-color, in repeatedly dichotomous cymes, numerous, long-pedicled; the pedicels filiform; calyx obconical; base slightly umbilicate; petals obovate, deeply emarginate: caps. ovoid-oblong. Eu.

42. \textit{pusilla}, Waldst. & Kit. Perennial, dwarf, villous on the petioles and at the base of the st., viscid above. cespitose, many-stemmed: sts. low, slender, leafy, dichotomous: lvs. radical, spatulate, the others short-lanceolate: peduncles long, capillary, 1 (rarely 2) -fld.: calyx glabrous or minutely glandular, turbinate; petals glabrous-clawed, blade white, obtuse, 4-toothed: caps. ovoid-alate-globe. Considered by some to be only a variety of \textit{S. quadrifólia}.

44. \textit{pennsylvánica}, Michx. (\textit{S. carolínæa}, Walt.:). \textbf{Wild Pink.} Perennial, 6–9 in. high, from a strong taproot, viscid-pubescent: sts. few: lvs. mostly basal, spatulate or oblongate, acute, base tapering to the long, ciliate petiole-pincinate on opposite, axillary, 1–5-fld. peduncles: calyx cylindrical-clavate, inflated, 10-lobate, pubescent-villos; petals 2-cut, the segments oblong, obtuse, the claw glabrous. Russia, E. Siberia, Caucasus, China and Japan, and in N. Alaska.

3168 \textbf{SILENE}

\textit{Silphium} (from the Greek name of an umbelliferous plant of northern Africa). \textit{Compasitae}. \textit{Rosinweed}. Tall-growing hardy perennial herbs native of the United States which are grown for their rather large showy flowers, which, except in one species, are yellow. Leaves opposite, alternate or verticillate, often forming water-holding cups by perfoliation of the st.: heads many-fl.: involucres thick, somewhat follicaceous bracts; ray-fls. or at least their ovaries in more than 1 series, fertile, and with elongated exserted discoidal ligules; achenes much flattened, falling free or only with the subtending bract.—About 25 species. \textit{Silphiums} are of easy cult. in any good soil. They require full sunlight and are prop. by division or seed.

\textbf{SILPHIUM}\n
\textit{S. Flower}: \textit{Albína}. S. \textit{Oak}: \textit{Gnèbèa rohómba}. S. \textit{Tree}: \textit{Abústia fahóbr}. S. \textit{Vine}: \textit{Péricon gregà}. S.-weed: \textit{Aeolípan}.

\textbf{SILPHIUM} (from the Greek name of an umbelliferous plant of northern Africa). \textit{Compasitae}. \textit{Rosinweed}. Tall-growing hardy perennial herbs native of the United States which are grown for their rather large sunflower-like heads of flowers which, except in one species, are yellow. Leaves opposite, alternate or verticillate, often forming water-holding cups by perfoliation of the st.: heads many-fl.; involucre of thick, somewhat foliaceous discoidal bracts; ray-fls. or at least their ovaries in more than 1 series, fertile, and with elongated exserted discoidal ligules; achenes much flattened, falling free or only with the subtending bract.—About 25 species. \textit{Silphiums} are of easy cult. in any good soil. They require full sunlight and are prop. by division or seed.

SILPHIUM

July-Sept. Ohio, west and south. B.B. (ed. 2) 3: 461. - It is said of this species that the st.-lvs. tend to point north and south.

AA. Foliage not cut.
B. St.-lvs. small.

terebinthinaeum, Jacq. PRAIRIE DOCK. St. about 6 ft. high, nearly or quite smooth: lvs. nearly all basal, usually 1 ft. long, ovate, cordate, dentate; fl.-heads 1½-3 in. across; rays 12-20. July-Sept. - Ont. and Ohio to Iowa and La. B.B. (ed. 2) 3: 462. - A striking and decorative herb.

bb. St.-lvs. large.

cc. Lvs. connate-perfoliate.

perfoliatum, Linn. (S. erythraea, Bernh.). CUP PLANT. INDIAN CUP. St. square, usually dentate, branched above, about 6 ft. high: lvs. thin, ovate or deltate, adnate to the lower st.; lvs. alternate, abruptly pinnate, sessile or petiolate; the axils, pedicelled; calyx-tube shortly and broadly turbinate, adnate, 5-angled or 5-winged, the limb foliaceous, broadly 5-cleft or -parted; corolla-tube nearly equal at the base or the posterior gibbous, long or broadly cylindrical, the upper part swollen or bell-shaped; lobes 5, spreading, or the 2 posterior smaller; stamens included, attached to the tube of the corolla; anthers broad, the cells confluent at the apex; glands of the disk 5, distinct, or the 2 posterior more crowded together or connate; ovary half inferior; style dilated at the tip; stigma concave, entire or slightly 2-lobed. - Species 20-25, Brazil. Allied to Gesneria, Isoloma, and Achiemines, and of similar cultural requirements.

The genus includes the cult. gloxinia, which is properly Sinningia speciosa, Benth. & Hook., but which is treated in this book under Gloxinia. Other than this species, the sinningias are little known horticulturally, although some of the species have much merit.

SILYBUM (an old Greek name applied by Dioscorides to some thistle-like plants). Compositae. Erect, glabrous herbs, sometimes grown in European gardens for ornament and also for the edible heads, roots, and for the oily seed and edible fr.: lvs. alternate, white-maculate above, sinuate-cleft to the middle or base: achenes smooth, obovate, terete, corymbosely branched above: lvs. lanceolate-ovate to ovate-lanceolate, opposite; fl.-heads numerous, 1-2 in. across, with 15-25 rays. Aug., Sept. Western prairies. B.B. (ed. 2) 3: 460. N. TAYLOR.

SÍLÍYBUM

(SINNINGIA)

SINNIGA

(SINNINGIA) (for the naturalist, F. W. Simmonds). Buxaceae. Evergreen shrubs, sometimes cult. for ornament or for the oily seed and edible fr.: lvs. opposite; fls. direnses, in the fl.-axis, apetalous; sepals imbricate; staminate fls. in clusters; stamens numerous; pistillate fls. single; ovary 3-celled, 1 ovule in each cell. A single species. Related to Buxus.

Sinningia speciosa, Benth. & Hook., is stated to have been one of its parents.

Regina, Sprague, G.C. III. 36, p. 88: "The turning-point in the history of our cultivated gloxinias, however, was in 1845, when an erect and regular-flowered plant was raised by Mr. John Fyfe, gardener at Rosethay, Bute; this had a white corolla with a violet center, and five perfect stamens, instead of the four usual in Gesneria-ceae. Unfortunately for the systematic botanist, no exact record of its parentage was made, though in Flores des Regras, t. 311, where it was figured three years later, Sinningia speciosa is stated to have been one of its parents.

Regina, Sprague, G.C. III. 36, p. 88: "The turning-point in the history of our cultivated gloxinias, however, was in 1845, when an erect and regular-flowered plant was raised by Mr. John Fyfe, gardener at Rosethay, Bute; this had a white corolla with a violet center, and five perfect stamens, instead of the four usual in Gesneria-ceae. Unfortunately for the systematic botanist, no exact record of its parentage was made, though in Flores des Regras, t. 311, where it was figured three years later, Sinningia speciosa is stated to have been one of its parents."
cessive pairs of leaves are usually close together on the stem, the effect is that of two many-flowered whorls, and is very fine." Brazil. G.C. III. 36:201. B.M. S182. Cl. 55, p. 206. This is a handsome and strikingly colored plant, with long flowering period. Var. hydrobioides, Hort., is a garden hybrid with much larger flowers. Var. grandiflora, Hort., is advertised, the flowers "several times larger than the type, and well displayed above the handsome dark green and purplish red foliage."

**conspicua**, Nichols. (Ranunculaceae, Regeli). Root tuberous: st. 1 ft. high: lvs. ovate-oblong, short-acuminate, somewhat heart-shaped at the base and dentate: fls. yellow, paler on the outside, marked on the lower part of the tube with purple dots and lines; calyx-tube (entirely united with the ovary) equally 5-parted, the segments lanceolate, spreading; corolla-tube obliquely and narrowly campanulate, swollen and recurved at the base; glands of the disk 2: caps. 1-celled: seeds many.

**ornata**, Benth. & Hook. (Ranunculaceae ornata, Van Houtte). A hybrid of the above species with a garden variety of Gloxinia, with flowers of a bright red; the result is a plant resembling *S. conspicua*, but differing in having the lvs. tinted on the veins and petals with purple and in having a somewhat more elegantly shaped fl., pure white while with purple lines on the outside of the corolla-tube and the inside of a yellowish-green, lined with purple. F.S. 23:2423.—Probably not now in the market.

**SINOFRANCHETIA** (for Adrien Franchet, French botanist who wrote much on Chinese botany). *Lardizabalaceae*. Deciduous climbing shrub allied to *Holboellia*, but easily distinguished by the deciduous lvs., by the roundish small sepals of the fls. borne in very long racemes, and from the last chiefiy in the structure of the fls. borne in very long, axillary, 8-12 in. long; fls. unisexual, short-stalked, 0.5 in. across, white striped brownish; sepals ovate, 4-5 in. long, the lateral lfts. obliquely ovate; racemes axillary, 8-12 in. long; fls. unisexual, short-stalked, 0.5 in. across, white striped brownish; sepals ovate; stamens 6, free, short: carpels 3, developing into ovoid many-seeded, bluish purple berries about 0.5 in. across. Cent. China. H.I. 29:2842.—The fruit racemes of bluish purple berries are strikingly handsome: the plant has proved perfectly hardy in southern England, but tender at the Arnold Arboretum. Prop. is by seeds and by layers, possibly also by cuttings like *Houtte*). A hybrid of the above species with a garden variety of Gloxinia, with flowers of a bright red; the result is a plant resembling *S. conspicua*, but differing in having the lvs. tinted on the veins and petals with purple and in having a somewhat more elegantly shaped fl., pure white while with purple lines on the outside of the corolla-tube and the inside of a yellowish-green, lined with purple. F.S. 23:2423.—Probably not now in the market.

**SINOFRANCHETIA** (for Adrien Franchet, French botanist who wrote much on Chinese botany). *Lardizabalaceae*. Deciduous climbing shrub allied to *Holboellia*, but easily distinguished by the deciduous lvs., by the roundish small sepals of the fls. borne in very long racemes, and from the last chiefiy in the structure of the fls. borne in very long, axillary, 8-12 in. long; fls. unisexual, short-stalked, 0.5 in. across, white striped brownish; sepals ovate; stamens 6, free, short: carpels 3, developing into ovoid many-seeded, bluish purple berries about 0.5 in. across. Cent. China. H.I. 29:2842.—The fruit racemes of bluish purple berries are strikingly handsome: the plant has proved perfectly hardy in southern England, but tender at the Arnold Arboretum. Prop. is by seeds and by layers, possibly also by cuttings like *Houtte*). A hybrid of the above species with a garden variety of Gloxinia, with flowers of a bright red; the result is a plant resembling *S. conspicua*, but differing in having the lvs. tinted on the veins and petals with purple and in having a somewhat more elegantly shaped fl., pure white while with purple lines on the outside of the corolla-tube and the inside of a yellowish-green, lined with purple. F.S. 23:2423.—Probably not now in the market.

**SIPHOCAMPYLLUS**

**SIPRONIA:** Heres.

**SISYRINCHIUM** (an old Greek name first applied to some other plant). Iridaceæ. SATIN FLOWER. BLUE-EYED GRASS. Rush Lily. Hardy or half-hardy perennials, usually with fibrous roots, sometimes used in the hardy border.

Stems simple or branched, 2-edged or winged: lvs. grass-like, lanceolate or terete: fls. small, fugacious, in umbellate clusters from a usually 2-lvd. spathe, blue or yellow, perianth nearly flat or bell-shaped, segms. 3, sharply silike: caps. globular, 3-angled.—About 150 species, all American, mostly in moist fields and sandy places and along shores. The species are of easy cult. in any good garden soil. They are very little known as horticultural subjects.

_a._ Fls. yellow.
_b._ St. leafless.

**b._** St. ½-bearing.

**c._** The st. slightly 2-edged.

**SITUCA** (S. anceps, Ker-Gawl.). Perennial, 1–3 ft.: st. leafless.

**cyaneum**, B. & B. (S. cyaneum, Cav.) Evergreen shrubs: lvs. alternate, short-petioled, elliptically lanceolate or terete: fls. blue, about 1 in. long: pedicels 3 in. long: calyx-teeth acute: petals serrate: berries black, berry-like fruit. They are mostly in woods, as they belong to a small group of short lived shrubs, not being reliably hardy far north as Wash­ington, D.C. S. portuguese is somewhat harder than S. japonica or Dennstredtia characterized by prostrate rhizomes and a cup-shaped nearly spherical involucre placed at the base of the depression of the lobes. The fern in question is Dennstredtia cicutaria, Moore (Sitolobium cicutarium, J. Smith. Dicksonia cicutaria, Hook. & Baker), a W. Indian species with bipinnate lvs.: lower pinnae 12–18 in. long and 6 in. broad, with deeply cut linear-acuminate pinnaules, the segms. oblong-deltoid and deeply cut.

**SITUM** (from Siam, old Greek name used by Dioscorides). Umbelliferae. Glabrous herbs, including one of economic value, S. Sisarum or skirret (which see), the roots of which are used as a vegetable: lvs. pinnate, the pinna dentate: umbels composite, terminal or lateral: involucres and involucral bracts numerous: fls. white, calyx-teeth acute: petals reflexed: fr. ovate or oblong, laterally compressed or constricted at the junction of carpels.—About 4 species, northern hemisphere, also one species in S. Afr., sp. to be subspecific.

**Sisarum**, Linn. SKEWER. Plant, 3–4 ft. high, tuberous-rooted: lvs. pinnatifid; segms. oblong-acute, serrate: involucres fl.; submersed, referred to E. Asia.

**latifolium**, Linn. WATER PARSNIP. Sts. 3–5 ft. high, angular, furrowed and erect: lvs. pinnate; lfts. oblong-lanceolate, evenly serrate, pointed: umbels terminal; involucres many, lanceolate. Ditches and rivers, England.—Like Ferales and certain other umbelliferous plants, it is valued less for its edible roots and handsome foliage than for its fls. F. TRACY HUBBARD.

**SKIMMIA** (Japanese, Skimm, meaning a hurtful fruit). Rutaceae. Ornamental woody plants grown chiefly for the bright red berries and the handsome foliage.

Evergreen glabrous shrubs: lvs. alternate, short-petioled, entire, dotted with transverse glands: fls. perfect or dioecious, the stamine fragrant and in large panicles; segms. 4–5; style with 5–lobed stigma; ovary 2–5-loculed: fr. a drupe with 2–4 1-seeded stones.—Four species from the Himalayas to China and Japan.

The skimmias are densely branched, usually low shrubs with medium-sized generally oblong acute leaves, small white flowers in terminal panicles and showy bright red, black berry-like fruit. They are tender, not being reliably hardy as far north as Wash­ington, D.C. S. fortunei is somewhat harder than S. japonica. Handsome shrubs for borders of evergreen shrubberies and especially valuable for planting in cities, as they belong to the best smoke-enduring evergreen shrubs; they are particularly beautiful when

3171

**cc.** Spathes very unequal in length.

**mucronatum**, Michx. Hardy perennial similar to the last: sts. narrowly winged: spathe usually purple-tinged, not gibbous: outer bract with the margin united a little above the base, 3 1/2–2 3/4 in. long, the inner 3 1/2–3 1/2 in. long: perianth violet (rarely white): caps. straw or greenish yellow. W. Mass. to Va. and Mich. B.B. (ed. 2) 1:554.

**F. W. BARCLAY.**

**F. TRACY HUBBARD.**

**SITOLOBIIUM** (name refers to the grain-like fruchti­cation). Polyopodaceae. Under this name one fern is still listed, but the group now forms a section of Dick­sonia or Dennstredtia characterized by prostrate rhizomes and a cup-shaped nearly spherical involucre placed at the base of the depression of the lobes. The fern in question is Dennstredtia cicutaria, Moore (Sitolobium cicutarium, J. Smith. Dicksonia cicutaria, Hook. & Baker), a W. Indian species with bipinnate lvs.: lower pinnae 12–18 in. long and 6 in. broad, with deeply cut linear-acuminate pinnaules, the segms. oblong-deltoid and deeply cut.

**SITUM** (from Siam, old Greek name used by Dios­corides). Umbelliferae. Glabrous herbs, including one of economic value, S. Sisarum or skirret (which see), the roots of which are used as a vegetable: lvs. pinnate, the pinna dentate: umbels composite, terminal or lateral: involucres and involucral bracts numerous: fls. white, calyx-teeth acute: petals reflexed: fr. ovate or oblong, laterally compressed or constricted at the junction of carpels.—About 4 species, northern hemisphere, also one species in S. Afr., sp. to be subspecific.

**Sisarum**, Linn. SKEWER. Plant, 3–4 ft. high, tuberous-rooted: lvs. pinnatifid; segms. oblong-acute, serrate: involucres fl.; submersed, referred to E. Asia.

**latifolium**, Linn. WATER PARSNIP. Sts. 3–5 ft. high, angular, furrowed and erect: lvs. pinnate; lfts. oblong-lanceolate, evenly serrate, pointed: umbels terminal; involucres many, lanceolate. Ditches and rivers, England.—Like Ferales and certain other umbelliferous plants, it is valued less for its edible roots and handsome foliage than for its fls. F. TRACY HUBBARD.

**SKIMMIA** (Japanese, Skimm, meaning a hurtful fruit). Rutaceae. Ornamental woody plants grown chiefly for the bright red berries and the handsome foliage.

Evergreen glabrous shrubs: lvs. alternate, short-petioled, entire, dotted with transverse glands: fls. perfect or dioecious, the stamine fragrant and in large panicles; segms. 4–5; style with 5–lobed stigma; ovary 2–5-loculed: fr. a drupe with 2–4 1-seeded stones.—Four species from the Himalayas to China and Japan.

The skimmias are densely branched, usually low shrubs with medium-sized generally oblong acute leaves, small white flowers in terminal panicles and showy bright red, black berry-like fruit. They are tender, not being reliably hardy as far north as Wash­ington, D.C. S. fortunei is somewhat harder than S. japonica. Handsome shrubs for borders of evergreen shrubberies and especially valuable for planting in cities, as they belong to the best smoke-enduring evergreen shrubs; they are particularly beautiful when
covered with their bright red fruits, which are retained through the whole winter if not eaten by birds. In the greenhouse two crops of berries on a plant may be seen occasionally. The skimmias are of rather slow growth and thrive best in a sandy loamy soil, but also grow well in strong clay; they prefer a partly shaded situation. On account of their handsome fruits they are sometimes cultivated in pots in a sandy compost of peat and loam. As the skimmias are polygamous and mostly unisexual, it will be necessary to plant staminate plants among the pistillate ones to secure well-fruited specimens. Propagation is by seeds sown in fall or stratified and by cuttings under glass with gentle bottom heat. William Scott writes: "Seeds sown in the fall and grown along in a coolhouse during winter can be planted out in a good loam the following spring, when they will make a vigorous growth, and can be lifted the following October. Their red berries make them very desirable as a Christmas berry plant."

**Japanese, Thumb. (S. obesata, Moore. S. fragrans, Carr. S. fragrantissima, Hort.).** Shrub, 5 ft. high, except the minutely pubescent infl. quite glabrous: lvs. crowded at the ends of the branchlets, short-petiolated, elliptic-oblong to oblong-ovate, narrowed at both ends, obtusely pointed, bright or yellowish green above, yellowish green beneath, 3½-5 in. long, 3-½ in. wide, 2½-3½ in. long: fr. small, ½ in. long; fls. white, sometimes fragrant; perianth 6-parted, white or yellow, ½ in. long; stamens 6; ovary 3-celled: seeds few, arranged in 1 series.-About 10 species, N. and Cent. Amer. and Temp. Asia.

**Vagnera** is an older name for this genus and is used sometimes cultivated in pots in a sandy compost of peat and loam. As the skimmias are polygamous and mostly unisexual, it will be necessary to plant staminate plants among the pistillate ones to secure well-fruited specimens. Propagation is by seeds sown in fall or stratified and by cuttings under glass with gentle bottom heat. William Scott writes: "Seeds sown in the fall and grown along in a coolhouse during winter can be planted out in a good loam the following spring, when they will make a vigorous growth, and can be lifted the following October. Their red berries make them very desirable as a Christmas berry plant."

**Skirret** (Stium Sisyrum, Linn.) is a vegetable of minor importance, the route of which are used like salisly or oyster plant. It is a hardy perennial umbelliferous herb, native to eastern Asia. It grows 3 to 4 feet high, has pinnate foliage and small white flowers in compound umbels. The roots grow in large clusters, something like those of a sweet potato or dahlia, but they are much longer, more cylindrical, and somewhat jointed. The roots have a sweet and slightly flousey taste and, if well grown, are tender. The chief objection to this vegetable is the woody core, which must be removed before cooking, as it is not easily separated from the flouesy part at the table and detracts from its quality. The thickness of the core varies greatly, no matter whether the plants are propagated by seed or otherwise.

**S. argentea, Mast.,** has obovate lvs. and a short panicle. S. rubella, Rehd. & Wilson. Shrub, or small tree, to 15 ft. : lvs. ovate, or oblong-ovate, 3½-5 in. long: fr. small, ½ in. long; fls. white, sometimes fragrant; perianth 6-parted, white or yellow, ½ in. long; stamens 6; ovary 3-celled: seeds few, arranged in 1 series.-About 10 species, Asia and N. Amer.

**Skunk cabbage** (Lysichiton王某, Linn.) is a vegetable of rather slow growth and thrive best in a sandy loamy soil, but also grow well in strong clay; they prefer a partly shaded situation. On account of their handsome fruits they are sometimes cultivated in pots in a sandy compost of peat and loam. As the skimmias are polygamous and mostly unisexual, it will be necessary to plant staminate plants among the pistillate ones to secure well-fruited specimens. Propagation is by seeds sown in fall or stratified and by cuttings under glass with gentle bottom heat. William Scott writes: "Seeds sown in the fall and grown along in a coolhouse during winter can be planted out in a good loam the following spring, when they will make a vigorous growth, and can be lifted the following October. Their red berries make them very desirable as a Christmas berry plant."

**S. foliosa, Thunb.** (S. japonica, C. A. Mey. Low, tufted perennial, very variable in foliage: lvs. long, oblong-lanceolate, acuminate, dark green above, light green beneath, 3½-5 in. long: fls. white, in oblong-ovate, obtuse, 3-½ in. long; fr. small, ½ in. long; fls. white, sometimes fragrant; perianth 6-parted, white or yellow, ½ in. long; stamens 6; ovary 3-celled: seeds few, arranged in 1 series.-About 10 species, Asia and N. Amer.

**Small-fruits** (Blackberry, Blueberry, Currant, Dewberry, Gooseberry, Raspberry.)

**Skirret** (Stium Sisyrum, Linn.) is a vegetable of minor importance, the route of which are used like salisly or oyster plant. It is a hardy perennial umbelliferous herb, native to eastern Asia. It grows 3 to 4 feet high, has pinnate foliage and small white flowers in compound umbels. The roots grow in large clusters, something like those of a sweet potato or dahlia, but they are much longer, more cylindrical, and somewhat jointed. The roots have a sweet and slightly flousey taste and, if well grown, are tender. The chief objection to this vegetable is the woody core, which must be removed before cooking, as it is not easily separated from the flouesy part at the table and detracts from its quality. The thickness of the core varies greatly, no matter whether the plants are propagated by seed or otherwise.

**S. Rubella, Rehd. & Wilson. Shrub, or small tree, to 15 ft. : lvs. ovate, or oblong-ovate, 3½-5 in. long: fr. small, ½ in. long; fls. white, sometimes fragrant; perianth 6-parted, white or yellow, ½ in. long; stamens 6; ovary 3-celled: seeds few, arranged in 1 series.-About 10 species, Asia and N. Amer.

**Smilacina** (resembling Smilax). Liliaceae. 
**False Solomon's Seal.** Perennial herbs, with simple stems from rootstocks (Fig. 3620), used for the hardy border or the wild-garden. Ligularia are alternate, nerved, and usually sessile: panicles or racemes terminal; fls. white or greenish white, sometimes fragrant; perianth 6-parted, white; petals spreading, without—passers; stamens ovary 3-celled: berry globose, 1½—2 inch in. broad. About 25 species, N. and Cent. Amer. and Temp. Asia. Vagnera is an older name for this genus and is used by some American writers; but on the principle of fifty years of established use, Smilacina is retained in the "nomina conservanda" list of the Vienna Congress.
SMILACINA

Smilacinas are of easy culture in any good soil. They prefer a rich loam in a moist but not wet partly shaded place. They are handsome plants both in foliage and flower, particularly when growing with natural companions. S. racemosa is probably the most attractive.

The genus Smilax, of which there are twenty-five species native to the United States, has been used very little in this country for planting in ornamental grounds, its value as a decorative plant having been largely ignored. The vines of the wild plants have been gathered locally for decorations and S. lanceolata, the Florida smilax of the trade, is extensively shipped from the southern states to the northern centers for use in large decorations. Most of the common woody species of the North are unsuited for planting in restricted areas as they spread rapidly by underground stems. None of the native species listed below is ordinarily handled by nurserymen.

The smilax of florists is Asparagus asparagoides. See p. 3175; also p. 409, Vol. I.

SMILAX

SMILAX (ancient Greek name). Leitzen. The greenbriers, useful for winter greens and outdoor planting.

Usually woody climbers with paired tendrils on the base of the petiole; sometimes shrubs or herbaceous perennials, young shoots little branched, old woody shoots becoming much branched above; shoots arising from a rootstock, slow-growing and woody in 9 with large fleshy tubers; in some species with long creeping rhizomes; lower lvs. reduced to scales, the upper simple

- slightly lobed, 3-7 (or more) -nerved, deciduous or completely evergreen, usually variable in outline on different types of branches: fls. rather small, dioecious, usually numerous in axillary peduncled umbels; pedicels uniform in length: berries normally globose, 1-6-seeded, blackish or red. - Over 200 species generally distributed over the world.

The genus Smilax, of which there are twenty-five species native to the United States, has been used very little in this country for planting in ornamental grounds, its value as a decorative plant having been largely ignored. The vines of the wild plants have been gathered locally for decorations and S. lanceolata, the Florida smilax of the trade, is extensively shipped from the southern states to the northern centers for use in large decorations. Most of the common woody species of the North are unsuited for planting in restricted areas as they spread rapidly by underground stems. None of the native species listed below is ordinarily handled by nurserymen.

The smilax of florists is Asparagus asparagoides. See p. 3175; also p. 409, Vol. I.
1. *herbacea*, Linn. A hardy perennial vine 4–10 ft. high, unarmed; Ivs. ovate to lanceolate, acute to cuspidate, obtuse or cordate at base, long-petioled, 7-9-nerved, glabrous and glaucous beneath; umbels 15–50-fl., long-peduncled; fls. carrion-scented; berry bluish black, about ¼ in. diam., normally 3–6-seeded. April–June. N. E. U. S. B. B. 1920. B. B. (ed. 2) 1:527. This species is undesirable on account of the strong carrion odor of the tis. There are several herbaceous species in N. Amer. and E. Asia, but only this and the following have been intro. to the trade.

2. *lasioneira*, Hook. (S. herbacea var. inodora, Hort. *Nemixia herbacea* var. melica, A. Nels). Similar to the above but with the Ivs. pulvulent-pubescent beneath; peduncles shorter than the Ivs.; fls. not carrion-scented. From Colo. to Man. in the Great Plains and E. Rocky Mts.—Distinguished from the other herbaceous forms by the lack of the carrion odor.

3. *hispida*, Muhl. (S. *Pseudo-china*, Auth., not Linn. *Bamboo Brier*. Fig. 3623. Rootstock short, woody, slow-growing, never spreading far; sts. clustered, high climbing, 20–50 ft. green, densely spiny below, unarmed or nearly so above: spines straight, black, slender, usually most numerous at lower nodes, never on upper nodes; Ivs. ovate, larger ones heart-shaped, decussate; peduncle longer than the petiole. Conn. to Minn., south to N. C. and Texas, absent from the coast. B. B. (ed. 2) 1:529. G. F. 5:53 (adapted in Fig. 3623).—This is the only one of the northern species that does not spread rapidly by rootstock; by proper attention to pruning this species will make an upright hedge-plant of merit.

4. *Siboldii*, Miq. Closely related to *S. hispida* from which it differs in its weaker habit, more pointed narrower Ivs. which in the growing plant are distinctly crenulate; peduncles fewer-fl., and little longer than petioles. Japan and Korea.

6. *excelsa*, Linn. Similar to the above in habit: sts. large, angled, with few heavy spines: Ivs. heavier and larger; fls. 3–10 in umbel: berries ¼ in. diam., coral-red. Peru, S. Eu. to Azores.

7. *Walteri*, Pursh. *Underground* sts. slender, creeping: sts. slender, terete, brownish; armed below with stiff short spines, naked above: Ivs. ovate to oblong: umbels few-fl., on short peduncles: berries over ½ in., densely packed in umbels, bright coral-red, white-flowered sports are known. Swamps in sandy regions, N. J. to Fla., west to Missouri River Valley. B. B. (ed. 2) 1:530.—The berries of this species are useful for winter decorations in the holiday season.

8. *glaucia*, Walt. *Cat-Brier*. Fig. 3622. *Underground* sts. spiny, tuberous but with long slender rhizomes: sts. slender, brown, spines below, disappearing above, when present always some at nodes: spines stout, recurved; the entire ovate Ivs. and often whole plant glaucous; berries 3-seeded, small, peduncles and pedicels slender, longer than petioles. Dry ground, Mass. to Fla., and Texas. B. B. (ed. 2) 1:528. G. F. 5:425 (adapted in Fig. 3622).—Ordinarily counted a bad weed, but perhaps of use in landscape plantings.

9. *Bona-nex*, Linn. *Saw-Brier*. *Underground* sts. spiny, often with large tubers, also long, creeping rhizomes: sts. stout, green, densely covered with stiff spines below, lower part of large sts. with a characteristic stiff stellate pubescence not found elsewhere in the genus: Ivs. variable, on vegetative branches distinctly hastate or with basal lobes, spiny on margins and midnerv below, smooth and green on both sides; upper Ivs. triangular, ovate, thick, fine net-veined: peduncles much longer than petioles, flat, many-fl.: berries 1-seeded, black, not glaucous. Va. and Fla., west to Kans. and N. Mex. B. B. (ed. 2) 1:529.—A rank-growing vine that becomes a bad weed along borders of woods and in half-wooded pastures.

10. *lanceolata*, Linn. *Florida Smilax*. *Underground* sts. short, large, fleshy tubers, densely clustered, suggesting large potatoes: sts. stout, often ¾ in. diam., lightly scabrous, glaucous when young, spiny below with stout recurved spines, unarmed above,
climbing to the tops of tall trees often 70-80 ft., much-branched above. The leaves are lanceolate, 2-4 in. long; peduncles shorter than pedi culoa, flowering in summer; young berries remaining over winter and ripening the next summer; berries 3-seeded, ½ in. or more diam. To Florida, Ark., and Texas. July, Aug. (A. asparagoides, ed. 2) 1:530. - The best American smilax for cult. as an ornamental vine.

11. *laurifolia*, Linn. False China Brier. Similar to the above in habit: lvs. narrow, oblong, thick, green on both sides, turning dark brown on withering; berries smaller. To Fla. and Texas. Aug. B.B. (ed. 2) 1:530.—This plant is always found near water, usually associated with *S. Walteri*.

*S. angustifolia*, Lind. & Rod. Tender foliage plant: st. wiry, slender, armed with short, stout thorns. lvs. lanceolate, becoming 8-10 in. long, dark green, blotted with gray, 3-nerved, short-petioled; fls. and fr. unknown. Bolivia. I.H. 85:312. J.H. 111: 86-77. According to F.F. Smith, this species is a robust healthy plant doing well in a moderate temperature and quickly forming ornamental specimens, which should be cultivated. *Ed.*

SMILAX, FLORISTS. The smilax of florists is an *Asparagus* (*A. asparagoides*, page 409). It is one of the most popular of all greenhouse vines for use in decoration.

Commercially, smilax is grown in deep solid beds under glass, and the tall growth is tied to strings. These strings are cut for sale. Some growers do not renew their beds of smilax for three or four years. It is doubtless most profitable to replant every year with young stock, which are 8 to 12 p. (Greek micron) and are beset with brownish or blackish spores known as chlamydospores. This plant is always found near water, usually associated with various parts of the host (or attacked plant), the swellings being eventually filled with brownish or blackish spores known as chlamydospores, which emerge, as a fine dust-like powder, when the cells burst or cracks. The chlamydospores produce upon germination a structure known as a promycelium (basidium) which gives rise to terminal or lateral sporidia (*cassidiospores*). The smut on Indian corn may be taken as typical. The disease usually appears on the leaves, ruptures, exposing the dark olive-green mass of spores. It spreads by the mycelium, which is 8 to 12 μ (Greek micron) and is beset with fine spines. Unlike most other cereals, maize can be inoculated at any age. Several smuts have been described, viz., loose smut of oats (*Ustilago avenae*), maize and teosinte smut (*Ustilago zeae*), loose smut of wheat (*Ustilago tritici*), smut of blue-stem grass (*Sorosporium avenaceum*), rye smut (*Urocystis occulta*), onion smut (*Urocystis cepula*), and mold smut of chicory (*Urocystis colchica*). For the loose smut of oats and wheat, the treatment of the seeds with hot water before planting is efficacious. The smut is best controlled by destroying the affected plants before the smut matures. The smut of corn is in part caused by *Emericella unida*, and is treated with sulfur, or formalin. JOHN W. HARSHBERGER.

SMOKINDUM (Greek, indurated mark; from the callous fr.). *Anacardiaceae*. Glabrous shrub, allied to *Rhus*: lvs. alternate, long-petioled, small, oval, and as much as possible clear off all the strings, because they may be useless if cut. Good drainage should always be provided.

SMOKINGIUM (Greek, smoking). The young bitterns of some species of *Neogilia of Regal* (see), a genus which has been given four years earlier to a genus of fungi; it is accepted by Fritzsch in Engler & Prantl’s *Pflanzentum.* The name under Smithi- antha of the cult. kinds are: *S. cinnabarina, Kuntze, S. aerinina, Kuntze, S. multiflora, Fritzsch; (S. ambabils, Kuntze), S. achinaeoides, Fritzsch.

SNAKEROOT (Smith’s flower, named for Miss Matilda Smith, botanical artist, Kew). A name proposed for the species of *Neogilia of Regel* (see), a genus which has been given four years earlier to a genus of fungi; it is accepted by Fritzsch in Engler & Prantl’s *Pflanzentum.* The names under Smithi- antha of the cult. kinds are: *S. cinnabarina, Kuntze, S. aerinina, Kuntze, S. multiflora, Fritzsch; (S. ambabils, Kuntze), S. achinaeoides, Fritzsch.

SMOKINGIUM (Greek, indurated mark; from the callous fr.). *Anacardiaceae*. Glabrous shrub, allied to *Rhus*: lvs. alternate, long-petioled, small, oval, and as much as possible clear off all the strings, because they may be useless if cut. Good drainage should always be provided.

For the loose smut of oats and wheat, the treatment of the seeds with hot water before planting is efficacious. The smut is best controlled by destroying the affected plants before the smut matures. The smut of corn is in part caused by *Emericella unida*, and is treated with sulfur, or formalin. JOHN W. HARSHBERGER.

Amer. The following account comprises the species ridges; column slender; pollinia •About 30 or more lute around the cllumn, terminal portion large, undul­solitary; sepals and petals spreading; labellum convo­membranaceous, few, in short, terminal racemes, or

SNAPDRAGON: Antirrhinum.

SOBOLEWSKIA (named for G. Sobolewski, Russian botanist). _Cruciferz._ Erect panicleically branched glabrous annual or biennial herbs, adapted to outdoor use: lvs. long-petioled, rotundate, coarsely crenate: fis. in corymbuse racemes, slender-pedicelled, without bracts, white; petals spreading, uniform at base: silique clavate, compressed or nearly terete, curved, leathery, glabrous annual or biennial herbs, adapted to outdoor in corymbuse racemes, slender-pedicelled, without

Tree: [image]

Leaves with sheathing bases, plicate-venose: fis. membranaceous, few, in short, terminal racemes, or solitary; sepals and petals spreading: labellum convolute around the column, terminal portion large, undulate, often limbricate, smooth or with longitudinal ridges; column slender; pollinia 8.—About 30 or more species, inhabiting the mountains of Mex. and Trop. Amer. The following account comprises the species that appear to be in the American trade, but others are to be found in the collections of fanciers. The plants have slender read-like sts. clothed with lvs. throughout their entire length. The sts. are tufted, forming bushy plants varying in height according to the species. The fis. are among the largest of the orchids, those of _S. macrantha_ attaining a diam. of 9 in. across the sepal.

They are, however, very transient, fading a few days after opening.

Sobralias are charming orchids, and when room can be given to large plants they well repay the space and care they require. Many of them, to be sure, are very fuzzy in their blooming, some lasting only a day, but nearly all of them make up for this by a succession of flowers which is more or less rapid. In size the individual blossoms vary from that of an ordinary _Cattleya labiata_ to one scarcely 1½ inches across, and the plants themselves present as great variety, ranging from such as _S. fragrans_, which grows less than a foot high, to that giant of the tribe, _S. Cattleya_, which will reach a height of nearly 10 feet. They also give as much variety in their coloring, ranging from a shade of lavender which is almost a blue through different shades of purple to the rich claret-color of _S. Lowii_, and from yellow to the purest white. Where space for large and bushy plants can be afforded, some of the sobralias will prove most charming plants, having the double advantage of pre­senting in a well-grown plant not only beautiful blossoms but a subject which is thoroughly attractive as a foliage plant. They also have the added advantage of being, in most instances, of rather easy culture. Given a suitable soil and a liberal supply of water they are almost sure to grow and bloom, although they will do better if they are given their time for rest, when less water is allowed without permitting the material about the roots ever to become quite dry. (F. J. Le­Mayne.)

INDEX.

a. Fis. white (see also Nos. 6 & 7).

b. Lip shorter than sepal, orange, center lined brown.

1. _leucôxantha_, Reichb. f. Sts. tufted, 3 ft. high, spotted: lvs. 4–6 in. long, lanceolate, acuminate: fis. 6–9 in. across; sepal linear-lanceolate, spreading and recurved, white; petals shorter, oblong, undulate above, also pure white; labellum with a ventricose tube; limb large, circular, notched in front and the margin irregu­larly lobulate and wavy, throat golden yellow, with a

BB. Lip nearly as long as sepal, yellow, center marked with orange.

2. _virginãlis_, Cogn. Sts. up to 3 ft. tall; lvs. coria­ceous, broadly lanceolate, 6–9 in. long, 1–1½ in. broad: fis. solitary, sessile, white except the yellow disk and throat; sepal revolute at apex, 3½ in. long; petals a little shorter than sepal, undulate; lip as long as petals, strongly undulate crisped. Colombia. C.O. 3. Var. _llâcina_, Cogn., has the lip tinted lilac. C.O. 3a.

AA. Fis. yellow.

B. Lip crisped and undulate on margin; fis. 5 in. or more across.

3. _xanthâleucâ_, Reichb. f. Sts. about 2 ft. high, tufted: lvs. spreading and drooping, lanceolate, 6–7 in. long, with speckled sheatha; fis. solitary, lemon-yellow, with a deeper shade on the lip; sepal linear-lanceolate, spreading and recurved; petals similar but shorter; blade of the labellum orbicular, crisp, and undulate,
Sobralia

bb. Lip fimbriate on margin; fls. less than 3 in. across.

4. franges, Lindl. A small species with sts. about 1 ft. high: lvs. 1 or 2; oblong-lanceolate, 4–5 in. long; fls. 2–3 in. long, pale salmon-yellow; sepals oblong, spreading; petals similar but erect; middle lobe of the labellum fimbriate on the margin and many fimbriated crests. Colombia. B.M. 4882.—One of the smallest of the genus.

aaa. Fls. chiefly purple or rose.

5. macrantha, Lindl. Fig. 3324. Sts. tufted, redlike, 4–7 ft. high, leafy all the way up: lvs. broadly lanceolate to oblong-lanceolate, long-pointed, 8–10 in. long; fls. several at the ends of the sts., rose-purple, with the front of the labellum deep purple; sepals linear-oblong, 4½ in. long, reflexed and twisted; petals broader, oblong, wavy above; labellum 5 in. long, with the expanded portion almost circular, 3 in. across and 2–lobed at the apex, very wavy; tube long, whitish within, with a yellow stain in the throat and several thin yellow ridges. May–July. Mex. and Guatemala. B.M. 4446. F.S. 7:669. P.M. 14:241 (var). G.C. 1. 0. 3: 75. Var. Kienstiana, Hort. (var. alba) has white fls. G.C. III. 48: 182. Var. athioida, Hort. Fls. very large, creamy white. Var. nana, Hort. Fls. smaller than type; lip dark violet-purple.

6. Bräntia, Kränzl. Sts. 3 ft. high: lvs. lanceolate, acuminate, 1 ft. long; fls. pubescent, with the labellum darker and having a yellow disk; sepals linear; petals twice as wide; middle lobe of the labellum very broad, divided into 2 diverging, rather acute lobes; anther-ker with a long recurved horn on each side. Resembles a medium-sized S. macrantha, distinguished by the long horns of the column, and black spots (not hairs) on the fl-sheaths. S. Amer.

7. Fenzliana, Rechbr. f. Sts. slender: shentha blackish, asperulate: lvs. oblong, acutish: fls. rose-colored; sepals oblong, acute; petals obvolute-cuneate, three-fourths as long as the sepals; labellum spreading, front portion ovate, notched, crenulate; horns of the column equaling the anther. Nicaragua. Var. alba, Hort., has pure white fls.

9. Cáttleya, Rechbr. f. Sts. stout: lvs. oblong, acuminate, peltate, bearing several lateral clusters of strong, thick fls. of a firm fleshly texture, with purplish brown sepals and petals and a purplish lip, with a white column and 3 yellow lines over the center of the lip. Colombia.

10. Löwii, Rolfe. An imperfectly known species intro. about 1802 from Colombia. It grows about 1½ ft. high and has fls. of a bright uniform purple.

Soil

The physical properties of soils concern the size and other physical property; chemically, into calcareous, humus, alkaline, and according to other striking chemical features. In the soil survey of the United States Department of Agriculture a local name is adopted for each type under which the specific character is given; examples of these are Hartford sandy loam, Norfolk sand, San Joaquin adobe.
arrangement of the particles, and the relation of these to each other and to the organic matter; also the soil atmosphere, the soil moisture, and the physical forces of heat and gravitation. In these there is an intimate relation with physiography or the form and exposure of the surface of the land, as well as to climatology.

There are, undoubtedly, constant physical changes going on in the soil, as well as chemical changes, which have much to do with the best development of vegetation. The soil-moisture may be looked upon as a nutrient solution, dissolving its material from the difficultly soluble compounds in the soil and from fertilizers artificially applied. The amount of substances in solution varies with the moisture content and with the way moisture is supplied to the soil. The dissolved substances, naturally present in the soil or derived from fertilizers, influence the solubility of the soil components, rendering them more or less soluble according to their nature and existing conditions. It is probable that there is a normal weathering of the soil material which produces a certain concentration in the soil solution which will be maintained on the gradual withdrawal of nutrient material by the plant. However, this natural weathering is often not sufficient in amount to produce the yield and quality desired, and this may be increased by methods of cultivation and fertilization so that crops may annually remove larger quantities of nutrient substances without any particular exhaustion to the soil.

It is certain that these nutrient materials do not accumulate to any considerable extent in soils in humid climates, as they are liable to be leached away and also to recombine, forming difficultly soluble compounds with the material of the soil-grains. A soil in good heart or good condition when the physical conditions, such as the water-supply, soil atmosphere, and temperature relations, are favorable, and when the weathering of the material is sufficient to furnish an abundant and constant nutrient solution in the soil moisture.

One of the most potent agents in the weathering of soils is the organic material contained. This is unquestionably due largely to the amount of carbon dioxide formed, which renders many of the nutrient matters much more soluble. Moreover, the organic matter forms a culture medium for bacteria, ferments, and the various organized and unorganized agents which assist in breaking down the organic material, and facilitate as well the weathering of the other soil components. Soils in general have remarkable power of absorbing on the surface of the soil-grains vast quantities of carbon dioxide, ammonia, and other gases, and of other nutrient materials, which, while soluble and actually dissolved, do not readily diffuse out into the solution between the soil-grains.

3625. How the gardener makes his soil, by letting it decay in piles. The larger pile is composed of sods.

The influence of fertilizers is therefore twofold: the direct addition of plant-food for the immediate use of plants, and the action of the fertilizing components upon the solubility of the otherwise difficultly soluble compounds in the soil. There are other offices which are very strikingly shown in the case of lime. This substance, when in the form of either caustic or slaked lime, corrects the acidity which is very often present in soils. It changes the structure of soils. It renders some of the soil components more soluble, especially when the lime is in the form of the sulfates or gypsum, and it has undoubtedly a physiological rôle which enables the plant to assimilate larger quantities of other nutrient matters even in amounts which would be detrimental if the lime-soil were not present in excess.

The principal objects of the cultivation of the soil are to secure proper aération, to conserve the moisture supply, and to improve the drainage. The irrigation and artificial drainage of soils are treated elsewhere.

The physical properties of texture and structure, that is, the size and arrangement of the soil-grains, have a greater practical importance with field crops and the relation of crops to soil under extensive cultivation than with the vegetables grown in the greenhouses, where intensive methods are used. Particularly in the eastern states, where the natural rainfall is relied upon for the water supply, these physical properties have great influence in determining the relative value of different soils. This is due in large part to the influence of the physical properties upon the water supply, and the commercial values of many soils are dependent largely upon this one condition. This is notably the case with the early truck crops, with corn, wheat, and grass lands, and with special products such as celery, cranberries, and other horticultural crops. With intensive cultivation, however, the flavor, appearance, texture, and general quality of the crop assume greater commercial importance, and even with intensive methods these are largely influenced by the character of the soil. This is shown in a striking manner in the localization of certain interests, even under the most intensive system of agriculture, such as the production of the fine lettuce around Boston, of the currants, stolons, tomatoes, and roses in other districts. With the present specialization in these lines, it is not only necessary that one should have a knowledge of the methods of cultivation, but should have the proper soil conditions as well as suitable climatic conditions; and to such an extent has this specialization been carried that different varieties of roses, for example, are best grown in different localities where the soils are slightly different. These matters must be realized by the horticulturist in order to attain the highest degree of success in any particular undertaking.

Milton Whitney.

Soils for potting.

Strictly speaking, there are but two distinct kinds of soils, though there are several modifications or physical differences in both. These are mineral soils and organic soils or peat. Peat is formed in temperate climates by the accumulation of vegetable matter in swamps, or in some parts of the world under peculiar atmospheric conditions (see Peat). Mineral soils, which cover the greater portion of the earth's surface, are formed by the disintegration of rocks and stones through the agencies of water, frost, or the atmosphere. Peaty soils are composed almost entirely of vegetable matter, with but little mineral matter. Mineral soils are just the reverse. The physical differences in peat are practically reduced to two, viz., the absence or presence of fiber. The physical differences in mineral soils vary considerably from almost pure clay to almost pure sand; indeed, the mechanical (or physical) analysis of mineral soils is based largely upon the proportions of clay and sand.
The composition of soils can be still further known by chemical analysis, but to the average gardener this is not necessary. Moreover, it is an operation of great nicety and one that requires an experienced chemist to perform. The chemical constituents which plants derive from the soil are present in varying degree, but they are sure to be present in ample quantity in the potting soil selected by an experienced gardener. The air and water may furnish as much as 95 per cent of the material with which the plant body is built up in some cases, and only the remaining 5 per cent be strictly derived from the soil. Three important nutrient elements are nitrogen, phosphoric acid, and potash. Nitrogen composes four-fifths of the atmosphere and the soil absorbs it chemically through the action of bacteria when the soil is in good physical condition. Hence the importance of remembering always that air in the soil is as important as water.

The ideal condition of a soil is one in which it resembles a sponge, a condition in which it will retain the greatest amount of nutritive substances and water without losing its capacity for absorbing air.

The capacity of soils to retain moisture varies considerably. A clay loam is more retentive of moisture than a sandy loam. The experienced gardener therefore selects a clay loam for his strong-rooting, large-leaved tropical plants, because transpiration is so much greater in these plants. For a general collection of greenhouse and small-growing tropical plants he selects a good loam. For cacti, agaves, and other succulent plants which will not take as much water at all seasons as other plants, he selects a sandy loam. For ferns, most of the Ericaceae and Gesneraceae, he selects peat; while for nepenthes, orchids, bromeliads, and the epiphytic aroids he selects fern or kalmia root. Other materials which a gardener should always have on hand when he has a large and varied collection of plants are: leaf-mold, which is made by collecting leaves and storing them for at least two years, turning them over occasionally to facilitate decay; living or fresh sphagnum moss; sand; charcoal, and some convenient manures, such as pulverized sheep-manure and bone-meal.

Growing plants in pots is very different from growing them in borders or the open ground. The experienced gardener digs the turf only from good pasture or meadow land, so that it shall be full of the fibrous roots of the grass. But before using the turf for potting it should be placed in square piles, turf downward, for at least six months in order to kill the grass and all vegetable life. Fern root should also be collected and stored the same length of time in order to kill out the ferns. (Fig. 3625.) Raw and very coarse soils are usually sifted before being used for most greenhouse plants. Shallow sieves are used for this purpose. (Fig. 3626.)

Except for sowing seeds and for potting seedlings and freshly rooted cuttings, thoroughly decayed and homogeneous soils should not be sifted, but should be broken into small lumps, as the small lumps assist materially in astringing the soil. If the soil is sifted too much it becomes very fine, packs close and allows too little aeration. Leaf-mold is decayed vegetable matter, or humus. It may have little manurial value, but is used by gardeners to make soils "light" or spongy. For most young plants a good proportion added to the soil is excellent as it encourages root-growth. Peat while not a new medium for potting cuttings of the larger number of plants. It is also added to soils to increase their porosity, especially when potting very young plants. Silver sand is best.

In potting plants, experienced gardeners make potting mixtures or add a variety of materials to the soil to suit the requirements of different plants. For young seedlings or for freshly rooted cuttings, the compost should be of a light and porous nature, but as plants increase in size and vigor a heavier and richer mixture is usually given, that is, if plants are to be grown on as specimens; but the proportion of nutrient substances used in a potting mixture should be determined by the vigor of the plants. It is always better to use too little plant-food than too much; if too much is used it often becomes available faster than the roots of plants can absorb it, with fatal results. Many amateur plant-growers in their over-anxiety to grow fine plants make this fatal mistake.

In most gardens the greenhouse space is limited, and a gardener cannot always develop his plants to their fullest capacity or he has to reduce his variety and numbers. This, then, determines in the mind of an experienced gardener the composition of his potting mixtures. His aim should be to grow the finest possible specimens in the smallest possible pots and space.

SOILS, STERILIZING. Greenhouse and plant-bed soils are specially liable to infection by disease organisms, as they are intensively cropped and not exposed to the action of frost and weather. Careful growers now resort to methods of artificial sterilization.

In practice, the sterilizing is accomplished either by heat applied by live steam, or by a chemical process employing a formalin drench. In either case, the work must be thoroughly performed if satisfactory results are to be expected; it will be required at least as often as every other year, and the situation is safer if sterilizing is practised annually.

Steam sterilizing is of two methods: by buried perforated pipes, and by a pan inverted over the soil and under which the steam may be conveyed. The latter is probably preferable in most cases. In either case, live steam should be applied for an hour or more.

"The perforated pipe method appears to consist, at its best," according to Selby and Humbert in Circular No. 151 of the Ohio Experiment Station, "in a system or set of perforated pipes, with crosshead and high-pressure boiler connection. These pipes are connected and buried in the soil of the bed, either with or without partial banking up of the soil; the surface of the bed is then covered with canvas or other covering and the steam passed into the system for such a period as is required to heat the soil to the necessary temperature. This temperature for best results is 180° to 212° F. maintained for a period of an hour or more. The time required to reach this temperature will vary with the boiler area, the pressure and other steam and soil factors. The length of pipes of the system will be adapted to the beds, being one-half or one-third the total length of large beds. Generally, 1 3/16-inch pipe is used with 3/4-inch holes bored in a straight line about 1 foot apart. These pipes are buried in the beds 12 to 16 inches apart."

Edward J. Canning.
For the inverted pan method, "The apparatus consists," according to W. W. Gilbert, "of a galvanized iron pan, 6 inches deep and 6 by 10 feet in size, which is inverted over the soil to be sterilized and the steam admitted under pressure. The pan is supplied with steam hose connections, has sharp edges, which are forced into the soil on all sides to prevent the escape of steam, and is fitted with handles for moving it from place to place, the weight of the entire pan being not over 400 pounds."

Remarking on the formaldehyde or formalin drench method, Selby and Humberg say that "Soils to be treated by any method of sterilization should be prepared as for use by addition of manure so that the latter is incorporated with the soil before treatment. The soil after spading or plowing is ready for treatment, whether by steaming or drenching. For the work of drenching it is rather difficult to make exact estimates as to cost of appliances, as well as labor outlay, since the appliances are the usual watering devices of greenhouses or coldframes, and the labor will be somewhat variable according to the effectiveness of these devices. The appliances used may be extremely various, though usually some form of sprinkling-can, a force pump with hose and nozzles or application through the overhead Skinner watering system. For outside beds the hose and force pump offer a convenient method. The best strength appears to be three to three and one-half pints or pounds to each fifty gallons of drench applied at the rate of seven-eighths to one gallon to the square foot of surface."

Leaves entire, leathery, shiny; fls. very large, white; the pedicels solitary and thick; calyx long-tubular, 2-5-cleft at the top; corolla funnelform, the tube cylindrical, the throat oblique and broad-campanulate, lobes SOLANUM (Latin, solamen, solace or quieting). Solanaceae. Nightshades. A vast group of temperate and tropical herbs, shrubs and even trees, comparatively poorly represented in temperate North America, of various horticultural adaptabilities, comprising ornamental subjects and also the potato, tomato, eggplant, ground cherry or physalis, red pepper or capsicum, also medicinal plants.

Leaves alternate: infl. mostly symподial and therefore superaxillary or opposite the lvs.; corolla gamosepal, free, or very short-connate; bifid; the tube cylindrical, the throat oblique and broad-campanulate, lobes broad; stamens 5; ovary 2-celled: berry globose, pulpy.

---About 4 species, Trop. Amer.

Solandas are attractive plants and their needs are simple. A warm greenhouse—one in which the temperature is never allowed to fall below 50° well suit them very well in the eastern states. The plants would probably do well outdoors in Florida and the far South. They take plenty of light and sunshine at all seasons of the year, and water should be given freely from early autumn till the latter part of spring, as they make their growth and bloom during that period. In summer, when the wood is ripening, a dry state is preferable for them. The soil that gives the most satisfactory results is a good, somewhat sandy loam. It is unwise to disturb the roots of established plants more frequently than is necessary. The chief point in growing solandas is to obtain short, sturdy branches, for those of rank growth seldom or never develop flowers; for this reason the use of rich soils and strong fertilizers should be avoided always. Propagated by cuttings of firm young shoots taken with a heel and placed in slight bottom heat. S. grandiflora is perhaps the best. The flowers do not last more than two or three days. They are of a pretty greenish white color when they first open and turn slowly to a rich brownish yellow. (Michael Barker.)

A. Plant about 2 ft. high, with trailing branches.

**longiflora**, Tussac (S. levii, Hook.). Lvs. oblong-ovate or obovate, acute; petioles purplish; fls. fragrant; corolla usually 1 ft. long, 3 times as long as the calyx, contracted at the throat, white or yellowish. B.M. 4845.

AA. Plant becoming 12-20 ft. high.

**grandiflora**, Sw. Fig. 3627. Lvs. obvate-oblong, acute, glabrous, thick; fls. fragrant; corolla twice as long as the calyx, not contracted at the throat, white or somewhat yellowish. B.M. 1874. G.C. III. 21:737.

**guttata**, Don. Shrub about 12 ft. high, erect, branched: lvs. alternate, pedioled, elliptic-oblong, acute or very short-acuminate, entire, rather glabrous above paler and copiously pubescent beneath, base broadened, rounded, 3-6 x 2-3 in.; fls. terminal, solitary, fragrant, ocrea-yellow, large; calyx tubular, pubescent, 3 in. long; corolla funnelform, 9 in. long, 5-lobed, lobes crenate and undulate, 5 purple-brown ridges at the throat. Mex. B.R. 1551.

**Hartwegii**, N. E. Br. Branched shrub: lvs. alternate, glabrous, elliptical, acute, short-acuminate or obtuse, base acute; fls. solitary, terminal, yellow, 6-8 in. across; calyx 3-4-lobed; corolla 2-10-celled, ripening into a berry which is sometimes paler and copiously pubescent beneath, base broadened, rounded, 3-6 x 2-3 in.; fls. terminal, solitary, fragrant, ocrea-yellow; calyx tubular, pubescent, 3 in. long; corolla funnelform, 9 in. long, 5-lobed, lobes crenate and undulate, 5 purple-brown ridges at the throat. Mex. B.R. 1551.

**SOLANUM** (Latin, solamen, solace or quieting). Solanaceae. Nightshades. A vast group of temperate and tropical herbs, shrubs and even trees, comparatively poorly represented in temperate North America, of various horticultural adaptabilities, comprising ornamental subjects and also the potato, tomato, eggplant, ground cherry or physalis, red pepper or capsicum, also medicinal plants.

Leaves alternate: infl. mostly symподial and therefore superaxillary or opposite the lvs.; corolla gamosepal, free, or very short-connate; bifid; the tube cylindrical, the throat oblique and broad-campanulate, lobes broad; stamens 5; ovary 2-celled: berry globose, pulpy.

**INDEX.**

| 1. tuberosum, Linn. Potato. Figs. 3628, also 3152, 3153, Vol. V. Low, weak-stemmed, much-branching perennial with tender, herbaceous tops, and perpetuates itself sexually as means of thickened or tuberous underground stems, golden or pubescent-hirsute; lvs. unevenly pinnate, the 5–9 oblong-ovate lfts. interposed with much smaller ones: lvs. variable in color, white passing through various tints and shades of purple, violet, and blue, in long-attenuate dichotomous clusters, fr. a gland 1/4–1 in. or more in diam., usually through lack of viable pollen not produced in the highly developed modern varieties except in favored localities and in the case of certain varieties, but fruiting abundantly in S. Chile and in Peru. Temp. Andes of Peru and Bolivia. See *Potato.*

2. Magála, Schlecht. *Darwin Potato.* Rough-hirsute branched perennial, with angled more or less winged sts. at least near the insertion of the lvs.: lvs. unequally pinnate, the terminal lft. 4 in. long, the lateral ones 2–3 pairs, elliptical, unequal at the base, acute at the apex, the interposed lfts. very small or sometimes wanting entirely: lvs. in dichotomous branches, the pedicels articulate about the middle; calyx hirsute, the lobes abruptly narrowed to a linear-acuminate point; corolla pure white, slightly lobed, the lobes acute. Inflowed along the Chilean coast from the vicinity of Valparaiso southward, and occasionally on the islands as far as the Chonos Archipelago. B.M. 6756.—Tubers gathered by the writer were about 4 in. long, dark purplish in the skin and flesh. Apparently very difficult to hybridize with *S. tuberosum.* It was at one time considered by some to be the original of the potato. Darwin describes the plant in his "Naturalist's Voyage."

3. Féneldier, Gray (*S. tuberosum* var. *boreale*, Gray). Herbaceous perennial with st. about 18 in. high, angled, and foliage somewhat resembling the common potato; lvs. 4–5 1/2 in. long, with 1–2 pairs of short-stalked lateral lfts., these 1 1/2–2 1/2 in. long, the terminal lft. somewhat larger, broadly ovate and abruptly rounded or subcordate at the base, acute at the apex, interposed lfts. very few, all pubescent on both surfaces with scattered hairs: lvs. violet, the pedicels 1/2–3/4 in. long; calyx-lobes about 1 line long, ovate, short-acuminate; corolla about 3/4–1 in. diam., the lobes pubescent without. New Mex.

---

**3628. Tubers of potato.—** *Solanum tuberosum.* (X 1/2)

3. Féneldier, Gray (*S. tuberosum* var. *boreale*, Gray). Herbaceous perennial with st. about 18 in. high, angled, and foliage somewhat resembling the common potato; lvs. 4–5 1/2 in. long, with 1–2 pairs of short-stalked lateral lfts., these 1 1/2–2 1/2 in. long, the terminal lft. somewhat larger, broadly ovate and abruptly rounded or subcordate at the base, acute at the apex, interposed lfts. very few, all pubescent on both surfaces with scattered hairs: lvs. violet, the pedicels 1/2–3/4 in. long; calyx-lobes about 1 line long, ovate, short-acuminate; corolla about 3/4–1 in. diam., the lobes pubescent without. New Mex.
ovate, usually confluent with the rachis, obtuse at the apex, ½–1½ in. long, the terminal one somewhat larger, the upper lateral pair sometimes more or less adnate with the terminal, interspersed lfts. very few or none; calyx slightly pubescent, the lobes ovate-acute, about a line long; corolla white or pale violet, rather deeply lobed, pubescent on the outer surface, rather strongly so toward the apex of the lobes. E. Argentina and Uruguay, usually in moist situations. Trans. Hort. Soc. vol. 5: 1. 10.—Of no value in the improvement of the common potato. See suppl. list, p. 3186.

AA. Species grown for the edible frs.: lvs. simple.

9. nigrum, Linn. BLACK NIGHTSHADE. Morella of the French. Low unarmed herbaceous annual or suffrutescent in warm climates, glabrous or the young parts sometimes sparingly pubescent: lvs. simple, ovate, narrowed at both ends, entire or more frequently sinuate-toothed, petioled: fls. small, white, in pedunculate lateral cymes; calyx much shorter than the corolla with small obtuse lobes; corolla about ⅜ in. diam.: berry globular, black, about ⅜ in. diam. A widely distributed weed in all temperate and tropical regions.—In the Dakotas, according to Hansen, the plant is often called “stubbleberry,” as it volunteers freely in wheat-stubble, and the fr. is used there for pies and preserves. Hansen finds that the plants with-

stand considerable frost. In warm countries, according to Vilmorin, the lvs. are sometimes eaten as spinach is, “and apparently without any injurious result, although such use brings no dangerous effect.” The species is extremely variable, and much difference of opinion exists in regard to the poisonous qualities of the berries. Possibly differences exist in this respect in different forms but not correlated with characters recognizable by the systematist. Var. guineense, Linn., with scarcely angled to angular smooth st., broadly ovate lvs. glabrous above and glabrous or sparingly pilose below, deeply lobed calyx and relatively large fr., is the “garden huckleberry” (Fig. 3629). This form is cult. to some extent in some sections and the fr. used for pies and preserves. Another form, S. Barbankii, bitter, with foliage rather dark green above, and erect or ascending peduncles, is stated by the originator to be a hybrid between the “garden huckleberry” and S. villosum of the Pacific coast. In some characters it appears to be intermediate between its supposed parents, and it is used as is the former.

10. muricatum, Ait. (S. guatemalense, Hort.). PEPINO. MELON PEAR. MELON SHRUB. Fig. 3629. An erect spineless bushy herb or subshrub. 2–3 ft. high, the branches often with rough warty excrescences, and usually glabrous or nearly so: lvs. entire or with slightly undulate margins, rarely ternate, oblong-lanceolate, or ovate, tapering to the more or less margined petiole and also toward the more or less obtuse or sometimes acute apex, the surface sparingly soft-pubescent: fls. in a long-stalked cluster, rather small, the corolla bright blue, deeply 5-lobed, puberulent on the outer surface, inclined or nodding: fr. ovoid or egg-shaped, long-stalked, drooping, yellow overlaid with splashes of violet-purple, 4–6 in. long when cult., flesh yellow and seedless under cult. Said to be a native of Peru and cult. in other parts of Trop. Amer. at temperate elevations. G.F. 5: 173. G.C. III. 3: 309.—This plant attracted some attention in this country about 25 years ago. It appears to have been intro. into the U.S. from Guatemala in 1882 by Gustav Eisen. A full review of the history and botany was made in Cornell Exp. Bull. No. 37 (1891). The fr. is aromatic, tender, and juicy, and in taste suggests an acid eggplant. In a drawer or box, the fr. may be kept till midwinter. In the N. the seasons are too short to allow the fr. to mature in the open, unless the plants are started very early. The pepino is properly a cool-season plant, and when grown in pots in a cool or intermediate house will set its frs. freely. It is readily prop. by means of cuttings of the growing shoots. The plant will withstand a little frost.

11. Melongena, Linn. (S. insanum, Linn.). Erect and much-branched herb or subshrub, 2–3 ft. tall, woody or scurvy, spiny; lvs. large and heavy, ovate or oblong-ovate, becoming nearly glabrous above but remaining densely tomentose beneath, shallowly sinuate-lobed: fls. large, mostly in clusters, the calyx waxy and often spiny, the spreading, deeply lobed, purplish corolla 1 in. or more across: fr. a large berry. Afr. and S. Asia. Original habitat probably S.W. Asia.

Var. esculentum, Nees (S. esculentum and S. odoratum, Dun.). COMMON EGGPLANT. GUINEA SQUASH. Aubergine. Figs. 3797–381, 1383, Vol. II. Cult. for its large frs., which are usually oblong, obovate, or egg-shape in form, and purple, white, yellowish or striped; differs from the wild plant in having fewer spines, mostly solitary fls., and much larger and more variable frs. There are 2 well-marked subvarieties: var. serpenth, Bailey. SNAKE EGGPLANT. Fr. greatly elongated and curled at the end. Var. stenanth, Bailey. DWARF PURPLE EGGPLANT. Fig. 1382. Low and diffuse, many of the branches finally resting on the ground, usually dark-colored, nearly glabrous and always spiny: lvs. small and relatively thin, less lobed: fls. small and longer-stalked: fr. purple, purplin. See Eggplant.
3630. Solanum Pseudo-capsicum. (x10)

12. aviculare, Forst. (S. lacinatum, Ait.). A leafy unarmed soft-wooded glaucous shrub 4–8 ft. high, with spreading branches, smooth or rather rough, barked, decurrent from the petiolo; lvs. variable in size and shape, 4–12 in. long or sometimes even longer, lanceolate or linear-lanceolate, entire or irregularly pinnatifid and the lobes linear or lanceolate and acute; fls. in cyrpose clusters in the axis of the upper lvs. or lateral; calyx-lobes broad and obtruse; fr. with an abrupt point; corolla violet, ¾–1 in. diam., the lobes short and broad; fr. a broad ovoid edible berry ¾–1 in. long, yellowish, New Zealand; also common in many parts of Australia, Tasmania, and in Norfolk Is. B. M. 349.

13. glaucum, Dun. (S. glaucophyllum, Deaf.). A perennial plant 6 ft. or more high, with round erect sts., suckering annually; lvs. 5–6 in. long, ¾–1½ in. broad, ovate-lanceolate to oblong-lanceolate, entire, narrowed toward the base and decurrent from the petiolo, acuminate at the apex, the surface glabrous and somewhat glaucous; fls. in terminal and lateral branched racemes or corymbs; corolla blue, star-shaped, about 1 in. diam., the lobes ovate: berry small, ovoid-globose, yellow. Province of Buenos Aires in Argentina, and in S. Brazil. B.M. 7945.

14. Pseudo-capsicum, Lind. JERUSALEM CHERRY. Fig. 3630. A small branching leafy shrub, reaching 3–4 ft., erect and glabrous throughout; lvs. narrowly lanceolate, oblanceolate, or oblong, entire or the margins slightly wavy, narrowed at the base to a short petiole, mostly obtuse at the apex, the surface bright green and shining, the veins prominent: fls. solitary or few in lateral clusters, small, white: fr. globose, scarlet or rarely yellow, ½–¾ in. diam. Widely distributed in tropical and semi-tropical regions, naturalized in Fla. Probably a native of the Old World, perhaps Madeira. --An old-fashioned plant usually grown as small specimens in pots for its showy scarlet fls., which persist for a long time. Var. nanum, Hort., is a dwarf compact form. Var. Weatherillii, Hort., Weatherill's hybrid, is a form with strongly veined undulate lvs. and pointed orange-colored fls.

15. Hendersonii, Hort. Very like S. Pseudo-capsicum, but the white fls. very numerous, and the fr. ovoid or olive-form, orange-red. A horticultural form, perhaps a hybrid. Also known as S. hybridum Hendersonii, but not related to the plant known in Old-World gardens as S. hybridum.

16. Capsicástrum, Link. Fig. 3631. A small shrub resembling the last but only 1–2 ft. high: st. more or less pubescent, with stellate hairs or glabrate; lvs. simple, oval, oblong, or sometimes slightly ovate, narrowed toward the petiolo, obtuse at the apex, the margins entire or slightly undulate, the upper surface green and somewhat pubescent, the lower more strongly so: fls. small, white: fr. ½ in. diam., orange-red or scarlet. Peru, Chile, and Uruguay. F.S. 12:1242. G.W. 3:529.—Frequent greenhouse and window-plant. Var. Melévinii, Hort., a compact form 12–15 in. high with ovoid berries. Var. variegatum, Hort., has variegated lvs.

E. Fls. usually ¾ in. or more diam., violet or rarely white in No. 22.

17. Rantonnetii, Carr. (incorrectly spelled S. Ranton­netii, Rantonii, etc.) (S. míticum, N. E. Br. S. japóni­cus, Hort.) An erect bushy grayish green half-shrub, growing 3–5 ft. high, the st. marked with raised lines decurrent from the petiolo; lvs. entire, lanceolate or ovate-lanceolate, narrowed to the petiolo, mostly acute at the apex, glabrescent or inconspicuously pubescent on the upper surface, pubescent with short hairs below: fls. 2–5, together in the axils, 1 in. or more diam.; calyx-lobes with an abrupt linear point, corolla violet with a light yellow center: the red fls. nearly or quite 1 in. diam., heart-shaped, drooping, and very ornamental. Margins of woods in Paraguay and Argentina. Cult. in warm temperate regions of Amer. and Eu. R.H. 1859, p. 135. Cl. 43:1401. —An excellent plant for blooming in the open in summer. Easily prop. by means of cuttings.

18. crispmum, Ruiz & Pav. An unarmed shrub, or sometimes attaining the size of a small tree, with rather long green flexuous branches puberulous when young, later becoming glabrous; lvs. 3–6 in. long, entire, thin, ovate to ovate-lanceolate, subacute at the base, acute at the apex, smooth above, the margins somewhat undulate and the nerves prominent on lower surface: corollas many-flled, corolla pale violet, about ¾ in. broad and twice as long as the calyx, the lobes ovate or ovato-lanceolate; fr. globose, pale yellow, about the size of a pea. In Chile from the central provinces to the Island of Chiloé, also in Peru. B.M. 3795. G.C. III. 30:424.

19. Xánti, Gray. A low shrub or at high elevations herbaceous from a woody base, the sts. slender, 1–2 or even 3 ft. high, the younger branches angled, somewhat vil­lous with many-celled usually gland-tipped simple hairs: lvs. membranous, ovate, ovate-oblong to oblong-lanceolate, ½–1½ in. long, wedge-shaped, rounded or subacute at the base, entire or lobed; fls. in umbel-like cymes, corolla ½–1 in. diam., rotate, angular or short-lobed, violet: fr. erect, berry-like, globose, light green or purplish in color. Throughout Calif., except in the desert region, ascending to 6,500 ft. altitude. B.M. 7821.

20. Wallacei, Parish. A shrubby plant often forming round masses and reaching a height of about 3 ft., the sts. slender, 1–2 or even 3 ft. high, the younger branches angled, somewhat vil­lous with many-celled usually gland-tipped simple hairs: lvs. membranous, ovate, ovate-oblong or oblong-lanceolate, ½–1½ in. long, wedge-shaped, rounded or subacute at the base, entire or lobed; fls. in umbel-like cymes, corolla 1–1½ in. diam., pale violet: fr. dark purple. Islands off the coast of Calif.
SOLANUM

21. umbelliferum, E. Sch. (S. californicum, Dun.). A densely villous rarely glabrate shrub: lvs. entire, usually obovate or oblong, rarely oval or ovate, ½–1 or 2 in. long: fls. in umbel-like terminal clusters; corolla pale violet or sometimes white, pubescent on the outer surface, ⅔ in. diam., showy and fragrant: berry large, purple. Calif.—The plant offered as S. umbellatum is very likely this species.

c. Plant more or less spiny, the lvs. sinuate or lobed.

d. Lvs. pinnately lobed.

E. Species perennial.

22. aculeatissimum, Jeaq. (S. cilatum, Lam. S. myriacanthum, Dun.). An undershrub 1–2 ft. high, st. branched, furnished with many long straight spines, interspersed in the younger parts with stiff bristles: lvs. solitary or geminate, broadly ovate or ovate-cordate, pinnately 5–7-lobed, 4 in. long, 3 in. wide, with rigid adpressed hairs on both surfaces, and spines on the upper surface of the principal nerves; petiole 1 in. long: cymes extra-axillary, few-fl.; calyx-lobes triangular, closely beset with spines; corolla rotate, 1 in. diam., snow-white, the lobes lanceolate: fr. globose, 1–2 in. diam. glabrous, orange or orange-yellow, flattened on the ends, corrugated. Widely distributed in tropical regions. F.S. 19: 1988. F.M. 1871: 521. RB. 20, p. 249. R.H. 1888, p. 78.

EE. Species annual.

23. citrullifolium, A. Br. (S. heterodoxum, Brit., not Dun.). An annual plant armed with straight prickles, glabrous pubescent with mostly simple hairs: lvs. 1–2-pinnatifid, the lobes obtuse and repand: inti. Dun.). An annual plant with many yellow- or orange-colored spines covering the st., both surfaces of the lvs., petioles, and sepalis, and the upper part usually somewhat villous with gland-tipped hairs: lvs. oblong or ovate, sinuately lobed or even deeply pinnatifid and the lobes sinuate or deeply cut: infl. terminal or soon lateral, racemose, the fls. rather numerous, light blue or white and 1 in. or more diam.: fr. globose, red, 1 in. or more diam., surrounded by the at length ovate-lanceolate calyx-lobes. Trop. Amer. and naturalized in waste grounds in the Gulf states. B.M. 2928; 3954. G.C. III. 43: 61.

25. cornutum, Lam. (S. Fontanesianum, Hort.). An annual herbaceous simple-stemmed spiny plant 1–4 ft. high: lvs. oval or ovate, pinnately lobed and the lobes again sometimes divided nearly to the center, the divisions oblong, acute, or rounded at the apex and tipped with an abrupt point, pubescent on all surfaces, that on the lower stellate: fls. terminal, in clusters of 3 or 4, corolla yellow, about 1–1¾ in. diam., villos on the outside, anthers uneven, the fifth ½–2½ in. long and twice the length of the other 4, enlarged at the base and shaped somewhat like a horn, hence the name: fr. small, spiny. Mex.

DD. Lvs. sinuately lobed.

26. Warscewiczii, Hort. (S. warscewiczodes, Hort.). Strong erect suffrutescent plant, reaching a height of about 6 ft., usually with a central st., densely rusty-tomentose and armed with many short stout hooked or straight greenish yellow spines: lvs. large, sometimes the blade a foot or more long, rather soft green and slightly pubescent at least along the veins above, grayish or rusty below and with dense stellate pubescence or tomentum, ovate, somewhat cordate at the base and rather deeply lobed with unequal lobes: infl. at first terminal, later lateral in 1-sided corymbiform racemes with numerous fls.; calyx deeply lobed, the segments oval and long-acuminate, spiny or unarmed, covered with numerous whitish hairs; corolla white, about 1½ in. diam., the lobes lanceolate and acute: fr. pale yellow, glabrous and shining. Probably S. American R.H. 1865, p. 430; 1896, p. 237.—A very striking plant for subtropical gardening and can easily be raised from seed in a single season; half-hardy perennial.

27. alatum, Seem. & Schmidt (S. robustum, Wendel.). Vigorous more or less spiny densely tomentose herb or shrub, the sts. winged, 3–5 ft. high: lvs. decurrent with the spiny petiole, sometimes 1 ft. long, broadly ovate or ovate-elliptic in outline, sinuately lobed, the lobes acute, upper surface green and tomentose-velvety, woolly with more or less rust-brown tomentum beneath: fls. in axillary racemes, calyx unarmed, corolla about 1 in. across, white, with ovate-lanceolate acute lobes; fr. globular, small, hairy, orange-colored. Brazil, R.H. 1863, p. 240; 1896, p. 236.—Bold species, useful for subtropical gardening.

EE. The lvs. with gray or whitish pubescence.

V. Fls. white

28. integrifolium, Poir. (S. cocineum, Hort. S. Loboba, Tenore) CHINESE SCARLET EGGPLANT. ORNAMENTAL EGG-PLANT. ETHIOPIAN EGG-PLANT. Fig.
3633. Solanum Wendlandii. (Much reduced.)

India and China, Malaya, and the Philippines. Doubtfully in the American trade.

36. Jasminoides, Paxt. Potato Vine (from the fls.). Fine greenhouse twining shrub, reaching several feet in height, glabrous; lvs. rather small, the upper ones lanceolate to lance-ovate and entire, the lower ones of about 3 narrow, ovate entire lfts.: fls. about 1 in. across, star-shaped, white with tinge of blue; pretty. S. Amer. P.M. 8:5. B.R. 33:33. Ga. 43, p. 433; 45, p. 162; 50, p. 19; 51, p. 358; 53, p. 28. —A most useful deciduous climber for the greenhouse, and much grown. Half-hardy, and useful for the open in the S. Will grow 10-20 ft. if given a chance. Var. grandiflorum, Hort, has very large trusses of fls. and is a robust grower; excellent. Gng. 1:259. Var. variegatum, Hort., has variegated foliage.

36. Seaforthianum, Andr. (S. azureum, Hort., not Fern. S. tenatum, Kunth). Beautiful slender unarmed herbaceous or slightly woody climber or trailer, with st. 3-4 ft. long, glabrous throughout: lvs. with 3 lfts., these 1½-2 in. long, or the upper ones simple, lanceolate, or ovate-lanceolate with entire or undulate margins: fls. numerous, in long drooping axillary panicles, on pedicels swollen at the apex, the corolla light purple or blue, star-shaped and usually 1 in. or less diam.: fr. ovoid or nearly globose, glabrous, scarlet. Brazil. B.M. 1952; 5823. B.R. 969. R.H. 1893, p. 177; 1897:424. —A very beautiful plant for the greenhouse. Begins to bloom when very young. Var. album, Hort., a variety with white fls. recently intro.

37. Wéndlandií, Hook. f. (S. Wéndlandií magníficum, Hort., fig.). Fig. 3633. Tall-climbing, glabrous, with a few scattered prickles: lvs. various, sometimes 10 in. long, the uppermost simple and oblong-acute, the others lobed or trifoliolate and with the terminal lft. much the largest, all with entire margins: fls. in large cymes, pale lilac-blue, the corolla 2½ in. across and shallow-lobed fr. globose. Costa Rica. B.M. 6914. G.C. 111. 14:399.
SOLANUM

G.M. 39:610. A.F. 12:1147. F.E. 8:828.—A splendid greenhouse climber, perhaps the most showy of the cult. solanums. Blooms in summer and fall. Ernest Brunton writes: "S. Wendlandii is a magnificent climber in this climate (Los Angeles), reaching 50 ft. or more and having umbels 12 in. across. It is perhaps the showiest vine in Calif. when in bloom. It is generally hardy here, although some winters nip and even kill the vine in the colder and lower parts of this city. Cut up an old vine, any kind of wood, stick the pieces in sand or light soil, and wait. Every cutting will grow. When in a robust condition it is a good feeder. It should be in full sun, though it does well anywhere."

c.c. Foliage usually more or less pubescent, sometimes glabrous or glabrate.

38. Dulcamara, Linn. Bttrri-sweet. Fig. 3034. A more or less pubescent or sometimes glabrous shrubby climber with st. 4-6 ft. long: lvs. entire or sometimes 3-5 parted, 1-3 in. long, the entire ones corate, ovate-cordate, or the upper ones hastate: fls. many, drooping, in panicked corymb opposite the lvs.: corolla white or violet, 1/2 in. diam., the lobes reflexed, each segm. furnished with 2 greenish spots near the base: fr. ovoid, 1/2 in. diam., red or rarely yellowish green. Naturalized from Eu.—Berries poisonous.

39. jasminifolium, Sendt. St. round, unarmed, sparingly pubescent or glabrate: lvs. ovate to ovate-lanceolate, entire or very slightly undulate, usually subcordate at the otherwise truncate base, acute or obtuse at the apex, indurate to 1-2 in. long; fls. several in a paniculate cluster; calyx campanulate, the lobes about the length of the tube; corolla violet, about 1/2 in. across; berry globose, 1/2 in. diam., red or rarely yellowish green.

SOLDANELLA (Latin, a small coin, referring to the shape of the leaves). Primulaceci. Small glabrous perennial herbs with short rhizomes, hardy and useful in the border or rock-garden.

Leaves short-petioled, thick, cordate-ovate or reniform, entire, or scapes slenderer, solitary or few, 1-3 ft. or many-ft., umbellate: fls. blue, violet, or rose, rarely white, nodding, about 1/2-3/4 in. across; calyx 5-parted, segments lanceolate, persistent; corolla hypogynous, funnelform-campanulate, 5-lobed at the middle, the lobes linear-lanceate; ovary ovate, ovoid, conic-oblong, many-seeded.—Species, 6, mountains of Eu. For account of species and cult., see Gn. 61, pp. 126, 127; for monograph, Pxt. & Knuth in 2 Jas Pflanzenreich, hft. 22 (IV. 257).

3634. Solanum Dulcamara. (X 3/4)

41. Wörstei, Hort. An unarmed woody climbing plant reaching a height of about 9 ft.: lvs. soft-pubescent, oblong-lanceolate, drooping, 6-12 in. long, frs. the size of a hen’s egg, clear light red in color; is a native of the highlands near Rio de Janeiro, Brazil, where it is used for the decoration of dwellings. In the upright stage the frs. are said to be prepared and used as a vegetable.

S. arculatum, Ait., is allied to S. verbaefolium, and is sometimes mistaken for it. Lvs. 6-7 in. long, ovate-oblong, acuminate, entire, velvety-tomentose above with branched hairs, more densely so and glaucous below, axes furnished with small lvs.; corolla subterminal, many-ft., umbellate: fls. white, not 1/2 in. across; berry globose. Ait.—S. betaceum, Cav., is Cyphomandra, for which see Vol. I. This shrub is a small tree, with cyphomandra like lvs. and the young parts clothed with rusty hairs; fls. white; fr. globose, grey, in the calyx. S. Brazil. B.M. 7451.-S. hystrix, Cav., "Violet," which attracted much attention a few years ago, is S. tuberosum, being similar to, if not identical with the variety known as "Blue Giant.—S.arcuatum, Linn. A rather weak, unarmed, branched half-shrub: lvs. 2-5 in. long, glabrous except for the channeled marg. ovate or lanceolate, entire or slightly lobed, frs. about 1/2 in. diam., blue or violet: fr. reddish orange, 3-5 in. diam. Native of Peru.—S. erectum is Cyphomandra betaceum.—S. Pluto, Pers. En. & Hout. has fr. the size of a walnut and shaped like a tomato, scarlet.—S. stoloniferum, Schlch. & Bouët.—S. bovei, Pers. has fr. and burrs of panne, the interspersed ones very numerous; lvs. mostly subcordate at the base and acuminate at the apex, sparingly pubescent with scattered flattened hairs on the upper surface, usually only along the veins on the lower surface, but puberulent on both surfaces: calyx glabrous, the lobes about the length of the tube; corolla hypogynous, funnelform-campanulate, 5-lobed at the middle, the lobes linear-lanceate; ovary ovate, ovoid, conic-oblong, many-seeded.—Species, 6, mountains of Eu. For account of species and cult., see Gn. 61, pp. 126, 127; for monograph, Pxt. & Knuth in 2 Jas Pflanzenreich, hft. 22 (IV. 257).

S. tuberosum is amongst the most famous flowers of the Alps, though not the commonest. S. alpina ascends to the mountains to the line of perpetual snow. Grant Allen, in "Flashlights on Nature," declares that the flower of soldanella actually thaws its way up through a solid block of ice. Soldanellas are cultivated in this country only in a few rock-gardens. Those who have limited resources and dwell in the region of changeable winters might attempt to grow these plants in pots under a frame in lieu of nature’s winter covering. They are said to prefer a half-shady or shady position and are propagated by seed or division.

S. erectum

alpina, Linn. (S. Clarzi, F. W. Schmidt. S. occiden
talis, Vrieh.) Fig. 3335. Sts. 3-6 in. high: lvs. roundish; margin slightly and remotely crenate; fls. violet. May—July. Gn. 61, p. 127. G.W. 15, p. 794.

b. Pedicels pubescent.

S. erectum

penniset, Sendt. A woody climber, more tender than S. Wendlandii; lvs. simple and entire, 2-4 in. long, somewhat glossy green and glabrous above, paler below, ovate or slightly cordate at the base, rarely narrowed toward the petiole; fls. in long panicles or racemes, the corolla purplish red changing to pale blue with white star-shaped center, rather deeply lobed and about 1 in. diam.: fr. globose, pale violet, about the size of a small cherry. British Guiana, the Amazon region and Surinam.

41. Wörstei, Hort. An unarmed woody climbing plant reaching a height of about 9 ft.: lvs. soft-pubescent, oblong-lanceolate, drooping, 6-12 in. long, frs. the size of a hen’s egg, clear light red in color; is a native of the highlands near Rio de Janeiro, Brazil, where it is used for the decoration of dwellings. In the upright stage the frs. are said to be prepared and used as a vegetable.

3635. Soldanella alpina. (X 3/4)
CV. Solidago ulmifolia, one of the common goldenrods.
SOLENANTHUS (Greek, tubus and floer, referring to the form of the corolla). Boraginaceae. Gray-villous hirsute or rarely glabrous perennial herbs, hardy and suitable for border planting: lvs. alternate; racemes sometimes elongated and simple, sometimes short, scorpioid, densely-fl., and numerous in terminal panicles: fls. blue or rose; calyx 5-parted, segms. narrow; corolla tubular or funnel-shaped, 5-lobed, the lobes small, obtuse; ovary 4-lobed, distinct: nutlets 4, depressed.—About 20 species, S. Eu., W. Asia, and Russia.

S. apenninus, Hohen. (Cynoglossum apenninum, Linn.). Plant hardy, 2½-3 ft. high: lvs. rather coarse, the radical ovate-oblong, those of the st. long-lanceolate: fls. blue, forget-me-not-like, in dense, axillary, paniced racemes. May, June. S. Eu.—A useful plant amongst shrubbery or in the back part of borders. Prop. by division or seed.

SOLENANTHUS (Greek, tube and flower, referring to the form of the corolla). Boraginaceae. Gray-villous hirsute or rarely glabrous perennial herbs, hardy and suitable for border planting: lvs. alternate; racemes sometimes elongated and simple, sometimes short, scorpioid, densely-fl., and numerous in terminal panicles: fls. blue or rose; calyx 5-parted, segms. narrow; corolla tubular or funnel-shaped, 5-lobed, the lobes small, obtuse; ovary 4-lobed, distinct: nutlets 4, depressed.—About 20 species, S. Eu., W. Asia, and Russia.

S. apenninus, Hohen. (Cynoglossum apenninum, Linn.). Plant hardy, 2½-3 ft. high: lvs. rather coarse, the radical ovate-oblong, those of the st. long-lanceolate: fls. blue, forget-me-not-like, in dense, axillary, paniced racemes. May, June. S. Eu.—A useful plant amongst shrubbery or in the back part of borders. Prop. by division or seed.

SOLENIDION (Greek, tube and thread, referring to the fact that the filaments are grown together, at their base, into a tube). Labiatae. Erect herbs allied to Coleus, probably similarly used: lvs. ovate, crenate, long-petioled: whorls of fls. laxly 6- to many-fl., arranged in long racemes or panicles: fls. small; calyx ovate-campanulate, upper tooth ovate with decurrent edges, lateral small, lower oblong, as long as the upper; corolla-tube exerted, slender, dilated and oblique at the throat, the limb 2-lobed, upper shorter, lower long, oblong, slightly concave; stamens 4, the filaments united at their base into a tube; disk glandular: nutlets ovoid, smooth.—Eight species, W. Trop. Afr.; one also occurs in Brazil.

Godefraye, N. E. Br. (Coleus Godefrayae, Godef.-Leb.). Herb, up to 2 ft. high, branches 4-angled: lvs. opposite, green, paler beneath, ¾-1¼ in. long, very wide-ovate or deltoid-ovate, base truncate or cuneate-truncate, slightly crenulate: racemes terminal, spike-like; fls. blue; calyx subequally 2-lobed; corolla, basal portion of tube, abruptly upcurved, upper portion abruptly deflexed, flattened-dilated, upper lip very short, crenately 4-toothed, lower lip compressed sideways. Trop. Afr. B.M. 8511. F. Tracy Hubbard.

SOLIDAGO (according to Gray, from solidus and ago, to make solid or draw together, in allusion to reputed vulnerary properties”). Compositae. Goldenrod. Perennial herbs very useful for borders and for colonizing, but little known in the trade.

Erect, of various habit, with simple alternate lvs. and many small yellow (rarely white) heads in spikes, thyrses, compound panicles, or racemes; heads oblong or narrow-campanulate, with small mostly appressed scales, containing few florets, the disk-florets all perfect and the ray-florets in one series and pistillate: pappus of 1 or 2 rows of roughish capillary bristles.—The genus is characteristic of E. N. Amer., where about 60 species occur. There are several species on the Pacific coast, a few in Mex. and S. Amer., and 2 or 3
Amongst the glories of the American autumn are the asters and goldenrods. They complement each other. The asters run in cyanic colors, goldenrods in xanthic, —the blue and blush on the one hand and the yellow and golden on the other. Because the goldenrods are so common, they have not been appreciated for planting. They improve in the garden, however, the plants becoming larger and the bloom fuller and richer. Some of them become weedy if the soil is very rich. The solidagos are variable, even within the same species. Therefore it is well to mark fine individual clumps when in bloom, for removal in late autumn or early spring. The observation of a single season should result in a fine collection of individual plants. A very attractive grouping of asters and goldenrods can be made entirely of native species:

**SOLIDAGO**

### S. canadensis, Linn. WREATH GOLDENROD.

A smooth slender perennial, often glaucous, simple or sometimes branched: lvs. stalkless, acuminate, the base narrowed, sharply toothed, 2⅓–3½ in. long; fls. in axillary racemes or head-like clusters, yellow or sometimes whitish; involucral bracts obtuse. E. N. Amer. Aug.–Oct.—Useful as a partial shade plant or in the open border.

### S. nemoralis.

A. Heads in small axillary clusters, not usually in large terminal inf.

### S. rugosa.

A. Heads in a terminal inf., usually a panicle, which is composed of 1-sided branches or clusters (secund).

b. Foliage fragrant; lvs. pinnately veined.

c. Lower lvs. lanceolate, sharply serrate.

d. Heads in a terminal inf., usually a panicle, which is composed of 1-sided clusters of fls. (secund).

### S. Virgaurea, Linn. EUROPEAN GOLDENROD.

A rough simple-stemmed but stout perennial 1–3 ft. high: basal lvs. 4–7 in. long, 2–2½ in. wide, obtuse or acute; upper lvs. sessile or narrowed into margined petioles; fls. in a dense terminal, rather narrow and often interrupted thyrsus which is often 8–10 in. long: bracts of the involucre acute or acutish. E. N. Amer. Aug.–Oct.—One of the best garden plants of the group. A prostrate form is offered. S. virgaurea, Hupe., is a compact and dwarf form, 6 in. or less high, with larger heads. S. Virgaurea is represented in the U. S. by S. Cutleri, Fern. (S. Virgaurea var. alpina, Bigel.), in the highest alpine districts of N. New England and N. Y.; this American species appears not to be in the trade.

### S. virgaurea, Linn. WREATH GOLDENROD.

A smooth slender perennial, often glaucous, simple or sometimes branched: lvs. stalkless, acuminate, the base narrowed, sharply toothed, 2⅓–3½ in. long; fls. in axillary racemes or head-like clusters, yellow or sometimes whitish; involucral bracts obtuse. E. N. Amer. Aug.–Oct.—Useful as a partial shade plant or in the open border.

### S. virgaurea var. alpina, Bigel.

A. Heads in a terminal inf., usually a panicle, which is composed of 1-sided branches or clusters (secund).

b. Foliage fragrant; lvs. pinnately veined.

c. Lower lvs. lanceolate, sharply serrate.

d. Heads in a terminal inf., usually a panicle, which is composed of 1-sided clusters of fls. (secund).

### S. virgaurea, Linn. WREATH GOLDENROD.

A smooth slender perennial, often glaucous, simple or sometimes branched: lvs. stalkless, acuminate, the base narrowed, sharply toothed, 2⅓–3½ in. long; fls. in axillary racemes or head-like clusters, yellow or sometimes whitish; involucral bracts obtuse. E. N. Amer. Aug.–Oct.—Useful as a partial shade plant or in the open border.

### S. virgaurea var. alpina, Bigel.

A. Heads in a terminal inf., usually a panicle, which is composed of 1-sided branches or clusters (secund).

b. Foliage fragrant; lvs. pinnately veined.

c. Lower lvs. lanceolate, sharply serrate.

d. Heads in a terminal inf., usually a panicle, which is composed of 1-sided clusters of fls. (secund).

### S. virgaurea, Linn. WREATH GOLDENROD.

A smooth slender perennial, often glaucous, simple or sometimes branched: lvs. stalkless, acuminate, the base narrowed, sharply toothed, 2⅓–3½ in. long; fls. in axillary racemes or head-like clusters, yellow or sometimes whitish; involucral bracts obtuse. E. N. Amer. Aug.–Oct.—Useful as a partial shade plant or in the open border.

### S. virgaurea var. alpina, Bigel.

A. Heads in a terminal inf., usually a panicle, which is composed of 1-sided branches or clusters (secund).

b. Foliage fragrant; lvs. pinnately veined.

c. Lower lvs. lanceolate, sharply serrate.

d. Heads in a terminal inf., usually a panicle, which is composed of 1-sided clusters of fls. (secund).

### S. virgaurea, Linn. WREATH GOLDENROD.

A smooth slender perennial, often glaucous, simple or sometimes branched: lvs. stalkless, acuminate, the base narrowed, sharply toothed, 2⅓–3½ in. long; fls. in axillary racemes or head-like clusters, yellow or sometimes whitish; involucral bracts obtuse. E. N. Amer. Aug.–Oct.—Useful as a partial shade plant or in the open border.

### S. virgaurea var. alpina, Bigel.

A. Heads in a terminal inf., usually a panicle, which is composed of 1-sided branches or clusters (secund).

b. Foliage fragrant; lvs. pinnately veined.

c. Lower lvs. lanceolate, sharply serrate.
**SOLIDAGO** (the Greek name). *Composita*. Mostly weedy plants, but some of the Canary Island species are good foliage subjects.

Annual or perennial, usually more or less succulent, sometimes frutescent, leafy-stemmed, mostly smooth and glaucous, summer-flowering: lvs. usually clasping entire, toothed or runcinate-lobed or even pinnatifid and laciniate, more or less prickly-margined: heads homogamous and ligulate, yellow-fld., with more or less imbricated involucral bracts, beaked or tumid at base, corymbose or paniculate: achenes ribbed or costate, not beaked, with fine white pappus. —Species 40 or more, in the Old World, some of them intro. in N. Amer. as weeds.

Certain bold foliage plants of this genus are more or less listed and mentioned abroad, the botanical identity of which is to be determined. *S. arborescens* laciniat us described as a "magnificent foliage plant with laciniated lvs." is probably a form of *S. pasquale*, which grows 3 ft. or so high, bearing glabrous pinnately parted lvs. with narrow entire or toothed lobes, native of Madeira. What is mentioned abroad and also in *S. Calii. as S. Jactauris, is probably S. compositus*. Wild, described as a beautiful foliage plant with long and broad crowded recurved oblong-lanceolate more or less pinnatifid lvs. (1 ft. or less long and 2-3 in. broad) and showy panicles of yellow flowers. *S. aureus*, in Canar. —is known as pastor’s lettuce (lachua de pastor), perhaps in allusion to availability of the foliage for salad. The lvs. of other species of *Sonicus* are said sometimes to be similarly used. The names *S. humifusa* and *S. laciniatus* sometimes appear in horticultural literature, representing ornamental plants 2-4 ft. high with divided lvs., the segments, very narrow; they are probably forms of *Canary or Madeira species*. L. H. B.

**SOLERILA** (adapted from a native name). *Syn., Cassebeira*. Herbs or small shrubs of various habits, with ornamental foliage, suitable for the greenhouse. Leaves similar or dimorphous, entire or serrulate, 3-5-nerved: lvs. in scorpionid racemes or spikes, frequently rose, rather large or some small; calyx glabrous or setose, tube turbinate, oblong or campanulate, 3-lobed, the lobes short; petals 3, ovate, obovate, or oblong; stamens 3 (rarely 6), the alternate ones smaller; ovary adherent or almost so to the tube of the calyx, 3-celled: caps. included in the turbinate, cylindrical, ribbed or 3-angled tube of the calyx, 3-valved.—About 75 species, India and the Malay Archipelago. This includes a number of dwarf tender foliage plants which must be grown in the greenhouse all the year round. The plants belong to the same cultural group with Bertolonia, Gravesia, and Monolena, and are distinguished by having their floral parts in 3s. The lvs. are usually rose-colored, glabrous, or less, and generally disposed in scorpionid racemes or spikes. The species described here are all caulescent plants with lvs. distinctly petioled, those of each pair being of equal size (except in *S. maculata*): lvs. 3-merous; stamens 3, long-acuminate.

It was long thought impossible to grow sonerila and its allies outside of a bell-jar or Wardian case. Gardeners now dispense with the “double glass” and...
grow these plants in tropical or even temperate greenhouses. For potting material they use a compost of fibrous peat and chopped sphagnum, sprinkled with sand and interspersed with bits of charcoal. The plants should have a partially shaded position, and should never be syringed. Never allow water to remain on the leaves. The species seed freely. The varieties are propagated by division.

Sonerilas thrive best in a close and moisture-laden atmosphere with just enough ventilation to keep them from melting or decaying. A temperature of not less than 75° suits them best. Cuttings of well-ripened growth are placed under a glass case or bell-glass in a bottom heat of 70° to 80°. Care must be taken every morning to allow the drops of condensation which gather on the glass to dissipate. For potting material use fine-screened leaf-mold, with plenty of silver sand intermixed and a little finely chopped fresh sphagnum on the top of the pots or pans. These plants have shallow roots, and require plenty of drainage, consisting of fine broken potsherds mixed with either charcoal or finely ground soft-coal clinkers. When the plants have made their full growth (which they do if started at the proper time in early spring) they start into new growth again. These plants make choice decorative plants in pans or even in wire baskets and can be used for choice table or mantel decorations. (H. A. Siebrelcht.)

Sonerila mar­

KEY TO THE SPECIES.

1. speciosa. Zender. This is practically the only species for its fls.: height 1 ft.; fls. opposite, cor­
date-ovate, green above, sometimes crimson beneath, mostly 7-9-nerved: fls. purple or rose, 4-14 in a cluster, 1 in. across. India. B.M. 4978 (as S. elegans); 5023. F.S. 29:2442.  
2. maculata. Roxtg. This differs from the other species by being described in having lvs. of unequal sizes. The larger one of each pair may be 3-5 m. long; the smaller a half or third as long: lvs. ovate or oblong, unequal at the base. mutuelv denticulate, 9-11-nerfed: lvs. violet.

India. R.H. 1865, p. 91, is too poor to determine.—Probably not in cult.

3. lêta, Stapf. Erect herb, 6 in. high: st. terete, glandular-puberulent: lvs. petioled, ovate or elliptic­

ovate, symmetrical or a little asymmetrical, not ciliate­
margined, the larger lvs. up to 4 x 2 in., green but white­
spotted above, purple and green-spotted beneath: cyme termini, contracted, 7-did; calyx oblong, spiri
drical, purple; petals oblong, subacuminate. China.—Closely related to S. maculata.  
4. picta, Korth. Erect or ascending, with scurfy or puberulous branches: lvs. short-petioled, broadly lance­
olate, wedge-shaped at the base, minutely serrate, 7-nerfed, lined with white along the primary nerves: fls. rosy. Sumatra.—S. picta of the trade is probably S. orientalis var. picta.  
5. orientalis, Lind. The botanical status of this name is doubtful. In horticulture it applies to a group of varieties sent out by Wm. Bull in 1891, and remarkable for two novel features: some of the varieties have dark purple or brassy colors; others are peppered all over with an infinite number of small, light-colored dots. All have dark purple nerves. G.W. 6, p. 327. In I.H. 7:118 the lvs. are described as ovate, acuminate, more or less cordate and unequal at the base, with 9 or 10 nerves, entire; color of fls. not recorded. Habitat not stated. The typical form is said to have bronzv lvs. with an amaranth reverse. Var. guttulata, Hort., has green lvs. peppered with small white dots and is pale green below. Var. punctata, Hort., is much like the preceding variety but has paler lvs. Var. picta, Hort., has purple lvs. of the type, with an irregular lanceolate strip of silvery gray down the middle. Var. Robert Saller, R.H. 20:61, has dark green lvs. peppered white and with a lanceolate figure of silver down the middle. Said to be a hybrid of vars. picta and punctata. It has the stripe of one and the dots of the other.

6. margaritacea, Lindl. This is the most important species. The name “margaritacea” means “pearly,” referring to the regular rows of pearly spots between the nerves and parallel with them, which are characteristic of the typical form. Lvs. ovate-lanceolate, acutely ser­rate, 7-9-nerved, glabrous, purplish brown, acute at the base: fls. rosy. B.M. 5104. F.S. 11:1126 (nerves too parallel). I.H. 2:40. G.W. 6, p. 326. H.F. 11: 4:72. Lowe 14.—Supposed to be native of Java. In Vol. II, edition 1, page 684, Gronowia guttata var. margaritacea is erroneously referred to Sonerila mar­
garitacea. It is readily told from Sonerila mar­
garitacea by its 5-nerved lvs. and floral parts in 5’s.

7. Hendersonii, Hort. (S. margaritacea var. Henderson­
sonii, Hort.). This is referred to Cogniaux to S. margaritacea, of which it is perhaps merely a horticultural variety. For trade purposes it is convenient to treat it like a distinct species. It seems to be the chief parent in the development of the numerous hybrids with blotched foliage. It differs from the type in having a broader leaf, with a shorter acumen and rounded base, and especially in being covered with irregular blotches, which, however, do not cross the nerves. F.S. 1875: 159. I.H. 23:230. G.W. 2, p. 265. G.Z. 19:161.—The blotches are all about the same size. S. Mamei, Lind., has more regular and roundish blotches, which are nearer white and on a darker ground, the under side netted with rosy purple. I.H. 23:254.

8. argentea, Hort. (S. Hendersonii var. argentea, Fourmir). For horticultural purposes this may be treated as a distinct species, characterized by its silvery foliage, resembling that of certain begonias, with no dark green except on the nerves. This is the parent of most of the forms that have a silvery cast of foliage, just as S. Hendersonii is responsible for the irregular blotches. G.W. 6, p. 325.
A very handsome hybrid between the orientalis and margaritae groups is called Mme. Paul du Toit. It has the serrate leaf and some of the silveriness of S. argentea, with the minute points of the S. orientalis group. It is much like Robert Sallier, but the central coloring is bronze as well as silver and more broken up by the green.

S. matronalis and S. picta of the trade are not accounted for botanically.

Wilhelm Miller.

F. Tracy Hubbard.

SOPHORA (Sophora, Arabian name of a tree with pea-shaped flowers). Including Styphnolobium and Edvardia. Leguminosae. Ornamental woody or rarely herbaceous plants grown chiefly for their attractive flowers and handsome foliage.

Deciduous or evergreen useful ornamental plants: Ivs. alternate, odd-pinnate with opposite usually small entire Ivs.: fls. pea-like, in racemes or terminal leafy panicles; calyx with 5 short teeth; standard orbicular or broadly obovate; stamens 10, free or connate only at the base; pod stalked, almost terete or 4-winged, rarely compressed, few- to many-seeded, moniliform, inedible or tardily dehiscent.

About 25 species in the temperate and subtropical regions of both hemispheres. The fls. and frs. of S. japonica yield a yellow dye, S. tomentosa has medicinal properties, and the seeds of S. secundiflora contain sophorine, a poisonous alkaloid.

S. tetraptera is a valuable timber tree in its native country.

The sophoras are handsome trees, rarely shrubs or herbs with graceful foliage, evergreen in some species, and with papilionaceous whitish, violet or pink, or yellow flowers in terminal panicles or in racemes, followed by long and narrow moniliform pods. Sophora japonica and the shrubby S. vicifolia are hardy as far north as Massachusetts, while S. affinis is less hardy. The evergreen species are tender and can be grown only in the southern states and California; they are usually showy in spring when they are in bloom; in England they are often planted against a wall, where they can be easily protected against light frost. S. japonica is especially valuable for its late-appearing flowers, which are white and disposed in simple panicles; the foliage is dark green and graceful and the tree is conspicuous in winter on account of its dark green branches. It is sometimes planted as a street tree, as it stands heat and drought well. The sophoras thrive best in well-drained sandy loam but grow fairly well in rather dry soil. Propagation is by seeds and the varieties by grafting on the typical form; some species are also increased by greenwood cuttings and by layers.

B. Ivs. 3½ in. long, or less; spineless shrub.

1. vicifolia, Hance (S. Davidi, Komarov, S. Mohlerothümü var. Davidi, Franck.). Fig. 3642. Spineless shrub, to 6 ft., with slender spreading pubescent branches; Ivs. 1-1½ in. long, short-petioled; fls. 11-15, sessile, elliptic, obtuse, and mucronulate, pubescent beneath, ¾-1½ in. long; fls. bluish violet or nearly white, about ¾ in. long, in short, 6-12-fld. racemes terminal on short branches; calyx shortly 5-toothed, violet; petals of nearly equal length; standard spatulate-obovate, reflexed; pod about 2 in. long, slender, long-beaked, glabrous. June. July. Cent. and W. China. B.M. 7883. A.F. 29: 155. G.C. III. 36: 3. Gn. 87; 78, p. 469. G.W. 16: 3. G.W. 11, p. 139. —Graceful shrub; has proved quite hardy at the Arnold Arboretum.

bb. Ivs. larger: unarmed trees.

c. Fls. in large terminal panicles.

2. japonica, Linn. (Styphnolobium japonicum, Schott). JAPAN PAGODA TREE. Figs. 3643, 3644. Tree, attaining 60 ft., with spreading branches, forming a dense round head: Ivs. 7-9 in. long; fls. 7-17, distinctly stalked, ovate to ovate-lanceolate, acute, rounded at base, dark green and glossy above, more or less pubescent, 1-2 in. long; fls. yellowish white, ¾ in. long, in loose panicles 15 in. long; pod distinctly stalked glabrous, terete, 2-3 in. long, ¾ in. broad. July—Sept. China; cult. in Japan. Gn. 24, pp. 210, 211, 214; 29, p. 222-27, p. 43. G.M. 58: 665. Gn. 6, p. 247. M.D.G. 1898: 12. F.E. 12: 1174. G.W. 8, p. 615; 12, p. 200; 13, p. 243. Var. pendula, Loud. Figs. 3645, 3646. With long and slender pendulous branches. R.H. 1876: 194; 195 (adapted in Figs. 3645, 3646). Gn. 9, pp. 600, 601; 24, pp. 202, 203, 211; 28, p. 27. M.D.G. 1898: 182. G. 6: 257. Gn. 9. p. 2: 106. G.C. III. 38: 479. F.E. 14: 1430, pl. 43. Var. columnaris, Schwerin. Of narrow pyramidal habit. Var. violacea, Carr. (S. violacea, Dipp., not Thwaites). Ivs. 15-17, sparsely pubescent above, densely so beneath, acute; fls. with pinkish lilac wings and keel, standard white.—The plants cult. as S. tomentosa, S. sinensis, and S. Korolkowii also belong to this species. The first, which is not to be confused with S. tomentosa, Linn. (see supp. list), has 15-19, smaller and broader, elliptic Ivs. densely pubescent beneath, less so above; the second has pale pink fls. and 11-17
ovate or obovate-oblong: fls. soft-pubescent beneath; the third has larger lanceolate fls. broadly cuneate at the base and slightly pubescent beneath. There is also a form with variegated lvs.

cc. Fls. in racemes.

d. Foliage deciduous; racemes axillary.

3. aflatris, Torr. & Gray. Small round-headed tree, with slender branches, to 20 ft.: lfts. 13-19, elliptic, obtusish or emarginate, broadly cuneate at the base, glabrous or with scattered hairs below, conspicuously veined, 1-1 1/2 in. long; fls. 1/2 in. long, white tinged with rose, with the lvs. in axillary nodding racemes 2-3 in. long: pod terete, moniliform, more or less pubescent, 1/2-3 in. long, black. Spring. Ark., Texas. S.S. 3:122.

4. secundiflora, Lag. Small tree, 35 ft.: Ifts. 7-9, elliptic or obovate-oblong to oblong, rounded or emarginate at the apex, cuneate at the base, silky-pubescent while young, dark yellowish green above, 1-2 1/2 in. long; fls. violet-blue, the standard marked on the midrib, 1/2-In. long: fls. about 1 1/2 in. long; standard about as long as wings. B.M. 1442; 3793. G. 34:503, 505. Gn. 24, p. 211. Gn. 12:87 also seems to belong here.

5. tetraepetala, Ait. (Edwardsia tetrapetala, Poir.). Shrub or small tree, 30, rarely 40 ft. high, with slender spreading branches: lfts. very numerous, almost sessile, elliptic or obovate-oblong to oblong, rounded or emarginate, broadly cuneate at the base, silvery-pubescent while young, dark yellowish green above, 1-2 in. long; fls. 1/2-1 in. long, in 6-12-seeded W. ASIa to Himalayas. Half-hardy.-S. grandiflora x S. microphylla, Cattleya. Orchidaceae. A name to designate the hybrids between the genera Sophronitis, Cattleya, and Lelia.

6. macrocarpa, Smith (Edwardsia chilensis, Miers.). Shrub or small tree, with the young branchlets densely tomentose: lfts. in 10-20 pairs, elliptic or obovate, obtuse, silky-pubescent beneath, 3-4 in. long: fls. 1/4-1 in. long, in short racemes; pod terete, not winged, 1-4-seeded. Chile. L.B.C. 12:1125. B.R. 2798.

SOPHRONITIS (Greek, modest). Orchideæae. Dwarf
epiphytic orchids, cultivated on account of their neat
habit and brilliantly colored flowers.

Pseudobulbs small, with 1 or rarely 2 small flat lvs.;
fls. from the top of the pseudobulbs, brightly colored;
sepals and petals nearly equal, spreading; labellum with
a broad middle lobe and small erect side lobes, the base
leading into a cavity in the wall of the ovary; column
short, the stigmatic surface covering 2 wing-like pro
jections at its summit; pollinia 8.—About 6 species,
closely related to Leilia. Cattleya, and the like; Brazil.

These plants, and also Sophrocattleyas and sophro
kilies, thrive in the temperature of the cattleya house.
In growing season, give a moderate supply of water and
plenty of fresh air. Rest them at a temperature of 55°,
and water scantily. Give a moderate supply of water and
plenty of drainage, and a thin layer of tepid sawdust
should be spread on top of the pot and finished with a
covering of Sphagnum. (Wm. Mathews.)

grandiflora, Lindl. (S. acuinea, Rechb. f.)
Pseudobulbs clustered: lvs. about 2 in. long,
inclive: fls. solitary, on short peduncles, 17-24
in. across, brilliant scarlet, often with a shade
of orange, with an orange lip; sepals and petals ovate;

S. grandiflora (S. grandiflora, Lindl.).—L. grandiflora.

S. grandiflora (S. grandiflora, Lindl.).—L. grandiflora.

S. Syn. Basliama. Rosálæae. Ornamental woody plants chiefly grown for their large panicles of white flowers and the handsome
pinnate foliage.

Pseudowurfs: lvs. alternate, odd-pinnate, with
serrate lfts., stipulate: fls. in terminal panicles; sepals
and petals 5; stamine 20-50: carpels 5, opposite to
the calyx-lobes, partly connate, dehiscent at the
ventral suture, with several seeds.—Eight species in B.

Asia. Formerly usually united with Spiræa but easily
distinguished by the stipulate, pinnate lvs. and the 5
carpels being opposite to the sepals.

Stamine are very handsome upright shrubs with
rather large, bright green pinnate leaves and small white
flowers in large and showy panicles appearing in sum
mer and followed by small capsular fruits; the panicles,
however, after the flowers have faded and dried up,
become rather unsightly and should be removed. S.
sorbi folia is hardly North and S. stelliptæa, and S.
Sorbaria—S. arborea have proved hardy at least as far north
as Massachusetts, while S. Açchiæomii is somewhat
more tender and S. Lindleyana still more so. They are well
adapted for borders of shrubberies and woods or for
planting on banks of brooks or rivers, but should not
be brought together with slow-growing and delicate
shrubs, as they spread in suitable soil rather rapidly by
means of suckers and are likely to overcrowd other
plants. The handsome bright green foliage appears
very early in spring. They are all much alike in habit,
but flower at different times from June to September,
beginning with S. sorbi folia, followed in order by S.
stelliptæa, S. assur gæns, S. arborea, and S. Açchiiæomii which usually
continues flowering until September.

On the whole they are much more hardy than the
S. arborea, a shrub, to S ft., with upright or
ascending sts.: lvs. 11-19, oblong-lanceolate, long-acuminate,
stellate-pubescent beneath when young or glabrous, 3-4 in.
long: panicles 6-12 in. long, puberulous; stamens longer than

S. assurgæns, Rehd. Shrub, to S ft., with upright or
ascending sts.: lvs. 11-19, oblong-lanceolate, long-acuminate,
stellate-pubescent beneath when young or glabrous, 3-4 in.

ALFRED RINDER.

SORBUS (ancient Latin name of S. domestica). Including Aria, Córnum, Micromése, and Tomninária. Rosáceae. Ornamental woody plants grown for their handsome foliage, attractive white flowers and ornamental usually red fruit.

Deciduous trees or shrubs: lvs. alternate, stipulate, simple and serrate or odd-pinnate, folded or rarely convolute in the bud; fls. in compound corymbs; sepals 3-5; stamens 15-20, with red or yellow anthers; petals or shorter. July, Aug. Himalayas and New Mex., in Asia south to the Himalayas. The close-grained wood of S. domestica is used for handles of tools and for similar small articles.

The sorbus are handsome trees or shrubs with graceful pinnate or with simple foliage sometimes silvery white beneath, and with showy clusters of small white raceme pumkin flowers in spring, followed by red or rarely whitish or brown fruits usually berry-like, rarely larger and apple- or pear-shaped. Most of the pinnate-leaved kinds are hardy North except some Asiatic species and S. domestica, which seem tender north of Massachusetts; many of the others are chiefly inhabitants of mountainous regions, and the northern species, as S. americana and S. decora, do not thrive well in warmer and drier climates, while the simple-leaved species, as S. alnifo­lia, S. intermedia, S. Aria, and S. terminalis, endure drought and heat and are hardy at least as far north as Massachusetts. The trees are often attacked by borers. Propagation is by seeds sown in fall or stratified, also by layers. Varieties and rarer kinds are usually budded or grafted on allied species, but most kinds will grow on S. Aucuparia or S. americana and on hawthorn. They all have handsome foliage, which usually turns orange-red in fall; their fruits are showy and often remain on the branches the whole winter if not eaten by birds. They are not particular as to the soil and are well suited for planting on rocky hillsides.

Those of the Aucuparia group are more adapted for cool and moist mountain regions; those of the Aria and Tomninária group, which grow especially well on lime­stone soil, are suited to warmer and drier climates.

S. hybrids is sometimes used as a small-sized avenue tree on account of its regular pyramidal habit.

INDEX.

A. Foliage pinnate.

b. Lvs. regularly pinnate, with the lfts. of almost equal size.

c. Frs. small, ¼-½ in. across, or slightly larger or broader.

D. Lfts. 9-17, ¼-½ in. long.

e. Winter buds plump, glabrous or sparingly ap­pressed, rusty-pubescent.

f. Frs. ¼-½ in. in.:

FF. Frs. ¼-½ in. across: lfts. acute or obtuse: fr. about ½ in. across:

BB. Winter buds covered with white villousomentum.

f. Young branchlets and lfts. pubescent.

g. Var. decora, Focke.

h. Young branchlets and lfts. glabrous.

d. Lfts. 10-20, ½-3 in. long.

cc. Frs. ½ in. or more across, apple- or pear-shaped, with grit-cells: style 5.

BB. Little, only pinnate toward the base, lobed or only serrate on the upper part, bearing much thorn on the same plant and occasionally only lobed.

Hybrids.
c. Habit tree-like .................................. 7. hybrida

CC. Under side of leaf grayish or whitish tomentose; ovary half-superior.
D. Leaf lobed or sharply serrate.
E. Shape of leaf ovate to oblong, usually acute.
F. Margin of leaf lobed.
  G. Base of the leaf broadly ovate, leaf mostly rounded .................. 10. latifolia
GG. Base of the leaf obovate-ovate, broadly cuneate ............ 11. intermedia
FF. Margin of leaf sharply and doubly serrate ............ 12. Aria
EE. Shape of leaf suborbicular to broadly oblong ............ 13. umbellata
DD. Leaves serrulate, grayish-tomentose or sometimes glabrescent beneath ............ 14. alpina
BB. Fr. with deciduous calyx bearing a circular scar; leaf quite acute.
c. Under side of leaf glabrous or slightly pubescent.
D. Styles usually 5: leaf ovate to elliptic-ovate ............ 15. alnifolia
DD. Styles usually 5: leaf elliptic-ovate to obovate-ovate ......... 16. caloneura
CC. Under side of leaf white-tomentose. 17. Popoli

Group 1. Aucuparia.

2. A. decora, Schneid. (S. americana var. decora, Sarg. Pyrus sambucifolia, Gray, not Cham. & Schlecht. Pyrus sitchensis, Rob. & Fern., not Piper S. scopulina, Brit., not Greene). Small tree or shrub, closely allied to the preceding; leaf 7-15, oval to ovate-lanceolate, or oblong, obtuse to short-acuminate, serrate, glabrous and dark green above, rather pale and usually pubescent beneath when young, or glabrous, 1½-3 in. long; fr. ½-1½ in. across, in 2-4-in.-broad and rather loose corymbs, sometimes few-fl.: fr. globose, aroid when young, about ½ in. across, with more or less upright calyx-lobes. May. Labrador to Minn., south to N. Y. and Va. S.S. 4: 173, 174.—Often confused with the preceding species; intermediate forms are not uncommon in regions where the two meet. Both are very handsome in autumn with their large clusters of bright red fr. and particularly S. decora is often planted for its showy fr.

3. A. Aucuparia, Linn. (Pyrus Aucuparia, Gaertn.). European Mountain-ash. Rowan Tree. Fig. 3649. Round-headed tree, 20-40, occasionally 60 ft. high: young branchlets pubescent, grayish brown when older: petioles more or less tomentose; leaf 9-15, oblong to oblong-lanceolate, serrate, entire toward the base, dull green above, pubescent beneath or rarely glabrous, ½-2 in. long: fr. white, ½ in. across, in flat, 4-6-in.-broad, tomentose or sometimes almost glabrous corymbs; stamens about as long as petals: fr. globose, about ½ in. across, bright red. May, June. Eu. to W. Asia and Siberia. F.E. 3: 1-44, pp. 78, 79. Var. dulcis, Kästel (var. moravica, Zengerling). Almost glabrous: petioles purplish: leaf oblong-lanceolate, 2-3 in. long, glabrescent beneath, usually serrate only above the middle. The frs. are of an agreeable acid flavor and recommended for preserves. The tree thrives well in cold northern climates where hardly any other fr-tree will grow. G.F. 152: 887. Var. róssica, Spaeth, is similar and also bears edible fr., but the frs. are larger and broader and more serrate. Var. Beissneri, Rehd. (var. dulcis lactiflora, Beiss., not var. lactiflora, Hert.), is a handsome and graceful form of var. dulcis with the frs. pinately lobed and the fr-stalks and young branchlets bright red. G.W. 3: 267. Var. fastigiata, Loud., forms a narrow pyramidal tree, with upright branches. Var. péndula, Hort., has long and slender pendulous branches. M.D. 1911, p. 246. Var. integerrima, Lange. Frs. entire or nearly so. Var. Fífeána, Dipp. (var. fructí-biteo, Hort.). Fr. yellow. There are also varieties with
variegated foliage.—This species is often planted as a street tree in mountain regions of Eu.

4. tianschanica, Rupr. (Pyrus tianschanica, Regel.) Small tree or shrub, similar to the preceding: young branches glabrous, red-brown and glossy when older; petals and lvs. glabrous; lfts. 11-15, lanceolate, acuminate, serrate, entire toward the base, dark green and glossy above, light green beneath, about 2 in. long; corymbs glabrous; stamens half as long as petals; styles 2-5: fr. globose, bright red. May, June. Cent. Asia. Gl. 40, p. 5. B. M. 7755.—Very handsome on account of the contrast of its dark green foliage and red-brown branches.

5. villosa, Schneid. (Cerasus foetida, French.) Shrub or small tree, to 20 ft.; lvs. slender; rachis slightly winged; lfts. 11-19, opposite or nearly so, oblong-elliptic, serrate above the middle, glabrous, 3/4-3 in. long; mid. loose, 1-3 in. wide, rusty-pubescent; fls. 3-5 in. across; stamens about 20; styles 5, nearly glabrous; fr. globose, red, ½ in. across. June; fr. in Sept. W. China. B.M. 5241.—A very graceful shrub.

Group 2. CORMUS.

6. domestica, Linn. (Pyrus Sorbus, Gaertn. P. doméstica, Smith. Cerasus domesticus, Spach.) Sauraves Trew. Fig. 3650. Round-headed tree, 30-60 ft. high; winter buds glutinous; petioles tomentose; lfts. 11-17, obovate-oblong to oblong, sharply and rather coarsely serrate, with acuminate teeth, usually entire near the base, green and glabrous above, floccose-tomentose beneath, at least when young, 1-2½ in. long; fls. white, ½ in. across, in broadly pyramidal rather loose, tomentose corymbs: fr. ½-1½ in. across, usually yellowish, with red or orange cheek, apple-shaped in var. malifera, Smith. Service Arb. 1:283; 6:649. M.D. 1897:376—S. H.W. 3, p. 86. S.L.F. 3:485.—A handsome in gardens as S. quercifolia hiberna nana. Var. decurrens, Koehne (S. decurrens, Hedd. S. lanuginosa, Hort., not Kit.), is a transition to S. aucuparia; only the 3 or 5 upper lfts. are connate into a terminal ft., which, like the upper separate lfts., is deciduous at the base, under side less densely tomentose. In some nurseries under the name of S. sambucifolia.

8. spuria, Pers. (Pyrus heterophylla, Dur. S. aucuparia × A. arbutifolia.) Shrub or small tree, attaining 15 ft., with slender, sometimes pendulous branches; lvs. ovate to oblong-ovate, obtuse, with 2-6 lobes or lfts. near the base, simply crenate-serrate toward the apex, 1½-3½ in. long, pubescent beneath: fls. white or pinkish white, in pubescent or glabrous corymbs 1-1½ in. broad: fr. subglobose or pear-shaped, dark purple. May, June. Of garden origin. B.R. 119.—Sometimes cult. under the name S. quercifolia floribunda nana. Hybrids of different origin are usually united under S. spuria; the more pubescent forms with dark purple fr. are probably the offspring of S. aucuparia and A. arbutifolia and represent typical S. spuria, while the more glabrous forms with usually blackish fr. have S. aucuparia and A. melanocarpa as their parents and may be called S. falkiae, Schneid. (S. heterophylla, Dipp.). A similar form with quite glabrous and more pointed lvs., is probably a hybrid of S. americana and A. melanocarpa, and is named S. sibirsifolia, Hedd. (S. Sargentii, Dipp.).

Group 3. TORMINARIA.

9. torrinensis, Crantz (Pyrus torrinensis, Ehrh. Torminaria torrinensis, Dipp. T. Clusi, Roem.) Wild Service Tree. Round-headed tree, with spreading branches, 40-60 ft. high: lvs. broadly ovate, slightly cordate to broadly cuneate at the base, with several triangular-ovate, serrate lobes on each side, the lower sinuses reaching about half-way to the middle, floccose-tomentose when young, finally glabrous, rarely with persistent tomentum, 2-4 in. long; petals 1½-3½ in. long: fls. white, ½ in. across, in broad, rather loose tomentose corymbs: fr. oval, ½-3½ in. high, brown, dotted. May, June. S. and Cent. Eu. H.W. 3:53, pp. 82-83.—The foliage turns bright red in autumn.

Group 4. ARIA.

10. latifolia, Pers. (Pyrus rostrijolia, Bechst. P. intermedia var. latifolia, Ser. P. Aria var. latifolia, Hort. Torminaria latifolia, Dipp. S. Aria × S. torrinensis.) Tree, attaining 30 ft., similar to the preceding: lvs. broadly ovate to ovate, usu-
11. intermedia, Pers. (Pyrus intermedia, Ehrh. Sorbus odoratissima, Fries. Aria suetica, Koch. Hahnia suetica, Dipp.). Tree, 20-40 ft. high, with oval head: lvs. oval to oblong-ovate, broadly cuneate at the base, pinnae lobed with broad and short, irregularly serrate lobes, and 3-5 pairs of veins, white-tomentose beneath, 2-3 in. long; petioles ½-¾ in. long; fls. about ½ in. across, in broad, tomentose corymbs: fr. globose or subglobose, about 1 in. high. May. Cent. Eu. to Himalayas and Sibera. G.M.44:291. Wenzig. H.W. 3: 52.-Desirable tree for dry and exposed situations, and very ornamental in foliage on account of the contrasting colors of the upper and under sides of the lvs. Var. decaisneana, Rehd. (Aria decaisneana, Lav. Pyrus decaisnei, Nichols. Pyrus Aria var. majestica, Prain. S. Aria var. majestica, Zabel). Lvs. elliptic or ovate, irregularly doubly serrate, 3-7 in. long; inf. 3-4 in. across; fls. ½-¾ in. across; stamens longer than styles; fr. oval, ½ in. across; B.M. 8184. Origin unknown, probably from the Himalayas. Var. edulis, Wenzig (Pyrus edulis, Willd. S. longifolia, Heil). Lvs. elliptic-oblong to oblong, rounded or acute at the apex, 2-5 in. long; fr. oval, ⅔-¾ in. high. There are some garden forms, as var. aurea, chrysophylla, and var. pendula, Rehd., with more or less yellow foliage. Aria. 13. umbellata, Fritsch (S. meridionalis, Guss. S. stellabilis, Schau. S. Aria var. stellabilis, Wenzig. S. glabella, Hort.). Small tree, attaining 20 ft.; lvs. orbicular to broadly oval, obtuse, usually broadly cuneate at the base, incised lobes above the middle, with the short lobes truncate or rounded and coarsely toothed, with 5-7 pairs of veins, white or yellow beneath, 1½-2½ in. long; fls. scarcely ½ in. across, in dense, white-tomentose corymbs: fr. depressed-globose, orange-red. S. E. Eu., W. Asia.—Cult. in some nurseries as Pyrus aures strigula. Var. crista, Schneid. (S. Aria var. crista, Rehd. Aria græca, Roem. S. Aria var. graeca, Koch.). Lvs. orbicular-ovate, doubly serrate, scarcely lobed, with 6-11 pairs of veins, 1½-3 in. long. S. E. Eu., W. Asia. 14. alpina, Eeyhn. (Aronia densiflora, Spach. A. Wildenowii, Zabel. S. Aria x Aronia arbutiformis). Shrub, similar to S. Aria, but lvs. smaller, densely serrulate, with fewer and less straight veins: infl. and fls. smaller; styles 3-4: fr. red or brownish red, ½ in. across. Of garden origin.—From Aronia arbutiformis it may be distinguished by usually larger lvs. with more numerous veins and with a less close and less glandular serration and by larger fls. with only 3-4 styles. A hybrid of similar origin, but it is certainly a good species. Var. pendula, Rehd. (Pyrus folgeri var. pendula, Veitch). Branches pendulous. —This is a very handsome and graceful species.
SORBUS

SOUTHERNWOOD (Artemisia Abrotanum, which see for botanical account) is a European herb, aromatic, much branched, woody-stemmed, rather tender, perennial, 3 to 5 feet tall, with pale green or grayish often-variegated leaves, small yellowish flowers and minute seeds. (Fig. 3653.) It is occasionally found in family gardens from seed, or more often, from its easily rooted cuttings, which are most readily obtained in early summer for its pleasant taste and tonic properties, which resemble those of wormwood. It is seldom offered by seedsmen in this country because of its slight importance.

M. G. Kains.

SOWBUGS. There are two common species, Armadillidium vulgare and Porcellio levus, known respectively as the greenhouse pillbug and the dooryard sowbug. These are small oval grayish terrestrial crustaceans (not insects) that live in damp situations. They feed, mostly at night, on decaying vegetable matter and sometimes attack germinating seeds and the roots, crown, and occasionally the leaves and blossoms of greenhouse plants, such as primulas, petunias, saxifrages, violets, geraniums, roses, and wisteria. Orchids, especially cattleyas, are liable to injury. Head lettuce is often infested, and sowbugs sometimes become a veritable pest in mushroom cellars. Sowbugs reproduce by means of eggs which are carried by the female in a pouch on the under side of the body. The young are similar in form to the adults and are carried by the female until they attain a considerable size. There is probably but one brood annually.

Sowbugs are destroyed in greenhouses and similar situations by the use of freshly sliced potatoes or beets dusted lightly with paris green or some other arsenical. There baits should be placed on the soil near the plants to be protected in the evening, since sowbugs are nocturnal in their habits. Another excellent bait is made as follows: To a quart of cornmeal add enough brown sugar to sweeten it, then add two tablespoonfuls of black pepper, and stir until it thoroughly mixed. Moisten the mixture with just enough water so that it will hold together. This bait is to be distributed around the plants as recommended above.

Water-cress sowbugs (Manacaulus brachyurus).—In the eastern United States water-cress is often seriously injured by an aquatic species of sowbug that attacks the submerged portions of the plant, cuts off the roots and stems, and causes large masses of the cress to float on top of the water. This form differs from the species found in greenhouses by having longer legs and antennae and being shrimp-like in form when viewed from the side. It is about ½ inch in length and gray in color. It often occurs in immense numbers so as practically to destroy the whole crop. Where cress is grown in natural streams or ponds no practical method of controlling the sowbugs has been devised. Some growers, however, have been able to overcome the difficulty by growing the plants in broad shallow beds sloping toward the center, where a trough 10 inches square, lined with boards, extends the whole length of the bed. When the sowbugs become abundant, the water is shut off for twelve to twenty-four hours, allowing the beds to drain. Water is retained in the trough in which the sowbugs become crowded. They may be destroyed by the addition of a liberal quantity of copper sulfate solution. Loss injury will result to the plants if the water is drained off soon after the cress has been gathered.

C. R. Crosby.

SOW THISTLE: A name for the prickly weedy species of Sonchus.

SOYBEAN (Glycine Soja, formerly called G. hispida) is a legume, long a staple crop in Japan, but somewhat recently cultivated more or less extensively in the United States. (Figs. 479, 483.) In its native country, Japan, the seed is an important human food product, but in the United States its principal use at present is as a forage plant for farm livestock and as a soil-renovator. It is an upright leafy branching plant, growing 3 to 4 feet high. Two distinct plants have been called soybean: the smaller one (Phaseolus aureus) is grown principally in southern Asia; the larger species, the true soybean, is Glycine Soja. This latter species has become popular in some sections of the United States because of its power of resisting drought and for the further reason that it may supply a large amount of forage rich in protein. In the northern states it is probable that the soybean will be acclimated and that it will serve as an adjunct to the maize crop as a food for stock, although it is coarse in leaf and stalk. It thrives best upon a warm well-drained loamy soil, and seed should not be planted until all danger from frost is over. The land should be prepared by plowing and harrowing in the early spring, and the harrow should be used two or three times before the seeds are planted. Best success is attained by planting in drills, rows to be from 2½ to 3 feet apart and the hills in the row 18 to 20 inches apart. During the early periods of growth, cultivation should be frequent, preferably with a fine-toothed implement. After the plants have grown so that the ground is well shaded, the tillage may be discontinued. It is doubtful whether the curing of the plants for hay will ever come into general practice, but the crop may be largely grown for green soil ing and for ensilage purposes. It may be cut into the silo with corn and serves to improve the quality of the food.

To the horticulturist the soybean is valuable chiefly as a soil-renovator. The soil of the orchard can be given clean culture during the early summer and the soybeans may be sown broadcast about July 1 and harrowed in. One bushel of seed to the acre will be required. One bushel of rye to the acre should be sown at the same time, for when the beans are killed down by the frost in the fall the rye will then serve as a cover-crop for the winter. When the soil is too hard and forbidding that clover will not thrive, the soybean may be made to serve as a nitrogen-gatherer. See Glycin.

L. A. CLINTON.
SPARAXIS

SPARAXIS (Greek word referring to the torn or lacerated spathes, a character which distinguishes this genus from Tritonia). *Iridaceae*. **Wand-flower.** Bulbs or corms with fibrous coating, the plants suitable for outdoor planting but grown mostly under glass.

Stems simple or slightly branched: lvs. few, flat, sword-like or broadly linear, erect or falcate; spathes spiny, often with bulbils in the axils: fis. solitary or few in a spike, yellow; perianth-tube Yzin. long. B:M.545 (as *Ixia grandiflora*; fis. rich purple, margined lighter); 779 (fis. primrose inside, furred purple outside).—The principal named forms are: Var. *atropurpurea*, Hort., dark purple; var. *anemoneflora*, Hort., pale yellow; var. *Lilägo*, Baker, white, flushed with claret-purple outside; and var. *stelläris*, Baker, dark purple, the segms. narrower than the type, obovate and acute rather than obtuse.

AA. *Throat of fl. bright yellow, often with a dark blotch on the lower part of each segm.*

tricolor, Ker. Fig. 3654. Differs from _S. grandiflora_ only in the color of the fis., which are very variable but always have a bright yellow throat and often a dark blotch at the base of each segm. B:M. 381 (as *Ixia tricolor*); 1482. F:S. 2:124. F. 1843:213 (as *S. picius*, *S. purpurea*, *S. pulchella*).—According to Baker, this is the favorite species among cultivators. It certainly has the greatest variety of colors and markings. In the works cited the floral segms. range from nearly white through rose, brick-red, carmine, crimson, and light purple to dark purple, red, or yellow, which latter color usually appears in the throat.

WILHELM MILLER.

SPARGANIUM (Greek, filled, referring to the ribbon-like leaves). *Sparganivæces*. **Bur-reed.** Marsh or aquatic herbs which may be used in the bog-garden or along the pond-edge. *Phanzenreich*, IV, S. 1900.

Leaves alternate, sessile, linear-longate, erect or floating, entire: fis. monocious, in globular, sessile, or pedunculate heads, the upper bearing 3-androus, naked fis. and minute scales, the lower consisting of numerous sessile or shortly pedicellate pistillate fis.; ovary 1-2-celled: fruit ovoid or spindle-shaped, 1-2-seeded.—About 15 species, temperate and subfrigid regions of the northern hemisphere and in Austral. Bur-reeds are marsh herbs closely allied to cat-tails but with fis. in globular heads instead of oblong spikes. A few hardy perennial kinds are advertised by collectors of native plants and one or two are procurable from specialists in aquatics. Bur-reeds are desirable only in bog-gardens or in wild-gardening operations. The beauty of these plants often lies in each species being massed alone, as well as in the mixing with other plants.

AA. *Infl. unbranched.*

*b. Infl. branched.*

*b. Height 3-8 ft.*

euryçærum, Engelm. Sts. stout, 3-8 ft. high, branching: fis. linear, flat, slightly keeled beneath: pistillate heads numerous, pistillate 2-4 on a st. or branch, 10-16 lines in diam.: fr. sessile, angeld, depressed at the sumit. May-Aug. N. Amer.

*b. Height 2-4 ft.*

rambsum, Huds. Lvs. 3-angled at the base, long and linear; heads 5-9, disposed in axillary and terminal, interrupted spikes, the lowest one larger and pistillate, the others wholly staminate; pistillate heads 8-10 lines in diam. July. Old World. WILHELM MILLER.

SPARMANNIA (named for Andreas Sparmann, 1747-1787). *Tilliaceæ*. Shrubs or trees, with soft stellate pubescence, grown in the greenhouse and also out-of-doors in the southern United States.

Leaves coriaceous, dentate or lobed: fis. white, in terminal, umbelliform little cymes; sepalis 4, petals 4, naked at the base; stamens numerous, free; ovary nearly 4-celled: caps. globose, spiny.—About 5 species, Afr.
SPAROMANIA

Sparmanlia africana is of easy treatment under glass in a moderate temperature with plenty of air and light. The plants are benefited by being plunged in the garden in the summer and syringed during dry weather. Plants should be potted early in spring. The tips of young shoots root readily with 60° of heat. A. Les. deeply 5-7 lobed.

	Palmata, E. Mey. A slender shrub much smaller in all its parts than S. africana: branches half-herbaceous: lvs. on long petioles, the lobes long-acuminate, incisely sinuate and unequally toothed, prominently 5-7-nerved below: fls. white or purplish, densely arranged on the subterminal peduncles: caps. 4-celled. S. Afr.—Sparingly cult. in S. Calif.; A. Les. not lobed.

SPARTINA (Greek, spartos, a cord, referring to the tough leaves). Grominea. Perennial marsh-plants of various parts of the world, most or all of which are found in the U.S.: culms rigid and reed-like: lvs. coarse and rough, usually becoming rolled inward: spikelets 1-flowered, strongly flattened, sessile, closely imbricated in 2 rows on a narrow rachis: spikes 2 to several in a raceeme.—Species about 10, most of them found in saline marshes of the seas.

MICHANIIANA, Hitchc. (S. eugamodes, Amer. Auth., not Roth). Fresh-water Coro.-Grass. Fig. 3655. Culms 6-18 ft. in. blades narrow, 2-4 ft. tapering to a long slender point, flat but soon involute in drying, the margins searobus: spikes 5-20., scattered, spreading, 2-4 in. long.—In the West known as "slough-grass." A common coarse fresh-water marsh grass, occurring across the continent in the northern states. Recommended for cult. along the margins of ponds and artificial lakes. Procurable from collectors.

S. eugamodes, Roth (S. pellitica, Wild.), on the Atlantic and S. johnson, Trim., on the Pacific coast act as mud-binders and are important factors in the natural reclamation of salt-marshes. In England, S. ericta, Roth, and S. Terna, Roth, Groves, perform the same service. G. C. III. 43 33. S. alterniflorus, Lodd., is common to the British Isles and the St. Lawrence and New England coasts.—A yellow-marginated form (S. eugamodes var. aureo-marginata) is shown in G. 31, 171.

A. S. HITCHCOCK.

SPARTOCYTISUS FILIPES, Webb. : Cytisus filipes.

SPATHELIA (from the Greek for a staff). Richard. Odd evergreen trees without branches, grown in the warehouse and the American tropics. Trunk simple, the lvs. aggregated at its extremity, so the plant has the look of a tree-fern or palm: lvs. alternate, odd-pinnate; lfts. many-paired, alternate, linear-oblong or sickle-shaped, subentire or serrate, the margin glandular: fls. polygamous, rather large, short-pedellated, in large panicles, which are terminal, elongated and branched, the ultimate branches somewhat cymose; calyx 5-parted, the segments spreading, valvate or subvalvate; petals 5, imbricate; disk none; stamens 5, ovary 3-angled, 5-celled: drupe without juice, elliptical-oblong, 3-edged, 3-winged, the shell stony.—About 5 species, W. Indies.

Simples, Linn. St. slender, usually leaning, resembling a palm, 20-50 ft. high: the lvs. and panicles are frequently several feet long: lfts. 20-50 pairs, very variable, opposite or alternate, sessile or petiolulate, cordate or obliquely rounded at the base, oblong- or linear-lanceolate, crenate or entire: panicle powdery. Sometimes planted in the W. Indies. B. R. 679.

A. F. Tracy Hubbard.
SPATHIPHYLLUM [Greek word, referring to the leaf-like spathes]. Araceae. Stemless or short-stemmed herbs, used as warmhouse foliage plants.

Leaves large, oblong or lanceolate, acuminate or cuspidate, midrib strong: spathe if-like, membranaceous, oblong or lanceolate; spadix shorter than the spathe, sessile or stipitate, cylindrical, densely fidd.; fls. hermaphrodite, all fertile; perianth-segments 4, 6, or 8, connate or coherent in a truncate or lobed cup; stamens 4, 6, or 8; ovary oblong, 3-4-celled: berry globose or oblong-cylindrical, 3-celled, cells 1-2-seeded. About 27 species, mostly from Trop. Amer., one or two Malayans. Monographed by Engler and Krauss in Engler’s Pflanzenreich, Teil 57 (IV. 253B), 1908. Gardeners recommend as soil for their cult., a mixture of leaf-mold, peat, and fibrous loam, together with some sand and charcoal.

A. Petals free, 6-8, in 2 rows, sometimes stuck together, never connate; stamens 6-8, rarely 4 or 6; ovary 3-4-celled, oblong, style pyramidal, more or less exserted, corona.

Section EUSPATHIPHYLLUM.

B. Ovary-cells 6, 8, or 4-celled.

cochlearispitum, Engler (S. heliconisfolium, Schott). Caudex short, lvs. thin, membranaceous, broadly oblong, margin usually slightly undulate, base rotundate or subcordate, 20-30 x 8-10 in.: spathe oblong, 6-12 in. long, base more or less acute, apex gradually narrowed to a cusp, somewhat decurrent on the peduncle. Dutch Guiana.

A.A. Petals free; ovary shortly obovatepyramidal, hexagonal, top truncate, style not at all distinct.

Section AMOPHYLLUM.

B. Petaloid about equaling or slightly shorter than blade.

floribundum, N. E. Br. Lvs. oblong-elliptic or oblong-lanceolate, base obtuse finally abruptly contracted to a knee or acute, apex acute, about 6 x 3 in., upper surface rich green, lower paler, minutely pubescent, obtuse, 3 in. long, long-cuspidate; spadix yellow-green or whitish. Colombia. I.H. 21:189.

AA. Petals almost twice as long as blade.

B.B. Petaloid twice as long as blade.

A.AA. Petals connate in a 6-angled cup which is truncate or 6-lobeled; stamens 6; ovary abovoid or cordate and 3-celled, top rather flat; cells 2, 4, 6, or 8-ovuled.

Section Massowia.

cannasfolium, Schott; also spelled kannasfolium (Pódoa kannasfolia, Dry. S. cannasform, Poepp.). Lvs. membranaceous, ovate-oblong or elliptic-oblong, base rather gradually running down to a knee, apex short-acuminate, slightly unequally so, 12-32 x 4-6 in., upper surface dark green, shining, lower paler and dull: spathe stiffly membranaceous, outside green, inside white, lanceolate, or elliptic-oblong, 4 1/2-8 in. long, base suddenly narrowed, scarcely decurrent, apex short-cuspidate; spadix greenish or yellowish. W. Indies. Colombia. B.M. 603.

SPATHOGLOTTIS

Hybrid, unclassified.

hybridum, N. E. Br. A hybrid between S. cannasform and S. Pattnii. Petioles 6-8 in. long; if-blades broadly lanceolate to oblong-lanceolate, acuminate, 8-9 in. long: spathe white on both sides, lanceolate, acuminate, 4-5 in. long; spadix 2 in. long. I.H. 29:450. G.C. II. 19:500.

S. Ehlersiana, Hort., as offered in the trade, but is unknown botanically. — S. platicephala, pl. Lind. =Rhodesia platya.

F. THOMAS HUBBARD.

SPATHODEA (Greek, spatho-like, referring to the shape of the calyx). Bignoniaceae. Small to large evergreen trees native of Trop. Afr. with large odd-pinnate compound leaves or sometimes ternate lvs., the lfts. entire, and with large fis. in terminal panicles or racemes: calyx large, split on one side and recurved, exposing the corolla to the base; corolla large, broadly campanulate and ven­tricose; stamens 4, exserted but shorter than the corolla, with spreading and pendulous anther-cells; disk large, cup-shaped; ovary oblong, with the ovules in several rows: caps. oblong-lanceolate, acuminate at the ends, loculicidal with woody valves; seeds elliptic. In England: -The spathodeas are handsome evergreen trees with large pinnate foliage and large and very showy orange-red or scarlet fis. They can be grown only in sub-tropical or tropical countries and demand rich and well-drained soil with sufficient moisture during the growing period; they are rarely grown in greenhouses, as they need much space and do not bloom until they have attained a large size. Prop. is by seeds or by cuttings. See also Radermachera for cult.

campanulata, Beauv. Tree, to 70 ft., glassescent: lvs. 1-1 1/2 ft. long; lfts. 9-10, short-stalked, ovate-lanceolate, abruptly short-acuminate, entire at the base with 2 or 3 fleshy glands, glabrous or somewhat pubescent beneath while young; 2-4 in. long; fis. scarlet, in many-flowered racemes or panicles; calyx coriaceous, broadly ovate-oblong, recurved, 2 1/2 in. long; corolla about 4 in. long, with ovate, plicate, and somewhat undulate lobes; ovary papilllose: caps. 8 in. long, glabrous. Trop. Afr. B.M. 5901. F.S. 8:380. J.F. 4:388. G.C. III. 50:458.

niitica, Seem. Shrubby tree, to 20 ft.; branchlets pubescent: lvs. 1/4-1 1/2 ft. long; rachis pubescent; lfts. 9-15, oblong-oblong, short-acuminate, entire, glabrous above, densely pubescent or tomentose beneath, 1 1/4-1 1/2 in. long; fis. almost like those of the preceding species, in short dense racemes; calyx densely tomentose, 1 1/2-2 in. long. Cont. Trop. Afr. H. Johnst. (Nothobractea annua). — S. speciosa, H. Johnst., pro­tectorate, 1:68. — In its smaller size this tree has an advantage over the preceding species the fis. of which are usually borne so high on the tree as to be almost out of sight.

S. divers, Beauv. is now referred to Newbouldia which differs from Spathodea chiefly in the shape of the calyx which encloses the base of the corolla and is split on one side and 2-lobed at the apex and in its funnel-form-campanulate corolla, the inserted stamens with parallel anther-cells: caps. elongated-linear with leafy tubes, seeds with the wing emarginate on one side. N. bent, Seem. (Spathodes speciosa, Brongn.). Shrub or tree, to 40 ft., nearly glabrous; lvs. opposite or ternate, 1-2 ft. long; lfts. 7-13, oblong-oblong, obtusely acuminate, serrate, glabrous or nearly so, 3-8 in. long; fis. white with purple spots or pink or purple, in dense terminal panicles; calyx oblong, 2-lobed at the apex; val­ves: caps. 2-2 1/2 in. long, limb slightly 2-lobed with spatulate-obovate lobes. Trop. W. Afr. B.M. 4292. J.F. 1:51. F. 8:634. H.U. 5:357. The bark has medicinal properties. — S. pentandra, Hook. (B.M. 3981), is apparently a form of N. levii with 6-lobed fis., whose purple corolla and 3 stamens.—S. speciosa, Brongn. =New­bouldia laxa.

ALFRED REHDER.

SPATHOGLOTTIS (Greek, spatha and tongue; said to refer to the shape of the lip). Orchidaeae. Plants agreeing with Bletia in habit and form of inflorescence; terrestrial orchids of the Old-World tropics, mostly with numerous flowers. Pseudobulbs broadly conic, 1-3-lvs.: lvs. elongate, long-petioled, narrow, plicate, articulated: scape lateral, bearing large fis. in a terminal raceme; sepals 3ve, subequal; petals similar or broader and longer;
SPATHOGLOTTIS

Labellum not spurred, lateral lobes somewhat convolute, middle lobe clawed; column slender; pollinia 8.—About 40 species in Asia, Austral., and the Malay Isls.

Spathoglottis grow best at the warm end of the culture, in a moist shady location. Pot culture suits them best, and the compost should consist principally of equal parts peat fiber and sphagnum moss with a little chopped sod added; about half of the pot should be devoted to drainage. They all require a liberal amount of water when growing, but only enough to keep them in sound condition when at rest. They are rather hard to increase by division and the supply depends upon new importations.

(ROBERT M. GREY)

PLICATA, Blume. Lvs. 2–4 ft. long, finely acuminate; scape 2–3 ft. high, with a raceme 6–12 in. long; fls. 1 in. across, lilac, sepals and petals broad, acute; middle lobe of the labellum long and narrow, cuneately dilated at the tip; calli yellow, villous. Malay Penins. 1911:48.

AUREA, Lindl. (S. plicata, Griff.). Lvs. 12–18 in. high, narrowly lanceolate; scape tall and stout, 2 ft. high; raceme 6–8 in. long; fls. 1½ in. across, golden yellow; sepals broad, obtuse; middle lobe of the labellum equaling the falcate lateral lobes, narrowly lanceolate. Malay Penins. G.C. III. 4:93.—The lip varies, being sometimes broad and reflexed at the apex.

VIELLARDII, Reichb. f. (S. Augustinii, Reichb. f.). Fig. 3656. Lvs. long-lanceolate, acuminate, 1–2 ft. long; scape 12–18 in. high; robust; raceme 6 in. long, broad, corby-like at first; fls. 2 in. across, very pale lilac, nearly white; sepals and petals ovate-oblong, subacute; labellum as long as the sepals, lateral lobes orange-brown, with orangy calli speckled with red, middle lobe at or near the base.

SPEGLULIS

S. Speculum, Hort., is a pretty little hardy annual herb with five-lobed blue flowers not quite an inch across. The plants grow about 9 inches high, bloom in spring and summer and are desirable for edging flower-beds. They are of easy culture. See Annuals.

A. Peduncles about 2-ft.

SPELTO (from Spergula, meaning rattling.) Spergula. Spergulaceae. Annuals and winter and summer and are desirable for edging flower-beds. They are of easy culture. See Annuals.

A. Peduncles 1–2-ft.

PENTAGONIA, DC. Calyx pilose, lobes spreading. Asia Minor. B.R. 56.—This species is not now advertised in Amer. Some specimens have narrow lvs. and longer calyx-tube than S. Speculum. An interesting feature of this species (and perhaps others) is the 5-angled fl-buds. TRACY J. HUBBARD.

SPEWELL: Veronica.

SPEWELL: Veronica.

SPECTRUM (from Spectum, meaning Venus' looking-glass). Campanulaeae. Venus' Looking-glass. Erect or decumbent, bipedal or glabrous annual herbs, suitable for outdoor garden planting.

Leaves alternate, entire or dentate: fls. blue, violet, or white, sessile or short-pedicelled, axillary; calyx-tube adnate, oblong or linear, limb 5-parted; corolla subrotate, or broad-campanulate, 5-lobed; stamens free; ovary inferior, 3-celled; caps. oblong or linear. —About 10 species, northern hemisphere. 1 also occurs in S. Austral. Closely allied to Campanula but differing by the very long calyx-tube, ovary, and caps. "The long calyx-tube is one of the most conspicuous features of the plant and has perhaps served to suggest the handle of the mirror. There is one North American species, S. perfoliata, which differs from all the rest in having perfoliate lvs. and the caps. dehiscing laterally near the middle instead of near the calyx-lubes. It is a weed. S. Speculum is a pretty little hardy annual herb with five-lobed blue flowers not quite an inch across. The plants grow about 9 inches high, bloom in spring and summer and are desirable for edging flower-beds. They are of easy culture. See Annuals.

A. Peduncles about 3-ft.

SPECTRUM VENUS: Speculum Veneris, DC. (Campanula Speculum, Linn.). Venus' Looking-glass. Fig. 3657. Erect, 9 in. high; calyx glabrous or pubescent, the tube constricted at the apex; lobes finally reflexed, according to Decandolle. B. M. 102. Var. Alba, Hort., is a white-flowered form. G. N. 72, p. 253. Var. procumbens, Hort., is offered abroad in addition to lilac and double forms. R. H. 1897, p. 254.

SPEWELL: Veronica.

SPEWELL: Veronica.

SPEWELL: Veronica.

SPEWELL: Veronica.

SPEWELL: Veronica.
Sphærolea (old Greek name). Labiatae. A score or more of shrubs or subshrubs, in Calif., Hawaii, and S. Amer., one or more of which has been listed for ornament, but apparently little known in cult. Fls. white or red, in the axils of small bracts and forming verticillate racemes or spikes which may be simple or branched; calyx campanulate, about 10-nerved, enlarging in fr.; corolla-limb 4-parted, scarcely labiate; stamens 4, didynamous or nearly equal; style 2-lobed: nutlets ovoid, smooth. S. chamissonis, Briquet (S. campanulata, Benth.), from Chile, is mentioned abroad: 2-3 ft., shrubby: Ivs. oblong- lanceolate or short-stalked, wrinkled; fls. pale blue, ½-1½ in. long, about 2 in a whorl. B.R. 1832. Coolhouse plant.

Sphærolea (Greek for globe, and Alcea, the generic name of the marshmallow). Malvaceae. Globe Mallow. Shrubs, subshrubs, or herbs, adapted to the warmer regions of N. and S. Amer. Several species have been mentioned in horticultural literature and occur occasionally in cult. One species has been intro. into Calif. Closely allied to Alceo. Leaves frequently angled or lobed: fls. short-pedicelled, solitary, or arranged in axillary fascicles or in terminal racemes or spikes, violet or flesh-colored, rarely long-peduncled or red; bracteoles 3, free or united at base; calyx 5-cleft; staminal column divided at the base of the corolla; anthers without appendages; fr. scarlet or rose, 1 in. across: peduncles axillary and terminal, numerous. Dry plains, Brit. Col. to Idaho and south. B.M. 3537 and B.R. 1306 (both as Alcea Mingana). A.G. 11:539. G. 25:453.—Advertised in 1890 as the "sunset plant." The same plant is said to be offered in some catalogues as Malva minitata.

**Sphærostema**: Tooea. Sphærostema: Schwend.

CXL. Spinach.—Above, a plant of Long Season variety. Below, spinach field near Norfolk, Virginia.
larger growth of sphagnum (which is often a foot or more in height), its soft appearance, pale green color, and the absence of root-hairs. The stems and leaves are enclosed or encircled by one, two, and often four strata of transparent cells connected with each other by small holes, which have the capacity of sucking up and retaining a large amount of water. These cells therefore perform the function of root-hairs, and it is this abundant water-storage tissue that makes sphagnum moss of so much use to gardeners in the cultivation of orchids, anthuriums, nepenthes, and sarraceniads, such as sarracenia and darlingtonia. Sphagnum often forms at least one-third of the compost in which pitcher-plants and epiphytes are grown. The fresh green tips of sphagnum are also most useful for surfacing pots of orchids and other plants. Besides giving them a better appearance, the moss acts as an index to the moisture condition of the pot. Sphagnum is also useful in the propagation of many stave plants, such as corydalis, nemophila, and the like; for starting tropical tuberous-rooted plants, such as fancy caladiums; for sowing seeds of orchids, anthuriums, nepenthes, and sarraceniads when fresh and chopped fine, as a mulch; as a non-conducting material for plants in pots in exposed positions in summer; and in packing plants for transportation, for which purpose it is an ideal material. Owing to its sponge-like character it may be used wet or dry, according to the character of the material being transplanted.

Unless one has an ideal position in which to keep sphagnum moss after gathering it from its native place, or unless one has conditions very similar to its native habitat, it is difficult to keep it living for any length of time. This does not greatly matter, except that sphagnum used for surfacing pots should always be living for the sake of appearance. That which is used in potting and propagating need not necessarily be living as long as it is fresh and not already decayed; slightly decayed moss may be used for mulching and packing.

**Edward J. Canning.**

### SPHAGNUM

**Sphagnocarpus** (derivation unknown). *Malvagiaceae*. Scendent or erect shrubs or subshrubs: lvs. opposite, entire, petiolate, without stipules, the petiole glabrous: fls. rather large, in 3-4-fld. umbels, collected in terminal panicles; calyx 5-parted, not glanular; petals unequal, short-clawed, the lobes dentate or nearly entire; stamens 10; ovary 3-celled: samaras 3, with a vertical dorsal wing.—About 5 species, Trop. and S. Afr. *S. mayeri*, *S. calicistylus* (*Acridocarpus mayeri*, *Juss.*).—A slender climbing shrub of its parts: lvs. opposite, ovate-oblong, 1-4 in. long: fls. subcorymbosely clustered at the ends of the branches, 1-1½ in. in diam., golden yellow; petals short-clawed, orbicular, margins crisped: samaras silky-pubescent. S. Afr. B.M. 7894.

**Sphenopholis** (Greek, sphen, a wedge, and pholis, a scale, referring to the broadly obovate second glume). Syn., *Eulobiæ*, *Eulobus*. S. Amer. Scendent or erect shrubs with rather delicate panicles: spikelets 2-3-fld., articulate below the glumes; glumes dissimilar in shape, the first narrow, the second obovate.—Species about 5. N. Amer. Three kinds have been catalogued among native plants offered for sale.

#### A. Panicide dense, spike-like, strict.

#### A. Panicile more loose and slender.

**Pallens**, Scribn. (Eulobiæ pennsylvanica, Gray). Lvs. 3-8 in. long; panicle-branches lax, nodding, glumes unequal, the first shorter. Moist woods and meadows. Maine to Texas. Ibid. 257.

---

**Spicile Bush**: *Benzoëm.*

**Spider Flower**: *Cleome*. S. Lilies: *Hymenocallis* and *Pan-cretum*. S. Plant: *Cleome*. Spiderwort: *Tradescantia*.

**Spigélia** (named for Adrian von der Spigel, physician, 1558–1625). *Loganiiaceae*. Annual or perennial herbs, some hardy, the others either greenhouse or greenhouse plants, rarely somewhat woody, with opposite membranous leather-leaved rarely 3–5-nerved lvs., and long or small, red, yellow, or purplish fls. with by-born or by-side somewhat curved spikes: calyx 5-lobed; segms. narrow; corolla tubular; lobes 5, valvate; stamens 5, attached to the corolla-tube; ovary 2-loculed; style articulate, simple, obtuse or somewhat capitulate and stigmatose at the summit: caps. flattened, circumscissile above the persistent base.—About 50 species, Amer.

**Splintlthes** (Greek, meaning spot-flower, in reference to the markings on the disk in some of the species). *Compositae*. Herbs, mainly weeds, some of them desirable for outdoor plantings, while others are grown as house-plants: lvs.: rays yellow or whitish, or none: achenes nearly always flattened, biauritate or without bristles, glabrous or strongly ciliate, in the latter case quite distinct in appearance. There are about 40 species of Splinthetes, widely distributed in both hemispheres, mostly confined to warmer countries, or, in the New World, also occurring in the South Temperate zone; one variety native to Amer. Good technical characters for distinguishing the different forms are found in but few cases. The latest monograph is in the Proceedings of the American Academy of Arts and Sciences, vol. 42, pp. 521–69. S. oleracea, Linn. (Tropics), is cult. for the pungent flavor of its lvs., used in salada; also, to a slight extent, as an ornamental, on account of its odd cylinder-like heads, in which the ratio of length to breadth is the greatest in the genus. Two types of it are named in the trade, Parà cress and Brazil cress, the latter said more commonly to have a brownish cast to sts. and lvs. Gt. 22, p. 295. Gt. 2, p. 36. While most of the species are of inferior appearance, several are distinctly worth cultivating or possibly hybridizing for ornament. The principal ones are enumerated below; all but S. callimorpho belonging in the radiate section, Acanthella, D.C.

**S. americana**, Hieron., var. répans, A. H. Moore. One of the best of the showy members of the genus. Erect or weak, ascending, decumbent, or rarely prostrate; lvs. large for the genus: rays bright yellow. By selection the erect type could probably be made to dominate. A hybrid combining with this the handsome lvs. and red at the base would be most desirable. Pair and S. callimorpho, Sept. Mo., Ark., La. to Fla. and Texas.—S. callimorpho, A. H. Moore. Decumbent or prostrate; lvs. long-nemiliniminate; flowers yellow; summer flowering. Moomian Prov., China.—S. charitops, A. H. Moore. One of the dainty species; a fair companion-plant to *S. indigéala*, but not so large. Dec. arb., with long internodes; small attractive heads. Yucatan, Mex.—S. glabella, A. H. Moore. Lvs. densely tomentose; rays large, red: in good packed bed.—S. hookeriana, A. H. Moore. A dainty little plant, with delicately green foliage: dark violet, the tiny rays cream colored. Porto Rico. Though not quite so charming, S. charitops would be a pretty good companion.—S. phanerentia, A. H. Moore. Decumbent or
SPINACH (Spinacia oleracea, which see) is an annual crop grown as a pot-herb, or for "greens." Fig. 3659. It is a cool-season plant, and therefore it is grown in fall to spring. It is a plant of easy culture, thriving in any good garden or field soil, although for quick results and for tender succulent foliage, land that has an abundance of available plant-food, and particularly of nitrogen, is most desirable. The plant is hardy, and when the land is well drained, it will ordinarily stand the winter climate as far north as the city of New York, and still farther in somewhat protected places.

Spinach is grown both as a fall and spring crop. The fall crop is raised from seed that is sown in August; in eight weeks the leaves may be large enough for eating. A fertilizer that is very rich in nitrogen gives best results; two or three sowings may be made in the home-garden for spring use, but after the middle of June spinach is likely to become tough and is in little demand. If spinach is wanted during the summer, it is better to use the New Zealand spinach, which is a warm-weather plant. This plant has no relationship with the ordinary spinach (see Tetragonia). It is usually best to sow spinach where the plants are to stand, although it is sometimes transplanted into frames for home use. Care must be taken that the plants do not become checked or stunted, else they will tend to run to seed. If the seed is sown too late in spring, when hot weather is approaching, the root-leaves will be very few and the plant will quickly throw up flower-stalks. Spinach is always grown as a succession or companion crop, as it occupies the land for a small part of the year. There are very few insects and diseases that are generally troublesome.

Spinach is usually transported to market in barrels or crates. Plants are usually cut so that an inch or so of the root is left with them. All dirt is removed, as also all broken and dead leaves. The plants are packed tight. It is essential that the plants be dry before they are shipped.

There are several important varieties of spinach. The large broad-leaved varieties are most popular in the market, such as the Viroflay and the Round-leaved. The prickly spinach is considered to be the most hardy and is chiefly recommended for fall sowing.

SPINACIA (from spina; alluding to the spiny fruit). Chenopodiaceae. Spinach. Spinage. According to Volkmann (in Engler & Prantl’s “Pflanzenfamilien”), there are only two species of Spinacia, S. oleracea, the common spinach, and S. tetrandra, Stev., although Bentham & Hooker had made the genus to include four species. S. tetrandra is an annual herb of the Asia Minor-Persian region, and is not in cultivation. The spinach is probably native to southwestern Asia, and it is now widely cultivated. It is an annual herb, developing rather large arrow-shaped root-leaves, and these leaves are eaten for “greens.” Later in the season it sends up a branching flower-stem 2 to 3 feet high, bearing axillary clusters of seed-like fruits. In one type these fruits are spiny: this is the form once described as S. spinosa, Moench, but which is not now considered to be specifically distinct. Whether the round-seeded or the prickly-seeded type is the original form of the spinach is not known, but as a matter of nomenclature, Linnaeus’ S. oleracea, which is the oldest name, is held to include all.

Spinacia belongs to the Atriplex tribe. The genus is distinguished from Atriplex in the fact that the pistillate flowers are bractless when inclosed in a pair of enlarging calyx-like bracts. Spinacia is dioecious, bearing the flowers in small axillary clusters; stamens 4 or 5, in a 4- to 5-toothed calyx; ovary 1, with 4 to 5 styles or stigmas, in a 2- to 4-toothed calyx, this calyx hardening and inclosing the achene and often becoming horned on the sides and giving rise to “prickly-seeded” spinach. The cultivated forms have developed much thicker and broader radical leaves, which are used for greens, often showing little of the halberd-pointedinate shape. See Spinach.
SPIREA

SPIREA (ancient Greek name of a plant used for garlands, derived from spirea, band, wreath; probably first used for the present genus by Clusius). Rosaceae, subfamily Spiraeoideae. Spirea. Ornamental woody plants grown for their profuse handsome white, pink, or carmine flowers.

Decidious shrubs: i.e. simple, short-petioled, dentate or serrate, sometimes lobed, rarely entire, without stipules, in umbel-like racemes, racemes perfect, rarely polygamous; calyx cup-shaped or campanulate, 5-lobed; petals 5, rounded; stamens 15-60, inserted between calyx and disk; pistils usually 5, distinct, developing into follicles delinquent along the inner sutures, with several minute oblong seeds. About 70 species in the temperate regions of the northern hemisphere, in Amer. south to Mex., in Asiat. south to the Himalayas. Many species formerly included under Spiraea are now referred to other genera; see Physocarpus, Helodictus, Sorbaria, also Chamaebatia, Leucodela, Petrophylleum, and Sibiraea for shrubby species, and Aruncus, Filipendula, and also Aster for the herbaceous ones. There is a monograph of Spiraea and the allied genera by Maximowicz in Acta Horti Petropolitani, vol. 6, pp. 105-261 (1879) and a monograph of the cult, species, with their numerous hybrids fully described by H. Zabel, Die strauchigen Spirien der deutschen Gärten (1898). There is much horticultural literature on spireas, for the plants are popular and about two-thirds of the known species and numerous hybrids mostly originated in gardens are in cult.

The spireas are very ornamental, usually low or medium-sized shrubs with rather small deciduous foliage and with small white or pink or sometimes nearly crimson flowers in showy corymbs or panicles followed by small inconspicuous capsule-like fruits. Many are hardy North; some of the best of them are S. arguta, S. Thunbergii, S. Vanhouthei, S. pubescens, S. triloba, S. nipponica, S. media, S. ulmifolia, S. alba, S. Douglasii, S. Menziesii, S. tomentosa. The recently introduced S. Henry, S. Velechi, S. Wilsonii, S. Rosthormii and S. Sarpentiana have proved hardy at the Arnold Arboretum, while S. blanda, S. Japonica, and S. abifolila require a sheltered position or protection during the winter, though S. Japonica and its allies, even if killed almost to the ground, will produce flowers on shoots of the same season. S. cantoniensis, S. Blume, S. canescens, and S. bella are more tender and not to be recommended for the North, but are hardy or nearly hardy in the middle states. S. prunifolia is hard as far north as Boston.

In regard to the flowering season, the spireas can be divided into two groups. The first one contains the species of the section Chaemadryon, with white flowers in umbels and blooming in spring, from April to June. The second group is composed of the sections Calospira and Spiraria, with white or pink flowers in corymbs or panicles appearing from June to autumn. Of the most important species, arranged according to their relative flowering-time, are the following: Early-flowering spireas—S. Thunbergii, S. arguta, S. hypericifolia, S. prunifolia, S. media, S. pubescens, S. chamadryoides, S. triloba, S. Vanhouthei, S. cantoniensis, S. nipponica. Late-flowering spireas—S. bella, S. Rosthormii, S. Wilsonii, S. Henry, S. Sarpentiana, S. Velechi, S. corymbosa, S. densiflora, S. canescens, S. japonica, S. abifolila, S. alba, S. Menziesii, S. Douglasii, S. tomentosa. Many species of the second group do not produce their flowers all at once like those of the first group, but continue blooming for a longer time.

The spireas are all medium-sized or low shrubs and well adapted for borders of shrubberies, as single specimens on the lawn, or for rockeries. Especially the species of the early-flowering group possess a graceful habit and make effective single specimens, except perhaps S. chamadryoides and S. media, which are sometimes what stiffer and less handsome and produce suckers. S. canescens, S. Henry, and its allies have the graceful habit of the first group. S. japonica and its numerous hybrids form very low, round bushes and are usually used as single specimens or in the border. S. alba, S. Doug- lassii, and S. Menziesii, and their hybrids should be planted in shrubberies only and especially in situations where their spreading by suckers does no harm; they are sometimes used for low ornamental hedges. For rockeries S. decumbens, S. betulifolia, S. corymbosa, S. densiflora, S. bullata, and some dwarf hybrids of S. japonica are to be recommended.

The species of the section Chamaedryon, and also S. canescens and S. bella, should be pruned as little as possible—only thinned out and the weak wood removed—while those of the sections Calospira and Calospora can be pruned more severely if necessary, since they produce their flowers at the ends of the young shoots. Some

KEY TO THE SECTIONS.

a. Inf. a simple umbel-like raceme: fls. white.
   Section I. CHAMAEDRYON. Species Nos. 1–20.

AA. Inf. compound: fls. white or pink.
   a. Fls. in corymbs.
   Section II. CALOSPIRA. Species Nos. 21–42.

BB. Fls. in panicules.
   Section III. SPIRÆA. Species Nos. 43–55.

Section I. CHAMAEDRYON. Species Nos. 1–20.

A. Fls. in sessile umbels with none or very small lvs. at the base or only the lower
   umbels on leafy stalks.
   B. Foliage entire or crenate mostly with small lvs. at the base; pedicels glabrous;
      petals broadly obovate, almost twice as long as stamens. 
      Var. trunciLta, Zabel Fig. 3661. Shrub, 5 ft. high, with slender arching
      or upright branches: lvs. almost sessile, cuneate-obovate to obovate-lanceolate, 3-
      nerved or with few lateral veins, almost glabrous, 1½ in. long: lvs. small, white, in sessile umbels; pedicels usually pubescent; petals almost orbicular, usually longer than stamens. April, May. S. E. Eu. to Siberia.
      —Variable species. Var. acuta, Ser. (S. acutifolia, Willd.). Lvs. narrower, obovate-lanceolate: fls. smaller, yellowish white; pedicels glabrous; petals obovate, shorter than stamens: lvs. somewhat earlier; but less showy.

2. Thunbergii, Sieb. Fig. 3660. Shrub, 5 ft. high, with spreading or arching branches: lvs. linear-lanceolate, sharply serrulate, 1–1½ in. long: lvs. pure white, about ½ in. across, in 3–5-fld. naked umbels; petals obovate, much longer than stamens: follicles with the spreading styles below the apex. April, May. China. Japan. S.Z. 1:69. G.F. 8:84, 85. J.H. III. 47:337.—A very graceful early-flowering shrub, the slender arching branches clothed with feathery bright green foliage, turning later in fall to orange or scarlet. Almost hardy, but tips of branches sometimes killed by severe frost; valuable for seaside planting.

found wild in Podolia, Poland."

6. **china**, Waldst. & Kit. Dense, bushy shrub, 3 ft. high: lvs. elliptic to oblong, acute at both ends, usually entire, grayish pubescent on both sides, more densely beneath, ½–1 in. long: fls. ¼ in. across, in dense head-like umbels; petals about as long as stamens; sepals reflexed in fr.; follicles curving outward. May. June. N. E. Asia. G.O.H. 10. nippouia, Maxim.

9. **pikoviensis**, Bess. (S. crenata × S. media, S. Nicosidtěriti, Hort.). Shrub, 4 ft. high, with terete upright branches; lvs. oblong, cuneate at base, with few sharp teeth at the apex or sometimes entire, peninnerved to 3-nerved, almost glabrous, 1–2 in. long: fls. white or greenish white, in many-fl. almost glabrous umbels; petals orbicular, shorter than stamens; sepals upright in fr.; follicles with the upright style somewhat below the apex. May. G.M. 53:157. —Supposed natural hybrid, found wild in Podolia, Poland.

10. **nipponica**, Maxim. (S. bracteata, Zabel, not Raf.). Fig. 3662. Shrub, 8 ft. high, with upright or spreading branches, quite glabrous; lvs. ovate, usually crenate at the apex; dark green above, bluish green beneath, of firm texture: lvs. ¼ in. across, in umbel-like racemes, sometimes compound at the base; petals orbicular, longer than stamens; sepals spreading in fr. June. Japan. Var. rotundifölia, Makino (S. media var. rotundifölia, Nichols.). —Lvs. broadly obovate or roundish obovate, ¼–1⅔ in. in long: fls. somewhat larger. G.C. H. 23:283; III. 37:149; 43:399. J.H.S. 33, p. 349. G. 29:663. G.M. 43:95. B.M. 7429. G.F. 7:305 (adapted in Fig. 3662).-Desirable hardy shrub of vigorous growth with showy umbels of pure white fls. and dark green handsome foliage remaining green until late in fall.

11. **Blumei**, Don (S. rupestria, Sieb.). Shrub, 4 ft. high, with spreading and arching branches: lvs. ovate to rhombic-ovate, incised-crenate-serrate, pale bluish green beneath and rather prominently veined, ¾–1¾ in. long: fls. polygamous, white, in many-fl. umbels, petals roundish-ovate, about as long as stamens: follicles with spreading or reflexed styles. June. Japan. B.H. 8:36.—Not hardy N., rare in cult.; often the following or other species are met with under its names.

12. **triloba**, Linn. (S. triloba, Linn.). Fig. 3663. Shrub, 4 ft. high, with slender spreading branches; lvs. almost orbicular, incised-dentate and often 3-lobed, obtuse, pale bluish green beneath, ½–1⅔ in. long: fls. pure white, in many-fl. umbels; sepals upright in fr.; follicles with ascending styles. May. June. N. China to Tibet. F.S. 2:317. G.M. 13:1271. G.F. 1:452. F.E. 30:45 (as *S. crataegifölia*).—Handsome bushy shrub, quite hardy; cult. under many different names as *S. aquilegifölia*, *S. adiantifölia*, *S. crataegifölia*, *S. Blumei*.

14. **canoniensis**, Lour. (S. Reevesiana, Sieb.). Shrub, 4 ft. high, with slender, arching branches; lvs. rhombic-ovate, incised doubly serrate, dark green above,
pale bluish green beneath, 1–2 1/2 in. long; fls. over 1/2 in. across, in rather dense umbels; sepals upright in fr.; follicles with spreading styles. May, June. China. B.R. 30:10. A.G. 18:356. G. 34:441. — Very handsome shrub, with large pure white fls., but only half-hardy N. Var. lanceata, Zabel (S. Rosescens flore-pleno, Hort.), with double fls. and narrower lvs. is still more tender. H.F. 1855:11. This species and the three foregoing are valuable also for their handsome foliage, which remains fresh and green until late in fall.

16. **chinensis**, Maxim. (S. pubescens, Lindl.). Upright shrub, 5 ft. high, with arching branches, tomentose when young; lvs. long-petioled, ovate, incisedly serrate only at the middle, 1–2 in. long; fls. pure white, about 3/4 in. across, in pubescent umbels; sepals upright in fr., ovate-lanceolate, tomentose like the follicles styles terminal, spreading. May, China. B.R. 33:36. — Handsome, but not hardy North.

17. **pubescens**, Turez. Upright shrub, 6 ft. high, with slender, arching branches: lvs. similar to those of the foregoing species, but more grayish tomentose beneath and somewhat smaller, petioles shorter: fls. 3/4–3/4 in. across, in glabrous umbels; sepals triangular-ovate, upright in fr.: follicles glabrous, with the spreading styles below the apex. May, N. China. G.F. 1:331. — Hardy N., and the large-fid. form as handsome as the foregoing species.

18. **media**, Schmidt (S. confusa, Regel & Koern.). Upright shrub, 5 ft. high, with terete branches, glabrous or pubescent when young; lvs. ovate to oblong, eu anate at the base, incisedly serrate above the middle, almost glabrous or pubescent, 1–2 1/2 in. long; fls. in many-fid. rather long-stalked, umbel-like racemes: follicles with the spreading or reflexed styles somewhat below the apex. May. S. E. Eu. to Japan. J.H. III. 46:533. G. 30:45. G. M. 49:504. R.F.G. 24:149. Var. glabrascens, Simonkai. Almost glabrous. Var. subintegerrima, Zabel (S. oblongifolia, Waldst. & Kitz.). Lvs. elliptic-oblong to oblong-lanceolate, narrowed at both ends, entire or with 1–3 teeth at the apex, nearly glabrous. Var. serrata, Regel (S. sericea, Turcz.). Lvs. pubescent on both sides.

19. **chamaedryfolia**, Linn. Shrub, to 6 ft., with angular glabrous branchlets: lvs. slender-petioled, ovate, incisedly or doubly serrate from below the middle, almost glabrous, bluish green beneath, 1 1/2–3 in. long; umbels many-fid., the lower ones on branchlets about 2 in. long, the upper ones often almost sessile; fls. about 3/4 in. across, follicles with the style upright and terminal. May, June. S. E. Eu. to Japan. G. W. H. 83. Var. ulmifolia, Maxim. (S. ulmifolia, Scop.). Lvs. more rounded at the base: umbels more elongated-hemispherical, S. E. Eu. R.F.G. 24:150. Var. transiens, Zabel. Lvs. narrower, oblong-ovate.—This and the preceding species spread by suckers.

20. **flexuosa**, Fisch. (S. chamaedryf6lia var. flexuosa, Maxim.). Similar to the preceding species, but lower and more spreading: branchlets slender, strongly angled, distinctly zigzag: lvs. oblong-ovate to lance-oblong, cuneate at the base, usually serrate above the middle only, 1–2 in. long; umbels few-fid., short-stalked. May, June. N. E. Asia. Var. stenophylla, Schneid. (S. chamaedryf6lia var. stenophylla, Zabel). Lvs. smaller and narrower, usually less than 1 in. long.

Section II. **CALOSPIRA.** Species Nos. 21-42.

A. Corymb on usually short lateral branchlets along the mostly arching branchlets of the previous year.

B. Lvs. 1/2–1 in. long, crenate-serrate, or serrate only at the apex; corymb in very short branchlets.

C. Branchlets angular: lvs. generally ovate, obtuse; winter buds with 3 outer scales

D. Lvs. pubescent on the upper surface of the lvs. glabrous; margin entire; flower-bud scaly

E. Upper surface of lvs. more or less pubescent, margin usually dentate below the apex.

F. Fls. perfect, white. lvs. 3/4–3 in. long.

G. Fls. perfect, white. lvs. 3/4–3 in. long.

H. Winter buds short, acute, with several outer scales: lvs. entire or dentate only above the middle. lvs. 1/2–1 in. long, crenate-serrate, or serrate only above the middle.

I. Upper surface of lvs. glabrous; margin entire; flowering branchlets 2–3 in. long. 23. Veitchii

J. Upper surface of lvs. more or less pubescent, margin usually dentate below the apex.

K. Fls. perfect, white. lvs. 3/4–3 in. long.

L. Fls. perfect, white. lvs. 3/4–3 in. long.

M. Winter buds short, acute, with several outer scales: lvs. entire or dentate only above the middle.

N. Upper surface of lvs. more or less pubescent, margin usually dentate below the apex.

O. Fls. perfect, white. lvs. 3/4–3 in. long.

P. Fls. perfect, white. lvs. 3/4–3 in. long.

Q. Winter buds short, acute, with several outer scales: lvs. entire or dentate only above the middle.

R. Upper surface of lvs. more or less pubescent, margin usually dentate below the apex.

S. Fls. perfect, white. lvs. 3/4–3 in. long.

T. Fls. perfect, white. lvs. 3/4–3 in. long.

U. Winter buds short, acute, with several outer scales: lvs. entire or dentate only above the middle.

V. Upper surface of lvs. more or less pubescent, margin usually dentate below the apex.

W. Fls. perfect, white. lvs. 3/4–3 in. long.

X. Fls. perfect, white. lvs. 3/4–3 in. long.

Y. Winter buds short, acute, with several outer scales: lvs. entire or dentate only above the middle.

Z. Upper surface of lvs. more or less pubescent, margin usually dentate below the apex.

AA. Corymb on usually short lateral branchlets of the previous year.
SPIRAEA

21. canescens, D. Don. Shrub, 6 or sometimes 12 ft. high, with spreading and arching branches; branchlets angled; leaves broadly oval to oblong, very short-petioled, cuneate at the base, acute, finely puberulous beneath and glaucous, glabrous above, ¼-½ in. long; corymbs ½-2 in. across, puberulous; flowers ¼ in. across; white; calyx puberulous; stamens longer than petals; carpels glabrous, upright. June. July. B.M. 5838. J.H.S. 35, p. 152, fig. 98. G.M. 52:598.—Like the two following closely allied species very handsome and hardy as far north as Mass.

24. Wilsonii, Duthie. Shrub, to 8 ft., with arching branches; branchlets dull purplish, pubescent while young; leaves short-petioled, oval to oblong or oblongate, obtuse or acutish, cuneate at the base, entire or with a few coarse teeth at the apex, dull green and pubescent above, grayish green and villous beneath, particularly on the veins, ¾-2¼ in. long; corymbs dense, 1¼-2 in. across, glabrous or nearly so; flowers ¼ in. across, pure white; calyx glabrous; foliages sparingly pilose, slightly spreading. June. Cent. and W. China. B.M. 8390. G. 35:851.

25. Henryi, Hemsl. Fig. 3655. Shrub, to 8 ft., with spreading branches; branchlets sparingly pilose or nearly glabrous; leaves obovate or oblong to oblongate, cuneate at the base, acute or rounded at the apex, usually coarsely dentate toward the apex, slightly hairy above, villous beneath particularly on the veins, ¾-3 in. long; petals ½-¾ in. long; corymbs 2 in. across, rather loose, pilose; flowers ¼ in. across; stamens shorter than petals; foliages hairy, slightly spreading. June. Cent. and W. China. B.M. 8270. G. 85, p. 44. J.H.S. 28:62, fig. 20. G. 37:35. Var. notabilis, Parquhar. Corymbs larger.

26. Rösthornii, Pritzel (S. Frutti, Schneid.). Shrub, to 6 ft., with spreading branches; branchlets yellowish brown, sparingly hairy while young; winter buds elongated, long-pointed, often as long as petals; leaves ovate to ovate-oblong, acuminate, cuneate at the base, rarely nearly rounded, serrate, hairy; leaves green, hairy on the veins beneath, 1¼-2¾ in. long; petals ¾-1¾ in. long; corymbs rather loose, 2-3 in. across, pilose, on elongated branchlets; flowers ¼ in. across, white, stamens longer than petals. June. W. China.—A graceful shrub with handsome bright green foliage.

29. expansa, Koch (S. béllá var. expansa, Regel S. fastigiata, Wall.). Closely allied to the foregoing; more vigorous and upright, 6 ft. high, with terete branches tomentose when young: lvs. ovate to ovate-oblong, acute at both ends, sharply serrate from the middle, usually pubescent on the veins beneath, 1½-3 in. long: fls. white, ⅙ in. across, in 1-4-in.-broad corymbs terminal on upright, often very long branches: follicles pubescent, diverging. July. Himalayas.-S. pulchella, Kunze (S. kumaonensis, Hort.), is supposed to be a hybrid of this and the foregoing species; it combines the broader corymbs of the latter with the brighter color of the first species, therefore handsomer than either parent; sometimes cult. as S. expansa rubra, but there is also another hybrid of the same name. See S. rubra in suppl. list.

31. japónica, Lind. (S. collèsa, Thunb.). Shrub, 4 ft. high, with upright branches glabrous or puberulous when young: lvs. ovate to oblong-lanceolate, acute at both ends or acuminate, doubly and incisedly serrate, pale bluish green and usually glabrous beneath, 1-4 in. long: fls. small, pale to deep pink, in usually much-compound and rather loose corymbs; sepals reflexed in fr.: follicles glabrous, diverging with ascending styles. June, July. Japan. China.-A very variable species. The variety most common in cult. usually under the name S. collesa is var. Fortunae, Regel. (S. Fortunae, Planch. S. collèsa, Lindl., not Thunb.). Higher, with quite terete branches: lvs. 2-4 in. long, oblong-lanceolate, acuminate, sharply and doubly serrate, with incurved, calloso-tipped teeth, rugose above, bluish white beneath: corymbs very compound, rather loose; disk less developed, sometimes wanting. E. and Cent. China. F. S. 9:871. B. M. 5164. B.H. 8:129.-Handsome shrub with the young unfolding lvs. of a pretty purplish color and very large much-compound corymbs. The Japanese forms grow less high, have smaller and broader, coarsely doubly dentate-serrate lvs., not rugose and less whitish beneath; the sts. are slightly striped by the decurrent petioles and the fls. are less compound. Other varieties of Chinese origin are the two following recently intro. varieties. Var. acuminata, Franck. Fls. ovate-oblong to lanceolate, acuminate, green and pubescent beneath, at least on the veins, 2-3½ in. long: fls. pink, in terminal corymbs 4-6 in. across. Cent. and W. China. Var. ovatifolia, Franck. Fls. oval to elliptic, acute, glabrous and glaucous beneath, 1½-3 in. long: fls. white, in corymbs 3-5 in. across. W. China.-Japanese forms little known in cult. are var. pubescens, Regel, with the lvs. pubescent beneath and the corymbs pubescent, and var. glabrata, Nichols. (S. glabrata, Lange), with ovate glabrous lvs. and bright pink fls. in glabrous corymbs. The following are garden forms: Var. astrosanguinea, Zabel. Fls. deep pink, in tomentose corymbs. Var. rubérrima, Zabel. Fls. deep pink, in puberulous corymbs. Var. macrophylla, Simon-Louis. Lvs. becoming 6 in. long, bullate: corymbs small. Var. variegata, Hort. Lvs. variegated with yellowish white. Most of the other forms enumerated as varieties under this species are hybrids.

33. Fórqué, Zabel (S. corymbosa × S. japonica). Similar to the preceding; branches more or less striped, almost glabrous: lvs. elliptic, doubly serrate, glabrous; fls. whitish or pinkish, in large, puberulous corymbs; styles spreading in fr. June, July. R. H. 1900, p. 117. Of garden origin.—Less desirable than the preceding hybrid.

35. albitifôra, Miq. (S. japónica alba, Regel. S. leucodermis, Lange). Fig. 3667. Low shrub, 1½ ft. high, with stiff, upright branches: lvs. lanceolate, coarsely serrate at base, entire or with a few teeth above the middle, pale or glaucous beneath, 1½-2 in. long: fls. white, in dense glabrous corymbs, about 1½ in. across. June, Va. to N. C. and Tenn. B.B. (ed. 2) 2:246.

39. virginiânsa, Brit. Much-branched shrub, to 4 ft., glabrous: lvs. lance-oblanceolate, acute, cuneate or rounded at the base, entire or with a few teeth above the middle, pale or glaucous beneath, ½-2 in. long: fls. white, in dense glabrous corymbs, about 2 in. across. June. Va. to N. C. and Tenn. B.B. (ed. 2) 2:246.

40. ficida, Douglas (S. corymbosa var. ficida, Zabel). Closely allied to S. corymbosa: branches yellowish brown or brown; lvs. more incisely serrate, oval or obovate: corolla glabrous, usually looser and more flat, broader. June, July. Brit. Col. to Sask., Wyo. and Ore.

41. betulifolis, Pall. Low, much-branched shrub: lvs. oval to obovate-oblong, usually cuneate at base and very short-petioled, ovate or crenately serrate, obtuse, glabrous or slightly pubescent on the veins beneath, ½-1½ in. long: corymbs usually glabrous, 1-2 in. across. June, July. Siberia to Manchuria, Kamchatka and Japan.—The three preceding species except S. virginiana are all closely allied and considered by some botanists varieties of S. betulifolia.

42. decumbens, W. Koch (S. procumbens, Hort.). Dwarf, procumbent shrub, about ½ ft. high, with ascending branches, glabrous: lvs. elliptic to oblong, acute at both ends, crenately serrate above the middle, glabrous, ½-1½ in. long: fls. white, in small corymbs, about 2 in. across; follicles glabrous, with upright terminal styles. June-Aug. Brit. Col. to Ore., Wyo., and Mont. G.F. 10:413.

Section III. Spiræa. Species Nos. 43-55.

A. Infl. a broad panicle, about as broad as high. (Hybrid of species of this and the preceding section.)

B. Panicles rather small, on lateral branches at the end of last year's branches. 43. Fontenaysii

BB. Panicles large, terminal on long, upright branches.

C. Lvs. glabrous or nearly so.

D. Apex of lvs. acute. 44. conspicua

DD. A petiole of lvs. obtuse or acute.

E. Shape of lvs. broadly ovate or oblong. 45. notba

EE. Shape of lvs. oblong or oval-oblong. 46. pyramidalta

GG. Lvs. pubescent or tomentose beneath.

H. Base of lvs. acute. 47. sanssouciens.

HH. Base of lvs. rounded. 48. Watsoniana

AA. Infl. an elongated panicle, longer than broad. (Spiræa proper.)

B. Foliage glabrous or nearly so.

C. Lvs. sharply serrate, except at the very base.

D. Panicles lomentulose. 49. salicifolia

EE. Fls. light pink. 50. alba

GG. Lvs. crenately serrate above the middle; fls. pink. 52. Menziesii

BB. Foliage pubescent or tomentose beneath.

C. Foliages glabrous: lvs. grayish or whitish tomentose beneath.
43. **Fontenayssii**, Billiard (S. fontenaysiiensis, Dipp. & S. cantescens × S. salicifolia). Shrub, 6 ft. high, with slender, upright branches; lvs. ovate or oblong-oval, rounded at both ends, crenately serrate above the middle, pale bluish-green beneath, almost glabrous, 1–2½ in. long: fls. white or pink, in 1½–3½ in.-long panicles; petals orbicular, about as long as stamens; sepals spreading in fr. June, July. Of garden origin.—Not quite hardy N. Var. alba, Zabel, is the white-flowered form. S. pruinosa, Zabel, is a similar form, but the lvs. are tomentose beneath and the fls. pink.

44. **conspicua**, Zabel (S. albiflora × S. alba). Upright shrub, 3 ft. high, with dark brown puberulous branches; lvs. elliptic-oblong, acute at both ends, usually or doubly serrate, almost glabrous, 1½–2½ in. long: fls. pinkish white, in broad finely pubescent panicles; petals shorter than stamens. July—Sept. Handsome form. A similar hybrid is S. syringaeflora, Lem. (L. albiflora × S. salicifolia), with oblong-lanceolate or lanceolate lvs., serrate above the middle, and pink fls. Closely allied is also S. semperflorens, Zabel (S. japonica × S. salicifolia, S. japonica or S. Fortunei var. paniculata, Hort.). Higher than the former: lvs. oblong-lanceolate, usually doubly serrate; fls. pink. R.H. 1890, pp. 496, 497. Gn. 45, p. 49. G. 3:191.

45. **nubia**, Zabel (S. corymbosa × S. latifolia). Shrub, 3½ ft. high, with brown, glabrous branches; lvs. broadly ovate to ovate-oblong, short-petioled, coarsely and doubly serrate, almost glabrous, 1–2½ in. long: fls. white to pinkish white, in broad, glabrous panicles; stamens almost twice as long as the orbicular petals. July, Aug.—Of garden origin.

50. **alba**, Dur. (S. salicifolia var. paniculata, Ait. S. lanceolata, Borkh.). QUEEN OF THE MEADOW. MEADOW-SWEET. Attractive upright shrub, attaining 6 ft., with reddish brown branches puberulous when young; lvs. narrow, oblong to oblong-lanceolate, acute, usually regularly simply serrate, 1½–2½ in. long: fls. white, in leafy pyramidal tomentulous panicles, the lower spreading ramifications much longer than their supporting lvs.; stamens with petals nearly as long as petals; follicles quite glabrous. June—Aug. From N. Y. west to Mo., south to Ga. and Miss. B.B. (ed. 2) 2:245. Also known as S. salicifolia.

51. **latifolia**, Borkh. (S. salicifolia var. latifolia, Ait. S. carpinsfolia, Willd. S. canadensis, Engelm. S. bethlehemensis, Hort.). QUEEN OF THE MEADOW. MEADOW-SWEET. Fig. 3668. Branching shrub, 2½—5 ft. high, with bright or dark red-brown glabrous twigs: lvs. broadly ovate to oblong or oblong, usually coarsely and often doubly serrate, 1½–3 in. long: fls. white, larger than those of S. alba, sometimes slightly blushed and with the stamens and disk more or less pinkish; panicles quite glabrous, broadly pyramidal, with spreading and elongated ramifications; stamens longer than petals. June—Aug. Newfoundland and Canada to N. C. Em. 2:485. G.C. III. 43:417.—This and the preceding species have been referred by most American botanists to S. salicifolia. S. alba is chiefly found west, S. latifolia east of and on the Alleghanies, while the true S. salicifolia is an Old-World species.

52. **Menziesii**, Hook. (S. Douglasii var. Menziesii, Preal.). Upright shrub, 4 ft. high, with brown, at first puberulous, branches: lvs. oblong-obovate to oblong, coarsely and unequally serrate above the middle, pale green beneath, 1½–3 in. long: fls. small, pink, in narrow, 5–8-in.-long panicles; stamens more than twice as long as the roundish petals; sepals reflexed in fr. June—Aug. Alaska to Ore.
53. Bliéridi, Herneq (S. Douglasii x S. salicifolia), Shrubs, 6 ft. high, with brown pubescent branches; lvs. oblong to oblong-lanceolate, acute, sharply and often doubly serrate, especially in the lower third, usually grayish-tomentose beneath, at least when young, sometimes almost glabrous at length, 2-3 in. long; fls. bright pink, in 5-8 in. long, tomentose or tomentulose panicles usually rather narrow and dense. July-Aug. Of garden origin. F.H. 5:24. F.E. 18:631. = S. Lando, S. biflora, S. triuncheus, S. extensa, S. Contra, S. californica, Hort., are very similar and probably of the same parentage.

54. Douglasii, Hook. Fig. 3669. Shrubs, 6 ft. high, with reddish brown, tomentose branches; lvs. oblong to oblong-lanceolate, rounded or acutish at both ends, unequally serrate above the middle, densely white-tomentose beneath, 1-2½ in. long; fls. deep pink, in dense, rather narrow or sometimes broad panicles, 4-8 in. long; lvs. twice as long as the obovate petals; sepals reflexed. Plants of this species are very similar, with reddish-brown branches. July-Aug. Of garden origin. H.F.5:24.

55. tomentosa, Linn. HARDHACK. STEEPLEBUSH. Shrubs, 4 ft. high, with upright, brown, tomentose branches; lvs. ovate to oblong-ovate, acute, unequally and often doubly serrate, densely white-tomentose beneath, 1-2½ in. long; fls. deep pink or purplish purple, in narrow dense panicles, brownish tomentose and 5-8 in. long; lvs. somewhat longer than the obovate petals; sepals reflexed. Garden hybrid. July-Sep. Nova Scotia to Ga., west to the same parentage.

S. Aitchisonii, onii, Hook. Fig. 3669. Medum-sized shrub with slender, arching branches; lvs. small, ovate, obtuse, entire or crenate above the middle, quite glabrous, fls. white, in hemispherical, mostly corymbose heads. Chinese. = S. gregata, S. Springfrid, S. gregata, S. nevada. F.H. 5:24.

S. Adoxa, Herneq. (S. Douglasii x S. salicifolia), Shrubs, 6 ft. high, with brown pubescent branches; lvs. oblong to oblong-lanceolate, acute, sharply and often doubly serrate, especially in the lower third, usually grayish-tomentose beneath, at least when young, sometimes almost glabrous at length, 2-3 in. long; fls. bright pink, in 5-8 in. long, tomentose or tomentulose panicles usually rather narrow and dense. July-Aug. Of garden origin. H.F. 5:24. F.E. 18:631. = S. Lando, S. biflora, S. triuncheus, S. extensa, S. Contra, S. californica, Hort., are very similar and probably of the same parentage.

54. Douglasii, Hook. Fig. 3669. Shrubs, 6 ft. high, with reddish brown, tomentose branches; lvs. oblong to oblong-lanceolate, rounded or acutish at both ends, unequally serrate above the middle, densely white-tomentose beneath, 1-2½ in. long; fls. deep pink, in dense, rather narrow or sometimes broad panicles, 4-8 in. long; lvs. twice as long as the obovate petals; sepals reflexed. Plants of this species are very similar, with reddish-brown branches. July-Aug. Of garden origin. H.F.5:24.

55. tomentosa, Linn. HARDHACK. STEEPLEBUSH. Shrubs, 4 ft. high, with upright, brown, tomentose branches; lvs. ovate to oblong-ovate, acute, unequally and often doubly serrate, densely white-tomentose beneath, 1-2½ in. long; fls. deep pink or purplish purple, in narrow dense panicles, brownish tomentose and 5-8 in. long; lvs. somewhat longer than the obovate petals; sepals reflexed. Garden hybrid. July-Sep. Nova Scotia to Ga., west to the same parentage.

S. Aitchisonii, onii, Hook. Fig. 3669. Medum-sized shrub with slender, arching branches; lvs. small, ovate, obtuse, entire or crenate above the middle, quite glabrous, fls. white, in hemispherical, mostly corymbose heads. Chinese. = S. gregata, S. Springfrid, S. gregata, S. nevada. F.H. 5:24.

S. Adoxa, Herneq. (S. Douglasii x S. salicifolia), Shrubs, 6 ft. high, with brown pubescent branches; lvs. oblong to oblong-lanceolate, acute, sharply and often doubly serrate, especially in the lower third, usually grayish-tomentose beneath, at least when young, sometimes almost glabrous at length, 2-3 in. long; fls. bright pink, in 5-8 in. long, tomentose or tomentulose panicles usually rather narrow and dense. July-Aug. Of garden origin. H.F. 5:24. F.E. 18:631. = S. Lando, S. biflora, S. triuncheus, S. extensa, S. Contra, S. californica, Hort., are very similar and probably of the same parentage.

54. Douglasii, Hook. Fig. 3669. Shrubs, 6 ft. high, with reddish brown, tomentose branches; lvs. oblong to oblong-lanceolate, rounded or acutish at both ends, unequally serrate above the middle, densely white-tomentose beneath, 1-2½ in. long; fls. deep pink, in dense, rather narrow or sometimes broad panicles, 4-8 in. long; lvs. twice as long as the obovate petals; sepals reflexed. Plants of this species are very similar, with reddish-brown branches. July-Aug. Of garden origin. H.F.5:24.

55. tomentosa, Linn. HARDHACK. STEEPLEBUSH. Shrubs, 4 ft. high, with upright, brown, tomentose branches; lvs. ovate to oblong-ovate, acute, unequally and often doubly serrate, densely white-tomentose beneath, 1-2½ in. long; fls. deep pink or purplish purple, in narrow dense panicles, brownish tomentose and 5-8 in. long; lvs. somewhat longer than the obovate petals; sepals reflexed. Garden hybrid. July-Sep. Nova Scotia to Ga., west to the same parentage.

S. Aitchisonii, onii, Hook. Fig. 3669. Medum-sized shrub with slender, arching branches; lvs. small, ovate, obtuse, entire or crenate above the middle, quite glabrous, fls. white, in hemispherical, mostly corymbose heads. Chinese. = S. gregata, S. Springfrid, S. gregata, S. nevada. F.H. 5:24.
and V&.

what unitecl With the petals; bbellum quadrate-oblong, sepals free, r,arrowly lanceolate, the upper one some­
crisp, obtuse or yellowish above. n0t contracted in the middle, wavy­

cent, bearing 4-5 lanceolate or oblanceolate lvs. near

leafy belo'v: spike 2--4 in. long: fIs. white or greerJsh, the base: fis. small; sepals and petals 'white, lateral

below and dilated at the apex, crisp. July, Aug. N. Y. to Fla. and La.

bb. Lvs. mostly withered at the flowering-time.

simplex, Gray. Root a solitary oblong tuber: lvs.
basal, ovate to oblong, short, absent at the flowering­time: st. very slender, 5-9 in. high: spike about 1 in. long: fis. white; labellum obovate-oblong, eroded and crisp.

gräulis, Beck. Roots clustered: lvs.
basal,obovate to ovate-lanceolate, petioled, mostly dying before the flowering-time: st. 8-18 in. high, bearing a slender, many­

fil., 1-sided or twisted spike: fis. white, fragrant; sepals longer than the labellum, the lateral ones free; labellum oblong, dilated in front, crenulate or wavy-crisp, thick and green in file middle. Aug.–Oct.

S. obertas, N.E. Br. (Neottia speciosa, Jacq.)= Stenorrhyzachus. HEINRICH HASSELBRING.

SPIRODÉLÀ: treated under Lemna.

SPIRONÉMA (name means spiral thread, alluding to structure of the filaments). Commelíaceae. One species, S. fragrans, Lindl., is sometimes listed abroad for hothouse culture, an odd herb from Mex. Sometimes raised under glass for the delicious fragrance and for the trans­

parency of its parts: st. fleshy, 2 ft. and more high: lvs. oblong-lanceolate, sheath­
ing, parallel-veined: fis. white, clustered and nearly sessile in a terminal branched panicle, small, the petals paleaceous and diaphanous, the 3 sepals greenish; stamens 6, B.R. 20-47, where it is written that the plant will be cherished “because its thin and delicate tissue allows the hidden motion of its fluids and the subtle texture of its fracturing organs to be watched with ease and pleasure.” It is very little known as a horticultural subject.

SPONDIAS (from a Greek word used by Theo­

phrastus). Anacardiaceae. A small genus of tropical trees, allied to the mango (Mangifera indica) and the cashew (Anacardium occidentale), cultivated for their fruits and often used for hedges because of the reach­

ness with which large branches, when cut and used as posts, take root and grow.

Leaves usually clustered toward the ends of the branchlets, alternate, imparipinnate, with opposite lts.: fis. polygamous, small, shortly pedicellate, dis­
poped in racemes or panicles; calyx small, deciduous, with 4 or 5 valvate segms.; petals 4 or 5, valvate; stamens 8-10, inserted at the base of the disk; styles 3-5, free at the apex; ovary sessile, 3-5-loculed, with 1 ovule in each locale: fr. a fleshy drupe, with a 1-5-loculed woody endocarp.—Species about 12, several of which are common in the W. Indies, Mex., and elsewhere in Trop. Amer.; one species comes from the Society Isls., another from India.

cytherea, Sonn. (S. dulcis, Forst.). OAHAEITHE-APPLE.
POMME-CYthereE. CAAJA MANGA. VI or EVI in Tahiti.

Fig. 3670. Erect, stately tree, with rather stiff branches. up to 60 ft. in height: lvs. 8-12 in. long; lfts. 11-13, oval­

long, 2½-3 in. long. 1½-2 in. broad, acuminate, serr­
rate: panicle 8-12 in. long; fis. white: fr. oval or oblo­
void, golden yellow, up to 3 in. long, the seed about 1½ in. long, oval, echinate. Society Icas, but widely spread in the tropics.

**Mombin, Linn. (S. pitiparna, Linn.).** *Spouand Plnm.* Paraguay--Paraguana. Curiously, Small tree, sometimes spreading, but with up to 25 ft. in height; lvs. 5-8 in. long; lfts. 16-21, oblong-elliptic, 1-1½ in. long, ½ in. broad, usually somewhat symmetrical, acute or blunt, subacute or serrulate; panicle ½-1 ft. long, the lvs. yellowish white: fr. ovoid, yellow, 1-1½ in. long, the seed oblong-ovate, ½-5 in. long, smoothish, Cosmopolitan in the tropics.

**Pitanga, Linn. (S. Monimis, Jacq., not Linn.).** *Hooq Plum. Msmbin.* Joso. Caia. Tall, handsome tree, up to about 60 ft. in height: lvs. 8-12 in. long; lfts. 7-17, ovate-lanceolate or lanceolate, 2½-4 in. long, 1-1½ in. broad, subacute or serrulate; panicle ½-1 ft. long, the lvs. yellowish white: fr. ovoid, yellow, 1-1½ in. long, the seed oblong-ovate, ½-5 in. long, smoothish. Cosmopolitan in the tropics.

**Pitanga, Linn. (S. monimis, Jacq., not Linn.).** *Hooq Plum. Mombin.* Joso. Caia. Tall, handsome tree, up to about 60 ft. in height: lvs. 8-12 in. long; lfts. 7-17, ovate-lanceolate or lanceolate, 2½-4 in. long, 1-1½ in. broad, subacute or serrulate; panicle ½-1 ft. long, the lvs. yellowish white: fr. ovoid, yellow, 1-1½ in. long, the seed oblong-ovate, ½-5 in. long, smoothish. Cosmopolitan in the tropics.

**Pitanga, Linn. (S. Monimis, Jacq., not Linn.).** *Hooq Plum. Mombin.* Joso. Caia. Tall, handsome tree, up to about 60 ft. in height: lvs. 8-12 in. long; lfts. 7-17, ovate-lanceolate or lanceolate, 2½-4 in. long, 1-1½ in. broad, subacute or serrulate; panicle ½-1 ft. long, the lvs. yellowish white: fr. ovoid, yellow, 1-1½ in. long, the seed oblong-ovate, ½-5 in. long, smoothish. Cosmopolitan in the tropics.

**Pitanga, Linn. (S. Monimis, Jacq., not Linn.).** *Hooq Plum. Mombin.* Joso. Caia. Tall, handsome tree, up to about 60 ft. in height: lvs. 8-12 in. long; lfts. 7-17, ovate-lanceolate or lanceolate, 2½-4 in. long, 1-1½ in. broad, subacute or serrulate; panicle ½-1 ft. long, the lvs. yellowish white: fr. ovoid, yellow, 1-1½ in. long, the seed oblong-ovate, ½-5 in. long, smoothish. Cosmopolitan in the tropics.

**Tuberose, Arruda. Linn. Unm. Linn. Low, spreading tree, 25 ft. in height, with crooked roots: lvs. 4-6 in. long; lfts. 5-9, ovate-ovate, 1-1½ in. long, ½-1 in. broad, sharply acute to acuminate, cordate at base, entire: panicle 4-6 in. long, lfts. whitish: fr. ovate, light yellow, 1½ in. long, the seed oblong-ovate, slightly flattened, ½-5 in. long, smoothish. Brasil.**

*Cultivation and uses.*

The Otahatic-apple, *S. clyerea,* is said to have been introduced to Jamaica in 1782, and again in 1782 by the famous Captain Bligh, who brought the broad-fruit from Tahiti to the West Indies. It has not become popular in Cuba, nor is it very extensively grown on the mainlands of tropical America. In South Florida it succeeds well, and fine specimens can be seen at Miami and other points. In California it has not yet thrived, so far as known, and seems to be too tender for successful culture in any but the most favored locations. Some of the early travelers who visited Polynesia spoke of it in very high terms, and more recently it has been recommended as a worthy of cultivation by numerous writers. Firminger, however, likens it to a "very bad mango." Probably a great deal depends on the variety. At its best the fruit is the size of a lemon; it is of deep golden yellow color when ripe, aromatic, with a thin but tough skin surrounding the soft, juicy, yellow pulp. The seed is large and oval, furnished with long woody spines over its entire surface. The flavor is sprightly, subacid, aromatic, suggesting the pineapple, but sometimes resinous and disagreeable. It is eaten out of hand, and also used to prepare jams and preserves.

The Spanish plum, *S. Mombin,* is much more common in tropical America, and occurs in a large number of varieties, some of which are of excellent flavor and quality. In Cuba, where this fruit is cultivated, the different varieties are distinguished by the addition of such words as rota (red), amarilla (yellow), and the like. In Brazil the species seems to be a little known, but in Mexico and Central America it is widely grown. It is successfully cultivated in South Florida, but so far as known has never thrived in California, though it may be possible to grow it successfully in favored locations. The tree, which is much smaller than the Otahatie-apple, is deciduous during a portion of the year, as are the other species.

The fruit is oval, about an inch long, usually purplish red in color, with a bright yellow, very juicy pulp of aromatic, subacid flavor. It is used like the Otaheite-apple.

The hog-plum, *S. lutea,* is one of the least esteemed of the genus. Its fruits are slightly larger than those of *S. Mombin,* but of a rank, pungent flavor which is not especially agreeable. Jumelle says that it makes an excellent refreshing drink. The tree is handsome, and handsome, and is a conspicuous feature of many Cuban landscapes. *S. panama,* the hog-plum or amra of India, is scarcely known in America. Indian writers, who do not usually speak highly of it, state that it is used for pickles, preserves, and tarts. Firminger advises using it as a stock for *S. clyerea.*

The imbú of Brazil, *S. tuberosa,* is a little-known species introduced to the United States in 1914 by the Bureau of Plant Industry. Previous to this time it seems to have been unknown outside of its native home, but on the dry lands of interior northeastern Brazil (states of Bahia, Pernambuco, and so on) it is exceedingly abundant and the fruits are highly esteemed by the natives. Its tuberous roots are an adaptation to arid regions. The fruits are the size of large plums, with a pale yellow skin, soft, juicy pulp and a large, nearly smooth seed. The flavor slightly resembles that of a sweet orange, and is very agreeable. An excellent jelly is made from this species, and also a sweet custard called imbuzada, prepared by mixing the strained and sweetened pulp with boiled milk. For eating out of hand it is probably superior to the other species, with the exception of the best varieties of the Spanish plum.

This genus is of very simple culture. All the species are easily propagated by cuttings of large wood, which may be set in permanent locations immediately upon removal from the parent tree. Seeds can easily be grown in flats of light soil, covering them to the depth of an inch. They usually germinate within four to six weeks. Most of the species seem adapted to a variety of soils. They can readily be transplanted, but this is not often practised in this country because of the ease with which cuttings can be grown. Improvement of all the species should be carried on by means of selection.

F. W. Popenoe.

**Spore,** a reproductive detached cell of a cryptogamous or so-called flowerless plant, not containing an embryo as does a seed. Spores are the reproductive bodies of ferns, mosses, club-mosses, liverworts, fungi, and similar plants. They are of interest to the plant-grower mostly as the means of propagating ferns. For description, see *Ferns and Fungi:* also the articles on *Ferns,* in Vols. III, V, VI. For propagation by spores, see the discussion under *Ferns,* page 1221, Vol. III.

**Sporobolus** (Greek, *spora,* seed, and *ballein,* to cast forth, referring to the grain readily falling from the spikelet). *Gramineae.* *Dropsed.* Spikelets 1-fl., awnless, usually small, in narrow or open panicles. About 80 species, chiefly of Temp. and Trop. Amer., of little value. *S. cryptandrus,* Gray, a widely distributed annual, is considered a good forage grass; *S. Wrightii,* Munro, *Saccation,* of the alkali lands of the S. W. and of Mex., and *S. airoides,* Torr., an allied species. *S. Wrightii,* Link, a slender annual with minute spikelets in a delicate panicle, is offered as an ornamental by some seedsmen under the name of *Agrostis muniflora.* The species are little known horticulturally. A. S. Hirtencohn.

**Spraguea** (named for Isaac Sprague, of Cambridge, Mass., botanical artist, collaborator of Asa Gray). *Portulacaceae.* Dwarf half-hardy, perennial herbs, well adapted to the rockery: lvs. radical, spatulate, somewhat fleshy; the cauline minute, alternate.
stipules small and scarious: fls. ephemeral, in dense, scorioid spikes, umbellately clustered on scape-like peduncles; sepals 2, orbiculate-cordate, membranaceous-hyaline, persistent; petals 4; stamens 3; ovary free; caps. membranaceous, rounded-compressed, 2-valved; seeds black and shiny. — One, possibly 2 species, W. N. Amer.

UMBELLÀTÀ, Torr. Sts. several, simple, erect, 2-12 in. high: radical lvs. spatulate or ob lanceolate; the cauleine similar but smaller: fls. white, tinged rose, in a dense capitulate umbel of nearly sessile spikes; sepals connate; petals oblong-ovate. Late summer. Sierra Nevada, at 3,000-10,000 ft. altitude, from the Yosem ite valley to the British boundary, usually in sandy dry soils. B. M. 5143. May be treated as an annual. Var. caudicifera, Gray, is a subalpine form in which the caudex-like branches extend for a year or more (lvs. below dying away) and are at length terminated by scapes an inch or so in length. Desirable for rockwork and edgings.

F. TRACY HUBBARD.†

SPRING: Diseases and Insects, page 1057, Vol. II.

SPREKÈLIA (J. H. von Spreckelsen, of Hamburg, who sent the plants to Lindley). Amaryllidaceæ. JACOBÀN LILY. Half-hardy bulbous plants, generally grown in the greenhouse, often known as amaryllis: lvs. appearing late, strap-shaped-linear; scape hollow, cylindrical, 4-6 ft. long: fls. large, showy; perianth gaping, tube narrow, about 2 in. long, bifid at the tip; pedicel erect: perianth bright yellow to red, tubular, 3-valved.-One species, Mex. For cultivation, see Hippeastrum, with which these plants are sometimes confused.

F. TRACY HUBBARD.†

SPRING-GARDENING. The gardening instinct is at its height in spring. The turn of the season invites it, and the wealth of quick-growing plant-material is great. On the plant-growing side, nothing need be said here and the wealth of quick-growing plant-material is great.

SPRAYING: Diseases and Insects, page 2589, Vol. V.

SPURRY (Spergula sativa, which see) has long been grown in Germany, France, Holland, and Belgium, where it has been known as a soil-renovator and as a forage crop was early recognized. It is an annual, and when sown in the spring matures seed in ten to twelve weeks from time of sowing. This plant possesses special value as a renovator for sandy soils. It has long been used by the farmers of Holland to hold in place the shifting sands along the seashore. So well adapted is it to sand that it has been termed "the clover of sandy lands." It is not recommended for the American farmer except where the soil is so poor that other plants fail. In such circumstances it may be used as a cover-crop to plow under. The seed may be sown any time from April to August, but in orchards it would better be sown in July. Sow at the rate of six quarts to the acre. The seed being small, it should be lightly harrowed in upon a well-fitted soil. It is very persistent in the production of seed, and upon fertile soils it will maintain itself for several years unless thorough cultivation is given. Where soils are in fair condition and other crops will grow, it is doubtful whether spurry has any place. Sometimes written spurrey.

F. TRACY HUBBARD.†

STACHYS (from an old Greek name applied by Dios corides to another group of plants, coming from the word for spike). Labiatae. WOUNDWORT. Tall perennial herbs or diffuse annuals, rarely subshrubs or small shrubs, both greenhouse and hardy plants, little known to gardeners.

Leaves very entire or dentate, the floral lvs. similar or reduced to bracts: floral whorls 2- to many-fl., axillary or arranged in terminal spikes: fls. sessile or very short-pedicelled, purplish, scarlet, pale yellow, or white, small or sometimes showy; calyx tubular-campanulate, 5-10-nerved, 5-toothed; corolla-tube cylindrical included or exerted, limb 2-lipped, the posterior often villous outside; stamens 4: nutlets ovoid or oblong. — About 270 species, mainly in the temperate regions but a few in the tropical and colder regions, scattered all over the world. The arrangement followed in the sections and sequence of species is that of Briquet in Engler & Prantl, Pflanzenfamilien, IV. 4c: 260. Very few of the species are cult., although there are several with showy spikes. They are usually found in moist or even wet places when growing wild. A tuber-bearing species (S. sieboldii) has come into notice as a kitchen-garden plant.

F. TRACY HUBBARD.†
INDEX.

1. densiflora, Benth. (Betonica incana, Ait.). Perennial, 1 1/4 ft. high; sts. erect, hisrate; lvs. 2-3 in. long, petiolate, oblong-oblong, obtuse, crenate, base cordate, soft-pilose or more or less villous; floral lvs., lowest corolla-cordate, short-petioled: floral whorls approximate in a dense spike, lower whorls remote: calyx campanulate: corolla villos: white-lanate beneath; floral lvs. narrow lanceolate, obtuse, base cordate at the base, 3-6 in. long; upper lvs. distant, sessile, oblanceolate, acute: fls. purple, in a dense, terminal spike. July. Eu., Asia Minor. —Rarely found as an escape in this country, and once cult. for use in domestic medicine. Useful for ornament, and now advertised for that purpose. There are white-flld. forms of the species offered in the trade under the names of Stachys albitflora and S. Betonica albiflora and there is also a large-flld. form with soft rose-colored fls. known as S. Betonica grandiflora.

2. officinalis, Franch. (S. Betonica, Benth. Betonica officinalis, Linn.). Brevov. Fig. 3671. A hardy perennial herb 1-3 ft. high: lower lvs. long-petioled, ovate-oblong, obtuse, crenate, base cordate at the base, 3-6 in. long; upper lvs. distant, sessile, oblanceolate, acute: fls. purple, in a dense, terminal spike. July. Eu., Asia Minor. —Rarely found as an escape in this country, and once cult. for use in domestic medicine. Useful for ornament, and now advertised for that purpose. There are white-flld. forms of the species offered in the trade under the names of S. Betonica albitflora and S. Betonica grandiflora.

3. grandiflora, Benth. (Betonica rösca, Hort. B. speciosa, Hort. B. grandiflora, Willd.). A hardy perennial about 1 ft. high: lower lvs. broadly ovate, obtuse-crenate, long-petioled, base broadly heart-shaped: the upper gradually smaller, nearly similar and sessile, the uppermost bract-like: fls. violet, large and showy, the curving tube about 1 in. long and 3 or 4 times surpassing the calyx, in 2-3 distinct whorls of 10-20 fls. each. Asia Minor, etc. B.M. 700. G.M. 53:628. Var. robusta, Hort. (Betonica grandiflora robusta, Hort. B. speciosa robusta, Hort.), is said to have tufts of corrugated lvs., to grow 18 in. high and spikes 3 in. long of rosy pink fls.

290. Var. superba, Hort. (Betonica grandiflora superba, Hort. B. superba, Hort.), is said to have showy spikes of intense mauve or a rich shade of purple-violet fls. There is a white variant of this known in the trade as Betonica grandiflora alba.

4. longijflora, Benth. (Betonica orientalis, Linn.). A hardy perennial herb about 1 ft. high, densely villous: lower lvs. petiolate, oblong-lanceolate, obtuse, crenate, deeply cordate at the base, 4-6 in. long; the upper lvs. similar in shape but sessile, those of the infl. bract-like: fls. reddish purple to pink, in a cylindrical, somewhat interrupted spike about 1/2 ft. long. July. Caucasus.—Briot in Engler & Prantl’s Pflanzenfamilien has adopted macrostachys as the specific name, basing his name on Betonica macrostachys, Wender, but authorities differ as to the identity of Wender’s material, hence his name on Betonica macrostachys, Wender, but authorities differ as to the identity of Wender’s material, hence his name on Betonica macrostachys, Wender, but authorities differ as to the identity of Wender’s material, hence his name on Betonica macrostachys, Wender, but authorities differ as to the identity of Wender’s material, hence his name on Betonica macrostachys, Wender, but authorities differ as to the identity of Wender’s material, hence his name on Betonica macrostachys, Wender, but authorities differ as to the identity of Wender’s material, hence his name on Betonica macrostachys, Wender, but authorities differ as to the identity of Wender’s material, hence his name on Betonica macrostachys, Wender, but authorities differ as to the identity of Wender’s material, hence his name on Betonica macrostachys, Wender, but authorities differ as to the identity of Wender’s material, hence his name on Betonica macrostachys, Wender, but authorities differ as to the identity of Wender’s material, hence his name on Betonica macrostachys, Wender, but authorities differ as to the identity of Wender’s material, hence his name on Betonica macrostachys, Wender, but authorities differ as to the identity of Wender’s material, hence his name on Betonica macrostachys, Wender, but authorities differ as to the identity of Wender’s material, hence his name on Betonica macrostachys, Wender, but authorities differ as to the identity of Wender’s material, hence his name on Betonica macrostachys, Wender, but authorities differ as to the identity of Wender’s material, hence his name on Betonica macrostachys, Wender, but authorities differ as to the identity of Wender’s material, hence his name on Betonica macrostachys, Wender, but authorities differ as to the identity of Wender’s material, hence his name on Betonica macrostachys, Wender, but authorities differ as to the identity of Wender’s material, hence his name on Betonica macrostachys, Wender, but authorities differ as to the identity of Wender’s material, hence his name on Betonica macrostachys, Wender, but authorities differ as to the identity of Wender’s material, hence his name on Betonica macrostachys, Wender, but authorities differ as to the identity of Wender’s material, hence his name on Betonica macrostachys, Wender, but authorities differ as to the identity of Wender’s material, hence his name on Betonica macrostachys, Wender, but authorities differ as to the identity of Wender’s material, hence his name on Betonica macrostachys, Wender, but authorities differ as to the identity of Wender’s material, hence his name on Betonica macrostachys, Wender, but authorities differ as to the identity of Wender’s material, hence his name on Betonica macrostachys, Wender, but authorities differ as to the identity of Wender’s material, hence his name on Betonica macrostachys, Wender, but authorities differ as to the identity of Wender’s material, hence his name on Betonica macrostachys, Wender, but authorities differ as to the identity of Wender’s material, hence his name on Betonica macrostachys, Wender, but authorities differ as to the identity of Wender’s material, hence his name on Betonica macrostachys, Wender, but authorities differ as to the identity of Wender’s material, hence his name on Betonica macrostachys, Wender, but authorities differ as to the identity of Wender’s material, hence his name on Betonica macrostachys, Wender, but authorities differ as to the identity of Wender’s material, hence his name on Betonica macrostachys, Wender, but authorities differ as to the identity of Wender’s material, hence his name on Betonica macrostachys, Wender, but authorities differ as to the identity of Wender’s material, hence his name on Betonica macrostachys, Wender, but authorities differ as to the identity of Wender’s material, hence his name on Betonica macrostachys, Wender, but authorities differ as to the identity of Wender’s material, hence his name on Betonica macrostachys, Wender, but authorities differ as to the identity of Wender’s material, hence his name on Betonica macrostachys, Wender, but authorities differ as to the identity of Wender’s material, hence his name on Betonica macrostachys, Wender.
9. **alpina**, Linn. Herbaceous, tall: st. erect, pilosely somewhat lanate; lvs. petioled, ovate, serrate-crenate, base cordate, both surfaces green or slightly canescent beneath; floral lvs. narrower, gradually smaller: floral whorls all remote, 10-15-fld.: calyx lanate, teeth ovate-lanceolate, very acute, spinose; corolla pink, spotted with purple, hairy; scarcely longer than the calyx. Himalaya region and N. Asia.—There is an older *S. sericea* (of Cavanilles), but its botanical status is unknown. It is a native of Chile.

**Section III. Eustachyos.**

**Subsection GENEROS.**

12. **Sieboldii**, Miq. *S. affinis*, Bunge, not Fresenius. *S. tuberifera*, Naudin. Chohog. Chinese or Japanese Artichoke. Known under the name *S. japonica* by the Chinese. Known as *S. sylvestris* in Europe. *S. Sieboldii*. (Fig. 3672) 2-3 in. long, slender, nodose, white, produced in great numbers just under the surface of the ground. China, Japan. G.C. III. 3:13.—Sent to France in 1882 from Pekin by Dr. Bretschneider, and about ten years ago intro. into this country. It iscult. for the crisp tubers, which may be eaten either raw or cooked. These tubers soon shrivel and lose their value if exposed to the air. The tubers withstand the winter in Cent. N. Y. without protection, so that a well-established plant takes care of itself and spreads. For history, chemical analyses, etc., see Cornell Bull. No. 37.

13. **aspera**, Mieh. Erect, usually strict, 3-4 ft. high, the st. retrose-hairy on the angles: lvs. oblanceolate to oblanceolate, mostly acuminate, serrate, petiolate; corolla small, glabrous, pale red or purple, in an interrupted spike. Caucasus and Asia Minor. Often grown as a bedding plant. Valuable for its very white herbage.

**Subsection RECtE.**

15. **recta**, Linn. *S. alyssoides*, Forsk.). Perennial: st. erect or ascending, about 2 ft. high; pilose: lvs. short-petioled, oblanceolate or lanceolate, obtuse, crenate, 1-1½ in. long, base rounded or narrowed, rugose, hairy: floral lvs. sessile: floral whorls about 10-fl., dist: calyx ovate-campanulate, hairy, teeth ovate, subspineous; corolla yellowish white, throat purplish, glabrous, twice as long as the calyx. S. Eu., Caucus. *Var. leucocarina*, Boiss. (S. leucocarina, Griseb.). Lvs. narrowly lanceolate, lower serrate, upper entire and linear: calyx somewhat seaboars, teeth as long as the tube. Caucus. **Subsection INFRACARLOES.**

16. **citrina**, Boiss. & Heldr. Subshrub, gray-canescence, pannose: lvs. 1-1½ in. long, all basal, long-petioled, elliptical, obtuse, base attenuate, entire or minutely crenulate; floral lvs. narrower: fls. in small terminal heads which are short-ovate, dense, the lower floral whors often subdistant and interrupted; calyx hirsute, campanulate; corolla sulfur-yellow, hirsute outside, included in the calyx. Greece, E.

**Subsection OILILE.**

17. **cirsica**, Pers. Fig. 3673. Slender prostrate pilose herb: lvs. about ½ in. long, petioled, ovate, very obtuse, broadly crenate, base rounded or subcordate; floral lvs. smaller: floral whors 2-4-fl., remote: calyx campanulate, hispid, teeth lanceolate, acute, subspiny; corolla pinkish white, twice as long as the calyx, the tube short-exserted. Medit. region.
STACHYS

STACHYS (Greek, spike and tail; in allusion to the form of the inflorescence). Stachydrus, formerly usually included in Thermophracta. Ornamental woodshrubs, not suited for their very early flowers and the handsome foliage.

Deciduous or evergreen shrubs or trees: Ivs. alternate, serrated, petioled; lfts. toothed; petals 4, imbricate; stamens 8 with slender filaments; ovary superior, incompletely 4-celled; style simple, with 4-lobed stigma: fr. a 4-angled capsule, containing small berry. - Five or possibly 6 species in Japan, China, and the Himalayas.

The species in cultivation are handsome shrubs with spreading branches, with medium-sized bright green, generally ovate to ovate-oblong leaves and pale greenish yellow flowerers in long pendulous spikes appearing early in spring before the leaves from the axils along last year's branches. They have proved hardy in sheltered positions as far north as Massachusetts, but the flower-buds which are formed in autumn and remain naked during the winter are killed by the frost, if not protected. They grow well in moderately moist well-drained soil. Propagation is by seeds or usually by softwood cuttings under glass and by layers.

praecox, Sieb. & Zucc. Fig. 3674. Shrub, to 12 ft.; young branchlets reddish brown or chestnut-brown and lustrous: Ivs. elliptic-ovate to ovate-lanceolate, acuminate, rounded at the base, serrate with somewhat spreading teeth, glabrous and lustrous beneath or slightly pubescent on the veins, 3-6 in. long; racemes 2-3 in. long: fls. campanulate, ½ in. long; style shorter than petals: fr. globose, ½ in. across, greenish yellow with red cheek. - Stachys praecox, Sieb. & Zucc. is offered in the trade, probably a hybrid form of S. grandiflora.

F. TRACY HUBBARD.

STANDARDS OF COLOR 3221

STACHYURUS (Greek, spike and tail; in allusion to the form of the inflorescence). Stachydrus, formerly usually included in Thermophracta. Ornamental woodshrubs, not suited for their very early flowers and the handsome foliage.

Deciduous or evergreen shrubs or trees: Ivs. alternate, serrated, petioled; lfts. toothed; petals 4, imbricate; stamens 8 with slender filaments; ovary superior, incompletely 4-celled; style simple, with 4-lobed stigma: fr. a 4-angled capsule, containing small berry. - Five or possibly 6 species in Japan, China, and the Himalayas.

The species in cultivation are handsome shrubs with spreading branches, with medium-sized bright green, generally ovate to ovate-oblong leaves and pale greenish yellow flowerers in long pendulous spikes appearing early in spring before the leaves from the axils along last year's branches. They have proved hardy in sheltered positions as far north as Massachusetts, but the flower-buds which are formed in autumn and remain naked during the winter are killed by the frost, if not protected. They grow well in moderately moist well-drained soil. Propagation is by seeds or usually by softwood cuttings under glass and by layers.

praecox, Sieb. & Zucc. Fig. 3674. Shrub, to 12 ft.; young branchlets reddish brown or chestnut-brown and lustrous: Ivs. elliptic-ovate to ovate-lanceolate, acuminate, rounded at the base, serrate with somewhat spreading teeth, glabrous and lustrous beneath or slightly pubescent on the veins, 3-6 in. long; racemes 2-3 in. long: fls. campanulate, ½ in. long; style shorter than petals: fr. globose, ½ in. across, greenish yellow with red cheek. - Stachys praecox, Sieb. & Zucc. is offered in the trade, probably a hybrid form of S. grandiflora.

F. TRACY HUBBARD.
STANHOPEA

STANHOPEA (named for the Earl of Stanhope, president of the Medico-Botanical Society, London). Orchidaceae. Epiphytic orchids easily grown and very interesting, but the fugacious character of their flowers has been unfavorable to their extensive cultivation.

Pseudobulbs clustered on the short rhizome, sheathed with scales and each bearing a single large plaited leaf. The flowers are produced on the thick scapes, which bore their way through the material in which they are planted and emerge from the bottom of the basket, large, fragrant, and curiously formed; sepals and petals usually reflexed, subequal or the petals narrower; labellum remarkably transformed, basal part or hypochil boat-shaped or saccate, often with two horns on the upper margin, passing gradually into the mesochil, usually fleshy and keeled but not saccate, base of the labellum continuous with the long-winged column.—About 50 species inhabiting Trop. Amer. from Mex. to Brazil. The flowers expand with a perceptible sound early in the morning.

Stanhopeas enjoy a shady, moist location. A temperature of 60 to 80°F. at night and 70 to 75°F. during the day should be maintained in winter, with a gradual advance of 10°F. toward midsummer. They should be grown suspended from the roof in orchid cubicles or terracotta baskets with large openings at the bottom, and adequate drainage is used it should be placed in such a manner that it will not interfere with the exit of the pendulous flower-scapes. Equal parts chopped sphagnum and peat fiber forms a good compost. By severing the rhizome here and there between the old pseudobulbs, new growths will be sent up and thus the stock may be increased. (R. M. Grey.)
INDEX.

S. Bucephalus, 5.

**KEY TO THE SPECIES.**

A. Labellum with an excavated or saccate base and a terminal lobe.

B. Mesochilus and pleuridia wanting: 1. aurea

BB. Mesochilus and pleuridia present: 2. Bucephalus

CC. Hypochil boat-shaped, short and sessile: 3. oculata

DD. Fls. pale yellow: 4. platyceras

EE. The hypochil purple or crimson: 5. Bucephalus

FF. Not purple; middle lobe triangular: 6. insignis

GG. The hypochil not spotted; purple ple; middle lobe ovate: 7. Shuttleworthii

HH. The hypochil with an excavated or saccate base and a plane terminal lobe: 8. devoniensis

II. Saccata, 11.

AA. Labelum reduced to a saccate pouch: 12. eburneia

1. *eburnea*, Lindl. (*S. grandiflora*, Lindl *S. calcicola*, Hort.). Pseudobulbs conical, 1½ in. long; Ivs. leathery, 8–12 in. long; scape pendulous, with small bracts 2–3-fld.: fls. 5 in. across, ivory-white; sepals broadly ovate, 3 in. long, solid, fleshy, excavated at the base and bearing 2 hooked horns over the mouth, spotted above with reddish purple; column pale green, with broad wings toward the apex; Guiana. B.M. 3359. B.R. 1529. I.H. 14: 531 (as var. aurea, Lindl.). Fls. golden yellow, with 2 dark purple; middle lobe orange; sepals Apted-marked with large crimson spots; lateral sepals round-oblong, concave, acute; petals lanceolate, revolute, the cavity in the base of the labellum deep velvety purple. Aug. Mex. and S. B.M. 5289. Gn. 51, p. 28. C.O. 2. Var. *aurea*, Hort. (*S. aurea*, Lodd.). Fls. golden yellow, with 2 dark spots on the hypochil. *Fragrant.*

2. *Wardii*, Lodd. Pseudobulbs 2 in. long; Ivs. large, broad, and leathery; fl.-st. 9 in. long. Bearing 3–9 fls., which are bright yellow to golden orange, spotted with crimson; upper part of the labellum colored like the sepals. B.M. 3359. B.R. 1529. I.H. 14: 531 (as var. calcicola, Lindl.). L.B.C. 15:1414 (as Ceratochilus grandiflorus).

3. *oculata*, Lindl. (*S. guttulata*, C. Koch). Fig. 3676. Lvs. ovate, with a blade 1½ ft. long; scape 1 ft. long, clothed with scarios yellow brown sheaths, 3–6-fl.; fls. 5 in. across, very fragrant, pale yellow, thickly spotted with purple; sepals 3 in. long, reflexed; petals half as large; hypochil narrow, white, spotted with crimson and having 2 large dark brown spots near the base. Mex. B.M. 5300. B.R. 1800. L.B.C. 18:1764 (as Ceratostilus oculatus). S.H. 2, p. 435. G.C. III. 19:264; 43: 19; 44:115; 52:121. J.F. 3:369–10. C.O. 6.—There are several varieties, differing in color and markings. Fig. 3676 is from an article by Safford on "Sacred Flowers of the Aztecs," named "the serpent-head orchid," in The Volta Review.

4. *platyceras*, Reichb. f. Pseudobulbs and Ivs. as in *S. Bucephalus* but stouter: scape 2-fl., with ovate acute bracts half as long as the ovary; fls. 7 in. across, pale yellow, with numerous ring-shaped spots and blotches of purple; sepals triangular-oblong; petals broadly linear, acute; hypochil boat-shaped, 2½ in. long; horns 1 in. long, broad, pointing forward, parallel with the tongue-shaped middle lobe; the hypochil is deep purplish crimson inside, paler and spotted outside, the upper part of the labellum colored like the sepals. Colombia. Gn. 33:534.

5. *Bucephalus*, Lindl. (*S. grandiflora*, Reichb. f.). Pseudobulbs crowded, rugose; Ivs. petioled, 9 in. long, pointed; the pendulous raceme bearing 4–6 large, tawny orange fls. marked with large crimson spots; sepals and petals reflexed, the former broad; lower part of the labellum curved, boat-shaped, bearing 2 curved horns and a broad fleshy middle lobe; column green and white, spotted with purple. Aug. Mex. Peru. B.M. 5278; 8517. B.R. 31:24.—Fls. very fragrant. Distinguished by its very short ovaries.

6. *insignis*, Frost. Figs. 3677, 3678. Pseudobulbs clustered; Ivs. broadly lanceolate; scape 6 in. long, covered with dark brown scales, 2–4-fl.: fls. 5 in. across, dull yellow, spotted with purple; sepals broad, concave; petals narrow, narrow; hypochil globose, almost wholly purple inside, heavily spotted outside, horns 1 in. long, falcate, middle lobe coruscate, keeled. July–Oct. Brazil. B.M. 2948, 2949. B.R. 1837. L.B.C. 20:1985. Gng. 2:117 (from which Fig. 3677 is adapted). G.W. 12, p. 283.—Marked by broad wings of column.

7. *Shuttleworthii*, Reichb. f. Pseudobulbs large, conical, sulcate: Ivs. broadly oblong, acute; raceme pendulous, loose; Ivs. petioled, with large brown spots near the base; the middle lobe concave; column white, crimson; horns flattened, suberect, terminal lobe triangular; column white, green along the middle and spotted with purple in the inside. Colombia.

8. *devoniensis*, Lindl. (*S. maculosa*, Knowles & Westc.). Lvs. about 9 in. long; scape pendulous, 2–3-
fd.: fls. 5 in. across, pale brownish, with broad reddish brown blotches; sepals oblong to oval-oblong, obtuse; petals narrow; hypochil rounded, ovate, purple, horns incurved, middle lobe ovate, channelled, obscurely 3-toothed. Peru. F.S. 10:974. F.C. 3:121.

11. saccata, Batem. Fls. smaller than those of the other species, greenish yellow, changing to deeper yellow at the bases of the segments, regularly speckled with brown; lateral sepals ovate-oblong, the upper one oblong-lanceolate; petals narrower, oblong, all reflexed; hypochil deeply saccate; horns flat, a little twisted, epichil flat. Mexico. Gen. & J.H. 8:270 (as S. radiata). Sepals and petals yellow, with numerous small purple blotches, the sepals elliptic-oblong, acute, the petals linear-oblong, acute, undulate; lip yellowish white, purple-spotted at base and on epichil, the hypochil with a dark black-purple eye-like spot on each side; the inside the same color, the epichil ovate-orbicular. Origin unknown.—S. persoonii, Rolfe. Fls. golden yellow; sepals obtuse, the dorsal oval, the lateral obliquely and broadly ovate; petals linear-oblong, revolute; lip with the hypochil suffused dark purple on sides; epichil obscurely ovate, purple-spotted. Peru. B.M. 8417.—S. radiata, Rolfe. Fls. ivory-white, faintly shaded yellow on lip; sepals elliptic-oblong, acute; petals lanceolate-oblong, acute, up with the hypochil pubescent inside, the epichil triangular, acute. Brazil.—S. Redigipila, Casse. Fls. about 6 in. across; sepals spreading, oblong-ovate, purplish-mottled below, maroon-mottled above; petals triangular-lanceolate, attenuate above, pale green; lip very fleshy, the hypochil suffused with maroon-purple below; the remaining blotched; epichil reticulated, triangular, obtuse, spotted with dull purple. Colombia. B.M. 7702. F.S. 41:492. G.C. III. 24:51.—S. Ruckeri, Lindl. Resemblance to S. Wards in color, but paler; hypochil obtuse; epichil stained pink. Mex. A.P. 6:831.—S. stenochilus, F. G. Lohm. & Krau. Seeds purplish white; petals apricot-colored, with purplish blotches; lip ivory-white at base, middle and interior parts yellow. Colombia.—S. Wasseriana, Hort. Var. saccata, S. tigrida. Fls. dull straw-color or pale orange; sepals obscuredly marked with wine-red, the spots on the petals larger. G.C. III. 38:102.

STANLEYA (named for Edward Stanley, Earl of Derby, 1779–1849). Cruicifera. Glauous glabrous perennials, similar to arrakis in habit, suitable for the flower-garden; lvs. undivided or pinnatifid; racemes elongated, strict, many-fl.: fls. yellow, buds elongated, sepals short, spreading; petals narrow, distinctly clawed: siliqua long-elliptiptate, slender, 4-cornered or rather terete, compressed, valves carinately 1-nerved.—About 10 species, Calif.

pinnata, Brit. (S. pinnatifida, Nutt.). Sts. flexuous; sepals very variable, sometimes pinnatifid; sepals lanceolate-oblong or obovate-oblong, rarely linear, almost entire; terminal segment larger: fls. deep golden yellow, according to D. M. Andrews. May–July. W. Kans. and Neb. to Texas and S. Calif., in dry clay or alkaline soils, against the column; sepals extended horizontally. Trop. Amer.—S. Liliacea, Rolfe. Sepals and petals creamy buff, the latter banded; lip ivory-white, the hypochil striped with dull maroon. Colombia. G.M. 36:192. G.C. III. 24:153.—S. Madagascariensis, Cogn. Fls. fragrant, 5–7 in. across; sepals and petals cream-white, the sepals with purple edge, the petals linear-oval, obtuse, undulate; lip yellowish white, purple-spotted at base and on epichil, the hypochil with a dark black-purple eye-like spot on each side; the inside the same color, the epichil ovate-orbicular. Origin unknown.—S. persoonii, Rolfe. Fls. golden yellow; sepals obtuse, the dorsal oval, the lateral obliquely and broadly ovate; petals linear-oblong, revolute; lip with the hypochil suffused dark purple on sides; epichil obscurely ovate, purple-spotted. Peru. B.M. 8417.—S. radiata, Rolfe. Fls. ivory-white, faintly shaded yellow on lip; sepals elliptic-oblong, acute; petals lanceolate-oblong, acute, up with the hypochil pubescent inside, the epichil triangular, acute. Brazil.—S. Redigipila, Casse. Fls. about 6 in. across; sepals spreading, oblong-ovate, purplish-mottled below, maroon-mottled above; petals triangular-lanceolate, attenuate above, pale green; lip very fleshy, the hypochil suffused with maroon-purple below; the remaining blotched; epichil reticulated, triangular, obtuse, spotted with dull purple. Colombia. B.M. 7702. F.S. 41:492. G.C. III. 24:51.—S. Ruckeri, Lindl. Resemblance to S. Wards in color, but paler; hypochil obtuse; epichil stained pink. Mex. A.P. 6:831.—S. stenochilus, F. G. Lohm. & Krau. Seeds purplish white; petals apricot-colored, with purplish blotches; lip ivory-white at base, middle and interior parts yellow. Colombia.—S. Wasseriana, Hort. Var. saccata, S. tigrida. Fls. dull straw-color or pale orange; sepals obscuredly marked with wine-red, the spots on the petals larger. G.C. III. 38:102.

STANLEYA (named for Edward Stanley, Earl of Derby, 1779–1849). Cruicifera. Glauous glabrous perennial herbs, similar to arrakis in habit, suitable for the flower-garden; lvs. undivided or pinnatifid; racemes elongated, strict, many-fl.: fls. yellow, buds elongated, sepals short, spreading; petals narrow, distinctly clawed: siliqua long-elliptiptate, slender, 4-cornered or rather terete, compressed, valves carinately 1-nerved.—About 10 species, Calif.

pinnata, Brit. (S. pinnatifida, Nutt.). Sts. flexuous; sepals very variable, sometimes pinnatifid; sepals lanceolate-oblong or obovate-oblong, rarely linear, almost entire; terminal segment larger: fls. deep golden yellow, according to D. M. Andrews. May–July. W. Kans. and Neb. to Texas and S. Calif., in dry clay or alkaline soils.
Stapelia, also known as devil's Tongue, is a genus of about 60 species of mostly succulent flowering plants belonging to the family Asclepiadaceae. These plants are native to Southern Africa, where they grow in semi-arid environments.

**Key Features**
- **Flowers**: Typically large, brightly colored, and often fragrant. They are usually solitary and open during the day.
- **Leaves**: Absent or reduced, often spinescent or tubular, with a range of colors from green to deep purple.
- **Stems**: Stems are usually thick and fleshy, often with a network of white or yellowish tubercles and excrescences.
- **Flowering**: Flowers are often unusual and grotesque, with a variety of shapes and colors.
- **Propagation**: Propagated easily by cuttings.

**Species**
- **Stapelia hirsuta**: One of the most common species, with a foot-wide flower that is usually white or yellow with purple spots.
- **Stapelia nobilis**: A species with flowers that are generally yellow, white, or purple with a distinct raised ring on the disk.
- **Stapelia gigantea**: Characterized by a large flower, up to 12 inches in diameter, with petals that can be pink, purple, or white.
- **Stapelia variegata**: Known for its distinctive coloration and variegated appearance, often with yellow and orange hues.

**Flowering Season**
Most of the stapelia species demand the same treatment as cacti, with a dry position during the growing and blooming seasons. They prefer a soil made porous with rubble. They are mostly self-fertilizing, but they can be propagated easily by cuttings. Some of the species have fleshy stalks, while others are relatively small. In fact, the flowers of St. gigantea are a foot across.

**Flower Description**
- **Corolla**: The corolla of most species has a distinct raised ring, which is visible when the flower is in bloom. The corolla is often composed of 5 parts, with the center of the disk cup-shaped.
- **Stamens**: Stamens are usually whorled spirally, with the anthers often grooved or ridged.
- **Pedicels**: Pedicels are often short and thick, sometimes slightly humped at the base.

**Flower Colors**
Colors can vary widely among species, including yellow, white, pink, purple, and even orange. Some species have a unique color pattern, such as the mottled or barbed appearance of some species.

**Propagation**
- **Cuttings**: Cuttings are the most common method of propagation for stapelia. They should be taken from healthy, mature plants and inserted into a soil mixture that is well-drained and slightly alkaline.
- **Watering**: Watering should be done sparingly, especially during the winter months, to prevent the development of rot.

**Cultivation Tips**
- **Temperature**: Preferable temperatures range from 70°F to 90°F (21°C to 32°C) during the growing season.
- **Light**: Full sunlight is necessary for the best development of flowers.

**Uses**
- **Ornamental**: Stapelia are popular in both amateur and professional collections due to their unique and colorful flowers.
- **Medicinal**: Some species have been used traditionally for medicinal purposes, although scientific evidence is limited.
dull green, angles much compressed; fls. 1 or 2 together, near the base or toward the middle of the sts.; corolla 11-16 in. diam., disk-like, center shallowly depressed, inner surface transversely rugose, pale-purple-hairy, light ochre-yellow, everywhere marked with transverse crimson lines, lobes 0-3/4 in. long. Trop. and S. Afr. B.M. 7968. G.C. II. 7: 693; III. 4: 729. G.F. 8: 515. —"The requirements of S. gigantea," Watson writes, "are somewhat exceptional. It thrives only when grown in a hot, moist stove from April till September, with the glass roof and the flower-buds show it should then be hung up or placed upon a shelf near the roof-glass in a sunny dry position in the stove."

4. nóbiis, N. E. Br. Sts. erect, decumbent and branching at base, 3-5 in. high, sides concave, softly pubescent, green: fls. 1-5 together, near the base or middle of the young branches; corolla very large, with a distinct campanulate tube about 1 3/4 in. deep, lobes 2 3/4-4 in. long, light reddish purple on the back, inner face transversely rugose, light ochre-yellow everywhere marked with irregular transverse crimson lines. S. Afr. B.M. 7968.

5. tsoeménsis, N. E. Br. Sts. 4-6 in. high, angles compressed and somewhat repand-dentate, opaque green: fls. 4-9 together, near the base of the young sts.; corolla 2 1/2-3 in. diam., outside glabrous, light green, inside with a few raised transverse ridges on the upper half of the lobes, entirely dull smoky purple, darker at the tips of the lobes. S. Afr. B.M. 7968.

7. glabriofóra, N. E. Br. (S. glabriofóla, Bailey, error. S. grandiflora var. minor, Hort.). Sts. erect, 4-9 in. high, puberulous, green, angles much compressed: fls. 1-2 together at the middle or lower part of young sts.; corolla 3-4 1/4 in. diam., velvety on the back, transversely rugose and quite glabrous on the inner face, not ciliate, dull reddish purple, darker at tips of lobes, with surface transversely marked with very narrow linear, irregular yellowish white lines. S. Afr. G.C. II. 6: 809; III. 44: 186.

8. ñímilis, N. E. Br. Sts. erect, 3-6 in. high, 4-6 angled, minutely puberulent, dull purple or gray-green, pubescent; angles somewhat denticate: fls. 3-5, born on the older sts.; corolla rotate, less than 1/2 in. diam. outer surface minutely pubescent, inside transversely rugose, glabrous, not ciliate, dark purple, lobes ovate, acute. S. Afr.

9. bèlla, Berger. Sts. erect, branching at or above the base, 5-7 in. high, sides concave, minutely pubescent, dull green: fls. 3-4 together at the base of the young sts.; corolla 1 1/2-2 in. diam., glabrous inside and out, inner face deep purplish red, browner toward the tips of the lobes, paler at the center, the small tube white, length of tube not marked, ciliate on the lobes. A hybrid of European raising. G.C. III. 31: 138; 44: 108.

10. mutábatis, Jacq. Sts. 3-18 in. high, acutely 4-angled, with rather stout conical, spreading teeth, glabrous, green, sometimes tinged with purple, slightly glaucous: fls. 1-3 together, from near the base of the younger or higher up on the older sts.; corolla with lobes very much recurved and then about 1 3/4 in. diam., glabrous on both surfaces, inner face slightly rugose to nodose, outer surface of the tube flat, reddish purple, dark purple-brown, the remainder pale yellowish or greenish yellow, covered with transversely elongate spots or thick or narrow, irregular transverse purple-brown lines. S. Afr. Var. discolor, N. E. Br. (S. discolor, Tod.). Corolla dark purple-brown with inconspicuous yellowish transverse lines on parts of the disk; annulus yellow with irregular purple lines. S. Afr.

12. puclhélia, Mass. Sts. 2-4 in. high, erect or decumbent at base, obtusely 4-angled, glabrous, green: fls. usually 3 or more together, near the base of the sts.; corolla 1 1/4-2 1/4 in. diam., smooth on the back, minutely tuberculate-rugulose and glabrous inside, not ciliate, sulfur-yellow, covered with numerous purple-brown dots. Lobes sometimes narrowly edged with purple-brown. S. Afr.

13. namaquénisis, N. E. Br. Sts. procumbent or decumbent, 1 1/2-3 1/4 in. high, obtusely 4-angled, with very stout, acute, conical spreading teeth, glabrous, green, sometimes tinged with purple, marked with irregular transverse ridges on the back, minutely pubescent, near the base or toward the middle of the young sts.; corolla 3-4 in. diam., back smooth and glabrous, inner surface very much transverse with rose-purple papillate ridges on the lobes which are 1-1 1/4 in. long, yellow, dotted with purple-brown. S. Afr. Var. ciliolicáta, Ruest. (Not Tod.). Corolla shortly ciliate, with simple or subclavate white or yellow and dark purple hairs mixed, spotting variable.

S. dióaméns, Spranger. A hybrid with partly whithat sts.; corolla 2 1/2-3 in. diam., dark purple-brown at the tips of the lobes, otherwise yellow with purple-brown transverse lines.—S. asterénsis, Mass. Stanislaus Flower. Dwarf; sts. mostly curved; corolla 4 in. diam., with spreading star-like segms.; violet-purple with transverse yellow-brown bars. B. M. C. 453 — S. ástrosanguinea, N. E. Br., with intense blackish crimson fls. in reality a Calatúnuma. C. ástrosanguinèn, N. E. Br.—S. antáctary-inalis, Berger (S. hybrida c antiáctariae). Hybrid; corolla 6 1/4-8 lines across, broadly campanulate, glabrous, suffused with red outside, brown-red inside, rather densely covered with red-brown bars.—S. Cáriló-Schmidtii is offered in the German trade.—S. cíndrella, Hort.—Echinoopsis cíndrella.—S. disígena, N. E. Br. Hybr. corolla about 2 in. diam.; inner surface rather densely rugose, itlagen yellow, marked with brownish crimson lines.—S. Magliríás, Schlecht. Fls. subcory; corolla dark brown, inner surface with small transverse, purple-purple spots or short lines, narrowly edged with the same color.—S. Shlecht. f. S. erect from a decumbent base, 3-5 in. high, corolla large, campanulate, tube 2-2 1/2 in. long, 1 3/4-2 1/4 in. across, dull fuscous-purple. Trans-
STAPHYLIA (Greek, staphyle, cluster, referring to the inflorescence.) Staphyleaceae, formerly referred to the Celastraceae. **Bladder-Nut.** Ornamental woody plants chiefly grown for their attractive white flowers and for their handsome foliage, and also for the inflated pod-like fruit. 

Deciduous shrubs or small trees, with smooth striped bark: lvs. opposite, 3-7-foliolate; lfts. serrulate, like the lvs. stipulate: fls. perfect, 5-merous in terminal panicles; sepals and petals 5, of about the same length, upright; stamens 5; pistils 2, usually connate below: fr. a 3-seeded, inflated, multilocular capsule, with a few subglobose rather large, bony seeds in each cell. 

Eleven species in the temperate regions of the northern hemisphere. 

The bladder-nuts are upright shrubs or small trees with handsome bright or light green foliage and ornamental white or pinkish flowers in nodding clusters followed by bladder-like fruits conspicuous by their size and pale green color. The species are all inhabitants of temperate regions, and S. holocarpa and S. pinnata are hardy North, while S. colchica, S. Bolanderi, and S. holocarpa are hardy at least as far north as Massachusetts; S. emodi is more tender and seems not to be in cultivation in this country. They are all desirable shrubs and flowers in early summer after the leaves except S. holocarpa which blooms in spring before or with the leaves. They are well adapted for shrubbery, but all except S. Bumalda are liable to become bare and unsightly at the base and are therefore not to be recommended for single specimens. S. holocarpa is perhaps the most beautiful species in bloom; also S. elegans, S. colchica, and S. Bumalda have very handsome flowers. S. colchica blooms at an early age and is sometimes forced, but S. holocarpa is probably evergreen and adapted for that purpose. Staphyleas grow well in almost any kind of soil and position, but do best in a somewhat moist rich earth and partly shaded situation. They are always interesting although not showy. Propagation is by seeds, layers, and suckers. Greenwood cuttings from forced plants root readily. 

**A.** Lvs. 5-7-foliolate, only occasionally 3-foliolate: panicles stalked. 

**b.** Panicle raceme-like, oblong, pendulous: fls. buds subglobose. 

**b.** Panicle broad, upright or nodding: fls. buds obovate-oblong. 

**AA.** Lvs. 3-foliolate. 

**b.** Middle lft. short-stalked, stalk ½ in. or less long: panicles sessile. 

**Bumalda, DC.** Shrub, 6 ft. high, with upright and spreading slender branches: lfts. broadly oval to ovate, shortly acuminate, crenately serrate, with awned teeth, light green, almost glabrous, 1½-2½ in. long: fls. about ½ in. long, in loose, erect panicles 2-3 in. long; sepals yellowish white, little shorter than the white petals: caps. usually 2-lobed, somewhat compressed, ¾-1 in. long. June. Japan. S.Z. 1:95. 

**bb.** Middle lft. slender-stalked: panicles stalked. 

**c.** Pls. after the lvs. 

**trifolia, Linn.** American Bladder-Nut. Fig. 3680. Upright shrub, with rather stout branches, 6-15 ft. high: lfts. ovate to ovate-acuminate, finely and sharply serrate, slightly pubescent beneath or almost glabrous, 1½-3 in. long: fls. about ½ in. in long, nodding panicles or umbel-like racemes: sepals greenish white, petals white: caps. usually 2-3-lobed, 1½-2 in. long. April, May. Que. to Ont. and Minn., south to S. C. and Mo. Gn. 37, p. 529. Var. punctiflora, Zabel. Low and suckering: lfts. smaller, broader, glabrous at length: fls. in short, 3-8-fld. racemes: fr. often 2-lobed, 1½-1½ in. long. 

**Bolanderi, Gray.** Fig. 3681. Shrub: lfts. broadly oval or almost orbicular, acute, sharply serrulate, glabrous, 2-3 in. long: fls. in many-fld. nodding panicles; stamens and styles exserted: fr. 3-lobed, much inflated, 2-3½ in. long. Calif. in the Sierra Nevada region. G.F. 2:545 (adapted in Fig. 3681). R.H. 1910, p. 305.—A rare shrub, probably not regularly in cult. 

**cc.** Pls. before the lvs. 

**holocarpa, Hems.** Shrub: or small tree, to 25 ft.: lfts. 3, oval to ovate-oblong, short-accuminate, serrate, pale and reticulate and glabrous or nearly so beneath, 2½ in. long: fls. white or pinkish, nearly ½ in. long, in glaucous slender-stalked panicles 1-4 in. long, axillary on last year's branchlets: fr. pear-shaped or ellipsoidal, abruptly acuminate or sometimes lobed at the apex, 1½-2 in. long; seeds light grayish brown, lustrous, ¼ in. long. Cent. China.—Very floriferous and handsome. The name has been misspelled S. holocarpa. Var. rosea, Rehd. & Wilson. Lfts. whitish tomentose beneath while young, later villous along the midrib beneath only: fls. pink, ½ in. long. Cent. China. 

**s. elegans, Zabel.** Intermediate between and supposed to be a hybrid of S. pinnata and S. colchica: lfts. usually 5; panicles very
STAPHYLEA

large and nodding. A very free-flowering variety with pinkish tinged fls. in var. 'Rosea' Zabel.—S. cerasifera Wall. Shrub or small tree: Ht. 3, oval to oblong, 2-6 in. long; stalk of terminal fl. about 1 in. long; fls. in peduncled, pendulous, raceme-like panicles; fr. 2-3 in. long; Himalayas.

ALFRED REHDER

STÁTICE (Greek name meaning astringent, given by Pliny to some herb). Syn. Armeria, Auth., not Linn. (see Vol. I, p. 298). Plumbaginaceae. Sea-Pink. Thrift. Interesting hardy border perennials, biennials, and annuals useful for both the many-flowered bright inflorescences and the stiff more or less evergreen foliage; flowers blue, lilac, white, yellow.

The genus Statice as defined by Linnaeus, "Genera Plantarum," ed. 5 (1754), is based on Statice, Toum., the same as var. Leuconora, Rubb.

INDEX TO STATICE.

A. Calyx produced into a spur.
B. Buds between the fls. small, scarcely exceeding the fruiting pedicles...
C. Calyx not produced into a spur.
D. Tube of calyx usually pilose all over.
E. Inner lvs. of the calyx-tube.
F. Apex of lvs. rather acute...
G. Involucr. pale brown, showy...
H. Involucr. green...
I. Tube of calyx glabrous or pilose only on the ridges.
J. Spikes setitate inside the involucr.
K. Spikes sessile inside the involucr.
L. Exterior lvs. of the rosette diffrering from the others.
M. Involucr. pale brown...
N. Involucr. white, showy...
O. Exterior lvs. of the rosette the same as the others.
P. Involucr. green...
Q. Involucr. dull brown...
R. The lvs. 3-cornered in cross-section...
S. Cespitosa
T. The lvs. 5-cornered in cross-section...
U. semi-evergreen character; of the tufted foliage also adds much interest. The plants are easy to grow, remaining for some years when well established, rooting deep. Usually grown from seed.

StaTICATE

Hoff., not Hook.). The name pseudoarmeria has also been used for two other species, but the Murray definition applies to this species and his is the oldest use of the name.

14. S. undulata, Bory & Chaub. (Armeria undulata, Boiss. A. argyrocephala, Wallr.). The following species and varieties, all of which are in the trade, are not included under Armeria in Vol. 1. According to Otto Kuntze and others there is but one species of Statice, A. armeria, all the others being variants of this polymorphic species. The great confusion in synonymy seems to uphold this view to some extent and it is certainly questionable whether the varieties of S. armeria, S. plantaginea, and S. pseudoarmeria are all of them distinct.

1. S. fasciculata, Vent. (Armeria fasciculata, Willd.). Glabrous, subsucculent at base; lvs. glaucous, linear, camellate, thick, stiff and pointed; involucral lvs. in several rows, fuscous, triangular-ovate, the inner ones white-margined; fls. pale pink. Spain, Corsica, and Sardinia.—The lvs. are somewhat yucca-like.

3. S. armeria var. variegata, Hubb. (Armeria maritima var. variegata, Hort.), forms compound masses of bright golden foliage and has heads of rose fls.

4. S. labrad6rica, Hubb. Port., equals A. bella, Boiss.; consists of bright golden foliage and has heads of rose fls. Var. grandi­flora, Hart., has white fls. Var. grandijlora, Little- or an(Jled above, branch Ids aJtiC-date. About 180 species well scattered about the world, but mainly alpine species—with bright rosy crimson fls.

6. S. armeria var. alba, Hubb. (Armeria armeria var. alba, Hort.). Leaves usually radical and tufted especially, in the herbaaceous species, generally rather long, alternate along the st. in the shrubby species, linear, spathulate oblong or oblanceolate, sometimes punctate or dissected; fls. blue, lavender, white, red, or yellow, in little- or much-branched panicles, borne on a leafless peduncle or scape; bracts subtend the 1-cluster scale-like, somewhat clasping, usually coriaceous on the back, and with membranous margins, usually with 1 or 2 fls. in their axis, sometimes with dense brownish to several-fl. spikelets; calyx funnel-shaped, often colored, usually the showy part of the fl., and scarious or persisting.—About 180 species well scattered about the world, but mainly sequested plants of the northern hemisphere and especially numerous in Asia. Limonium is of many exact species, but many of them occurs in the trade-life and are probably not in it.

7. S. plantaginea var. alba, Hubb. (Armeria plantaginea var. álba, Hort.), grows 1 ft. high and has white prf~f~r

8. S. plantaginea var. alba, Hubb. (Armeria plantaginea var. álba, Hort.), has large heads of white fls., 1 ft. high. Var. gigantea, Hubb. (Armeria plantaginea var. gigantea, Hort.), grows 3 ft. high, has rigid sts. and large heads of glistening pink fls. Var. grandiflora, Hubb. (Armeria plantaginea var. grandiflora, Hort.), grows 1 ft. high and has large crimson fls. Var. rósea, Hubb. (Armeria plantaginea var. rósea, Hort.), grows 1 ft. high and has pink fls. Var. rúbra, Hubb. (Armeria plantaginea var. rúbra. Hort.), grows 1 ft. high and has red fls. Var. splendens, Hubb. (Armeria plantaginea var. splendens, Hort.), grows 1-1/2 ft. high and has brilliant rose-colored earlier fls. May, June.

9. S. pseudarmerias. var. álba, Hubb. (Armeria cephalotes var. álba, Hort.), has white fls. Var. grandiflora, Hubb. (Armeria cephalotes var. grandiflora, Hort.), grows 1½ ft. high and has large heads of rose-colored fls. Var. rúbra, Hubb. (Armeria cephalotes var. rúbra, Hort.), has rosy red fls. Var. splendens, Hubb. (Armeria cephalotes var. splendens, Hort.), grows about 1½ ft. high forming large tufts of foliage and has large heads of vivid rose fls.

10. S. majellénisis, Hubb. (Armeria majellénisis, Boiss.). Cespitose, glabrous, base hardened; sheaths persistent, spreading squarrose; lvs. spreading to somewhat recurved, short, stiff, rather broad-linear, margin cartilaginous, folded to channelled, obtuse, 3-nerved: scales medium height; heads large; involucres few­ered, pale. Italy.

12. A. armeria var. riibra, Boiss. (Armeria armeria var. riibra, Boiss. A. splendens, H. & A. Albuli, not Hook.). Cespitose, base hardened: sheaths withering: lvs. spreading to somewhat recurved, short, stiff, rather broad-linear, margin cartilaginous, folded to channelled, obtuse, 3-nerved: scales medium height; heads large; involucres few­ered, pale. Italy.

Subsection 11. VERNONIUM.

Section 1. PSEUDOLACUS.

a. Inferior bracts unilaterally
b. Spikelets 1–2-fld.
   c. Branches of the panicule recurved
   d. Spikelets 3–4-fld.
   e. Panicule-branched narrowly 2-flowered or less.
   f. Spikelets 2–3-flowered.
   g. Calyx 3–5-toothed

Subsection III. GONOLONUM.

a. Inferior bracts unilaterally
b. Spikelets 2–3-flowered at the apex.
   c. Branches of the panicule recurved
   d. Spikelets 4–5-flowered.
   e. Calyx 3–5-toothed

Subsection IV. CHROMONUM.

Subsection IV. CHROMONUM.

1. tataricum, Mill. (Statice tataricum, Lnn. Gonolinum tataricum, Boiss.). Perennial, glaucescent; about 1 ft. high; lvs. ovate-oblong, 3-footed, coarsely serrate, broadly obtuse, sharp at base; branches and spikelets panicled, narrowly 2-flowered; scape densely corymbose above, more or less broadly 3-wughed, "lugs produced into rotundate cymes; corolla yellow, limb truncate, crenulate, corollas yellowish white, Aug. Medit., reg. B.M. 6066. Var. speciosum, Kuntze. (Statice speciosum, Hort.), has lance-oblong leaves, more or less divided, sharply serrate and sinuate, yellowish white, July. Teneriffe. B.I. 3776. P.M.

2. collinum, Hubb. (Statice collina, Grise. S. bestemmiana, Friv., not Schult. Gonolinum collina, Boiss.). Perennial, glaucescent: lvs. oblong-lanceolate or lanceolate, acute, serrate-cuneate, narrowed to the petiole; scape nearly 2-flowered; branches elongate, spreading-recurved, narrowly 2-flowered; spikelets 2–3-flowered, densely arranged in a terminal cyme; calyx white, green-nerved, tube short-puberulent, about 2 ft. long; lvs. oblong-obovate, obtuse, short-puberulent;

3. speciosum, Kuntze (Statice speciosa, Lnn. Gonolinum speciosum, Boiss.). Perennial, glaucescent, about 1 ft. high; lvs. suborbicular or oblong-obovate, abruptly attenuate-cuneate, narrowing to the petiole; scape densely corymbose above; branches narrowly 2-flowered; spikelets 3–4-flowered, densely imbricated in a terminal cyme; parts white, tube densely appressed-pubescent; corolla rose or purplish pink, very deciduous. July. S. Russu, Caucasus. B.M. 560. L.R. 14:1336.

4. eximium, Kuntze (Statice eximium, Schroch. Gonolinum eximium, Boiss.). Perennial, glaucescent; about 1 ft. high; lvs. oblong-obovate or ovate, acute, serrate-cuneate, narrowed to the petiole; scape nearly 2-flowered; branches narrowly 2-flowered, spreading-recurved; spikelets 3–4-flowered, densely imbricated in a terminal cyme; parts white, tube densely appressed-pubescent; corollas rose or purplish pink, very deciduous. July. S. Russu, Caucasus. B.M. 560. L.R. 14:1336.

2. collinum, Hubb. (Statice collina, Grise. S. bestemmiana, Friv., not Schult. Gonolinum collina, Boiss.). Perennial, glaucescent: lvs. oblong-lanceolate or lanceolate, acute, serrate-cuneate, narrowed to the petiole; scape nearly 2-flowered; branches elongate, spreading-recurred, narrowly 2-flowered; spikelets 2–3-flowered, densely arranged in a terminal cyme; calyx white, green-nerved, tube short-puberulent, about 2 ft. long; lvs. oblong-obovate, obtuse, short-puberulent; June. July. S. Eu., Caucasus, Russia, and Siberia. B.M. 6371. Var. angustifolium, Hubb (Statice tataricum var. angustifolia, Hort. S. Besseriana, Schult. S. inaeia, Boiss., not Lnn. S. inaeia var. kryloviana, Gomolimon etalurn, Boiss.). Perennial, glaucescent, about 1 ft. high; lvs. oblong-obovate, acute, serrate-cuneate, narrowed to the petiole; scape corymbose-pallate a little above the base; branches and spikelets panicled, abruptly 2-flowered; scape elongate, spreading-corymbose above, more or less broadly 3-wughed, "lugs produced into rotundate cymes; corolla yellow, limb truncate, crenulate, corollas yellowish white, Aug. Medit., reg. B.M. 71. G.W. 7, p. 220—Usually treated as a annual. Var. candoinsimum, Hubb. (Statice candoinsima var. candoinsima, Hort.), has pure white fls.—A good plant for edging. The material known in the trade as Stanice avata hybrids are hybrid forms of this species.

7. Bondueiili, Kuntze (Statice Bondueiili, Lnn.; also miseploped Bondueiilli, P.G. 3082). Annual or biennial about 1 ft. high; lvs. ovate, obtuse, obtuse-oblong, hairy, sharply serrate, black at base, blackish at apex. Calyx green, limb 3-toothed, corolla yellow, June-Oct Algeria. B.I. 2129. If F. 2:220—the Calif. material seems to have more broadly winged branches and branchlets than usual.

8. Thouinii, Kuntze (Statice Thouinii, Lnn. S. seguillea, Pers.). Annual, glaucescent; about 1 ft. high; lvs. sinuate or pinnatifid-lobate, lvs. and sinus rounded, margin short-ciliate; scapes nearly 2-flowered; branches and spikelets panicled, narrowly 2-flowered; branches and spikelets panicle-flowered; corolla deeper yellow, June-Oct Algeria. B.M. 5138. F.S. 20 1219. If F. 2:220—The Calif. material seems to have more broadly winged branchlets and branches than usual.

9. arborescens, Kuntze (Statice arborescens, Boiss.). Shrub about 2 ft. high; stems terete, naked; lvs. broad-obovate-oblong, petioled, obtuse, serrate-cuneate, base attenuate, leaves nearly 2-flowered; branches nearly 2-flowered; branches and spikelets panicled, with the branches narrowly 2-flowered; branches and spikelets panicle-flowered; corolla yellow, July. E. Tenerife. B.I. 3776. P.M. 4:217 (under the name Stanice arborea).
10. fruticans, Kunth (Stütice fruticans, Webb, S. arborea, Brou. S. fruticosa, L.).-Shrub: st. short, naked, terete: lvs. in a rosette at the base of the cape, very acute, very oblong, pinnately crenate, very oblong, narrowly lanceolate, shortly attenuate to the petiole; scape very short, corymbosely-peduncled above, it and the branchies winged; branches 2-winged, wings at base very narrow, broadened upward, running out into short, unequal rotundate auricles below the spike; spikelets 1-flowered, 1-fid., very short, second spikes: calyx blue, tube glabrous, limb acutely ciliate, corolla yellow. Sommer. Tenero. F.S. 4: 333. R.U. 4, p. 104.-Commonly allied to S. arborescens from which it differs in the smaller size of its lvs., which are 1½-2 in. long, the scape 4-6 in., 2-edged, not winged and the number of the branchies rotundate.

11. macrophyllum, Kunth (Stütice macrophylla, Brou. S. Hultfordii, Hort.).-Subshrub about 2 ft. high: lvs. radially pubescent, very obtuse, lower part long-attenuate, oblong, ciliate above the petiole; scape 3-7 ft. high, the whole plant shortly soft-tomentellous: IV8. H.U. 1: 217.-Section GENUINUM.

16. Perezii, Hubb. (Statice Perezii, Stapf).-Subshrub, less than 2 ft. high: lvs. slightly short-pubescent, ovate, canaliculate, in a rosette at the base of the cape, rather acute, apex bearing a small triangular decurrent on the petiole: scape 3½-4½ in. long and the same wide, very narrow, the lower leaves remote and retractive, spike short, 3-5-fid., the same wide, 2-edged, 2-nerved: corolla yellow, white. July. A. S. 8: 425-437.

17. pectinatum, Kunth (Stütice pectinatum, Ait.).-Subshrub, about 2½ ft. high: lvs. radially pubescent, lanceolate, obtuse, margin short-ciliolate, 2½-3½ in. long: IV8. Hart. (H. U. 1: 217).-Section GENUINUM.

18. vulgaris, Mill. (Statice vulgaris, Linn. in Lam.).-Perennial, about 1 ft. high: glabrous; lvs. oblong-elliptic, acute; scape from which it differs in the 3 times smaller lvs., which are 1½-2 in. long, the scape 4-6 in., 2-edged, not winged and the number of the branchies rotundate. Subsection CHRISTEANUM.

19. sinense, Kunth (Stütice sinensis, Girard, S. Fortunei, Kuntze).-Perennial, about 1 ft. high: glabrous; lvs. oblong-elliptic, acute; scape from which it differs in the number of the branchies rotundate; corolla yellow. July. A. S. 8: 425-437.

20. vulgare, Mill. (Statice vulgaris, Linn. in Lam.).-Perennial, about 1 ft. high: glabrous; lvs. oblong-elliptic, acute; scape from which it differs in the number of the branchies rotundate; corolla yellow. April. China. R.U. 31: 63. F.S. 2: 42.
Section 4. LIMONIUM.

23. limonidiformis, Kuntze (Sít&ce limonidifórmis, Girard; S. Willd.).** Perennial, 1-2 ft. high; Ivs. oblong-lanceolate, obtuse or retuse, spreading, oblong-lanceolate, 6-8 in. long, entire or usually coarsely runcinate, the base or branched; spikelets 2-3-fl.d., densely clustered; calyx-tube somewhat glandular, pubescent, 5-toothed, rose-red; corolla tubular, rose-red, lobes ovate-rotund. July, Aug. Spain.

24. bicornua, C. E. Salmon (L. occidentale, Kuntze; Sít&ce bilobum, G. E. Smith, S. occidentalis, Lloyd; S. curvifolia, Vahl). Cespitose perennial, 6-10 in. high, Ivs. lanceolate-spataulate, without nerves, rather linear-spatulate. Sepals 6, linear, acute; corolla 3-fl.d., rather densely and distichously clustered in spreading, redundaent spikes: Ivs. rosulate. small, obovate or oblong-spatulate, very obtuse, margm somewhat ciliate, opposite or subopposite, slender, flexuous, very much branched almost from the base; branches short, strict, flaxen, very much branched almost from the base, forming an oblong panicle; spikelets 2-4-fl.d., rather densely and distichously imbricated in spreading or erect-spreading, oblong-spikelets: calyx-tube long, apiculate, linear-spatulate, the spikes forming a small densely crowded panicle: fls. blue, rose-red. S. W. Eu. and Morocco.

25. limonium, Hubb. (Sít&ce limoníum, Thunb.; Sít&ce purpurea var. longifolium, Boiss.). has Ivs. oblong-lanceolate or nearly linear, up to 10 in. long, 2 lines wide, usually much smaller. S. Afr.

Subsection 3. HYALOLEPIDEA.

26. limonium, Hubb. (Sít&ce limoníum var. díbos, Hubb.; Sít&ce limoníum var. a&en, Hubb.). Perennial or subshrub, about 9 in. high, glabrous, rarely pubescent, rather cespitose; Ivs. rosetulate, small, obovate or lanceolate-spatulate, obtuse or retuse, scales deep, slender, branched from the base; branches straggly, slender, lower ones sterile, upper corymbose-fasciculate; spikelets 2-3-fl.d., disposed in lax often fasciculate straight terminal spikes: calyx-tube slightly pubescent or glabrous, limbus white, deeply 5-lobed, lobes ovate, plinate, rather obtuse; corolla redish. July, Aug. S. Frans.
beryl globose, finally splitting open.—About 10 species, China and Japan.

The stauontiineae are beautiful evergreen climbers and well adapted to the soil and climate of the South Atlantic and Gulf regions. Both *S. hexaphylla* and the related *Holballa latifolia* (known also as *Stauontina latifolia*) grow well in the writer's Florida garden, although they are not such very luxuriant climbers as *arc* the allamandas, thunbergias, and bigonias. It requires a few years before they are fully established. They are excellent subjects to be planted on old stumps and on small trees, such as catappa and mulberry trees, which they perfectly cover in the course of time with their pretty evergreen leaves and their rather insignificant but powerfully fragrant flowers. They will not flourish in dry hot sandy soil, demanding for their welfare rather moist shady spots containing a profusion of humus. A little commercial fertilizer containing a fair amount of nitrogen and potash will also prove very beneficial. The need of some kind of a stimulant is shown by the plant itself, which assumes a rather yellowish cast in the green color of the foliage. A few days after it has received some plant-food the foliage shows a very beautiful dark green color. These two species and the beautiful *Kadsura japonica* are valuable additions to the garden flora of the southern states. (H. Nehrling.)

*S. hexaphylla*, Deane. Fig. 3655. A handsome vine becoming 40 ft. high: its oval, about 2 in. long, stalked: its in axillary clusters, white, fragrant in spring: berry about 4 in. long, splashed with scarlet. *Japan*. A.G. 12:139.

F. W. BARCLAY.

**STAUROPSIS** (Greek, cross and stigma, in allusion to the cross or star-shaped stigmas). Tuberous stoloniferous herbs, adapted to the warm-house: lvs. long-petioled, hastate-cordate in outline, pinnately cut or 1-2-pinnately parted, the pinnnae solitary or several, as long as the lvs.; spathe erect, lanceolate, base connectate, gaping open above; spadix cylindrical: fls. monccious, all perfect, the male and female corniculated periangu: perianth wanting: berries subglobose, deeply 3-5-sulcate, 2-5-celled, the cells 1-seeded.—About 7 species, Trop. Amer. The oldest name for this genus is Asterostigma. *S. cotanenum*, Koch. About 1½ ft. high: young lvs. reniform, pedately cut, the segms. obovate-lanceolate, the oldest 3-parted, the middle part pinnately cut, elongated-oblong, the lateral parts cymose bisected or trisected; the petioles marked with pale violet and dark purple; spathe narrow-lanceolate, very acute; spadix white and purple, the male part dense-flid.; peduncle vivid purple, shorter than the petioles. *Brazil*. L.B.C. 16:1690 (as *Caladium buridum*). Variable. *S. Luchneodilea*, Koch (*Asterostigma Luchneodilea*, Schott). Lvs. 1-2 ft. long, deep green, pinnatifid, broadly ovate, the 2 lower segms. deflexed, deeply cut into 3-5 lobes, the remaining segms. 4-6 pairs, sessile, remote; the petioles 6-12 in. long, white, with long-petioled young lvs.; spathe deep green within and speckled with brown, reticulated externally, 2-4 in. long, erect, cylindric, acute; spadix cylindric; anthers scarlet; ovaries white; spadix subglobose, finally splitting open above; spadix cylindrical: fls. moncious, all perfect, the male and female corniculated perianth wanting: berries subglobose, deeply 3-5-sulcate, 2-5-celled, the cells 1-seeded, —About 6 species, Phil., Polynesia. (known also as *Fieldia luchneolda*, Gaudich. *Vanda luchneodilea*, Lindl. V. B. 11. 32:59. J.H. III. 63:71. Desc. also under *Vanda*.)

**STEIRONEMA** (Greek, sterile threads, referring to the staminodia). *Primulaceae*. Loosestrife. Erect glabrous herbs useful for borders in damp soil. Leaves opposite, or rarely whorled, entire: fls. rather large (6-12 lines broad), yellow, axillary, solitary or clustered: peduncles slender: corolla rotate, 5-parted; lobes crose and often cuspitate, each separately involute around its stamen; stamens 5, opposite the lobes, with 5 alternating subulate staminodia; filaments distinct, or nearly so; ovary superior, 1-celled with free central placentas, becoming capsular in fruit; seeds many; style and stigma 1. Differs from *Lysimachia* in the presence of the sterile stamens, and in the evagination of the corolla.—About 5 species. N. Amer. All perennial. Offered by collectors of native plants, for colonizing, borders and wild-gardens.
STELIS (an old Greek name used by Theophrastus for some parasitical plant). Orchidaceae. Epiphytic herbs, some of them adapted to the warmhouse and others to the intermediate house; stts. cespitose or creeping, with simple branches 1-lvd. at the tip and frequently 1-lvd. or 2-lvd. below the inflorescence, not pseudobulbous. Inflorescences frequently short; Ivs. leathery, often contracted at the base to the petiole which is frequently concave or channeled and sometimes articulated near the base; fls. small to minute, short-pedicelled in an elongated raceme at the base of the terminal fl., secund, rarely opposite, distinctly or only sometimes distinct; bracts alternate, various; sepals frequently subequal, broad or triangular, spreading, more or less connate; petals much shorter, broad, the margins thickened; labellum sessile at the base of the column, equal and similar to the petals or narrower and sometimes a little acuminate; column equaling or shorter than the labellum; hp hooded, about as long as the petals. About 200 species, Mex. and W. Indies to Brazil and Peru. Treatment the same as for Pleurothallis.

S. borbata, Rolfe, is a species differing from S. Endressii in having long-bearded sepals and a tridentate labellum. Fls. are greenish ochre-yellow with purple hairs and red-brown blotches. Costa Rica. - S. Brunnii, Wilderm., grows about 2 ft. high; Ivs. thick, 2-3 in. long, deeply channeled above; racemes 1-3, many-fl.: fls. greenish white, not spotted; sepals and petals concave; petals very short, about half as long as the sepals. Rio de Janeiro. - S. Bruckneri, Lindl., has Ivs. 1-2-2 in. long; Ivs. yellowish green outside, pale purple within, disposed at intervals along the rachis; sepals broadly ovate, acute, spreading, hairy within, petals and lip linear, all green, freely united. Mex. (B.M. 660). - S. B:M. 660. - S. OphlOglo8soides, Hitchc. (Lysimachia quadrifiora, Sims. L. longiflOll, Pursh. S. longifOllum, Gray. St. 4-angled, 1-3 ft. high; Ivs. thick and firm, sessile, subhyaline, 1-4 in. long, smooth and shining; margins slightly revolute; basil often broader; veins obscure. E. U.S. B.M. 660. K. M. WIRGAND.

STELLARIA (Latin, star, referring to the form of the flower). Caryophyllaceae. Annual or perennial herbs, mostly diffuse, tufted or weakly ascending, glabrous or pubescent, of little cultural value.

Leaves opposite, simple: fls. usually white, in terminal or axillary, naked or leafy paniculate cymes or rarely subsolitary; sepals 3, very rarely 4; petals as many as the sepals, 2-leaf or rarely 1-leaf per sepal, nearly or wholly emarginate; stamens 10 or fewer by abortion; ovary 1-celled: caps. globose, ovoid or oblong, dehiscent by as many or twice as many teeth as there are carpels. - About 100 species, scattered all over the world but chiefly in the temperate regions.

AA. Fls. 7–10 lines across.

Hofstede, Linnaeus, Easter Bell. A hardy perennial, erect, 0-15 in. high, simple or somewhat branched, from a creeping rootstock: lvs. sessile, lanceolate, 1-3 in. long: fls. white, abundant, in a terminal leafy panicle; sepals one-half or three-fourth as long as the petals. May, June. Eu., Asia. B.B. 2:22. - This and the next are desirable for dry banks where grass will not grow well and for other carpeting purposes.

AA. Fls. 2-5 lines across.

BR. Lvs. narrow.

graminea, Linnaeus. A slender-stemmed, prostrate, creeping perennial plant not usually over 6 in. high, from a creeping rootstock: lvs. sessile, linear-lanceolate, usually about 1 in. long: fls. white, in terminal or lateral scarious bracted open panicles; sepals and petals nearly equal in length. May, June. Eu., Asia. B.B. 2:23. - S. aurea, Hort. Golden Stitchwort, has pale yellow lvs. and is lower and more matted in growth. Well adapted for sandy banks where grass does not grow well.

BB. Lvs. ovate.

média, Cyril. Chickweed. Fig. 3686. A low, decumbent annual weed common in all rich, moist, cult. soils, especially troublesome during the cooler months of the growing season and in frames, and the like, during winter. Lvs. 2 lines to 1½ in. long, the lower petiolate, the upper sessile: fls. axillary or in terminal leafy cymes; sepals longer than the petals. Eu., Asia; naturalized. B.B. 2:21. - It is considered to be a good fall and winter cover-plant in orchards and vineyards, but is never cult. It is a surface-rooting plant.

F. W. BARCLAY.

STEMONA (Greek, stamen, alluding to the folia-um). Syn., Roxburghidce. Tall climbing perennial herbs, from a tuberous fusiform root, suitable only for other carpeting purposes. Stems 4-5 in. long, oblong-linear, rather broad, long-tapering at the base; raceme slender, 1-sided, pedunculate; fls. greenish, with a tinge of purple, minute. W. Indies. B.R.

3686. Stellaria media. (Flower X9)
CVII. Effective shrubbery border.—Spiraeas in good form.
to Austral. S. Cúrtisii, Hook. f. St. twining, leafing and flowering at the same time; lvs. 4–5 in. long, alternate; the petiole very long and slender; fls. small, apparently unisexual. India. B.M. 7254. Similar to the following. S. tuberosa, Lour. (S. gloriosae, Vogt. Rottboellia gloriosae, Jones. R. gloriosa, Pears. R. widtflora, Smith). Tubers cylindrical, 6–12 in. long: st. woody below, twining, leafing and flowering at the same time; branches terete; lvs. 4–10 in. long, broadly ovatecordulate, acuminate, membraneous, shining; peduncle 1–2 in. long, usually 2-fl.: fls. erect, fetid; perianth spreading and revolute, segms. lanceolate, acuminate, greenish with many purplish nerves, or ovate-oblong, 5–6-seeded. India and Assam. F.S. 2:86. B.M. 1500. H. U. 3, p. 353. The plants are allied to the lily family.

**STENÁCTIS:** Eriogonum.

**STENÁNDRIUM** (Greek, narrow anthers). Acanthaceae. Nearly stemless or short-stemmed herbs, frequently villous or pubescent, adapted to the warm- or coolhouse; lvs. often radical or clustered at the base of the st., very entire: spikes scape-like, peduncled, dense or interrupted: fls. usually small at the axils of the opposite bracts, solitary, sessile, spicate; calyx 5-parted, segments narrow, acute; corolla-tube slender, cylindrical, limb ovate, acute, retuculate, reticulate; stamens 4, didynamous: caps. oblong or subflattened, subterete, 4-seeded or by abortion fewer-seeded.—About 30 species. Trop. and Subtrop. Amer.

**STENÁNHIMIUM** (Greek, narrow flower; referring to perianth-segments). Liláceo. Bulbous plants, useful both out-of-doors and in the greenhouse.

Stems erect, tall, simple except for the infl.: lvs. radical or at the base of the st. long, linear or linear-lanceolate, smaller upward along the st. or none: fls. polygamous, 2-fl.; perianth-segments 6; stamens 6; ovary ovoid, 3-celled: caps. ovoid-oblong, partly dehiscent into 3 carpels.—About 5 species; one native of Sachallale Island, another Mexican, the others W. American.

**occidentális**, Gray. St. slender, 10–20 in. high: lvs. linear-lanceolate, acuminate, 3–10 in. long: raceme simple or branched at the base; pedicels slender, spreading or recurved: fls. campanulate, nodding, brownish purple; perianth-segments 6–8 lines long, oblong to lanceolate, acuminate. Rocky banks, Ore. to Brit. Col. and Idaho.

palústris, Bedd. (S. scádens, J. Smith). Rootstock widely climbing: lvs. 1-3 ft. long, with pinnae 4-8 in. long; fertile pinnae slender, 6-12 in. long; texture leathery. India. S. 1:224.—A vigorous grower and coarse feeder, much used in cooler houses of large fancies. It will form a mass of rootstocks several feet long if grown on a fern stem, producing a large number of the rather pale lvs.

sorbiólium, Linn. Rootstock climbing, often prickly: lvs. 12-15 in. long, 6-12 in. wide, with close veins; fertile pinnae 2-4 in. long, narrow. E. and W. Indies to Brazil.

R. C. BÉNÉDICT.

STENOGLOTTIS (Greek, narrow and tongue). Orchidaceae. Terrestrial herbs, with short s.t. and tuberiferous or thickened fleshy fasciculate roots, which are suitable for the intermediate house, but not commonly cult.: lvs. radical, numerous, rostrate or tufted: fls. small, short-pedicelled, arranged in loose somewhat 1-sided racemes; bracts small; sepals free, subequal; petals somewhat narrower than the sepals and suberect; lip continuous with the base of the column, cuneate-oblong without a spur, 3-5-cleft at the apex; column very short and broad; pollinia granular: caps. narrowly obovate-oblong, acute, bright green, usually with few or numerous blackish or purple-black blotches; styles recurved sheaths; racemes 4-10 in. long, stout, 9-21 in. high, with numerous linear-lanceolate-oblong, acute, bright green, usually with few or numerous blackish or purple-black blotches; flowers erect, slender, 6-12 in. high: racemes 1½-6 in. long, lax, many-fl.: fls. light purple with a few elongated dark purple blotches on the lip; sepals broadly ovate, obtuse or subacut; petals ovate, subacute; lip linear-oblong, 3-cleft or 3-parted: caps. narrowly obovate, suberect. S. Afr. B.M. 5872. B.R. 778 (as Chrysalidium flavum, Herb. A tender plant: bulb somewhat globose, 1 in. through: lvs. about 1 ft. long, oblongate, obscurely petioled, at first compressed on the margin; scape 1 ft. high: fls. bright yellow, 1½-2 in. long, usually few in an umbel. B.M. 2461. B.R. 78. (as Chrysalidium flavum).

F. W. BACILY.

STENORHÝNCHUS (Greek for small and beak). Orchidaceae. Terrestrial plants: scape arising from a rosette of lvs., bearing a raceme or spike: fls. with a distinct chin; dorsal sepal and petals forming a helmet, parallel; lip with a broad base and narrower apex, the base surrounding the column; beak narrow and long.—About 10 species, in Trop. and warm Temp. Amer. speciosa, Rich. (Spéránthès colorándis, Bedd. Br. S. floróvora, Hentl.). Lvs. elliptic, green; bracts acuminate, oblong-lanceolate, as long as fls.: fls. crimson. Trop. Amer. B.M. 1374 (as Neottia speciosa).

GEORGE V. NASH.

STENOSPERMÁTUM (Greek for small and male element). Sometimes written Stenospermátum. Aráceae. Climbing warmhouse plants: lvs. with long-sheathed petioles; blades elliptic or lanceolate, inequilateral, the primary lateral nerves numerous, ascending; peduncles rather long, at first nodding at apex, later erect: spathe convolute, at length expanding; spadix stipitate, cylindric, white: fls. perfect; staminodes 4.—About 20 species, natives of the Andes of Peru and of N. Brazil.

multivolválum, N. E. Br. Three to 6 ft. tall: blades 12-18 in. long, 4-6 in. wide, oblong-elliptic-oblong, coriaceous, opaque green, paler beneath: peduncle 12-18 in. long; spathe 5-6 in. long; spadix 4½-6½ in. long. Colombia. GEORGE V. NASH.

STENOTÁPHRUM (Greek, stenos, narrow, and taphros, a trench, the spikelets being partially embedded in the rachis). Graminéae. Creeping grasses with compressed culms, flat divergent blades and narrow flat spikes; spikelets as in Panicum, imbedded in the surface of a broad rachis forming terminal spikes.—About 3 species of tropical regions, one species found along the Gulf coast, especially in Fla., where it is utilized as a lawn grass. In this respect it is similar to Bermuda-grass, being naturally adapted to a sandy soil, which it binds by its rhizomes and creeping habit as does that grass.

The introduced form of St. Augustine grass is one of the most valuable lawn grasses for the extreme South. It will grow on almost any soil and thrives even in shade. The leaves are rather broad, never over 6 inches high and require little mowing. This grass does not become coarse, does not hold dew or rain, and is particularly good for house lots and lawns. It does not

AA. Style longer than the perianth.

flánum, Herb. A tender plant: bulb somewhat globose, 1 in. through: lvs. about 1 ft. long, ob lanceolate, obscurely petioled, at first compressed on the margin; scape 1 ft. high: fls. bright yellow, 1½-2 in. long, usually few in an umbel. B.M. 2461. B.R. 78. (as Chrysalidium flavum).

F. W. BACILY.

STENOTÁPHRUM

3687 Stenotaphrum secundátum. (×2)
need as much water as Bermuda or St. Lucie grass. It is propagated mostly by cuttings. (E. N. Reasoner.)

**secundatum**, Kunz (S. americanum, Schrank). Sr. Atwater. Gt. 45:150. Fig. 3687. Flowering branches erect, 6-12 in. high. Var. variegatum, has lvs. striped with white, and is used as a basket-plant. G.W. 15:681 (as S. glabrum). Dept. Agric., Div. Agrost. 20:42.

**STEPHANÁNDRA** (Greek, steфанανδρα, crown, and amer, admirable, alluding to the persistent crown of stamens). **Rosaceae**. Ornamental shrubs grown chiefly for their handsome graceful foliage.

Deciduous; lvs. alternate, lobed and serrate, stipulate: lvs. slender-pedicelled, small, with cup-shaped calyx-tube, incised lobes and petals 5; stamens 10-20; carpel 1; pod with 1 or 2 shining seeds, dehiscing only at the base.—Four species in China and Japan. Closely allied to Neillia and distinguished chiefly by the cup-shaped calyx-tube and the incompletely dehiscent 1-2-seeded pod.

The stephanandas in cultivation are low graceful spreading shrubs with slender more or less zigzag branches, bright green medium-sized or rather small lobed leaves and small white flowers in loose terminal panicles. They are hardy as far north as Massachusetts, but **S. incisa** is sometimes killed back in severe winters; it grows, however, freely from the base and is not injured in its appearance except that it remains rather low. They are well adapted for borders of shrubberies or rocky banks on account of their graceful habit and handsome foliage. Propagation is by greenwood cuttings under glass, which root readily, and by seeds; also by division, and **S. incisa** by root-cuttings with bottom heat in early spring.

**incisa**, Zabel (S. fenzliana, Sieb. & Zucc.). Fig. 3688. Shrub, to 8 ft. high, but usually lower, almost glabrous; with angular spreading distinctly zigzag branches: lvs. triangular-ovate, cordate or truncate at the base, long-acuminate, usually 3-lobed and serrate, the lower incisions often almost to the midrib, pubescent only on the veins beneath and grayish green, 3/4-1 1/2 in. long: lvs. white, about 1/2 in. across, in terminal, short, 8-12-fl., usually panicled racemes; stamens 10-20; carpel 1; pod with 1 or 2 shining seeds, dehiscing only at the base.—Four species in China and Japan. Closely allied to Neillia and distinguished chiefly by the cup-shaped calyx-tube and the incompletely dehiscent 1-2-seeded pod.

**STENOTAPHRUM** (perhaps a personal name; or by some derived from the Greek word for a garland or crown). **Menispermaceae**. More than 30 climbing shrubs (rarely herbs) of the Old-World tropics, as defined by Diels in Engler’s Das Pflanzenreich, hft. 46 (IV. 94), 1910, differing from Cocculus in the solitary ovary, often more than 3-merous lvs., and a nearly basal rather than nearly terminal style-scar: lvs. usually peltate: fls. in axillary, simple or compound clusters, diclinous; males with 6-10 free sepals, 3-5 fleshy petals, and 6 connate anthers; females with 3-5 sepals, petals like those of the males, 1 ovary with 3-6-parted style: fr. a glabrous drupe with ring-like seed. The species are little known in cult., although the following may be expected in southern regions or sometimes under glass as an ornamental climber. **S. herandiafolia**, Walp., in India, Austral., Afr., and Malaya, has striate glabrous branches, and ovate or somewhat deltoid obtuse or acute more or less pubescent lvs. 3-6 in. across: fls. in capitately peduncled puberulent umbels of 8-12 rays: drupes red. **S. japonica**, Miers (Cocculus japonicus, DC.), a common roadside weed in parts of China and Japan, has glabrous lvs. and infl.; probably not cult.

**STEPHANOPHYSUM** (Greek, crown and bladder, in reference to the shape of the crown). **Acantthaceae**. Herbs with more or less dentate or entire lvs., the fl. in lateral umbellate cymes: fls. red; calyx 5-parted, corolla-tube short, the lobes erect or more or less spreading; stamens 4, didynamous: caps. contracted from the base to the middle. Trop. Amer. with the exception of the below-mentioned. The genus is now included in Ruellia. **S. Bolletii**, Hook. Subshrub, 2-3 ft. high, branches 4-angled, opposite; lvs. opposite, about 6 in. long including the petiole, ovate-lanceolate, entire, acuminate, attenuate at base; pani. terminal, many-fl.: fls.
opposite, sessile, scarlet; calyx-segments narrow, erect, linear-subulate; corolla more than 2 in. long, tubular-
funnel-shaped, curved, the lobes triangular; ovary sunk in
H. F. II. 3:182.—This species is apparently not known
today and has not been recently treated in works on Trop. Afr.

3690. Stephanotis floribunda. (X4)

STEPHANOTIS (from Greek words for crown and ear, alluding to the five ear-like appendages on the staminal crown). Aselepiadaceae. Twinning glabrous shrubs of the Old-World tropics, of about fifteen
species, one of which, S. floribunda, is one of the best of greenhouse climbers.

Leaves opposite and coriaceous; fls. large and showy, white, in umbell-like cymes from the axils; calyx 5-
parted; corolla funnel-shaped or salverform, the tube
cylindrical and usually enlarged at the base and somet-
times at the throat, the lobes 5; crown mostly of 5 scales
that are usually free at the apex and adnate to the anthers on the back, the anthers with an infixed tip or
membrane; fr. a more or less fleshy follicle.

There are few plants that have all the good qualities
of S. floribunda. It is a splendid grower, has good foli-
age, is very free-flowering, and the flowers last well on
the plant or when cut for decorative work. Cuttings
are secured from half-matured wood, and can be rooted
at any time of year, although spring is the most con-
vienient time. Pot the cuttings singly, in small pots, in a
moist loam with enough sand added to keep the soil
porous. When the shoots have grown to a height of
about 2 ft., cut them back several joints. This will
make the plants break into several leads. As S. flor-
ibunda comes from Madagascar, it can stand a good
heat, but does not like so humid an atmosphere as many
other tropical plants. About 65° will generally be
found sufficient after it has started growing in the
spring. By midsummer the young plants may receive
another potting, and again be cut back to make sure of
having a good foundation for the following year. About
the end of October, begin to withhold water from the
roots, and cease syringing, which must be attended
to during the period of active growth. Reduce the
temperature to 55° to 60° during the night and give
only enough water to keep the leaves from shriveling.
As the sun gets higher in March, they will show signs of
activity and the weak wood may be all cut back, and
the plants repotted in a good strong loam with ample
drainage. If not repotted for a specimen plant, stephan-
отис may be planted out on a well-drained bench and
trained to wires over the roof. It is astonishing the
amount of space a single plant will cover in course of
time. For specimen plants, the shoots should be
trained to strings until they set flowers; when they may be
trained on a trellis in any shape desired. They will do
in the same size of pot for many years, if fed during their
growing period as advised for ixoras. Mealy-bug and
scale are sure to locate on stephanotis, but during
the winter they may be treated with fumigations with
hydrocyanic gas, as already advised for other plants,
and if syringed well when out of flower, will be easily
held in check. (Geo. F. Stewert.)

floribunda, Brongn. Fig. 3690. Glab-
rous, 8-15 ft.; lvs. elliptic, with a short
point, thick and shining green, entire; fls.
1-2 in. long, of wax consistency, white
or cream-color, very fragrant, in many
umbels, the calyx one-fourth or less the
length of the corolla-tube: fr. 3-4 in.
long, ellipsoid, glabrous, fleshy, contain-
ing melon-like seeds which are provided
with a tuft of hair. Madagascar. B.M.
23:144; 57:397. Gn. 21, p. 541 (showing
a pygmy plant blooming in a small pot
and not climbing); p. 208; 55, p. 150;
73, p. 211. G.C. II. 14:169 (a dwarf
variety, the Elveston); 24:817; 25:137;
50:165.

S. Thandartia, Brongn. From Madagascar,
appears to be the only other species in cult.,
but it is not in the American trade. It has elevate
lvs., fls. in 3s., and sepals about one-third the
length of the corolla-tube.

L. H. B.

STERCULIA (Sterculia of Roman
mythology, from stercus, manure; applied
to these plants because of the odor of the
leaves and fruits of some species). Sterculiaceae. Trees grown in the green-
house, but also outdoors in the South.

Leaves undivided, lobed or digitate; infl.
panicle or rarely racemose, frequently axillary,
with the terminal fls. commonly feminine and earlier;
fls. unisexual or polygamous; calyx 5-crenated or 5-parted,
rarely 4-merous, often colored; petals none; stamens
united in a column which bears a head of 10-15 seedy
anthers; pistil of as many carpels as calyx-lobes and oppo-
site them, each carpel 2- to many-ovuled, the stigmas
free and radiating: fr. follicular, each carpel distinct and

3001. Mature foliodes or fruits of Sterculia piantanifolia, bearing seeds on the margins. (X1/2)

5. colorata, Roxb. Large tree, bark ashy: lvs. roundish, 5-9 x 5-12 in., glabrescent, palmately 3-lobed, lobes triangular, acuminate, base cordate; petiole 4-9 in. long; panicle terminal, many-fld.; pedicels covered with orange-red tomentum: calyx ¼ in. across, tubular, elavate, orange-downy outside, 3-lobed; corolla 2-3 in. long, stipitate, glabrous, membranous. India.—Intro. into Calif.

6. acerifolia, A. Cunn. (Brachychiton acerifolium, F. Muell.). BRACHYCHITON. FLAME TREE. Evergreen tree, reaching a height of 60 ft., glabrous: lvs. long-petioled, large, deeply 5-7-lobed; the lobes of lanceolate to rhomboid, glabrous and shining: fls. brilliantly scarlet, the calyx about ¼ in. long, in large, showy trusses: foliodes large, glabrous, long-stalked. Austral.—A most showy tree when in bloom, and planted on streets and lawns in Calif. Thrives in either dry or fairly moist places. (See also page 538.)

7. alata, Roxb. Large tree, the young parts yellow-pubescent, the bark ash-colored: lvs. large, cordate-obtuse, acute, 7-nerved: fls. about 1 in. across, in few-flowered panicles shorter than the lvs., and which arise from the leafless axils, the calyx tomentose and the segments linear-lanceolate: foliodes 5 in. diam., glabrous, with winged seeds. India.—Intro. into S. Fla.

8. diversifolia, Don (Brachychiton populneum, R. Br.). Tree, 50 ft.: fls. large, glabrous, the calyx 1-1 in. diam.: fls. very various, mostly ovate to ovate-lanceolate in outline, often entire, sometimes variously 5-3-lobed on the same tree, all parts acuminate; fls. tomentose when young, bell-shaped, greenish red and white or yellowish white: foliodes 1-2½ in. long, ovoid, glabrous, stalked. Austral.—Planted in Calif., and commoner than the last. (Page 538.)

Var. occidentalis, Benth. (Brachychiton Grégorii, F. Muell. S. Grégorii, Hort.). Lvs. deeply 3-lobed, the lobes narrow, sometimes with short lateral ones: fls. salmon-color; calyx smaller and more tomentose. W. Austral.—Offered in S. Calif.

9. rupestris, Benth. (Delabêrèe rupestris, Lindl.). BOTTLE-TREE. Considerable tree: trunk often swelling out to a large size, contracted top and bottom: lvs. glabrous, either quite entire and oblong-linear or lanceolate, 3-6 in. long, or digitate, consisting of 5-9 linear-lanceolate, sessile lfts. often above 6 in. long: calyx about 4 lines long, campanulate, tomentose both inside and out: foliodes ovoid, acuminate, about 1 in. long, on stalks longer than themselves. Austral.

S. acuminata, Beaut.—Cola acuminata.—S. Ruseckii, Hort., is said to be an aralia-like plant with the same leaf and petiole light green and the narrow divisions of the fl. very dark green. Offered in the trade but not known botanically.

F. TRACY HUBBARD.

STEREOSPERMUM (Greek, hard seed). Bignonid.- About 12 species of tropical evergreen trees in Afr. and E. India, with handsome once- or twice-pinnate foliage and large bignonia-like fls., pale yellow or rose-colored to purple, in large and loose terminal panicles; calyx campanulate, 2-5-lobed or 5-toothed; corolla funnelliform-campanulate, with round crisped or toothed lobes; stamens 4, included; disk terete or 4-angled, 2-valved; seeds in 2 rows, with the thick nutlets deeply impressed in the thick spongy sepal. Only the following species seems to be in cult.

S. suaveolens, DC. Tree, 30-60 ft.: lvs. simply pinnate, 12-18 in. long; fls. 7-9, broadly elliptic, acuminate or acute, entire or serrate, hairy white, about 5 in. long: panicle many-fl., viscous-pubescent: calyx campanulate, with 3-5 short lobes; corolla 1½ in. long, pale or dark purple, puberulous outside, with crestedly crisped lobes: car. 18 in. long. Ind.—Adapted for tropical or subtropical regions only and prop. by seeds or cuttings, also by air-layering.

3. citrium, Hance—Radermacheriana alata.
STERIPHOMA

(Greek, foundation, alluding to the large peduncle of the fruit). Capparidaceae. Unarmed shrubs with the branches and influ. stellate-pubescent, grown in the warmhouse: lvs. long-petioled, with 1 ft. which is lanceolate, entire; the petiole thickened at the top: fls. showy, orange, in terminal racemes; the pedicels bent or curved down, 1-ft.; calyx cylinadr- campanulate, 2-4-lobed at the top; receptacle very short, expanded into a ring-like disk; petals 4, sessile; stamens 6; ovary ovate or oblong; berry globose or angular, ciliate, pulpy.—Four species, Trop. Amer.

paradaxum, Endl. (S. cleomoides, Spreng.). Leafy shrub, 4-10 ft. high: branches erect or ascending, slender: lvs. alternate, crowded toward the ends of the branches, 4-7 in. long, oblong or ovate-oblong: raceme terminal, dense-ft., 1-3 in. long: fls. abruptly deflexed from the apex of the orange-yellow pedicels; calyx bright orange, oblong-cylindric, irregularly split halfway down; petals linear-oblong, pale yellow: fr. said to be cylindrical. Venezuela. B.M.5788. P.F.5:564-565. Gt. 57, p. 242.

STERINBERGIA (named for Count Caspar Sternberg, a botanist and writer, 1761-1838). Amaryllidaceae. Low-growing bulbous herbs, hardy and used for outdoor planting.

Leaves produced after or with the fl. strap-shaped or linear: scape short: fls. frequently solitary, rarely 2, bright yellow; perianth-funnel-shaped, erect, tube short or rather long, lobes linear, erect-spread- ing; filaments filiform, free; ovary 3-celled: fr. fleshy, ovoid or oblong, scarcely dehiscent; seeds subglobose.—About a dozen species, E. Eu. to Asia Minor. The bulbs should be planted rather deeply, about 6 in. J. N. Gerard says of their culture in G.F. 10:168 that they require a rather heavy soil, in a somewhat dry sunny position where they will be well ripened in summer.

a. Fls. and lvs. appearing together.
b. Blooming in fall.

F. W. BARCLAY.

STEUDNERA (bears the name of Steudner, a German botanist). Araceae. About 5 or 6 perennial herbs of E. Asia, sometimes seen under glass in collections, requiring the treatment of other aroids. Plant with a mostly short ascending sheathed caudex, and ovate-oblong long-stalked peltate lvs.: spathe ovate-lanceolate, recurving above the middle and convolute at base, much surpassing the spadix: fls. imperfect, the female with a subglobose 1-loculed ovary and 2-5 short staminodia: fr. a many-seeded berry. S. colocalisia-folia Koch. St. short and fleshy: lvs. green above and paler beneath, the petiole often colored: spathe yellowish, purple or redish inside; spadix white, erect, one-third as long as the spathe. S. discolor, Bull (S. colocalisia-folia var. discolor, Hort.), has purple-blotched lvs., and spathe yellow on both surfaces but reddish at base. These plants are warmhouse subjects, grown for the foliage and interesting habit, as well as for the inf."
Stewartia connate: fr. a woody, usually hirsute caps., loculicidally dehisc into 5 valves; seeds 1-4 in each locule, compressed, usually narrowly winged.—Six species in E. N. Amer. and E. Asia.

The stewartias are very desirable ornamental plants, with handsome bright green, rather large foliage which turns deep vinous red or orange and scarlet in fall; they are very attractive in midsummer with their white cup-shaped flowers, which are in size hardly surpassed by any others of our hardier shrubs. *S. pentagyna* and *S. Pseudo-Camellia* are hardy as far north as Massachusetts, while *S. Malachodendron* is tender north of Washington, D. C. They thrive best in deep, rich, moderately moist and porous soil, preferring a mixture of peat and loam, and, at least in more northern regions, a warm, sunny position. Propagation is by seeds sown soon after maturity and by layers; also by cuttings of half-ripened or almost ripened wood in late summer under glass.

A. Styles united; petals always 5.
B. Stamens purple, spreading; caps. subglobose.

This is one of the showiest species, but tender.

Bb. Styles united; petals 5.

**Stewartia Pseudo-Camellia, Sieb. & Zucc.** Shrub or small tree; lvs. oval to oval-oblong, acute at both ends, remotely serrulate, slightly pubescent beneath, light green, 1½-2½ in. long; fls. white, 1½ in. across, with flat, spreading, obovate petals; stamens connate at the base; anthers violet; fr. about ¾ in. across. Japan. S.Z.I: 96.—This is the least desirable species and probably as tender as the preceding; it is doubtful whether it is in cult. Plants intro. under this name seen by the writer proved to be *S. Pseudo-Camellia*. Also the closely allied *S. serrata*, Maxim., differing in its glabrous lvs. and larger fls. with serrate sepals and distinct stamens is apparently not yet intro.

cc. Bracts small, shorter than calyx.

**Pseudo-Camellia, Maxim.** (S. grandiflora, Briot. *S. japonica* var. grandiflora, Hort.). Fig. 3693. Shrub, with upright branches, or tree attaining 50 ft. or more in Japan: trunk with smooth red bark, peeling off in larger thin flakes; lvs. elliptic to elliptic-lanceolate, acute at both ends, often acuminate at the apex, thickish, bright green, glabrous or nearly so beneath, 1½-3 in. long; fls. hemispherical, 2-2½ in. across; petals almost orbicular, concave, silky-pubescent outside; anthers orange-colored; seeds 2-4 in each cell, narrowly winged. dull. July, Aug. Japan. B.M. 714S. R.H. 1879: 450. G.C. III. 4: 187. Gn. 43: 172. G.F. 9: 30 (adapted in Fig. 3693). M.D.G. 1900: 450. R.B. 28, p. 81. F.S.R. 3, p. 263. J.H. III. 54: 57. S.I.F. 1: 73.

aa. Styles 5, distinct; petals often 6.

**pentagyna, L'Héro. (Malachodendron ovatum, Cav.).** Fig. 3694. Shrub, 6-15 ft. high; lvs. ovate to oblong-ovate, acuminate, usually rounded at base, remotely serrate, sparingly pubescent and grayish green beneath, 2½-5 in. long; fls. cup-shaped, 2-3 in. across; petals obovate, with wavy crenulate margin; stamens white, with orange-yellow anthers; caps. ovate, pointed, sharply 5-angled; seeds narrowly winged. July, Aug. N. C. and Ga. to Tex. and Fla. B.M. 3018. B.R. 1104. M.D.G. 1900: 479. H.U. 3, p. 366. This shrub is handsomer than the preceding species and as hardy. Var. grandiflora, Bean. Fls. 4½-½ in. across, with purple stamens. A very desirable variety which was found along with the yellow-stamened one in the woods of Ga.; the flowers are as beautiful as those of *S. Malachodendron*, and the plant is much harder.

ALFRED REHDER.
STIGMAPHYLLON (Greek, stigma and leaf; referring to the leaf-like appendages of the stigmas). Sometimes written: Stigmaphylhum. Malpighiaceae. Woody vines, grown in the greenhouse and also out-of-doors in the extreme South.

Leaves usually opposite, entire or denticulate, rarely lobed; petiole with 2 glands; stipules minute: fls. yellow in umbel-like corymbs which are peduncled and axillary; calyx 5-parted, 8-glandular; petals clawed, unequal, glabrous, stamens 10, unequal, 6 perfect, 4 without anthers or deformed; ovary 3-5-celled, 3 lobed, dorsal lobe gibbose: samarre 1-3, extended above into a wing.—About 55 species. Trop. Amer.

ciliatum, A. Juss. A tender woody twining vine: lvs. evergreen, smooth, opposite, cordate, ciliate: fls. bright yellow, large, in peduncled axillary clusters of 3-6. P.M. 16:77. Gn. 35:170.—Apparently the only species in the trade and possibly the handsomest of the genus. G. W. Oliver says that S. ciliatum is one of the best medium-sized vines for outdoor trellis-work. For pot culture it is of little service and thrives in the greenhouse only when planted out. Sept. is the best month for prop. On outdoor plants much of the wood is useless for this purpose, being thin and soft. Choose the wood made early in the season; a heel or joint is not necessary; root in bottom heat and carry through the winter in the greenhouse as small plants. Winter in the greenhouse only is stand temperatures at least to —10° F. It is readily grown from seeds but is not easily transplanted.

sylvatica, Linn. QUEEN’S DELIGHT. QUEEN’S-ROOT. YAW-ROOT. Root perennial, woody: sts. clustered, herbaceous, 1-3 ft. high, with an umbel-like top: lvs. lanceolate to oval or oblong, glandular, crenulate to obtusely ciliate, acute or obtuse: spikes 2-3 in. long: fls. small, yellow. Spring to fall. Va. to Texas.

3695. Stipa eleganssima. (x 14)

3696. Stipa pennata. (x 14)

STIPA (Greek, stipe, tow, in allusion to the plumose awns of some of the species). Gramineae. Perennial grasses with narrow involute lvs. and usually loose panicles: spikelets 1-4d.; glumes membranaceous, longer than the indurated lemma; lemma with a sharp hairy callus below and a stout persistent awn above, falling from the glumes at maturity. —A large genus of about 100 species, throughout the world except the colder parts. Particularly characteristic of the plains, savannas, and steppes. The longawned, sharp-pointed frs. of some species are troublesome or even dangerous to stock, especially sheep, on account of their tendency to work through the skin and into the vital organs. The species here mentioned are cult. for ornament, including the making of dry bouquets.

a. Awns and pedicels not plumose.

b. Fr. or mature lemma, excluding the long awn, 3/4-1 in. long.

capillata, Linn. Similar to S. pratensis: fls. more numerous but smaller in every way; lemma about 1/2 in. long; lower part of awn only minutely pubescent, the upper or bent portion sinuous. Plains, Eu.

spartea, Trin. PORCUPINE-GRASS. Culms 2-3 ft., in bunches: panicles contracted; glumes broad, nerved, about 1 in.; awn usually about 6 in. long, the lower half erect, pubescent but not plumose, strongly twisted, the upper half bent to one side, rough. Ill. to Calif. Dept. Agric., Div. Agrost. 20:62.

b. Fr. or mature lemma, excluding the short awn, less than 3/4 in. long.

spíndens, Trin. (Lasiógrósis spíndens, Kunth). Culms 3-6 ft.: panicles rather dense, about 1 ft. long, nodding; spikelets numerous, small, the glumes less than 3/4 in., pearly and shining, tinged with purple at the base; lemma 3/4 in., villous, the awn 3/4-1 in. Steppes of W. Asia.
AA. Axils or pedicels plumose.

b. The pedicels plumose.

elegantissima, L., Habit. Fig. 3695. Culms 2-3 ft., erect from a horizontal rhizome: lvs. narrow and erect: panicles, very loose, 6-8 in. long, the capillary panicle branches and pedicels plumose; spikelets 4-6 lines long; awn 1½ in. long. Austral.—Thrive in sandy soil.

BB. The awns plumose.

Pennata, L., Feather-Grass. Fig. 3696. Culms 2-3 ft., in bunches: glumes narrowed into awns an inch or more long; lemma ½ in. or more long; awn about a foot long, the lower portion smooth and twisted, the upper very plumose, giving the panicle a feathery ornamental appearance. Sometimes erroneously called B. gigantea. Steppes of Eu. and Siberia. Gn. 9, p. 199. V. 3:247. R.H. 1890, p. 489.

tenacissima, Linn. Esparto-Grass. Culms 2-3 ft., in bunches: lvs. narrow, smooth, cylindrical, elongated: panicles contracted; awn 1-2 in. plumose below the bend. Spain and N. Afr.—The lvs. furnish fiber from which are made ropes, mats, paper, and the like. In Afr. it is called halfa or alfa. A. S. Hitchcock.

STIZOLOBIUM (name refers to the stinging pods). Leguminosae. Velvet Bean. Some of the species are grown as ornamental vines in warm countries, as the growth is very strong, but the genus is valuable mostly for its forage species and therefore does not demand extended treatment here.

These plants are allied to Glycine, which includes the soybean. The lvs. are large and 3-foliate: lts. in axillary clusters, long or oblong, large, dark purple (sometimes white or yellowish) but turning black when dried, the corolla much longer than the narrow-lobed calyx; the keel long, boat-shaped and usually twice or thrice longer than the obtuse standard and also longer than the wings; stamens diadelphous (9 and 1) the anthers not uniform in kind: pod often hairy, bristly or pubescent, containing pea-like seeds.—Species perhaps a dozen, tropics of Old World. The genus Stizolobium was formerly included under Mucuna, but is now distinguished from that genus (which see, p. 2074, Vol. IV) by its seed and other characters. In Stizolobium the seeds are nearly spherical, or flattened-oval in shape, with the hilum covering often less than one-sixth of its circumference and never more than one-fourth, while in Mucuna the seeds are nearly circular in outline, flattened, and with the hilum extending at least three-fourths of its circumference. In germination Mucuna has alternate scale-like lvs., while Stizolobium has petiolated, trifoliate lvs. with cordate lts. Mucuna is perennial, while Stizolobium is strictly annual. Such species of Stizolobium as are cult. for forage have pods which are nearly smooth, or are covered by a dense velvety pubescence; but there are a number of other species, notably S. pruriens, grown in the tropics, in which the pods have a dense covering of bristly stinging hairs, and are known under the common name of “cowage” or “cowitch.”

The principal economic use of the velvet beans or stizolobiums is as a winter pasture crop in the southern states. They are commonly planted with corn, the stalks of which give the necessary support, without which they produce few seeds. Some cultivators plant two rows of corn and then one row of the beans, while others plant the beans in alternate hills with the corn; the former method gives more corn to the acre, while the latter yields the heavier crops of beans. The crop is seldom cut for hay, as the vines are too long and tangled to be handled easily, but is left in the field until it is killed by frost, and is then grazed, as the vines, leaves, and seeds may remain on the ground a long time without injury from frost or rain. There are many varieties of this bean, some of which mature in about one hundred days from planting, while others fail to ripen without ten to eleven months free of frost. Some varieties produce profitable crops as far north as Tennessee, while others often fail to mature even in southern Florida. Among the many kinds now cultivated in the United States the best known is the Florida velvet bean (S. Deeringianum, Bort). This is of unknown origin, but it has been cultivated as an ornamental vine in Florida many years. About 1890 its value as a forage plant attracted attention, and thousands of acres are now grown for feeding cattle and hogs. This species makes a wonderful growth, producing vines 60 to 100 feet in length, and bearing clusters of large purple pea-shaped flowers which are followed by pods 2 to 3 inches in length containing four to six nearly spherical seeds. In recent years several sports or varieties have been developed, which mature seed in 110 to 130 days from planting, and are now cultivated largely in the region from Florida northward to northern Georgia and Tennessee. Among the more common of the recently introduced kinds are the Lyon velvet bean (S. niveum, Kunze) which bears racemes fully 3 feet in length with white flowers; the Chinese, which is similar but has shorter racemes and matures much earlier; the Black (S. capitatum, Kunze), which has very long racemes with purple flowers, and late-ripening pods covered with a velvety pubescence; and the Yokohama (S. Hassio, Piper & Tracy), which matures within three to four months from planting. In addition to these there are numberless crosses and hybrids. As all the species are natives...
of tropical or semi-tropical regions they require a long season without frost for their successful cultivation. For botanical and other accounts, see Bulletins Nos. 141 and 179, Bureau of Plant Industry, United States Department of Agriculture; also Belling on inheritance problems in crossing stizolobiums, Report of Florida Experiment Station for 1914.

The varieties most grown for ornament are the Lyon, with flowers in racemes often 3 feet in length; the Chinese, which is very similar to the Lyon but shorter racemes and blooms much earlier; and varieties of *S. chlorospermum*, Piper & Tracy, with flowers light purple. All of these have pods 5 to 6 inches in length, f-shaped (the ends curved in opposite directions), somewhat brown- or gray-bristly. The most common species in this country is the Florida Speckled, *S. Deeringianum*, Hort. (Fig. 3697), which has been grown in Florida many years, and has been commonly known as “the vine.” This seldom matured much seed north of central Florida, but in recent years several varieties have been developed which mature as far north as Tennessee. The pods of this species are usually less than 3 inches long, and are covered with a black velvety pubescence. All are annual climbers, growing to a great length. The branches are somewhat appressed-hairy, the leaves more or less silky beneath, leaflets ovate, or the lateral ones rhombic-ovate, obtuse but apiculate.

The cowpea or cowage, *S. pruriens*, Medic. (Dolichos pruriens, Linn. *D. multiﬂorus*, Hort., *Mucuna pruriens*, DC.), is apparently the oldest species known, and has become naturalized in the West Indies, but is not grown in the United States. The pods of this species are red or reddish black in color, nearly straight, and 4 to 5 inches in length. They are very bristly-hairy, the bristles are easily dislodged by a touch and are extremely irritating to the skin, often producing trouble problems in crossing stizolobiums, Report of Florida Experiment Station for 1914.

The handsome globular beans (3⁄4 to 1⁄2 inch diameter) have marking which suggests the castor bean. The cowpea does, although it can not be grown so far north as that plant. It is a good ornamental plant, growing 10 to 20 feet high when supplied with support. The handsome globular beans (3⁄4 to 1⁄2 inch diameter) have marking which suggests the castor bean.

**STOKES.** Popular florists’ flowers, single and double, white, blush, pink, purple, yellowish, suitable for cut-flowers (Fig. 3698). They are divided into two groups; they bloom profusely in the autumn. See *Matthiola*; also *Cheiranthus* for the closely related wallflower (also *Wallower*). Virginian stock is a very different plant and is not a regular florists’ flower; it is grown for its small fragrant single ﬂs.; see *Malcomia*.

Florists now frequently grow stocks in benches instead of carrying them through as potted plants. They are in considerable demand for Memorial Day. After the early bedding plants are removed to the frames, the benches are filled with soil and the plants that have been growing in pots since the seed was sown in December are then planted in them. Stocks may also follow chrysanthemums, the seed, having been sown in August.

The seed of the summer stocks, or, as they are commonly called, “ten-weeks’ stocks,” is sown from the end of February until April, mostly in a lukewarm hotbed, which must be sunny and well aired. Good clean garden soil, well mixed with sand and humus, is proper soil in which to sow the seed. The seed will germinate in six to ten days, the light-seeded sorts germinating more quickly than the dark-seeded kinds. Air must be admitted as soon as the seeds have sprouted, very much in warm weather and less when the weather is raw, until finally the sash may be entirely removed during the day. If the seedlings need water it should be given in the morning, so that they are dry at night. It is an interesting fact that when any two distinct forms, both having relatively smooth pods, are crossed, the first generation always produces forms heavily covered with stinging hairs, although the second generation usually shows a large percentage of nearly smooth pods. This seems a strong indication that *S. pruriens* is the original type of the genus. Cattle have been fed successively on the meal made of the beans ground in the pod, but persons have been made sick by eating the green cooked beans, because of its vigorous growth; the velvet bean promises well as a soil-renovator.
the can is hot the seedlings must be shaded. If the seed
is to be raised from pot-grown plants a good well-
manured, sandy garden soil should be used which con-
tains an admixture of well-rotted sod or the soil taken
from river-bottoms. The pots are about 6 inches high,
with a diameter of 7 inches. In culture they show, their
fourth leaf the seedlings are planted firmly into these
pots with a dibber, pots being well filled with the above
soil; care should be taken that the roots are inserted
vertically. From six to eight plants are put into such a
pot. These pots are then placed on sunny stages, usually
protected by telt-roofs. The development of the
plants depends now principally on careful watering,
which is done mostly with watering-pots and at the
beginning with a fine spray attached to the spout of
the pot. After a crust has formed on the top of
the soil, the spray is discontinued and the pots are
watered with the pipe of the can. This watering is done
at night during warm weather and in the morning when
the weather is fair. Very little watering is necessary in
continuously cloudy or rainy weather. The watering of
the stocks is the most particular and important part in
the cultivation in pots, for if due care is not exercised
a white maggot will make its appearance while the plants
are in bud and destroy the roots. The common flea-bolde
is another of the enemies of stocks; this often appears
in large numbers and eats the leaves of the young
plants. Frequent syringing with water is the only
remedy found so far against these pests when they infest
stocks. After the plants have been in bloom for a
while the double-flowering specimens are cut out
and the watering is continued carefully until the seed-
pods which form in the single plants show indications
of ripening, which is in October. The plants are then
pulled up and tied in bundles, which are hung up in dry
sheds until the middle or the latter part of November
and December, in which time the seed fully matures in
the pods. Now comes the most important part of seed-
seving of stocks. The bundles of plants are taken down,
the roots and part of the stems cut off, and the stalks are
taken in hand by expert gardeners who sort them for
common seed and also for the seed-stock. The pods indicate by their shape, size, and form whether the
seeds contained therein will produce a high percentage
of double flowers the following year, and the selection is
made with care. The seed that goes on the market
can be vastly improved by the removal of "wild" pods,
which contain seeds that produce nothing but single
flowers. The seeds are removed by hand from the pods,
mostly by women and children.

CARL CROPP.

STOKESIA (Jonathan Stokes, M.D., 1755-1831,
English botanist). Compositae. Stokes' Aster is one of
the choicest and most distinct of American hardy per-
ennial herbs, although little planted.

Heads many-fl.; marginal fls. much larger, deeply
5-cut: involucres subglobose; outer leafy, the inner with
foliculate, pectinately spinulose-ciliate, spreading ap-
pendages; receptacle fleshy, flat, and naked: achene
3-4-angled, smooth; pappus of 4-5 thread-like, decid-
uous scales. The species is a blue-fl. plant about a foot
high which at first glance has points in common with
China asters, centaureas, and chicory. The heads are 3
or 4 in. across in cult. The marginal row of fls. is com-
poved of about 15 ray-like corollas, which have a very
short tube at the base and are much broadened at the
apex and cut into 5 long, narrow strips.

The plant is hardy as far north as Rochester, New
York, and Boston, Massachusetts. Probably many
persons have been deterred from trying it because it
is native to South Carolina and Georgia, and because it
is considered a greenhouse subject in some standard
works on gardening. The fact that it is found wild in
wet pine-barrens is also deceptive, for the roots, as Wool-
son and Keller testify, will decay if water stands on the
soil in winter. Moreover, the plant has been praised by

Moehan for its drought-resisting qualities. Stokes' aster
should be planted in a well-drained sandy loam,
not in cold and heavy clay. It blooms from August
until hard frost. According to Chapman, the heads of
wild specimens are only an inch across, but the size of
heads in cultivated plants is stated by many horti-
cultural experts to be 3 to 4 inches across. The heads are
frequently used for cut-flowers. In the wild the heads
are few in a cluster or solitary; in cultivation a good
branch sometimes bears as many as nine heads. No
double form seems to have appeared but a white-flow-
er form is now on the market.

Moehan, Hill (S. cyanea, Lin.). Fig. 3699. Much-
branchered, hardy perennial herb, 1-2 ft. high; branches
often purplish, sometimes hairy when young; lvs. lan-
ceolate; radical ones entire, tapering at the base into
long, flattened stalks; cauline lvs. gradually becoming
sessile, the uppermost with a few teeth near the base and
half-clasping; fls. blue or purplish blue, 3-4 in. across.

Var. alba, Hort., has white fls. Var. praecox, Hort., is
a lavender-fl. sort.

WILHELM MILLER.

STONECROP: Sedum.

STORAGE and refrigeration of fruits and vegetables.
The storage house has become a very important
adjunct to fruit-growing. In fact, fruit-growing would
not be possible in present-day large-scale practice
without storage, or some means to preserve the fruit
from deterioration. Without some way to hold fruits in
sound condition during the time required to trans-
port them from the place of production, the develop-
ment of the large fruit industries of the West and South
would be impossible. The two most important factors
underlying the success of modern fruit-growing are the
discovery of methods of controlling insects and dis-
ees and the application of refrigeration to the trans-
portation and storage of the crops. The time required
to transport fruit crops to the centers of consumption
varies from a few hours to ten days, and in some cases
two or three weeks are required, especially when the
fruit is exported to foreign countries. Under these con-
ditions, the trip to market really becomes a period
of storage and the application of storage principles is as important as transportation principles. The object of refrigeration in the transportation of fruits involves only the holding of the fruit in sound condition long enough to reach the consumer. Storage, on the other hand, includes the holding of the product for a long or short period, thereby lengthening the season of marketing as well as increasing the territory over which it may be distributed. The lengthening of the season of storage during which the product may be sold, is very essential when the production of fruit crops has reached a point greater than can be consumed during the normal season. This is aside from the general advantage of having a product out of season, for which many consumers are willing to pay a higher price. The conservation of the surplus crops through storage enables the equalization of the selling or marketing season, giving the consumer the advantage of obtaining supplies during a longer period, and giving the producer a chance to market larger crops at profitable prices. The application of storage to the apple industry has resulted in making this fruit an all-the-year-round staple food, as supplies are easily held from one season to the next. The advantages of this to both consumer and producer are manifest. If the apples had to go into consumption during the normal season of this fruit, there would be alternate periods of plenty and scarcity. The same is true, although to a less extent, of other fruit crops, such as pears, grapes, peaches, and oranges. Many of all others who are likewise held successfully in storage for longer marketing periods than their normal seasons. Potatoes, celery, cabbage, onions, and even lettuce and cauliflower are successfully stored for varying periods.

Storage also finds application in other horticultural industries. The nurserymen are enabled to hold their stocks of trees, plants, cions, or cuttings until the proper season of planting or propagation arrives. Bulbs, lily-of-the-valley crowns, and cut-flowers are also successfully stored, sometimes known as "dry storage." The products are held in their original or "fresh" condition throughout their normal life, provided they have been properly operated.

Another unfortunate fallacy, that cold-stored products may be used as fresh, has been over-emphasized. The present high cost of living has resulted in making this fruit an all-the-year-round staple food, as supplies are easily held from one season to the next. The advantages of this to both consumer and producer are manifest. If the apples had to go into consumption during the normal season of this fruit, there would be alternate periods of plenty and scarcity. The advantages of this to both consumer and producer are manifest. If the apples had to go into consumption during the normal season of this fruit, there would be alternate periods of plenty and scarcity. The same is true, although to a less extent, of other fruit crops, such as pears, grapes, peaches, and oranges. Many of all others who are likewise held successfully in storage for longer marketing periods than their normal seasons. Potatoes, celery, cabbage, onions, and even lettuce and cauliflower are successfully stored for varying periods. Storage also finds application in other horticultural industries. The nurserymen are enabled to hold their stocks of trees, plants, cions, or cuttings until the proper season of planting or propagation arrives. Bulbs, lily-of-the-valley crowns, and cut-flowers are also successfully stored, sometimes known as "dry storage." The products are held in their original or "fresh" condition throughout their normal life, provided they have been properly operated.

Another unfortunate fallacy, that cold-stored products may be used as fresh, has been over-emphasized. The present high cost of living has resulted in making this fruit an all-the-year-round staple food, as supplies are easily held from one season to the next. The advantages of this to both consumer and producer are manifest. storage are frequently responsible for untimely deterioration, and the practice should be discouraged; but so far as fruits and vegetables are concerned, it is perfectly safe to state that no injurious effects have ever followed the use of these cold-stored foods. The evidences of deterioration are plainly visible, fruits and vegetables and there are no hidden germs or ptomaines. No one is likely to be deceived into eating a deteriorated fruit or vegetable.

The agitation against cold-stored food products has resulted in a demand for legal regulation of the storage business. Several states have passed laws prescribing certain conditions which must be met. Attempts have been made to obtain federal regulation, and no doubt federal laws concerning the cold storage of fruits and vegetables will eventually be enacted. The state laws now in effect and the proposed federal legislation place arbitrary limits upon the time the products may be held; provision is also made regarding the marking of the products, and the inspection of the goods from time to time is provided. Legal regulation of this business is desirable and wise, but it is not wise to present arbitrary obstacles to the development of refrigeration. It is questionable whether the adoption of an arbitrary maximum will fully meet all possible conditions, and the entire plan of restriction is open to criticism. Not only does the length of time vary for different classes of goods, but within the same class the condition of the product at the time it is placed in storage or its treatment previous to storage very materially influences the time the product may be held in whole or in part. Not only does the length of time vary for different classes of goods, but within the same class the condition of the product at the time it is placed in storage or its treatment previous to storage very materially influences the time the product may be held in whole or in part.

Through this system of food conservation, the extension of markets and the territory over which different commodities may be distributed are very materially increased. In the use of cold storage or refrigeration, the first establishments depended on ice for the refrigerating medium. In the earliest plants natural ice was used. This was gathered or "harvested" during the winter and used during the spring and summer months. There is a very large quantity of natural ice used under modern conditions, but the manufacture of ice is increasing and the use of "artificial" ice is likewise extending, even in districts where natural ice may be obtained without difficulty.

Systems of refrigeration.

In modern cold-storage plants two systems of refrigeration are used: (1) ice refrigeration, and (2) mechanical refrigeration. There are several methods of applying each system. In the use of the first, ice alone may be the refrigerant, or a mixture of ice and salt may be used to obtain lower temperatures than are possible from ice alone. In the application of the ice-and-salt refrigerant, several systems may be used, as will be explained later. The ice used may be manufactured or natural, depending on the relative cost.

In the mechanically refrigerated plant, the refrigeration is secured directly without first producing ice. It is apparent that the direct application of the refrigeration results in a very material saving in both time and energy. In this way, the cumbersome method of first manufacturing the ice and the consequent inconvenience in handling it are avoided.

There are two kinds of cold-storage plants—the general warehouse, provided with cold-storage equipment for handling all classes of commodities; and the storage plant constructed especially for the storage of a particular commodity, such as eggs, dairy products for example. It is evident that the large general warehouse may have a very great advantage in economy of operation. The general warehouse handles a mixed business which often results in a more economical distribution of overhead operating expenses than is possible when the entire burden of expense must be borne by a single commodity or single class of commodities. It is easy to see that the greatest efficiency and economy of operation occur where practically the entire capacity of the plant is used during the year. This is hardly feasible with fruits, with the possible exception of apples which are now held largely during the greater part of the year. But even in the case of apples, there cannot be a full use of the equipment constantly, as the withdrawals will be gradual throughout the season. Nevertheless, the construction and operation of cold-storage plants for apples or other fruits is constantly increasing. These plants may be owned by special corporations or built and operated by growers' organizations or by growers who have sufficient acreage to warrant the extra provision of storage facilities. In some instances the ownership or control of cold-storage facilities has rendered the storage of a particular commodity independent of its production. The ice used may be owned by special corporations or built and operated by growers' organizations or by growers who have sufficient acreage to warrant the extra provision of storage facilities. In some instances the ownership or control of cold-storage facilities has rendered the storage of a particular commodity independent of its production.

Mechanical refrigeration depends on the compression of a gas or vapor. The compression exerted heats the gas, and in some instances, liquefies the gas. The heat is absorbed by means of cooling water, and when the gas is allowed to expand, an equal number of heat units is absorbed from the surrounding medium. This, briefly, is the general principle upon which depends the operation of air-compressing machines. The gases used may be air, ammonia, sulfur dioxide or carbon dioxide, commonly known as carbonic-acid gas. In the cases of air machines, the air is simply compressed under very heavy pressure and cooled by means of water. There is no liquefaction of the air attempted in the case of these machines. The advantages of the air-compressors are that they are comparatively easy to manipulate and there are no injurious effects in case of leakage from the compressed vapor. These machines are used to a great extent on shipboard, and in England to a much greater extent than in the United States. Improvements in the construction of air-compressing machines are resulting in their increased use. The disadvantage of the air-refrigerating machines is that they are relatively inefficient for low temperatures. There being no liquefaction of the gas, the advantage of the latent heat due to the change of state is absent, and consequently there is a loss of efficiency to the extent of the latent heat necessary, first, to change the gas to the liquid and then back from the liquid to the gaseous state.

In the machines which utilize a liquefiable gas, that is, a gas which may be liquefied at comparatively high temperatures, the latent heat due to the change of state adds greatly to the efficiency of the machines, and consequently, much lower temperatures can be secured for a given amount of power. One of the essential qualities of the gas which may be used for this purpose,
is that it must be comparatively inexpensive and must be within the means of utilization by a comparatively simple apparatus. Ammonia, sulfur dioxide, and carbon dioxide are in general use in about the order named. Ammonia is the most common, and is in many respects the best. It may be supplied at a lower pressure and a higher temperature than either carbon dioxide or sulfur dioxide. Carbon dioxide is, therefore, somewhat less efficient to the extent that the high pressure requires more power, there is greater friction to overcome, and colder temperatures are not always obtainable within ordinary means. Carbon dioxide has the advantage of being a non-irritating and non-poisonous gas. If leaks occur in the system, there is no great danger of serious injury either to the operators of the machinery or to the goods stored in the rooms. If leaks occur in the ammonia system or in the sulfur dioxide machines, there is very great danger of injury to the workmen about the plant and the food commodities exposed to these gases may be very seriously injured, even with slight leakage. Nevertheless, the greater ease with which the ammonia machines can be manipulated is considered a sufficient advantage, and this type of machine is much the commonest in use.

The system of operation of the refrigerating plant is comparatively simple although rather complicated machinery is required. It is not essential that the fruit-grower who contemplates the erection of a refrigerating plant be conversant with all of the complicated details or that he understand the principles upon which the machines are designed. For the erection and planning of a complete storage plant depending on refrigerating machinery, the services of a competent refrigeration engineer are essential. While it may be possible for a mechanically inclined fruit-grower to design and have erected a complete refrigerating plant, it must not be forgotten that slight errors in the calculation of the power required and the capacity of the machinery necessary to handle a given load will frequently render the operation of the plant very much more expensive than need be, or the efficiency of the plant may be very seriously impaired. Refrigerating machinery is, of necessity, expensive; it is likewise necessary in many respects.

There are many styles and designs of refrigerating machines. All, however, are dependent upon the same general principles. There is, first of all, the motive power which may be either the gasoline or electric motor, or the steam engine, which furnishes the power to operate the compressor. The compressor exerts pressure on the gas, heating it to a rather high temperature. If the machine is operating with ammonia gas, the compression results in a dense hot vapor. From the compressor, this hot vapor passes to the condenser, which is a system of pipes arranged in such a way that streams of cooling water may be passed continuously around the pipes containing the hot gas. The absorption of the heat from the dense vapor condenses it into liquid ammonia. This liquid is ordinarily run into a tank, again heated, and the process repeated.

When one contemplates the installation of refrigerating machinery, one of the most important factors to consider is the supply of water needed for condensing. This is ordinarily of very much greater importance than is appreciated. Large quantities of water are needed unless the temperature of the water is very low. The higher the temperature of the water-supply, the larger the quantity needed. The same water may be used continuously if there is some means at hand to cool it after it has served to absorb the heat from the condensing ammonia. In large refrigerating plants this is taken care of by means of large racks or towers in which streams of cooling water may be passed continuously. In towers, the water is run through screens which break it into fine streams, thus increasing the evaporation and cooling the water by the absorption of its heat. Unless some means is at hand to cool the water, a constant supply must be provided; otherwise, the efficiency of the machinery will be very greatly reduced. This point is of the utmost importance when refrigerating plants are to be located in fruit-growing districts. In fact, the practicability of operating the refrigerating plant successfully depends primarily on the presence of a sufficient supply of water for condensation.

Ice systems.

Refrigeration may be obtained from the use of ice alone. In this instance, however, only cool-storage effects can be obtained, except in winter and in climates where the outdoor temperature is low enough to offset the lack of refrigerating effects from the ice. The minimum temperature obtainable from ice is its melting point, which is just above 32° F. or, under the very best conditions, about 33° or 34°. Generally, ice-cooled chambers cannot be maintained below a temperature of 38° or 40° and these temperatures are obtainable only under the most favorable conditions. To obtain a temperature of 32° F. from ice, the addition of salt is necessary. The mixing of salt with the ice lowers the melting-point and, consequently, the temperature is lowered, although the rapidity with which the ice is consumed is very greatly increased. When the mixture of ice and salt is used, the quantity of ice necessary for storage is much greater. A lower temperature is necessary to hold the storage chambers at 32° F. because of the heat leakage into the chambers through the walls.

There are two methods of obtaining refrigeration from ice and salt. One of these is the indirect method, known as the gravity-brine system, and the other is the direct circulation of air through the ice and salt mixtures.

The gravity-brine system, the invention of Madison Cooper, acts as the reverse of a hot-water heating system. It depends on the principle of the greater density of a cold liquid, and its consequent downward flow when confined in a impermeable medium; in this way the refrigeration is obtained. After expansion, the ammonia gas is passed back to the compressor where it is again compressed and afterwards liquefied, the same gas being used over and over again. Instead of the compressor, the same effect can be obtained from what is known as the absorption system. This is a combination of a chemical and mechanical process. No compressor is used. Dense aqu-ammonia, which is simply a strong solution of ammonia gas in water, is heated in a reservoir, and as the ammonia escapes from the solution, it is under high pressure and becomes a dense vapor. From this tank the gas is passed through condensing coils and liquefied, just as is done in the compression system. After liquefaction, it is allowed to expand in coils and the gas is then returned to a tank or a series of tanks known as absorbers. These absorbers contain cool water which readily absorbs or dissolves the ammonia gas. From the absorber, the ammonia gas is pumped into the heating tank, again heated, and the process repeated.

After expansion, the ammonia gas is passed back to the compressor where it is again compressed and afterwards liquefied, the same gas being used over and over again. Instead of the compressor, the same effect can be obtained from what is known as the absorption system. This is a combination of a chemical and mechanical process. No compressor is used. Dense aqu-ammonia,
The cold brine passes through the secondary coils, and, as it absorbs the heat from the rooms or chambers, its density is decreased and it flows upward and is returned to the top or primary coils, where it is cooled and the process repeated. Fig. 3700 is a diagram illustrating the principle upon which the Cooper gravity-brine system depends. At the top of the illustration the primary coils are shown and the methods of placing the pipe systems or coils is indicated.

The cooling effects secured from the Cooper brine system are indirect in that the refrigeration obtained from the ice-and-salt mixture is first exerted upon the brine solution and this solution is the means of carrying the refrigeration to the place where it is needed. There is an inevitable loss in the indirect method because of the loss of refrigeration in the conducting pipes.

In the second system of securing refrigeration from ice and salt, the air is passed directly through the mixture and, consequently, the refrigerating effect is obtained directly from the mixture. Experiments have shown that very low temperatures can be obtained by passing a current of air through an ice-and-salt mixture, the temperature depending on the proportion of salt used in the mixture. The higher the percentage of salt the lower the temperature obtainable. The device for obtaining refrigeration in this way is simple. It consists of a tank for holding the crushed ice and salt. At the bottom of this tank openings are provided through which a current of air can be forced. The particular working out of the design for obtaining refrigeration in this way has been accomplished by S. J. Dennis, of the United States Department of Agriculture. Dennis’ apparatus has been used successfully in several plants on the Pacific coast, and owing to the fact that it was developed as a part of the Departmental investigations, its use by the citizens of the country is free. It is essentially an ice-and-salt tank of “magazine” type. As the ice is melted at the bottom the supply from above drops down. From 7 to 10 per cent salt has been found to yield satisfactory temperatures. The apparatus can be constructed by almost any ordinary mechanic who can follow detailed drawings or instructions. A fan is used to draw the air through the ice-and-salt mixture and to force the refrigerated air into the storage chambers. Ducts are provided for the return of the air, and in this way the same air is used continuously.

There is another method of securing refrigeration from ice and salt which may be designated as the “tube system.” In this system the mixture of ice and salt is contained in tubes located at the sides of the room. The tubes are filled with the mixture from the top and the refrigeration is obtained by the cooling of the air in contact with the tubes. The number of tubes necessary to cool a given quantity of goods depends upon the character, size, and insulation of the room. The tubes are constructed of galvanized iron and are about 8 or 10 inches in diameter. The tops of the tubes open above the storage room, so that the filling can be done without opening the room itself. A proper arrangement of pipes at the bottom to carry off the brine is necessary, and in arranging for this melting outlet, a proper trap must be provided in order to prevent the wastage of the cold air. This system has found considerable application in the Hudson River Valley of New York state, and is very effective for a short season of storage.

Systems of applying refrigeration
Refrigeration may be defined as the cold obtained from a refrigerating medium or directly from mechanical appliances. The temperature-reducing properties of the ice-and-salt mixture and those of the liquid ammonia are the refrigerating qualities of these agencies. Refrigeration is ordinarily measured in terms of melting capacity in a day of twenty-four hours. For example, a machine which is rated as yielding a capacity of ten tons a day is based upon the melting of ten tons of ice in that time. Ordinarily, it is not the quantity of ice which can actually be produced by the machine, except when ice manufacture is the primary object.

There are three systems of applying the refrigeration secured by mechanical means: (a) direct expansion; (b) brine circulation; (c) air circulation. The claims for this system are that the work is direct; therefore there is no loss in conducting the refrigeration obtained from the pipe surface. The greatest objection to this system, especially with ammonia or sulfur dioxide plants, is the danger of leaks. Small leaks may allow a sufficient quantity of gas to escape to damage the goods stored in the room. There is also great danger to the workmen, which has already been referred to. The greatest care is necessary in constructing the direct-expansion system. With the perfection of mechanical devices for welding and fastening pipes, the danger from leaks has been reduced to a minimum, and there are many direct-expansion systems in operation in which no injuries have ever been recorded. One disadvantage is the fact that there is no reserve power except that which is contained in the liquid receivers. Should it be necessary to shut down the machinery for repairs for any considerable length of time, there would not be sufficient reserve to continue the refrigerating effects and the temperature of the storage rooms would be likely to rise to a considerable extent.

In the brine-circulation system, the expansion coils are surrounded by a non-congealable brine such as a solution of calcium chloride, which has a very low freezing-point. The brine is cooled in the pipes and this cold brine is circulated through coils in the rooms by means of pumps. In applying this method, there is first, what is known as a brine-cooler in which the brine is cooled.
collected in a brine tank of sufficient capacity to operate the plant for a considerable length of time. This really acts as a reservoir of cold, and from this reservoir the cold brine is circulated throughout the entire cold-storage plant, the temperature and quantity of the brine circulated being governed by the results desired.

The coils of pipes in the rooms are commonly referred to as the "piping." These coils or racks of pipes are the most important for refrigeration, and the number, coils or length of piping depends upon the size of the room and the temperature desired. Low-temperature rooms or freezers have a large number of coils and a great length of pipes. Pre-cooling rooms should also have heavy piping and many pipes. The advantages of the brine-circulation system are that there is no danger from leakage of ammonia or other irritating gas. The statement is also made that there is a more uniform temperature, the flow of the brine being under constant and easy control. The temperature of the brine is also under definite control. Perhaps the greatest advantage is that the supply of cold brine acts as a reservoir of refrigeration and a reserve supply can be drawn upon in case of necessary shutting down of the machinery.

In placing the pipes in cold-storage chambers, it is important to have them located at the upper part of the room. Ordinarily, the dependence for the circulation throughout the room is upon the natural circulation of the air within the room. The air in contact with the pipes is cooled and, being rendered more dense, flows to the floor, the warmer air from other parts of the room taking its place. In this way, a constant circulation is maintained throughout the room. It is easy to see, therefore, that the placing of the pipes in the upper part of the rooms is essential; otherwise, there is danger that the parts of the room above the pipes may be beyond the refrigerating effects. The air is, therefore, the medium of applying the refrigeration. It is due to convection currents that the transfer from the refrigerating pipes is effected, and it is very difficult to obtain a uniform cooling in all parts of the room unless the pipes are carefully placed.

In the air-circulation system of applying refrigeration, there is a forced air circulation. The air is forced through conduits or ducts by means of fans. In this system the expansion coils of pipes are in groups or batteries, what are known as bunker rooms, or more correctly, coil rooms. The refrigerating capacity of the plant is, therefore, concentrated in one place. In arranging the coil pipes, baffles are placed in such a way that the air passing through the coil rooms must come in contact with all of the pipes. If all of the pipe surfaces are not reached by the air, the full refrigerating effect of the plant is not obtained. The coils may be direct-expansion coils or brine-circulating coils, that is, have the brine circulating through them. The Cooper gravity-brine system may also be used. For this purpose, the secondary coils are located in coil rooms where the air to be cooled can be forced through.

In placing the fans for such a plant, the arrangement must be such that the air is drawn from the coil room and forced through ducts to the storage chambers. With this arrangement there is a constant pressure in the rooms which is preferable to the exhaustion of the air. Any leakage which occurs, therefore, is outward from the room instead of inward. Return ducts are provided which conduct the air back to the coil rooms, the same air being used continuously. Impurities from the storage rooms are absorbed by the air and deposited in the moisture which freezes on the cold pipes. The impurities, therefore, are very largely absorbed by the frost, and the circulation of the current of air through the coil rooms acts largely as a purifier of the air of the storage rooms. Some ventilation, however, is frequently desirable. The problem of ventilating a cold-storage chamber is a difficult one and special appliances must be provided for this purpose. The outer air cannot be admitted directly into the storage chamber unless it is at the same temperature as the air of the storage room. In warm weather, therefore, the admitted air must be cooled and in extremely cold weather it must be warmed. There are special mechanical devices for accomplishing both of these purposes.

Shape of storage plants.

Many storage plants are planned without consideration of the factor of the most economic shape; that is, the most efficient as well as the most economical size of plant to be constructed. The first consideration is that the plant should be planned to supply the required floor space and cubical capacity. In figuring the size of storage rooms to accommodate packages of fruits, the size of the fruit packages must be taken into consideration and enough space must be made to allow the air to circulate between the stacks or bales of packages. A barrel of apples, for example, requires 8 to 10 cubic feet. Another factor which must be considered is the economical handling of the packages in the storage rooms. Where the storage season is comparatively short, the extra exposure of packages in the rooms must be considered. Where, however, the storage season is to be long, higher stacks may be made and, consequently, rooms of greater height will be most economical. In the cubic contents of the chamber are determined, the next consideration is the shape of the plant or room.

The most economical shape for a storage plant is the cube. This is due to the fact that the ratio between the cubical contents and exposed outside surface is smaller for the cube than for any other shape. It is important to take this into consideration because of the fact that there is no perfect insulating material and, consequently, when the ratio of exposed outside surface is very high, the rate of heat leakage into the room is increased considerably when the shape of the room differs materially from the cube. Such a room must have either much heavier insulation or considerably more power supplied to offset the greater heat leakage. Sometimes limitations of space, as for example, utilizing parts of buildings, require that the rooms be of odd shapes. When this is necessary, it will require considerably more insulation or power, as suggested. The capacity of the plant must be determined by the shape of the commodity to be stored. Large rooms are easier to maintain at a desired temperature after the entire load of the room is reduced to the required temperature. In large rooms, however, it is more difficult to cool uniformly unless some special attention is given to the placing of the pipes, or the duct openings where forced air circulation is used. For periods of short storage, such, for example, as the more perishable fruits like berries, rooms of smaller capacity are more desirable than very large rooms.

Insulation.

There are three ways in which heat may be transferred: radiation, convection, and conduction. Radiation is the transference of heat from one body to another through a third medium without perceptibly affecting the medium. The heat which one feels when standing before a fire is radiant heat. The conduction of heat is accomplished by the passing of heat from one body to another by contact with the heated body. The heat that one feels when the hand is placed on a warm pipe is conducted heat. Heat is transferred by convection by means of a third medium, usually air. In attempting the construction of storage houses, all three methods of heat transference must be taken into consideration. The heat actually radiated is comparatively small in storage buildings. The quantity of heat transferred by conduction is greater, but the most
important problem of heat transference is through convection currents. In order to offset this heat transference, specially constructed walls must be provided. A storage chamber is a room so constructed that the temperature may be maintained at or near a constant point. In order to offset changes of temperature, sufficient refrigerating capacity must be provided, or some provision must be made to prevent the actual transmission of the heat from the outside to the inside of the room. The latter provision is known as the insulation of storage rooms. Therefore, the rooms are constructed in such a way that the walls act as barriers against the transmission of heat. Convection currents actually occur in filled walls, although slight, gradually destroy the insulating effect. Attempts to prevent this have been thought to be efficient insulation. Still air is a necessity where this method of insulating the wall is used. A slight leakage into the wall is sufficient to allow outer air to enter and, consequently, to destroy the insulating effects. In walls constructed of free air spaces, convection currents occur within the spaces, which act as effective transferers of heat either inward or outward, as the case may be. Fig. 3701 shows the action of convection currents within air spaces. When one air space is used, the transfer of the heat is very easily accomplished, as shown by the direction of the air currents—shown by the arrows in the diagram. Simply thickening the walls, therefore, does not act as a sufficient insulation. The effect of air spaces is constantly improved by breaking up the walls into smaller air spaces. The diagram shows the convection currents occurring in walls of one, two, three, or four air spaces. As the number of spaces is increased, the effect of convection is very greatly reduced, so that a wall consisting of four air-tight spaces may be considered as fairly efficiently insulated. It is, however, extremely expensive to construct these air-tight divisions, and some other means of insulation is desirable.

It is preferable to use some material to fill the walls. Such a filler breaks up the air spaces within the walls and confines the air in the small interstices between the particles. In this way, the air held within the wall approaches more nearly the desirable "dead-air" condition. Convection currents actually occur in filled walls, but they are very sluggish and the effect is very slight. Filled walls are effective barriers against heat conduction or radiation, provided, of course, that poor conductors of heat are used.

The most effective insulating material is a substance of low-heat conductivity which has many pores or cells. These cells are filled with air (practically still air); consequently the efficiency of the heat barrier is increased a number of times that are effective for storage walls. The requirements for an insulating material, besides non-conductivity of heat, are as follows:

1. Odorless; any strong odor would affect the goods stored in the rooms.
2. Moisture-proof or low capacity for moisture; dampness decreases the efficiency as an insulating material, and some substances ferment or rot when damp.
3. Vermic-proof; there should be no inducement for rats or mice to nest in the walls.
4. Non-liability to inherent disintegration or spontaneous combustion.
5. Lightness in weight; not only on account of the reduction of the actual weight of the walls, but because light materials are usually the best non-conductors of heat.
6. Elasticity; when packed firmly in the walls the material should not settle, as any settling within the walls results in open spaces in the insulation. After the walls are once constructed, these inequalities cannot be reached for repairs without completely rebuilding the walls.
7. Relative cheapness and economical handling; the material should not be so high in cost as to be prohibitive. In addition, the material must not be of such a nature that it is economical handling is impracticable.
8. Must allow of practical application in general work; very specialized material which would not lend itself to general conditions could not be considered as efficient insulating material.

The list of materials available for insulation may be divided into two classes: Those that can be considered as commercial insulation—that is, materials which are manufactured especially for insulating purposes; and common or waste materials.

Among the most common of the first class are the following: granulated cork, cork sheets or boards or bricks, hairfelt, linofelt, mineral wool, and lith.

Granulated cork is considered to be one of the best and most effective insulating materials. It is prepared from the trimmings of cork mills, and when used in the granulated state is simply filled into the walls and packed tightly. Cork sheets, bricks, or boards are manufactured of the cork particles which are compressed in molds at a high temperature. There is no cementing material used, the heat and pressure being sufficient to liquefy the natural gums and resins of the cork and these hold the particles together. Cork boards or sheets are also made by the addition of asphaltum pitch which renders the particles water-proof but may decrease the insulating efficiency.

Hairfelt is manufactured of waste cattle hair which is washed and deodorized. It is pressed or felted together by special machinery into sheets from 1/4 to 1 inch in thickness.

Linofelt is a patented material manufactured from...
flax fibers. It is prepared in sheets or quilts, from ¼ to ½ inch thick, somewhat like cotton-battting. These sheets are ordinarily quilted between water-proof paper. This material is used largely for insulating household refrigerators and refrigerator cars.

Mineral wool is also known as rock-wool, rock-cotton, rock-cork, or silicate cotton. This material is usually made from the slag of blast furnaces with the addition of limestone. Rock-wool is usually made from a mixture of granite particles and limestone. The crushed rock is mixed with coke and fused in furnaces at a temperature of about 3,000° F.; the molten slag or rock is run out through the bottom of the furnace by a high-pressure steam blast. This blows the slag into very fine shreds or fibers, much resembling fleece or wool. The result is a material which contains from 92 to 96 per cent air spaces and, although consisting primarily of a substance of high-heat conductivity, is fairly efficient as insulation. It is practically vermin-proof, fire-proof, and not liable to decay. It absorbs moisture very easily, and one of the greatest disadvantages is the difficulty of handling. The fibers are very penetrating and are glass-like, which result in considerable inconvenience in handling the material.

Lith is a manufactured insulation composed of flax fibers, lime rock-wool, and water-proofing compound. It is prepared in boards of standard sizes and thicknesses and is accepted as a standard insulation by refrigerating engineers. It is a very efficient insulating material.

Common forms of insulating material which are usually at hand or can be easily obtained for the construction of storage buildings are: straw, chaff, hay, dry grass, dry leaves, hulls of various grains, sawdust, and mill shavings.

All except sawdust and mill shavings can be considered as suitable only for temporary structures. These materials are all fairly efficient as non-conductors of heat provided they are dry and means are used to keep them in a dry condition after being built into the walls. There is also some danger from the depredations of rats, and the greatest possible care must be used to prevent these rodents from gaining entrance. Sawdust from different woods has about the same insulating effect. The sawdust must be thoroughly dried, otherwise its efficiency as insulation is very greatly impaired and, in addition, there is danger of fermentation and heating, and even spontaneous combustion. It is more difficult to obtain dry sawdust than mill shavings, and whenever sawdust is used it should be very carefully dried before being placed in the walls. It has not as great elasticity as mill shavings and, consequently, is likely to settle after packing unless very carefully pressed into place.

Mill shavings consist of small chips and shaving from planing mills. This material has largely replaced sawdust for insulating purposes and is much more effective. It is obtained easily in a dry condition, owing to the fact that the mills of this kind usually work dry lumber. It is much more plastic than sawdust and does not pack or settle down. If thoroughly dry, and means are taken to keep it so, it is a very efficient insulating material and will remain in good condition for many years. It should be packed in the walls at the rate of eight or nine pounds to a cubic foot.

Whenever walls are filled with insulating material in loose condition, much will depend upon the method of constructing the walls. Not only is it necessary to use the proper material in a dry condition, but unless the walls are properly built, the insulation will not retain dry any great length of time. Walls that are not practically air-tight allow the outside air to gain entrance and to mix with particles of insulating material; condensation of moisture takes place, and the insulating efficiency of the material is seriously impaired. The conditions for the condensation of moisture upon the insulation particles are ideal unless special means are used to prevent it. Contact with the inside walls lowers the temperature of the insulation to such an extent that when the warmer air from outside comes into contact with it, the moisture is deposited and absorbed. Therefore, it is necessary to build the walls in such a way that they will be practically air-tight. This is accomplished by having layers of elastic water-proof paper on the outside and inside of the walls. The proper method of constructing such walls is shown in Fig. 3702. The wall consists of two layers of matched boards on each side, between which the water-proof paper is placed. The figure also shows the proper method of overlapping the paper at the corners. It is very essential that these details be attended to; it is also necessary to prevent the tearing or breaking of the paper when placing it, and for this reason only elastic paper should be used. The more brittle forms of paper are so easily broken that it is almost impossible to place them without seriously injuring them. Any breaks at the corners or tears in the paper will allow considerable air leakage into the walls and very seriously impair their efficiency. This is probably one of the most important details in the construction of storage houses, both for cold-storage and for common-storage purposes. Too great stress, therefore, cannot be placed on this point.

Storage temperatures; humidity.

The general principles governing the application of low temperatures to the preservation of fruit products depend primarily on the fact that temperature is the most important factor governing the life activities of these products. A fruit or vegetable is a living organism in which the functions or life processes are continually proceeding as long as the body remains in a normal condition. The various processes of ripening depend upon the chemical and physiological changes within the
organism. Contrary to common belief, the life processes do not cease when the fruit is removed from the parent plant. These processes continue until the life cycle of the organism is completed. The fruit organisms respire and transpire just as plants do and the measurement of the end products of these respiration and transpiration processes serves as an index of the rate at which the life activities are proceeding. Definite measurements on a large scale has shown that the temperature factor is the most important from the standpoint of the rate at which the life activities proceed. Each fruit organism has a definite life span or life cycle, and it is easy to see that if in any way these activities can be retarded, the life span can be lengthened. The reduction of the temperature of the organism materially reduces the life processes, and the rates at which these activities proceed is slackened to such an extent that the definite life functions of the organism may continue slowly during a long period. The retardation of the life activities through the reduction of the temperature thus induces a slowness of the rate and a consequent increase of the length of the life span. This is the essential physiological principle upon which cold storage and common storage of fruits depend.

The most satisfactory temperature for storage purposes is one which is low enough to reduce the life activities to a minimum but not so low as to have the fruit become so cold that it is injured. It is important to remember that a complete stoppage of the life functions of a fruit organism means the death of it, and when this occurs, the fruit soon thereafter becomes unfit for food.

Much careful investigation remains to determine the most satisfactory temperatures for various fruit products. Many factors are involved. One of the most important of these is the condition of the product when it is placed in storage. Fruits of the same kind and the same variety have different cold storage qualities and require different storage treatments, depending upon the place where the fruit is grown or its previous handling. Until these factors are all known and controlled, it is unsafe to say that any particular temperature is exactly correct for all fruits. For this reason, it is difficult to limit storage periods by law, because no arbitrary limit can be satisfactory for all fruits. It would not be safe, for example, to state that apples should not be kept longer than a certain length of time. The same is true of pears, but with this fruit the conditions are even more extreme. Different varieties of apples and pears may be held in storage different lengths of time, and all warehousemen know by experience that the same varieties of fruits produced in different districts or in different seasons have different storage qualities.

The proper storage temperature for a fruit should be the lowest possible—that is, the lowest temperature at which the fruit can be held without actual injury. This is due to the fact that when other conditions are satisfactory, the lower it is possible to hold a given product the longer it will remain in good condition. This means, then, that the freezing point of the fruit can be safely approached under ordinary conditions. There are, naturally, some important exceptions to this general rule.

As has been indicated above, different fruits have different rates of life activities, and the more perishable fruits are those that have the most rapid rate. For example, perishable fruits like berries, peaches, and some varieties of grapes have very rapid life activities, while the less perishable fruits such as apples, pears, and the citrus fruits have a very low rate of life activities. This condition affects the storage period of a given fruit for the most favorable conditions. It is a well-known fact that the more perishable soft fruits cannot be held in storage for any great length of time. The naturally short life can be lengthened considerably but not to the same extent that the life span of the harder fruits can be lengthened.

Berries of various kinds, cherries and cranberries, may be hard frozen and held in such condition for several months when the product is intended for use in making sauce or pies. When the hard-frozen fruits are removed from storage they must be used immediately, as they soon become soft and break down physiologically.

The most desirable cold-storage temperature for a fruit, according to present knowledge of the subject, is 32° F. for apples, pears, peaches, plums, strawberries, raspberries, loganberries, blackberries (short time), cherries, grapes, mangos, celery, lettuce (short time). An apparent exception is in the case of apples from the middle coast section of California. The apples produced in this section require a somewhat higher storage temperature, due to the fact that a peculiar discoloration of the flesh develops when this fruit is held at the standard 32° temperature. This fruit is more safely held at about 35°. The varieties which are affected by this trouble are principally Yellow Newtown, Missouri Pippin, and, to a less extent, Yellow Bellflower. This apparent storage weakness seems to be confined to the mid-coastal district; apples from the mountains and other districts of the Pacific coast seem to possess normal storage qualities.

For potatoes, 35° to 40° F., for citrus fruits, 45° to 50° F., are the most satisfactory temperatures. Citrus fruits seem to be an exception to the general rule that fruits of low life activities can be held at temperatures near their freezing-point. Investigations show that temperatures below 45° F. are injurious to citrus fruits, except for a very short period. The low temperature seems to affect the skin of the fruit, inducing the deterioration by scald or stains and the development of various fungous diseases. At a temperature of 45° to 50°, or a common-storage temperature of 50° to 60°, citrus fruits may be held for several months without serious deterioration, provided means are taken to prevent shriveling. Lemons are sometimes held from four to six months at common-storage temperatures without serious deterioration, when humidity conditions are carefully attended to.

The proper humidity of the air of storage rooms is an important factor. Very little investigation of this
and when the air of the storage rooms becomes excessively dry, the fruit may become seriously wilted by excessive evaporation. The reduction of the temperature of the air reduces its water-holding capacity; consequently, as the air temperature is reduced to the freezing-point or below, all the excess moisture is removed and the air becomes saturated with water vapor for the temperature at which it is held. The total volume of water vapor is thereby greatly reduced. When the temperature of the air rises without the addition of moisture, its capacity for absorbing moisture from the fruit increases and, consequently, the drying effects due to refrigeration may be seriously overdone. The most satisfactory humidity condition in the storage room has never been correctly determined. Experience shows that the humidity condition should be as high as possible to prevent shrinkage from evaporation, but without danger from excessive moisture, which may induce the growth of mold.

Excessive wounding of fruits in storage is not always due to evaporation. Fruits which are picked in an immature condition wilt and shrivel seriously under the most satisfactory storage conditions.

From what has been said, it will be seen that humidity conditions in artificially refrigerated chambers very largely take care of themselves, due to the ameliorating effects of the refrigeration of the air. The control of the conditions becomes more important at high storage temperatures, e.g., it is very important in the storing of citrus fruits without artificial refrigeration. Under these conditions the humidity of the storage rooms or cellars must be held relatively high, because the higher temperature has a decided effect upon the life activities of the fruits, and a correspondingly high humidity is, therefore, essential. The fruit must be very carefully watched; otherwise, mold will occur when humidity conditions are too high. A relative humidity of about 80 to 85 per cent at a temperature of 50° F. has been found to be most satisfactory under the conditions which exist in California lemon-storage houses. It would not be safe to say that this humidity percentage is exactly correct, because the complexity of accurately measuring humidity conditions under different temperature conditions renders the problem very difficult.

Common storage.

The difference between common storage and cold storage has been explained (page 3246). The principal difference is that with cold storage, artificial refrigeration is used while in common storage there is no artificial refrigeration. Common storage is sometimes referred to as “dry storage,” inferring that cold storage must necessarily be wet. This assumption is incorrect; cold storage is not in any way connected with moisture nor is it more likely to produce moisture in storage rooms, provided they are operated as cold storage as is common storage. Any excess of moisture in the cold-storage room means some defect in the construction of the plant or in its operation. It has been said that cold-stored fruits are more moist when withdrawn from storage than common-stored fruits. Here again, the difference is due to the difference in the temperature. The cold fruit from the artificially cooled storage chamber, coming in contact with the warm moist air, will condense moisture on its surface. Fruits from the ordinary storage rooms may not be cold enough to condense moisture; hence, the assumption that the cold-stored fruit is more moist than that from common storage.

Common storage is not practicable for all fruits. The very active or highly perishable fruits cannot be held satisfactorily under common-storage conditions because there are no ready means at hand to cool them to the desired temperatures. Citrus fruits are eminently adapted for common storage. The curing of lemons is really a process of common storage. Winter varieties of apples and pears are also suitable for common storage. This method of storage is used to a considerable extent in New York and is coming into wide use in the Pacific Northwest. In the operation of common-storage rooms, dependence is placed on the ventilation for the cooling. There is a vast difference between ventilation due to the actual change of air by the opening of windows and due to the circulation of air. Ventilation means the admission of outer air, and circulation may refer merely to the movement of the air within the room or plant, the same air being used over and over again. This distinction is necessary because frequently the circulation of the air within the room is designated as ventilation.

In the operation of common-storage rooms, the rooms are ventilated, or outside air is admitted, when its temperature is low enough to cool the fruit. The ventilators are closed during the day and during warm periods, thus conserving to a certain extent the low temperature obtained through the low-temperature outside air. It is essential, therefore, that there be cold nights or cold weather. Otherwise, common-storage plants become mere cool-storage chambers, and the storage season is considerably shortened, due to the fact that the relatively high temperatures result in a high rate of life activities in the stored products. When the temperature of the common-storage room can be maintained somewhere near 32° early in the season there is no apparent reason why the storage period should not be extended to almost the same length of time that can be obtained under cold-storage conditions.

In the early part of the season, especially when there are few cold nights, it is difficult to reduce the temperature of the fruit to the desired point. This is the critical period, as the rapidity with which the temperature of the fruit can be reduced determines the length of time the fruit may be held in good condition. It is easy to see, therefore, that under common-storage conditions, usually the fruit must remain at a comparatively high temperature for a considerable length of time. The ripening which occurs during the period of high temperature cannot be offset by low temperatures later on. The developments which take place in this period of high temperature shorten the life span under storage conditions, and when the temperature is high and the fruit held warm for a considerable length of time, the storage period may be very materially shortened. There are frequent warm spells during the fruit harvest, and the nights are not so cold.
There is a widespread notion that common-stored fruits are better than cold-stored. It is difficult to understand how this opinion has become so fixed in the minds of many persons. It is probable that one reason is the fact that a comparison of fruit from common storage and from cold storage is really a comparison of fruits held under different conditions. The common-stored fruit is usually withdrawn after a shorter period and, therefore, may be in good condition. The cold-stored fruits are usually held for a long period and frequently the period is too long for the best condition of the product. Many carefully planned experiments show conclusively that cold-stored fruit remains in better condition during a longer period and, when carefully handled, remains in better condition after withdrawal than common-stored fruit. If the fruit is promptly and rapidly cooled at the beginning of the storage period, its life activities will be retarded to such an extent that the life span will be very materially increased. If this can be done under common storage, there is no reason why the fruit cannot be held in good condition. Frequently the fruit is placed in common storage during the fall and early winter; frequently also the common-storage room where the fruit is held is only a makeshift. After being held in this unsatisfactory condition for a time, the fruit is placed in cold storage later in the season when market conditions have improved. This is the wrong way to store fruit. The time when cold storage is most urgently needed is at the beginning of the storage period, in order that the fruit may be promptly cooled. It would be more reasonable to remove the fruit from cold to common storage later in the season, because common-storage rooms may then be held in a satisfactory condition and the fruit would be in a much better condition for holding.

It has been suggested that a combination of cold and common storage is really the solution of many of the problems of successfully holding the fruit in the district where it is produced. Where ice can be obtained at a reasonable price, it can be used at the early part of the storage season to cool the fruit promptly and quickly. After weather conditions are such that cool nights prevail, the place can be operated as an ordinary common-storage plant for the remainder of the season.

Common-storage buildings.

The earliest form of common-storage buildings for fruits was caves or pits. These were used for the storage of fruits under the impression that the earth is cool and also to protect the fruit from freezing in extremely weather conditions. The earth is cooler than the outside air in summer; in winter it is warmer, under ordinary conditions. Ordinarily, the temperatures of the ground range from 50° to 60° and this temperature remains fairly uniform below the frost line which, of course, varies materially under different climatic conditions. The protection against freezing in winter, therefore, is ideal, but unless some artificial method of cooling the room is at hand, the temperature of the earth itself is too high for best storage conditions. In the later development of the cave storage, ice was used to cool the chambers; this was naturally not satisfactory, due to the dampness and to the difficulty of ventilating.

Cellars have been a favorite place for common storage. They are open to the same objection as caves. The insulation for a common-storage room or building may be of the commercial kinds, which have been described, or use can be made of some of the cheaper common materials, such as straw, chaff, dry leaves, sawdust, and mill shavings. The principles of constructing the walls and using the insulation are all applicable to common-storage buildings and should be followed carefully if one expects to secure the best results. In addition to the insulation of the walls, an outer ventilat-
ing space is effective, especially during warm weather. Fig. 3704 is a diagram which shows the proper method of constructing a common-storage wall with an outer ventilating space designed to carry off most of the heat absorbed by the outer wall. Windows are not satisfactory for ventilating common-storage plants. The openings should be at or near the floor and there should be corresponding openings at the top, as shown in the diagram illustrated by Fig. 3704. The taking-in of the outer air depends upon the difference in temperature between the bottom and top parts of the building; therefore the greater the number of openings, the more rapidly the air of the room can be changed. A false floor is a distinct advantage, and will add very materially to the efficiency of the plant. The construction and use of such a false floor is illustrated in Fig. 3705. When the false floor is used, the openings or ventilators should open directly under the floor, so that the outer air may have an opportunity to pass directly beneath the product stored in the room. A forced circulation is very much more satisfactory and will result in a more rapid change of air. In order to accomplish this, an exhaust fan should be placed at the top of the chamber, so that the air of the room can be drawn to the fan and exhausted into the outer air, thus creating a reduction of the air pressure within the rooms and the consequent drawing-in of the air to the room when the ventilators or traps of the room are open. Fig. 3705 shows a cross-section of such a chamber and the proper location of the fan.

In the combination of the ice cooling and common storage, ice and salt or even ice alone can be used to cool the fruit at the early part of the season. The tube method may also be used with ice and salt or the gravity system before described can be advantageously utilized.

A diagrammatic cross-section of a combined ice-cooled and common-storage plant is shown in Fig. 3706. The design permits of the closing of ventilators and the opening of trap-doors, to utilize direct cooling from the ice stored above. A similar arrangement for the use of ice in small rooms can be made with the ice room or bunker placed at the end or side of the chamber.

The Figs. 3707 to 3713 are diagrams showing the proper construction of walls and the method of insulating walls, ceilings, and floors both with commercial insulation and common materials. Figs. 3707, 3708, and 3709 show the proper method of applying insulation to stone, brick, and concrete walls; while Figs. 3710, 3711, 3712, and 3713 show the method of applying insulating to ceilings and floors.

In the operation of common-storage plants, the fruit must be carefully watched at all times. The temperature should be taken frequently. It is very desirable that the actual temperature of the fruit itself be recorded from time to time. For this purpose, glass thermometers, the bulbs of which can be imbedded in the fruit, are desirable. Long-stem thermometers can be obtained which have the bulb at the end of a long tube and the recording scale at the upper end, thus allowing the temperature to be taken at the interior of the package. It is possible to note temperature conditions of the fruit by observing the influences of the temperature within the package upon the temperature of the room. When the fruit is thoroughly cooled throughout the mass, there will be little change in temperature after the closing of the ventilators. If the insulation of the room is effective, the change in the temperature of the air of the room will be very slight. If, however, there is any considerable heat left in the body of the fruit, there will be a marked and rather abrupt rise in the temperature after closing the ventilators.

Careful attention to the condition of the fruit is necessary also to determine whether the humidity of the room is too high or too low. This will be shown by the appearance of the fruit. Excessive ventilation, i.e., the circulation of large volumes of air through the room, will cause shrinkage or shriveling, while insufficient circulation will favor mold. Special recording hygrographs which record the changes in humidity almost instantly upon a chart are very convenient adjuncts to storage rooms in order to observe the humidity conditions. Instruments which record both relative humidity and temperature on the same chart are obtainable. When one desires to operate properly, an investment in such an instrument is a distinct advantage.

The length of time which different fruits may be held varies for the kind of fruits and even for different varieties of the same kinds of fruits. The importance of storage, then, is relative; it is most important for fruits

3706. Diagram showing construction and proper arrangement of ventilators in combined ice and common fruit storage room. Dotted arrows show directions of air when ice cooling is used.
which may be held longest. A short period of storage may be relatively as important for the short-season fruits, such as the perishable berries. The ability to hold these fruits even for a few days may result in a great profit due to changes in market conditions. The holding of short-period fruits for a brief time is important for canneries because the fruit may be held in its best condition and this may result in a great saving to the canneries or factories when sufficient help cannot be obtained.

Storage is most important for the apple. This fruit has the longest storage period of all. There are cases in which apples have been held in fair condition for as long as two years. It is, of course, not profitable or desirable to hold apples as long as this. The most important season is during the winter and spring months and until the fresh fruits come into the markets. As indicated above, the cold storage of the apple has resulted in making it an all-year-round fruit. Many varieties are held from one season until the summer apples of the next season are available. The so-called winter varieties are held to the best advantage.

There are three classes of apples: summer, fall, and winter. The summer varieties have the shortest storage season. The fall apples have a longer season but not so long as the winter varieties. It is upon the last class that dependence is placed for late-season supplies. The following fall varieties are the ones chiefly used for storage and, as a general rule, these may be held in first-class condition until the Christmas holidays or until the middle of January: McIntosh, Farmhouse, Yellow Bellflower, Jonathan, Grimes. The following winter varieties are the ones of most importance for storage purposes: Baldwin, Ben Davis, Winesap, Winesap, Yellow Newtown, Gano, Rome Beauty, Esopus, Northern Spy, Stayman-Winesap, Banana, Ortleppe, Delicious, Lawrence, Rhode Island Greening, Northwestern Greening, and York Imperial.

The varieties of pears which may ordinarily be used for storage are: Bose, Easter, Anjou, Clairegeau, Comice, Howell, Winter Nels, Duchess, Sheldon, and Kieffer.

The holding of short-period fruits for a brief time is important for canneries because the fruit may be held in its best condition and this may result in a great saving to the canneries or factories when sufficient help cannot be obtained.

Factors underlying successful storage.

By means of investigations of the United States Department of Agriculture, the factors which govern the successful storage of fresh fruits have been carefully determined. The investigations have been extended through a number of years, since the work of Powell with apples in 1901-1902. There has been more work with apples than with other fruits but studies of the storage of grapes, peaches, pears, plums, cherries, and small-fruits have also been made. It is beyond the scope of this article to give in detail the results of researches with all of these fruits. In general, it has been found that there is a very definite relationship between the character of the fruit and the treatment given it in preparing it for storage, and its behavior in storage. The results from extensive experimental storage holdings have been consistent throughout; there have been no exceptions to the general principle of this definite relationship. It has been found, for example, that the influence of the place of production is frequently of great importance. The place and condition under which the fruit may be grown have a material influence on its behavior in storage. This is contrary to prevailing impressions but it is definitely certain. The character of the soil upon which the fruit is grown may have an important bearing on its storage quality. For example, apples from the lighter loam soils have better keeping quality than fruit grown on heavy or wet soils. In the study of the storage of grapes, it was found that the fruit grown in certain types of soils have better market and storage qualities.

Factors underlying successful storage.

The investigations have been extended through a number of years, since the work of Powell with apples in 1901-1902. There has been more work with apples than with other fruits but studies of the storage of grapes, peaches, pears, plums, cherries, and small-fruits have also been made. It is beyond the scope of this article to give in detail the results of researches with all of these fruits. In general, it has been found that there is a very definite relationship between the character of the fruit and the treatment given it in preparing it for storage, and its behavior in storage. The results from extensive experimental storage holdings have been consistent throughout; there have been no exceptions to the general principle of this definite relationship. It has been found, for example, that the influence of the place of production is frequently of great importance. The place and condition under which the fruit may be grown have a material influence on its behavior in storage. This is contrary to prevailing impressions but it is definitely certain. The character of the soil upon which the fruit is grown may have an important bearing on its storage quality. For example, apples from the lighter loam soils have better keeping quality than fruit grown on heavy or wet soils. In the study of the storage of grapes, it was found that the fruit grown in certain types of soils have better market and storage qualities. Some Tokay grapes, grown in California in light sandy soil, reach the limit of their market condition in November, while grapes of the same variety grown in heavy black soil may be kept in good condition until after Christmas. The Emperor grape, which has become an important storage fruit in California, is produced under best conditions in the red soils of the higher benches of the foothills of the Sierras. The same variety grown under valley conditions where the soil is of a different character, does not color so well and does not have as good storage qualities. The same is true of the Almeria grape, which is likely to become a very important storage fruit in California. At present the supplies of this grape come almost exclusively from Spain. The grapes are packed in granulated cork and the Spanish product is frequently held for several months in common stor-
age. California-grown Emperor and Almeria grapes are packed in redwood sawdust and are successfully held in cold storage, the former until the middle of January, and the latter several months later.

The growth of one to three months in the storage quality of some varieties of apples has been found to be due to the place of production. Mention has already been made of the storage weakness of the Yellow Transparent grown in the Central Pacific coast district of California. The same varieties grown in the Pacific Northwest and in Virginia and other sections of the country are free from this particular weakness.

The care of the orchard and method of culture given the trees have been found to be important factors. The character of tillage, pruning, age of trees or vines are also considerations, especially when taken in connection with different climatic conditions. The fruit from young trees or vines has weak storage quality; it is usually large, coarse, sappy, and cannot be held in storage nearly so long as fruit of the same variety from older and more mature trees. Dense-headed trees produce fruit of paler color; the green, poorly colored apples produced under such conditions do not have high storage quality. Such fruit is very susceptible to the trouble known as storage-scar; the loss from this source may be avoided and the storage quality of the fruit improved by thinning the trees or vines. Pruning to open up the crowns of the trees will improve light conditions, especially where intense sunlight does not naturally prevail. Some growers actually cut away the leaves of the vines to allow light to color and mature the grapes to better advantage. In sections such as the arid regions of the Pacific coast, where intense light conditions prevail, the opening-up of the tree crowns must be done with greater care. It is not necessary to open up the trees to such an extent as is necessary where intense light is not naturally available.

Late growth also affects the storage qualities, as it prevents the proper maturing of the fruit. In irrigated districts, the late application of water may stimulate the growth while the fruit is maturing and this may result in sappy poorly colored fruit of low storage quality. The question is often asked whether the fruit produced in irrigated districts has as good storage qualities as that from non-irrigated districts. The impression seems to prevail that it does not. This is erroneous, as has been shown by extensive investigations. It is manifestly impossible to compare directly the fruit grown under irrigation in one district with fruit grown in another. The varieties grown in different districts and other factors may operate to change conditions in the one case or the other. There are thousands of boxes of irrigated fruits held in the best possible condition in storage, and this would seem to be a direct answer to the question of the keeping qualities of fruits grown under irrigation. It is necessary, of course, to have the irrigation properly applied; if overdone by applying large quantities of water late in the year in order to induce large sappy growth, the results are fruits of poor storage qualities.

In sections which have dry summers, where tillage is depended on to conserve the moisture, the work must be thoroughly and properly done; otherwise, the moisture remaining in the soil may be destroyed by evaporation and other trees or vines will be under stress on account of the lack of sufficient moisture. Fruit produced under such conditions has very low storage quality. Any condition of soil, climate, and orchard treatment which results in the production of abnormal fruits may be important governing factors in their behavior in storage. Spraying for the control of insects and diseases is an important factor in the storage standpoint. It is necessary to be thoroughly and properly done, as insect and disease injuries render the fruit liable to deterioration. The insect or disease may be of itself or the cause of the decay or deterioration. There is also an indirect effect: when the trees are weakened by the effect of insects and diseases, the results may be weak fruit of poor storage quality.

Seasons affect the quality as well as the quantity of the crop. In seasons of unusual drought, for example, the fruit may be so weakened that its storage qualities are impaired. On the other hand, years of unusually wet seasons result in the production of sappy fruits which deteriorate rapidly. In seasons of unusual drought, the orchards under irrigation have a distinct advantage, provided the application of the water is properly done and other factors are considered.

Experiments with apples held at a comparatively high temperature for picking fruits is difficult; it must be learned by actual experience. Over-ripeness or over-maturity occurs when the fruit begins to soften. In some instances, growers are in the habit of allowing the crop to remain on the trees until all the fruits are fully colored. When a fruit is ripe but not fully matured, it is a wrong practice, as some fruits mature before the others. Frost-injured fruit of poor storage quality.

The insect or disease may be of itself or the cause of the decay or deterioration. There is also an indirect effect: when the trees are weakened by the effect of insects and diseases, the results may be weak fruit of poor storage quality.
ing. There is also a direct influence on the occurrence of scald. Prompt cooling, as a rule, prevents the occurrence of this disease. This factor is of special importance for early-season fruits or early varieties of apples, like Jonathan. The practice which prevails in many sections of allowing the fruit to accumulate for some time before placing it in storage is likely to result disastrously if the storage temperatur is warm. This is especially true where the fruit must be packed while warm. The ideal condition is the placing of the fruit under refrigeration immediately after picking from the tree and the nearer this can be approached in practice, the longer the fruit can be held in storage.

The proper storage temperature for different kinds and varieties of fruits has already been referred to. The influence of a low temperature, especially for apples, is most important. Experiments show the occurrence of scald to be less severe at 32° than at a higher temperature. The use of a low temperature is also important because of the rapidity with which the fruit within the package can be cooled. In operating either a common- or cold-storage plant, the temperature of the fruit is an important factor to consider. When a fruit is first placed in the storage room, a considerable length of time may be required to reduce its temperature to the desired point, if means are not at hand to increase the air circulation. In cold-storage rooms the cold can be hastened by holding the air of the rooms at a temperature several degrees lower than the desired temperature. A temperature of 25° to 27° F. may be safely maintained until the fruits in the packages approach the storage temperature. In this way the operator can materially hasten the cooling effect, and this hastening is desirable. It is commonly assumed that the cooling should be gradual, but as yet there is no experimental evidence to indicate that rapid cooling is necessarily less injurious.

The investigations of the United States Department of Agriculture show conclusively that the character of the treatment given the fruit in preparing it for market or storage has a material influence upon its keeping quality. Fruits which are roughly handled, bruised or injured to any extent have their storage qualities seriously affected, and decay and deterioration follow the injuries. There are some forms of decay or deterioration which cannot develop unless there are injuries of some kind on the fruit. A break in the skin will allow blue mold to gain entrance, while a sound skin may prevent the development of this form of decay. Blue mold is one of the most common forms of decay. Blue mold and cold storage are therefore factors which should be taken into consideration in relation to the problem of scald.

There are other decay which affect apples and other fruits: the principal diseases affecting apples are brown-rot, leaf-canker, anthracnose and bitter-rot. These diseases are not dependent upon the care in handling the fruit so far as the occurrence of bruises or injuries is concerned. The spores are present on the fruit when it is packed and the control of the disease in storage goes back to the orchard treatment and the control of the fungi on the trees. All three of these diseases occur on the trees; the fungus spores which inhabit the fruits develop from these cankers. Control of the cankers by cutting out or spraying will materially reduce the occurrence of decay in storage.

There are other forms of deterioration which, so far, have not been traced to any definite organism. These are obscure physiological diseases and result in the breaking down of the flesh of the fruit, or in burning of the tissues, or in a scaled appearance of the skin.

For the general principles of its management, consult Greenhouse Management.
SOLDIER. In England the planting of this species is discouraged from the fact that it spreads too rapidly. Pests arise rising from among the lvs. to a few inches above the water, much thickened at the top, bearing a spathe of 2 bracts: ovary and stigmas nearly as in Hydrocharis, but the fr. is ovoid and somewhat succulent. G. 2:466.

F. TRACY HUBBARD.

STRAWBERRY. The species of Fragaria, grown for the fruit. (For the morphology of the strawberry fruit, see Vol. I, page 40.)

The strawberry is an herbaceous perennial. It naturally propagates itself by means of runners that form chiefly after the blooming season. Seedage is practised only with the Alpines, and in raising new varieties. Division of the crown is useful for propagating varieties that are practically runnerless, as the Bush Alpine and Pan-American. The runner plants, either transplanted or allowed to remain where they will form, will bear the following year. Usually the plants will continue to bear for five or six years, but the first and second crops are generally the best. The plants are sometimes secured from plants over ten years old, especially when they are grown under hill training and intensive culture, but this is a special practice. It is therefore the custom to plow up strawberry beds after they have borne from one to three crops. The better the land and the more intensive the cultivation, the shorter the rotation. In market-gardening areas and in some of the very best strawberry regions, the plants are allowed to fruit but once. The plants therefore occupy the land only one year and the crop works into schemes of short-rotation cropping. When the bed is fruited more than one year it should be renewed immediately after the crop is harvested. In the case of matted or spaced rows, this consists of reducing the number of old plants, using the leaves and burn them. In the case of hill or hedge-row plants, renewal consists of mowing and in drawing about an inch of fresh soil around the plants, so that new roots will form above the old ones. Throughout the North, and as far south as Kentucky and Missouri, beds are fruited but one year, occasionally two, rarely longer. In Florida and the coastal plain of the Gulf states, the plants occupy the ground but six to eight months. In the lower Mississippi Valley and on the Pacific coast, beds are fruited three to six years. The strawberry delights in a rich rather moist soil and a cool season. It can be grown in the cool part of the year in the South and thereby becomes one of the most cosmopolitan of fruits. The young plants may be separated from the parent and put into new plantations in August; but under average conditions in the North it is usually better to wait until early the following spring, since the weather is likely to be too hot and dry in the late summer of Virginia, Tennessee, and Arkansas, and on the Pacific coast, most of the planting is done in the fall or winter months. Plants that have not borne are best for setting. They are plants of the season: that is, plants
CVIII. Strawberry.—The Climax variety.
be been found that under most conditions the plants
even 30 inches apart in the rows, much depending on
fruits are found on plants along the outside of the
fine fruits. These first runners are usually "bedded-in,"

growth vigorously, the first runners are used, as it has
30 to 36 inches apart and the plants from 18 to 24 or
almost necessary to crush fruits on the outside of the
rows are so wide that to pick fruit in the center it is
then allowing the runners to grow and root at will,
results, plants are generally trained in narrow rows.
In hill training, each mother plant, and are kept in alignment, forming
single, double, or triple hedge row; all other runners
this means. In the "narrow matted row," which is
surplus runners are pulled off or are cut off with a
knife, hoe, or one of the many types of runner-cutters
may be attached to the cultivator. Circular cutters
are used for hill plants. In late fall, the matted row
may be thinned by pulling out the weaker plants with
an iron rake or spike-toothed harrow.
In the North, strawberries are usually mulched in the
fall, in order to protect them from alternate freezing
and thawing in the winter and early spring and to
prevent the soil from heaving. In some cases the mulch
is allowed to remain on the plants rather late in the
spring, in order to retard the season of bloom. Some-
times the crop may be retarded a week or ten days by
this means. It should not be removed until settled
spring weather has come, nor left on so long that the
plants bleach. The mulch is more necessary in regions
of light and precarious snowfall than in those in which
the snow blanket is deep and lies all winter. In regions
of deep and continuous snowfall, a heavy mulch is
likely to prove injurious. Experience has shown that
the best mulch is some strawy material. Along the
seacoast, salt hay from the tide marshes is much used.
In interior places clean straw, in which there is no grain
to sprout and to make weeds, is very largely employed.
(Fig. 3717.) In the South, pine needles are used.
Some
times loose strawy manure is used, and the mulch adds fertilizer to the soil as well as affords protection. Corn fodder, leaves, bracken, seaweed, evergreen boughs, and other wild herbage are used occasionally. Cowpeas and sorghum are grown for mulching material when straw is scarce. The practice of growing oats, barley, or some other small grain between the rows of strawberries, to fall down and mulch the berries, is not generally advisable. Under ordinary conditions the mulch is 3 or 4 inches deep over the plants after it is fairly well packed down. It is not always possible, however, to mulch as heavily as this, since the material is likely to be expensive when one has a large area. The mulch is usually applied late in the fall after the ground has frozen, and, if the material is abundant, both the plants and the intervening spaces are covered. In the spring the mulch is raked from the plants as soon as they begin to start. Some persons allow it to lie between the rows as a cover to retain moisture and to keep the berries clean. The most expert growers, however, prefer to take the mulch from the field and to till the plantation once or twice before the plants are in bloom; the material is then returned and spread on the loose soil between the rows and beneath the vines. In the northern prairie states, heavy mulching is essential. For western Minnesota and Dakota a covering of at least 6 inches of straw is advised. This mulch is easily provided, since straw is so abundant in that country.

In the southern prairies the material is then returned and spread on the loose soil between the rows and beneath the vines. In the northern prairie states, heavy mulching is essential. For western Minnesota and Dakota a covering of at least 6 inches of straw is advised. This mulch is easily provided, since straw is so abundant in that country.

It is preferable to plant an early-blooming pollinator on one side of the rows of the pistillate sort, and a late-blooming pollinator on the other side. When planting pistillate varieties, every third row should be a pollen-bearing kind. Pistillate varieties as a class are somewhat more productive and harder than stamine varieties as a class; but this fact has little weight, since some stamine sorts are fully as prolific and hardy as the best pistillate varieties. It is an inconvenience to be obliged to mix varieties for pollination; hence pistillate varieties are steadily declining in popularity. In time, all North American varieties will be stamine, as is now the case in England. The horticultural bearing of the sexual characters of the strawberry in the United States is clearly explained in this country by Nicholas Longworth of Cincinnati (see page 1585; also his essay on the subject in his "Cultivation of the Grape," 1846, and the "Strawberry Report" of the Cincinnati Horticultural Society, 1848). When many of the staminate "seeds" of the strawberry are not fertilized or are killed by frost or other means, the berry fails to develop at that point and a "nubbID," or imperfect berry, is the result (Fig. 371D). Nubbins are usually most abundant late in the fruiting season, when the pollen-supply is small and when the plants are relatively exhausted.

Ordinarily the common varieties bear but once a year, in the spring. Under certain conditions of temperature and moisture they may become "double croppers," and give a fall crop as well. In the South, particularly in southern California, the bearing season may be extended over several months; but no varieties were consistently everbearing in the North until 1868, when Samuel Cooper, of Delevan, New York, found the Pan-American in a row of Bismarck. European everbearers, which are hybrids of the common strawberry and the Alpine, do not succeed here. The numerous descendants of the Pan-American are true everbearers; they yield a small spring crop, followed by a heavy summer and fall crop from spring-set plants. It is better, however, to cut off all blossoms until midsummer; then there will be considerable fruit from August until frost, but not so much as a good crop from a spring-bearing variety. The culture of the everbearers does not differ materially from that of other sorts, save in the cutting of the blossoms weekly, which is a heavy expense. They require rich soil and an equable supply of moisture; they fail in a dry season. The market for berries in late summer and fall is limited, and the cost of picking is heavy. The following spring, a year from the time they were set, the everbearers produce a good crop, perhaps equaling that of single-bearing sorts. This is one point in which the North American everbearers are distinctly superior to those of Europe. The everbearers have little commercial future merely for supplying summer and fall berries, but their habit of bearing a heavy spring crop, also, may make them useful to some growers who cater to personal demand. They are not likely to find favor with those who grow strawberries for the wholesale market. The everbearers are valuable mainly for the home-garden.

The cost of growing an acre of strawberries under commercial conditions in Oswego County, New York, is approximately as follows:

- The cost of planting:
  - One point in which the North American everbearers are distinctly superior to those of Europe.
of them. These three are the most important North American varieties; two-thirds of the 348 varieties of known parentage have descended from them. Other old favorites, now no longer grown, are the Cumberland, Triumph, Downer Prolific, and Charles Downing. European varieties do not succeed here; notable exceptions are Jucunda, and Triumph. Over 1,800 varieties of North American origin have been introduced but less than 150 of these have attained prominence. The oldest North American variety now cultivated is the Longworth, introduced in 1851; it is still prized in the San Francisco market. The dominant commercial varieties of today are the Dunlap, Haverland, Marshall, Klondyke, Aroma, Gandy, Glen Mary, Bubach, Brandywine, Clark, Warfield. At least fifty others are grown to a considerable extent. The accompanying pictures (Figs. 3720-3725) show types of American strawberries.

The strawberry has been in cultivation but a short time, as compared with other fruits. It has been grown in gardens less than 600 years, and was not cultivated commercially to any extent until early in the nineteenth century. The first record of garden culture is in France, early in the fourteenth century. This was the wood strawberry, Fragaria vesca. The common wild strawberry of eastern North America, F. virginiana, was introduced into Europe early in the seventeenth century. Neither species showed much promise under cultivation. F. chiloensis, which is native to the Pacific coast of America, was brought to Europe from Chile in 1712, by M. Frezier, a Frenchman. See Fragaria. Although the berries are large, this species found little favor because of shy bearing and poor quality; it gave practically no improved varieties. Near the middle of the eighteenth century the Pine strawberry (referring to the pineapple fragrance of the fruit) appeared in Europe, and became the principal progenitor of the garden strawberry. The botanical origin of the Pine is obscure. One view is that it was a form of F. chiloensis; another, that it resulted from the hybridization of that species with F. virginiana in European gardens; all the early importations of the Chile were pistillate plants, and varieties of the Scarlet were commonly planted with them. The first of the modern race of large-fruited varieties was the Keens’ Seedling, originated by Michael Keens, of England, in 1819; it was a Pine, and from it have sprung most of the European varieties of today. The Hovey, from which modern North American varieties have descended in large measure, was undoubtedly a Pine in part, but there is considerable evidence that one of its parents was a variety of F. virginiana.

Wild strawberries were so abundant in North America that there was no garden culture of this fruit until about 1770. The Alpine and Hauhock types of strawberries (F. vesca) were introduced then from Europe, but did not become popular; preference was given to transplanted wildings of the Scarlet. These varieties have never been grown here except by a few amateurs. Commercial strawberry-culture began soon after 1860, mainly in the vicinity of the four largest towns of that period—Boston, New York, Philadelphia, and Baltimore. The varieties used were slightly improved forms of F. virginiana, notably Large Early.
Scarlet, Hudson's Bay, Early Hudson, and Crimson Cone. These persisted until the introduction of the Wilson. The first variety of any fruit produced in North America by hand-crossing was the Hovey, originated by C. M. Hovey, of Boston, in 1836. The Hovey was a failure as a market variety, except in a few places, but it was an excellent amateur variety and greatly increased interest in strawberry-culture. The heated discussion of "Longworth's Theory" (1841-1845) concerning sex in the strawberry also stimulated interest and offered a practical solution of a pressing cultural problem. As yet, however, the strawberry was mainly a fruit of the open fields and home-gardens; the commercial planting was very limited. The total quantity of fruit marketed in 1854 was less than 40,000 bushels, the product of about 1,400 acres.

The variety that marked the beginning of commercial strawberry-culture in North America was the Wilson, originated by James Wilson, of Albany, New York, in 1851. Until then, strawberry-culture had been difficult, and the results very uncertain; the Wilson thrived under even indifferent care. Its introduction was followed by a remarkable increase, coincident with the modern refrigerator-car system, which made possible the great shipping districts of today, and made possible the great shipping districts of today, and greatly increased interest in strawberry-culture. The value of the crop is $20,000,000 annually. The Wilson, originated by C. M. Hovey, of Boston, in 1836. The Hovey was a failure as a market variety, except in a few places, but it was an excellent amateur variety and greatly increased interest in strawberry-culture. The heated discussion of "Longworth's Theory" (1841-1845) concerning sex in the strawberry also stimulated interest and offered a practical solution of a pressing cultural problem. As yet, however, the strawberry was mainly a fruit of the open fields and home-gardens; the commercial planting was very limited. The total quantity of fruit marketed in 1854 was less than 40,000 bushels, the product of about 1,400 acres.

There are several serious fungous diseases and insect pests of the strawberry. White grub is controlled by avoiding newly plowed sod land when setting the bed, by planting largely of pistillate varieties or profuse-blooming staminate sorts; leaf-roller, by spraying with arsenate of lead, and burning the leaves; root-louse, by setting clean plants in clean land. The several types of leaf-blight (Fig. 3726) may be prevented to a considerable extent by spraying with bordeaux, but it is more practicable to plant resistant varieties. The fundamental treatment of all these is to fruit the bed but once, or at most but twice, and to grow succeeding crops on other land, cleaning up the old plantation thoroughly after the last fruiting. Short, quick, and sharp rotations and clean culture do much to keep all enemies in check.

Strawberry-growing in the South.

The strawberry is by far the most important small-fruit grown in the South, being raised commercially in every state. The industry is more concentrated in the South than in the North. This concentration is probably due to the fact that nearly all of the strawberries are shipped by freight to distant markets. The strawberry industry in the South has developed as an independent unit, or as an adjunct to truck-growing rather than in connection with other fruit-growing enterprises.

An important consideration in growing strawberries for northern markets is the selection of a location where the soil and climatic conditions are conducive to early ripening of the fruit, so that there will be little competition from regions farther north. In many southern sections where strawberries are grown on a commercial scale, shipments practically cease as soon as berries from a more northern location begin to move in car lots. This is due to the fact that toward the end of the picking season the berries are small and cannot compete successfully with the larger fruit from a region nearer the market that is just beginning to harvest its crop.

While strawberries are grown on nearly all types of soil and in nearly all climates, they are most successfully grown where the soil is rich, well drained, and the climate mild. The best varieties for commercial growing are those that ripen early, are large, and hold their color well. The most important shipping districts are: California, 7,000 acres; New Jersey, 5,000 acres; New York, 5,000 acres; Pennsylvania, 3,000 acres; Illinois, 2,000 acres; Ohio, 1,000 acres; Indiana, 1,000 acres; Michigan, 8,000 acres; Wisconsin, 3,000 acres; Illinois, 7,000 acres; Missouri, 5,000 acres; and others.

The strawberry is fourth in commercial importance among deciduous fruits, being preceded by the apple, peach, and grape. The most important shipping districts, according to the Census of 1900, are Maryland, 14,292 acres; Tennessee, 10,761 acres; Missouri, 9,048 acres; New Jersey, 8,684 acres; Michigan, 8,061 acres; Arkansas, 7,361 acres; Ontario, 7,702 acres; Delaware, 7,194 acres; Virginia, 6,606 acres. Sussex County, Delaware, has the largest county acreage, with 8,041 acres in 1908.
soil in the South, sandy and gravelly loams are considered best. A warm quick soil, although poor, is preferred to a heavy retentive soil well supplied with plant-food. Plant-food can be supplied by the addition of fertilizers, but the physical condition of the soil can be modified only with difficulty and loss of time by cultivation, drainage, and the addition of humus. The soil for strawberries should be well supplied with humus in a well-decomposed state. Many growers think that new land is essential for good results, but when old soils are well supplied with organic matter they will yield as large crops as new soils.

Few soils in the South that are adapted to strawberries growing are rich enough to produce large crops of fruit without the addition of fertilizers. Stable or barnyard manure is the best fertilizer for strawberries as it supplies both humus and plant-food. It is best, however, to apply the manure to the crop preceding the strawberries in order that it may become well-decomposed, and so that most of the weed seeds will have germinated. When manure is not available, commercial fertilizers are applied in large quantities, but these should be used in connection with green-manure crops such as cowpeas, soybeans, velvet beans, vetch, and clovers. Some growers use as high as one ton, or even as much as 2 tons and a half, of commercial fertilizer to the acre. However, under most conditions, 1,000 to 1,500 pounds of a fertilizer analyzing 2 to 3 per cent of nitrogen, 6 to 8 per cent of phosphorus, and 6 to 8 per cent of potash, should be sufficient. On land where legumes have been grown, a part of the nitrogen may be left out. It should be borne in mind that large applications of commercial fertilizers are profitable only when used on soils in good physical condition, and well supplied with humus.

There are three systems of growing strawberries in the South: the hill system, the hedge-row system, and the matted-row system.

In the hill system the plants are set separately, one plant in a place, and no row plants are allowed to form. The plants are set 12 to 14 inches apart in rows 3 to 3½ feet apart. This makes a large, vigorous plant, producing large uniform berries which ripen evenly. This system is followed in Florida. The quantity of berries produced is not so large as under the other systems, but the quality is better and the percentage of first-class berries larger.

In the hedge-row system the plants are set 10 to 18 inches apart in rows 3 to 3½ feet apart, and runners are allowed to form plants along the row in a strip a few inches wide. This system is practiced in the southern part of the lower tier of southern states, with the exception of Florida, where the hill system is used.

In the matted-row system the plants are set 15 to 18 inches apart in rows 3½ to 4 feet apart. The runners are allowed to form plants 6 to 9 inches on either side of the row. Sometimes the plants are allowed completely to cover the ground. This system probably produces the largest crop of berries, but the fruit is usually smaller and does not ripen so well as under the other systems.

Strawberries are planted in Florida any time from June to November, whenever the soil and climatic conditions are favorable. In other southern sections of the South Atlantic and Gulf Coast states, the plants are set in late summer or autumn. In all other sections of the South, the plants are usually planted in late winter or early spring, and no crop is allowed to be produced the first season.

The length of time that a field should be allowed to produce fruit depends upon many conditions and varies in different parts of the South. In sections where weeds and grass grow very rapidly and where the picking-season is long, as is the case in the lower South, usually only one crop is grown. In the upper sections of the South, two or more crops are produced. Some growers allow their fields to produce five or six crops, but under most conditions two crops should be the maximum, as the fields become weedy and the soil compact. It is possible to clean up an old patch in such a way that large crops can be secured for several years, but very few growers give the fields the attention necessary to produce heavy crops of first-class fruit.

When the field bears more than one crop, the strawberries should be thoroughly cleaned out, thinned, cultivated, and fertilized after the fruit has been harvested. As a rule, the best crop is produced on new plantings and for this reason frequent renewal is recommended.

Cultivation should begin soon after the plants are set, and should be continued whenever weeds start or a crust forms. Frequent shallow cultivation will make it unnecessary to do much hand-hoeing or hand-weeding. A cultivator which merely breaks the surface without disturbing the roots is to be preferred. Any weeds which interfere with the development of plants or fruits during the picking-season are pulled by hand, or cut off with sharp hoes.

In most sections of the South, some form of mulch is used to hold moisture during the picking-season when the soil is not stirred, to keep the berries clean, and to prevent "heaving out" in regions where freezes occur. The materials used for mulch are pine straw, oat, wheat, or rye straw, leaves, and marsh hay. These materials are of value as humus when turned under. In sections where freezes do not occur, the mulch is usually applied in late winter.

For best results in growing strawberries a good system of rotation should be followed. In any system of rotation, a leguminous crop should be turned under once in three or four years, and a cultivated crop grown on the area the season before the strawberry plants are set. The following system of rotation is a good one for the South:

1. Strawberries one or two years, followed by cowpeas after the strawberry plants are plowed under.
2. Early vegetables followed by cowpeas or late vegetables.
3. Corn with cowpeas between the rows. The corn stubble and the cowpeas should be turned under for...
strawberries the following year, in case the plants are set in the spring.

In sections where vegetables are not grown commercially, oats may follow the cowpeas turned under the second season.

The varieties of strawberries grown in the South are Klondyke, Missionary, Lady Thompson, Excelsior, Aroma, Gandy, Chesapeake, and Early Ozark. In the lower sections of the South, the Klondyke and Missionary are grown more than all others. For a succession of crops the Excelsior or Early Ozark may be grown for early fruit, the Missionary, Klondyke, and Lady Thompson for medium, and the Aroma or Gandy for late ripening. In the upper sections of the South, the Early Ozark, Chesapeake, Klondyke, Aroma, and Gandy are all grown, but very rarely does any grower raise more than two varieties for commercial purposes.

As a large part of the strawberries grown in the South are shipped to distant markets, they must be picked before they are fully ripe. For long distances the berries should be fully grown and about three-fourths ripe. When picked before they are at all colored, the berries will shrink and wither, making them unfit for sale.

The berries should be well graded and packed before being shipped. When experienced pickers are employed the best results can be secured by grading the berries in the field, as they are picked, so as to avoid rehandling and the consequent bruising and deterioration of the fruit. The common practice, however, is for expert packers to do the grading and packing in a packing-shed to which the fruit is delivered by the pickers. The top layer of berries should be placed so as to hold them in place, but care should be taken not to put small inferior berries in the center and large berries on top. All types of berry boxes are in use in the South, but the tendency is toward a standard full-size quart box. In some sections of the South, particularly in Louisiana, pint boxes are used for the early shipments. The fruits carry better and the price received is higher; later in the season as fruits become more abundant and the price is lower, fruit from these same regions is shipped in quart boxes in crates holding twenty-four or thirty-two quarts. A long narrow box is objectionable.

Berries which are well graded and sorted and put in clean, neat, attractive packages of standard sizes command the highest price and sell most readily. The type of crate depends upon the boxes used. Any crate that is substantially built and well ventilated is satisfactory, but the cost is an important consideration, as they are not returned to the shipper. The largest crate that can be handled conveniently is the one to use, as the large ones are cheaper in proportion to the quantity of berries they carry. The twenty-four- and thirty-two-quart crates are in most common use, although in some sections the sixty-quart crate is employed. Crates with hinged lids have the advantage that they can be opened easily and quickly, and as a result invite inspection. A large part of the Florida crop is packed in quart boxes which are placed in pony refrigerators for shipment to northern markets.

The cost of growing strawberries in the South is from $75 to $150 an acre, divided about as follows:

- Interest on investment (land and equipment)...
- Preparation of land...
- Manure or fertilizer...
- Plants...
- Setting plants...
- Cultivating and hoeing...
- Mulching...
- Picking, grading, and packing crates...
- Hauling to station, loading, etc...

The lower estimate is about the average for most sections of the South, while the higher figures cover the extreme cost. The average cost in Florida is between the two estimates, but nearer the higher.

H. C. THOMPSON.

The strawberry in California and northward.

California conditions include both those most favorable and most trying for the growth of strawberries. There are situations where, through local topography and proximity to the ocean, winter temperatures are very seldom too low for the growth and fruiting of the plants and where, by summer irrigation to maintain this continuous activity of the plants, it is possible to gather fruit every month in the year. This fact is not, made of much commercial account, however, nor is it widely true that one can have strawberries all the year round in the open air. It is true, however, that even on the lowlands, where the commercial crops are chiefly grown, the winter is so mild that strawberries begin to ripen in shipping quantities as early as March and by proper cultivation and irrigation the fruiting is continued until late in the autumn, and the grower has therefore a very short closed season. The trying condition for the strawberry is found in the long dry summer, which enforces dormancy as early as June on light soils. The plants become dry and hot to a depth of several inches in spite of surface cultivation and cause the dwindling and death of a shallow-rooting plant like the strawberry unless frequent irrigation is begun in time. This trouble is less acute on more retentive soils in regions of lower summer temperature and greater rainfall, and plants in such situations may survive the summer dormancy, but it is true that everywhere in California and even in the more humid states on the north that strawberry-grow-
STRAWBERRY

The varieties chiefly grown in California are different from those popular at the East. New varieties from the eastern states and from Europe are freely tried, but few are successful and they retain local popularity after abandonment in their birthplaces. A striking instance of this fact is the continued popularity of Longworth Prolific, Sharpless, Monarch of the West, Wilson, Albany, and the like. Longworth has survived more than fifty years' continued growing. Other popular varieties are Melinda, Jessie, Dollar, Brandywine, Marshall, and Lady Thompson. Brandywine (Fig. 3725) is the most widely approved variety. In the state, the Dollar and Marshall lead among the newer kinds and the Banner is exclusively grown by some producers for the San Francisco market. Jessie and Dollar are largely grown for shipment to interior states and to the northern coast before the local fruit ripens.

The growth of strawberries is almost wholly in matted rows, the rows usually occupying low ridges only sufficiently elevated to allow the slightly depressed intervals to serve as irrigation ditches and as walks during picking. The slight elevation of the plants also assists in surface drainage, when heavy rains fall during the early part of the fruiting-season, and this promotes early growth and fruiting of the plants. Where the soil is too coarse to permit free rise of water from the depressed ditches, the conditions are reversed and low levees are made to inclose blocks of plants which are irrigated by flooding the inclosures. In the chief commercial regions a fine loam is used and irrigation from the small ditches on both sides of the ridges, which are about 2 feet wide, is the ruling method. Nearly level land is selected and grading is done before planting to reduce dry knolls and fill low places so that the water will flow slowly and will evenly moisten the whole field. Subirrigation by tile has been often advocated but never has been employed to any extent.

One of the chief strawberry-shipping districts in central California is characterized by a shallow loam underlaid by an impervious indurated clay or hardpan, which prevents the percolation of the irrigation water and enables growers to maintain a large acreage by means of the small water-supply secured by windmills. In this case water is applied very frequently, even oftener than once a week in some cases, but the total amount for the season is small. Quite in contrast to this is the growth on light deep loams where water sinks so rapidly that the plants suffer, although water is almost constantly running in the ditches. In such cases mulching and sprinkling are the price of success, and these are too costly except on a small scale for home supply. The largest producing districts have soils midway between the extremes above noted, viz., deep retentive loams, situated rather low in the valleys and with irrigation available either by ditch system or by wells both flowing and pumped. The pump wells require usually only a short lift, and abundant water is secured cheaply by the use of modern pumps and motors.

In addition to supplying the home markets, which are very good, California strawberry-growers find a good outlet for the fruit all through the region west of the Missouri River. Southern California supplies the southern portion of this district, while the pears grow in central California, chiefly near Florin in Sacramento County, make large shipments eastward as far as Colorado and northward to all the great interior states and to Oregon.
Washington, and British Columbia before the locally grown fruit in those regions is available.

The states of Oregon and Washington in their areas lying west of the Cascade Mountains have conditions excellently suited to the growth of the strawberry. Their conditions more nearly resemble those in the eastern states than any other part of the coast. The cooler weather and abundant moisture give a better spring season than that of California, but the season is on the whole much shorter because of the longer winter. Irrigation is also necessary in most places for continued fruiting during the summer. The most famous district is Hood River, Oregon, where grid conditions east of the Cascade Mountains are modified by western influences which reach through the gap in these mountains where the Columbia River flows through. Irrigation is regularly employed and a large commercial product grown. The varieties chiefly grown in this region and in adjacent parts of Washington and Idaho are of local origin, the Hood River (Clark Seedling) and Magoon being widely approved. Jessie, Sharpless, Wilson, Havenland, Crescent, Cumberland, Jucunda, and Parker Earle are also recommended by growers in the northwestern states.

E. J. WICKSON.

Cultivation of the strawberry on home grounds.

Of all the fruits which can be grown in the garden, the strawberry offers to the amateur the greatest inducements on account of ease of growing, delicious quality, long season and comparatively quick-bearing habit, and wide geographical range. No garden should be without this important fruit. It can be grown in almost any soil and in so many different ways that even in a most crowded garden some space may be found for it.

The strawberry thrives best in a sunny location but will also do well in partial shade like that from small-fruit bushes or young fruit-trees. Heavy shade draws the vines up, and while a luxuriant growth of foliage will also be without this important fruit. It can be grown in almost any soil and in so many different ways that even in a most crowded garden some space may be found for it.

The strawberry-bed in the garden is very important and should be governed to a large extent by the other crops. Remembering that the strawberry offers to the amateur the greatest inducements on account of ease of growing, delicious quality, long season and comparatively quick-bearing habit, and wide geographical range. The strawberries thrive best in a sunny location but will also do well in partial shade like that from small-fruit bushes or young fruit-trees. Heavy shade draws the vines up, and while a luxuriant growth of foliage ensues there will be but little fruit. On the other hand southern slopes where the berries are exposed to the unbroken rays of the sun will result in scalded fruit unless some artificial protection can be given.

The location of the strawberry-bed in the garden is very important and should be governed to a large extent by the other crops. having prepared the ground as outlined, the next question to settle is the system under which to grow the bed. There are three systems which may be used for the garden strawberry-bed: the wide matted-row, the hedge-row, and the single-hill systems; and as the plan of a system depends very much on the variety grown it will be necessary to consider variety in this connection. In the selection of varieties for the home-garden, the following conditions should be carefully considered: quality, attractiveness of the fruit, productivity, vigor of plants, season. Many very productive varieties lack quality and attractiveness while as a rule the quality berries are not good commercial varieties-and it is often difficult to procure the plants of the better varieties in the nursery.

As it is practically impossible to obtain all of the points outlined above in one variety, it is generally best to plant at least three, not alone to insure a longer season but variety in the fruit is very essential; also some years one variety alone does not do well while with a number of varieties some are sure to succeed. This will be found especially true when late spring frost may entirely ruin one variety and not injure another.

Vigorous-growing varieties with good clean-growing watering may be practised, it is often done at the expense of quality in the fruit. Soils may be easily improved. A light soil can be well filled with manure or humus of some sort, and a heavy soil drained with tile. If possible the land should have a slight slope to turn off surplus water in the winter, but if this is impossible,
pot-grown plants should be secured and a good compost of garden loam. Place in the barrel and over the holes cut in the center of the bottom a piece of 6-inch drain-tile about a foot long, filling the center of the tile with coarse gravel or small stones. Put the roots of the plants into the 1/2-inch holes in the sides of the barrel and fill the barrel with the compost, adding pieces of tile to that in the center as the barrel is filled so that the drain-pipe comes up to the top of the barrel. A row of plants may be planted on the top of the barrel so that sides and top are covered. Watering should be done through the drain-pipe and if the coarse material used inside the drain is satisfactory, the plants will take up about the proper amount of water before it all passes through the barrel. The barrel should be carefully protected in winter by covering with straw and pine branches and the top protected so that excessive rain will not get in; elevating the barrel on stones will help the drainage.

Having decided upon the method or system of growing strawberries, the season for planting should be the next consideration. As a rule the early spring, from April 1 to May 10, is the best time to plant in the North, although in many gardens which have to economize space, August and September planting is made necessary,

as the strawberry has to follow some of the other early crops, as peas, beans, lettuce, and the like. For August or September setting, pot-grown plants are better than the runner plants unless one can take runner plants directly from one's own bed and transplant them under favorable weather conditions. To obtain the best pot-grown plants, the runners of the current season's growth should be used, as these make better plants than those of last season's growth which have been placed in cold storage and potted after their natural season of planting has gone by. If layer plants are used in spring, great care should be taken in planting so that the plants may be assured of a good start. Remove practically all of the foliage and cut back the roots at least one-half. If the ground has been prepared carefully the hand may be used in making the hole for the roots, but in stony ground it is best to use a trowel. Be sure that the crown of the plant is not set too deep or too far above ground. The crown should be on a level with the surface of the soil. When setting, spread the roots out fan-shape and be sure to press the soil firmly about them. Be sure that the rows are straight. Various devices are used on commercial

STRAWBERRY 3269

STRAWBERRY

3730. Brandywine strawberry.
farms but for garden culture nothing is better than a line for securing straight rows.

Whether set in spring or fall, cultivation of the soil should begin as soon as the plants are set and kept up until late September, when cultivation should cease and the plants given a chance to harden up for the winter. Cultivation, whether done by wheel-hoe, hand-hoe, or weeder, should be shallow, never more than 2 inches deep, as the strawberry roots are near the surface and light cultivation of the surface soil does as much good as any other form. Weeds of all kinds should be kept down and comparatively little weeding will be necessary provided the ground is kept stirred.

During the summer at least three applications of fertilizer should be made, preferably before or during a rain. If the fertilizer mentioned previously cannot be obtained, bone-meal will give good results, particularly if wood-ashes are added.

If the season is particularly dry or the land is inclined to dry out rapidly, artificial watering may be practised, but it is better not to use water if it can be avoided. Plenty of cultivation will grow good plants on nearly all soils.

In the late fall after heavy frosts have come and the ground freezes slightly at night, it will be necessary to put some winter protection on the strawberry-bed. Many kinds of materials may be used, but first it is best to have a light mulch of well-rotted stable-manure scattered among the plants and worked under the foliage. Following this the winter protection may be put on. This should be of coarse hay, cornstalks, or very strawy manure, care being taken not to put on too much. A good rule to follow in placing a covering is that it must not be too close to prevent seeing some of the foliage of the strawberry plants under the mulch. The mulch may be held in place by brush, light cordwood or even soil, and in places where there is little snow great care must be taken to keep the mulch in place. It must be borne in mind that this careful protection is not to prevent the ground from freezing but rather to prevent the alternate freezing and thawing of unprotected ground in winter. In the spring as soon as danger from extreme frosts is past, the material for holding the mulch in place should be removed and also a part of the mulch itself, leaving some of the covering on the land to serve as protection to the fruit in the fruiting-season and to keep the soil moist. Some persons prefer to remove all the mulch and to cultivate the ground, and in some cases this is desirable; but, when the plants have had good culture the previous year it is just as well not to do much cultivating in the spring. Fertilizers should be added at this time, preferably bone-meal and wood-ashes mixed at the rate of one-half pound of ashes to one pound of bone-meal and put on about one-eighth pound to the square foot.

If the weather is dry and the soil more or less inclined to dry out, water may be applied one-half inch two or three times after a short rest in July. Many of these everbearing varieties do very well in the usual strawberry season and those which are now been permanently established are great sources of satisfaction to strawberry-lovers to have fruit after the regular season is over. There are several varieties of these everbearing strawberries, and every garden should have a few of them. They may be planted in any of the ways suggested for the regular varieties but they should have plenty of water during the summer to insure the full development of the fruit. In most locations in the northern states these varieties begin to ripen early in August and continue until heavy frosts are past. It is advisable to cut off the blossoms in May if the weather is dry and the soil more or less inclined to dry out, water may be added at this time and up to the time the fruit is well set, being careful not to water during the daytime when the sun is shining. The question of watering strawberries is a very difficult one as so many conditions enter into the discussion. Some soils are naturally moist, and when water is added artificially to these, the tendency is for the plants to go to foliage or soft fruit or decayed berries. Too much water on a dry soil, particularly if added as the berries are coloring, is likely to injure the quality of the fruit while increasing the size, so that quality often is sacrificed to bulk. Generally speaking, in most seasons, if the land has been well cultivated the season before and the bed has been well mulched, there will be enough moisture in the land to carry the crop to maturity.

As quality in the strawberry depends very much upon ripeness and condition, it is well not to begin to pick too soon, but wait until the fruit has colored all over and has taken on the characteristic depth of tint which may be common to the variety. Be sure to pick the fruit early in the morning before the sun gets hot, keeping what is not used early in the day on ice. Pick the fruit with a stem; and for household use berries are much more attractive when picked in a shallow basket with some kind of foliage.

Within the past few years a new race of strawberries has been developed commonly called everbearing from their habit of producing fruit after the regular strawberry season has passed. This strain has now been permanently established and it is a great source of satisfaction to strawberry-lovers to have fruit after the regular season is over. There are several varieties of these everbearing strawberries, and every garden should have a few of them. They may be planted in any of the ways suggested for the regular varieties but they should have plenty of water during the summer to insure the full development of the fruit. In most locations in the northern states these varieties begin to ripen early in August and continue until heavy frosts are past. It is advisable to cut off the blossoms in May if a large crop is wanted in August, but they will fruit at both times after a short rest in July. Many of these varieties have a tendency to make more foliage than is wanted in August, but it is well to follow the same general directions as given for growing the standard varieties. Most of these everbearing varieties do very well in the usual hill culture.

Wilfred Wheeler.

Forcing of strawberries. (Figs. 3731, 3732.)

The forcing of strawberries for a winter crop has not as yet become of any great commercial importance in North America. Some gardeners grow a few potted plants for either Christmas or Easter decoration. Very few, if any, commercial growers are forcing strawberries exclusively to any profitable extent. The few strawberries that are forced are grown either in pots or planted out on benches. The former method is the one generally employed. There are several good reasons for this, some of which are: first, the confinement of the roots; second, the ability to ripen the crowns in the fall; third, the control of fertilizers and liquid manure; fourth, the privilege of having the crop grown in several houses at one time or brought from a coolhouse into heat; and fifth, the opportunity to supply particular demand of the potted plants or their fruits. The first expense of the pot method is considerably more than when the plants are grown in the benches, but after
the pots are once purchased the cost of each method should be about the same.

The pot method as practised at Cornell University is about as follows: As early in the spring as possible large plants are set in well-enriched soil. The first strong runners made by these plants are secured and potted. Numerous 2- or 3-inch pots filled with good soil are plunged to the rim along the strawberry row. The runners are trained to these pots, and a small stone is placed on each runner to keep it from growing beyond the pot. When the pot is filled with roots the young plant is cut from the parent stock, the pots lifted and taken to the potting-shed or other convenient place, where they are at once shifted into the fruiting-pots (usually a 6-inch pot). The soil used at this time should be three parts fibrous loam and one of good sharp sand. This potting-soil should have mixed with it bone-flour or dissolved rock at the rate of about one pint to two bushels of soil. Ample drainage should be given, as through the season of ripening the crowns and the following forcing-period, a large quantity of water must be given and none should be allowed to stand around the roots.

The pots should then be plunged to near the rim in some coarse material, preferably coal-ashes, which, if deep enough to extend from 4 to 6 inches below the plunged pots, will prevent the earthworms from entering the pots. The use of a frame in which to plunge the pots is recommended for protection against heavy rains or early frosts. Attention to watering is all that will be necessary through the growing season. Late in September or early in October the pots will be filled with roots and the plants will have attained their full growth. At this time larger and firmer crowns will be had by careful attention to watering and subsequent drying off to almost the wilting stage than by watering the plants up to the time of freezing weather. The drying process seems to represent the late fall season and causes the plant to store up material in the crowns at an earlier period. At the coming of cold weather the soil in the pots may be allowed to freeze. It is very desirable that the soil be on the dry side before freezing, for if the ball of earth is wet there is danger of breaking the pots when the cold becomes intense. The period of forcing, from the time the frozen plants are brought in until the ripening of the fruits, will be about eight weeks. The time will vary slightly under different conditions of heat and sunlight. When first brought in, the plants should be cleaned of all dead or diseased leaves. The pots should be plunged to near the rim in some material that will retain moisture, e.g., tanbark or coal-ashes. The benches or shelves should be as near the glass as convenient. A thorough spraying with bordeaux mix-ture or some other fungicide should be made at once.

For the first few days the house should be held at about 35°, with little if any rise through the day. After a week a rise of 10° may be given. At the end of the second week 50° at night, with a rise of 10° to 15° through the day, will be about right.

Strict attention must be given to syringing the foliage every pleasant day. Keep the walks wet until the time of blossoming. This moisture keeps down the red-spider. At blossoming time the house should be allowed to dry out, and a free circulation of air should be maintained through the middle of the day, in order to ripen the pollen. It is necessary to pollinate each flower by hand. The pollination may be done in the middle of the day while the houses are dry. A small camel-hair brush is useful for distributing the pollen. A ladle or spoon should also be provided in order to carry the surplus pollen. The surplus pollen may be used on varieties that are pistillate or do not have pollen enough to set their own fruits. Six to eight fruits are enough for a 6-inch pot. When these are set the remaining flowers should be cut off, in order that the entire strength of the plant may go to swelling the chosen fruits. After swelling begins, liquid manure should be given. During the first week give one dilute application. After this give two applications a week, increasing the strength of the manure liquid each time. Well-rotted cow-manure or sheep-droppings furnish good material for this purpose. When the fruits are coloring the liquid manure should be withheld and only clear water given. As they swell, the fruits will need support, and the best method of furnishing this is probably by using small-squared window-screen wire cut into suitable squares. These squares may be laid over the pot, under the clusters of fruits. They hold the fruits away from the sides of the pots, protect them from any water or liquid manure that is given the plants, and enhance the beauty of the potted plant. After one fruiting, the plants are worthless.

C. E. HUNN.

STRELITZIA (for the wife of King George III, Charlotte Sophia, of the family Mecklenburgh-Strelitz, a patron of botany). Musaceae. Bird-of-Paradise Flower. Perennial herbs, adapted to the warmhouse, or grown for the banana-like foliage and the very showy flowers. Rhizome sometimes subterranean, sometimes an erect woody st.: lvs. large, long-petioled, scarcely terminal or in the upper axils, short-exserted from the sheaths of the lvs.: bracts large, spath-like, boat-shaped, acuminate, solitary at the end of the scape or 2 slightly dis-tant: perianth long-exserted; sepals free, long, carnate; petals very dissimilar; stamens 6; ovary 3-celled, many-seeded.—About 5 species, S. Afr. The genus has been monographed by K. Schumann in Engler’s Pflanzen-reich, hft. 1 (IV. 45) 1900.

The Strelitzia Reginae requires a strong soil, a copious supply of water, and considerable sunlight. It is a serviceable plant for house decoration or for the porch or lawn in summer. It will endure much neglect, but unless well cared for it may fail to bloom regularly and well. A night temperature of 50° is sufficient. This plant may be induced to set seed if the flowers are hand-fertilized. The usual method of propagation, however, is by suckers and division.

1. Plant nearly stemless.
2. Lvs. ovate or ovate-oblong, margin crisped.

Reginae, Banks. Bird-of-Paradise Flower. Fig. 3733. About 3 ft. high: roots large, strong-growing: lvs. oblong, about 1 ft. long, stiff, concave; fl.-stalks all radical, 2-3 times as long as the lvs.: scape higher.

Strelitzia Reginea. (X 1/4)

Andr. (S. juncce, Link), has lvs. with practically no blade: spathe green margined with magenta, sepals orange, petals rich blue, white-tipped. S. Afr.—The species is probably not cult. Var. junccea,

3733. Strelitzia Reginea. (X 1/4)

STREPTOCARPUS

There are 7 species of Streptocarpus, according to Mez (DC. Monogr. Pl. Nov., vol. 9), of Brazil. The genus differs from Bromelia in the long corolla-tube. No species are in the American trade, but S. Fürstenbergii, Hort., is described in horticultural literature (sometimes as *Euchema Fürstenbergii*, Morr. & Wittm.). It is a stemless pineapple-like plant, with 20-40 long, narrow, linear, terete, splitting in 2, rarely 4 valves. About 60 species, natives of S. Afr. and Madagascar. In Oct. 1826, there bloomed at Kew a most interesting gloxinia-like little plant, seeds and specimens of which had been collected in S. Afr. by Bowie, on the estate of George Rex, at Knysna. The plant was described as *Didymocarpus Rexi*. It is a stemless plant, with 1 or rarely 2 long-tubular nodding pale blue fls. on each of several short scapes, and with several clustered root-lvs. It proved to be a profuse bloomer and easy to grow. “So abundantly does it produce seed,” wrote W. J. Hooker, in 1830, “that new individuals come up as weeds in the neighboring pots, and a succession of flowers may be obtained at almost every period of the year.” In 1828, John Lindley made the genus Streptocarpus for this plant, calling it *S. Rexi*, the name it now bears. It appears to have been nearly thirty years after the intro. of *S. Rexi* that another streptocarpus bloomed in England. This second species was *S. polyanthus*, which may be taken as the type of a group that has one leaf lying on the ground and from the midrib of which arise successive several-fld. scapes. The intro. of this curious plant seems to have revived the interest in streptocarpuses, an interest that has been kept alive by the frequent introductions of other species. The chief stimulus to the systematic breeding of these plants seems to have been the appearance of *S. Dunnii*, said by J. D. Hooker to be “quite the monarch of its beautiful genus” (but now excelled by *S. Wendlandii*). Seeds of this species were sent to Kew in 1884 by E. G. Dunn, of Cape Town. It is one of the monophyllous section to which *S. polyanthus* belongs. In the meantime, *S. parviflorus*, a species allied to *S. Rexi*, had been intro. from the Cape region. With the three species, *S. Rexi*, *S. parviflorus*, and *S. Dunnii*, Wm. Watson of the Royal Gardens, Kew, set to work systematically to breed a new race of streptocarpus, and his efforts met with unqualified success. When the hybrids came to notice in 1887, the Gardener’s Chronicle made the following comment on the value of the work: “The results are very striking, and we can hardly doubt that Mr. Watson has set the foundation of a new race of plants, parallel in importance to the Achimenes and Tyldenas.” Several hybrid races have now been produced and several interesting species have been intro. from the wild, so that Streptocarpus seems to be destined to become a very important and popular garden genus.

Bentham and Hooker’s treatment divides the Ge-
STREPTOCARPUS

neriaces into two great tribes: Gesnerieae, with ovary more or less inferior and fruit a capsule; Cyrtandraceae, with ovary superior and fruit sometimes a berry. The latter tribe, the species of which have been monographed by C. R. Clarke in red. V of De Candolle's "Monographie Phanerogamorum," contains the genera Streptocarpus, Episcia, Cyrtandra, Echysanthesia, Ramanodia, and others. Streptocarpuses are of three groups: the stemless monophyllous species, with one prostrate leaf from the midst of which the scapes arise (this leaf is really an enlarged cotyledon, the other cotyledon not enlarging); the stemless species, with several or many radical more or less primuloid-like leaves (whence the English name, "Cape primroses"); the stem-bearing species, with opposite cauline leaves. The cultivated species chiefly represent the first two sections. In the American trade, four specific names chiefly occur, S. Rezii, S. Galpinii, S. Dunii, and S. Wendlandii; but since the hybrids represent several other species, these additional species are inserted in the following account. Streptocarpus is an African genus. The stem-bearing section is confined to central Africa and Madagascar, and the others to South Africa. Clarke's monograph, 1883, describes nineteen species, but S. Dunii, S. Wendlandii, S. Galpinii, and many others have since been discovered.

Streptocarpuses are not difficult plants to grow. They are usually raised from seeds, the seedlings blooming in eight to fifteen months from starting. The seeds are very small, and care must be taken not to cover them too deep. Give an open sunny place in an intermediate temperature. They are not stove or greenhouse plants. Of the new hybrid forms, seeds sown in February or March should produce plants that will bloom the following fall and winter; after blooming, the plants may be discarded, for better results are usually secured from new plants than from those more than one season old. The season of most profuse bloom is summer, but the bloom continues until winter. The monophyllous species can be propagated also by cuttings of the leaf. Some fanciers of Cape primroses advise propagating select types by leaf-cuttings or by division.

INDEX.

1. albescens, Vatke. Acaulescent, hispate: lvs. petioled, oval-oblong, entire, rather repand, spiculate, obtuse, base contracted to the petiole, puberulent above, villous beneath: fls. blue, 3½ in. across; calyx hirtellous, lobes linear; corolla up to nearly 3½ in. long, 6 times longer than the calyx, limb strongly unequal. Trop. Afr. B.M. 6814.
2. Rexii, Lindl. (S. Gärdenii, Hook.). Fig. 3734. Acaulescent: lvs. several, subrect, 8 to 12 in., oblong, crenate, hairy on both surfaces: scapes several, 4 to 12 in. high, 2 to 4-flowered: calyx-labellae narrowly oblong, hairy; corolla 2 in. long, about as wide, blue or mauve, tube 1½ in. long, very narrowly linear-funnel-shaped, lobes a little unequal. S. Afr. B.M. 3005; 4862. B.R. 1173. L.B.C. 14:1055. F.S. 12:1214. Var. biflorus, Oortgens, differs in having stouter 2-flowered scapes. Gt. 6:204.
3. cyaneus, S. Moore. St. prostrate, slightly elongated, bearing 4 lvs.: lvs. linear-oblong, crenate below the middle into a narrow petiole-like portion, spatulate: scapes almost 2-flowered: fls. varying from pale lavender or blue to rose-pink or rosy mauve, with a few streaks of red on the lower lobes and a blotch of yellow in the throat; calyx-labellae linear-oblong, pilose-pubescent; corolla about 1½ in. long, puberulent outside. Transvaal. B.M. 8521. G.C. III. 55:31.—Allied to S. Rezii.
4. parviflorus, Mey. Acaulescent: lvs. several, spreading or suberect, nearly or quite sessile, elliptic to elliptic-oblong, 8 to 12 in., oblong, 2½ to 3½ in. long, puberulent below, crenate, villose on both surfaces, almost tomentose beneath: peduncles and fls. almost as in S. parviflorus: corolla shorter, white, throat yellow, or almost white penciled with purple, tube slightly widened upward, capsule 1½ in. long, arched, limb 5-lobed.
5. luteus, C. Clarke. Lvs. several, petioled, elongate-oblong, 8 to 12 in. long, oblong, attenuate at base, crenate, villose on both surfaces, almost tomentose beneath: peduncles and fls. almost as in S. parviflorus: corolla shorter, white, throat yellow, or almost white penciled with purple, tube slightly widened upward, capsule cylindrical, sepal unequal, linear, recurved; corolla hisrate outside, 1½ to 2 in. long, arched, limb 5-lobed.

KEY TO THE SECTIONS.

A. Plants of native origin.
B. Sts. elongated; lvs. opposite.
C. Sts. lacking or very short; lvs. all radical.
D. Lvs. several, forming a rosette.
E. Lvs. solitary.
F. Lvs. not decurrent on the petiole.
G. Corolla-tube much curved, limb very oblique.
H. Corolla-tube cylindrical, nearly straight, limb slightly 1-sided.
I. Section I. CAULESCENTES. Species 1-7.
J. Section II. ROSULATI. Species 8-17.
K. Section III. UNEOFLORI. Species 18-22.
L. Section IV. HYBRIDA. Species 13-17.

STREPTOCARPUS 3273

3734. Streptocarpus Rexii. (X½)
STREPTOCARPUS

oil-rose, lobes rotund, the lower yellow-blotched at base. S. Afr.

Section III. UNIFOLIATA.
A. Corolla-tube broader than long. 7. Galpinii
AA. Corolla-tube longer than broad.
B. Fls. rose to redish.
BB. Fls. bluish or purplish.
C. Tube of corolla linear-cylindrical. 9. polyanthus
CC. Tube of corolla more or less widened at the mouth.
D. Limb of corolla much shorter than the tube. 10. grandis
DD. Limb of corolla nearly as long as the tube.
E. Lf. rarely over 1 ft. long; corolla usually less than 1 in. across. 11. Saundersii
EE. Lf. usually over 1 ft. long; corolla usually more than 1½ in. across. 12. Wendlandii

8. Dunnii, Mast. Fig. 3735. Acaulescent, soft glandular-pubescent or tomentose; lf. solitary, very large, 2-3 ft. long, sessile, ovate-oblong, obtuse, margin irregularly lobulate and crenate, pubescent between the reticulate veins, midrib thick and villous beneath; flowers numerous, clustered, produced serially, stout, 1 ft. or more high, bearing many-fl., second panicles; fls. 1½ in. long, pale brick-color to rose, short-pedicelled, linear-cylindric, both surfaces closely hairy, red-purple beneath; scapes several, up to 1 ft. high, forked; inf. 6-8 in. long, 30-tid.; calyx-segments linear-oblong; corolla curved, tubular-funnel-shaped, puberulent, lobes short rotund, ciliolate. S. Afr. B.M. 6903. G.F. 3:609 (adapted in Fig. 3735).—A plant sometimes produces more than 100 fls.

9. polyanthus, Hook. Acaulescent; lf. solitary, 5-7 x 3 in., round or elliptic, obscuringly crenate, hairy on both surfaces: scars 1-3, up to a foot or more high, rather stout, 4-10-fl.; calyx hairy, teeth linear; corolla pale blue, about 1½ in. long, tube linear-cylindric, curved, limb unequal, the 3-lobed lip much longer than the 2 upper segms. S. Afr. B.M. 4850. Gt. 6:206.

10. grandis, N. E. Br. Acaulescent; lf. solitary, radical, 2-3½ ft. long, 1-2½ ft. broad, ovate, base cordate, crenate, pubescent on both sides; cauline lvs. none or few, small, ovate, sessile; pedicels several, bearing above 2-6 lax racemes, pubescent; fls. in 2's, lavender or light blue outside, white within, marked with 2 broad-blue stripes in the throat; corolla-tube about 1 in. long, bent downward, upper lobes pale blue or lavender. Zululand. B.M. 8042.

11. Saundersii, Hook. Acaulescent; lf. solitary, sessile, flat on the ground, 14 x 12 in., very broadly elliptic, dark green; flowers numerous, clustered, produced serially, stout, 1 ft. or more high, bearing many-fl., second panicles; fls. 1½ in. long, tube more or less widened at the mouth; calyx-segments linear-oblong; corolla curved, tubular-funnel-shaped, puberulent, lobes short rotund, ciliolate. S. Afr. B.M. 5251. F.S. 17:1802. Gt. 24:826.

12. Wendlandii, Sprenger. Fig. 3736. Acaulescent; lf. solitary, attaining a size of 30 x 24 in., crenate, closely hairy, red-purple beneath; flowers several, 1-2½ ft. high, forked; inf. 6-8 in. long, 30-tid.; calyx lobes linear, hairy; corolla pale blue with purple blotches in the throat, tube somewhat funnel-shaped, a little curved, limb oblique, 2 lobes much shorter. S. Afr. B.M. 7447 (part of which is colored in Fig. 3736). G.C. III. 22:275. Gn. 45, p. 511; 50, p. 394. J.H. III. 23:223. G. 17:181.—One of the finest species in cult.

Section IV. HYBRIDA.

(For colored pictures of modern hybrid types, see Gn. 29:545; 41:843; 50:1092.)

13. achimeniformis, Hort. Acaulescent; lvs. several, radiating or opposite, rather elliptical, somewhat fleshy, brilliant light green; fls.—st. stiff, most often 1-fl.; fl. as large as a gloxinia, but with the corolla divisions more deeply cleft, and finely dentate, bright lilac tinted with marine blue through pale lilac to pure white, the lower part of the corolla is always striped with deeper color. Possibly a garden hybrid. R.H. 1906, p. 309. Var. Albus, Hort., is offered in the trade as a large-fl. white form. Var. gigantisans, Hort., is offered as a lavender-blue form. Var. roseus, Hort., is offered as a soft delicate rose form.

14. Bruantii, Hort. (S. Rexii x S. polyanthus). Lvs. very large, not cordate, very velvety, bright green; scarps up to 14 in. high: fls. about double the size of

3735. Streptocarpus Dunnii. (X about ½)

3736. Streptocarpus Wendlandii. (X ¾)
of *S. polyanthus*, about 1½ in. long, blue or bright mauve, throat yellowish white. Garden hybrid.

16. *kewensis*, Hort. (S. Reticii × S. Dunnii). Fig. 3737. Lvs. 2 or 3, large, but not so large as those of *S. Dunnii*, oblong or elongate-ovalate, bright green; fl.-sts. numerous, each 6-8-fl.d., forming a tolerably compact mass; fls. bright mauve-purple, striped with dark brownish-purple in their throat; corolla about 2 in. long, 1½-1½ in. across. Garden hybrid. G.C. III. 2:215.

The following species are either little known or have not found their way into general cult.: *S. Arnottanae*, Baker & Moore, is closely allied to *S. Dunnii*, differing in having a corolla much less funnel-shaped and straighter, with less spreading lobes; originally described as solitary-led, but 4 lvs. are said to have developed in the capsule. *S. A. × B. Birds*, Lynch (S. Wendlandii × *S. Dunnii* hybrid), has 2 lvs. about 10 × 13 in. for the lower, the second somewhat smaller: fls. large, purple-blue. Garden hybrid. G.C. III. 56: 192.- *S. bicornis*, Pucei, is a name appearing in horticultural journals for some unknown plant, which is said to have several blue fls.- *S. bicornis-polyanthus*, Duch., is a hybrid, the female parent of which is *S. polyanthus*, the male the above-mentioned *S. bicornis*: it is said to have 5 ovate-oblong, crenate lvs.; several scapes 8-10 in. long: berry red. May-July. A garden hybrid.

**STREPTOPUS** (Greek, twisted stalk, referring to the peduncles). Liliaceae. TWISTED STALK. Perennial herbs, with the aspect of Polygonum, hardy and adapted to the wild-garden; should be grown in shade or with rich, loose, and moist soil in sunlight.

Stems erect from a short, dense, or longer, repent rhizome, simple or slightly branched: lvs. alternate, ovate or lanceolate, membranaceous, sessile or clasping; fls. medium-sized, solitary or paired in the axil, nodding, rose or whitish; perianth campanulate, segms. distinct or connate at base; stamina 6: style 3-delt.; ovary sessile, ovoid, 3-celled; berry subglobose, indehiscent. About 6 species, Eu., Temp. Asia, and N. Amer. Woodland plants closely related to Disporum which has terminal fls.

1. *roseus*, Michx. Fig. 3738. Rootstock short, stout: st. 1-2 ft. high: lvs. sessile, only partially clasping, 2-4 in. long: peduncles less than 1 in. long, mostly 1-fl.d.: fls. about ½ in. long: berry red, ½ in. thick. May-July. Moist, rich woods in the northern states, S. to Ga.

2. *S. americana*, Hook. f. (S. Wendlandii × S. Watsonii), has 2 or 3 lvs., the largest of which is 15 x 9 in. and another is 12 x 7 in., green beneath, in some cases reddish toward the tip, in others with the color here and there; scapes 8-10, each with 6-14 fls. about 1½ in. long. A garden hybrid. B.M. 7857.- *S. Veitchii*, Hort., is offered in the trade.

**STREPTOPUS** 3275

3738. Streptopus roseus. (X½)

3737. Streptocarpus kewensis. (X3½)

**STREPTOPUS** 3275

3737. Streptocarpus kewensis. (X3½)

**STREPTOPUS** 3275

3738. Streptopus roseus. (X½)

AA. Fls. greenish white.

**amplexifolius**, DC. Rootstock short, stout; st. usually taller than *S. roseus*: fls. clasping, 3-6 in. long: peduncles 1-2 in. long, usually 2-fl.d.: fls. about 1½ in. long; berry red. May-July. Moist rich woods, N. U. S. and Canada south to N. C., and New Mex.; also in Eurasia.

F. W. BARCLAY.
STREPTOSOLEN

F. TRACY HUBBARD.

STROBLANTHES

STROBLANTHES (named in honor of Sir C. W. Strickland). Arosieris. Perianth narrowly funneled, tube short, segments oblong, equal; stamens, one to five, filaments united half-way in a cup, lanceolate above it, without any teeth below; ovary globose, 3-lobed, 3-celled; capsules short, deeply 3-lobed,iloculicidally 3-valved; seeds many, small. One species, Andes of Ecuador. S. crenatioloides, Baker (Leptenion crenatioloides, Baker. Pterodon crenatioloides, Bentham. F. STICKLANDI, Baker). Bulb ovoid, 2 in. diam.; tunics brown, membranaceous; leaves 2 to 3 ft. long, ovate, acute, base broad-oblong, suborbicular, entire, with a few short-pedicelled, sometimes in dense or interrupted terminal spikes or the peduncles clustered at the axis; calyx deep green, 5-parted, segments linear, corolla-tube slender at the base, widened above; limb spreading, 5-lobed, lobes ovate, perfect stamens 4 or 2; caps. oblong or linear, 2-celled at or near the base. About 200 species, India, Malay Peninsula, Java, and Japan.

S. STICKLANDI, New. Shrubs, 2-3 ft. high, glabrous, exserted, one to three at a time, the latter, acuminate at both ends: racemes axillary, very numerous, conical, 2-3 in. long; bracts rounded, white, tipped with green; flowers white, projecting slightly from the cone. Hymenophyllum.

S. crenatioloides, New. Shrubs, 2-6 ft. high, glabrous, exserted, one to three at a time, the latter, acuminate at both ends: racemes axillary, very numerous, conical, 2-3 in. long; bracts rounded, white, tipped with green; flowers white, projecting slightly from the cone. Hymenophyllum.

S. degeneri, New. Shrubs, 2-6 ft. high, glabrous, exserted, one to three at a time, the latter, acuminate at both ends: racemes axillary, very numerous, conical, 2-3 in. long; bracts rounded, white, tipped with green; flowers white, projecting slightly from the cone. Hymenophyllum.

S. degeneri, New. Shrubs, 2-6 ft. high, glabrous, exserted, one to three at a time, the latter, acuminate at both ends: racemes axillary, very numerous, conical, 2-3 in. long; bracts rounded, white, tipped with green; flowers white, projecting slightly from the cone. Hymenophyllum.

S. degeneri, New. Shrubs, 2-6 ft. high, glabrous, exserted, one to three at a time, the latter, acuminate at both ends: racemes axillary, very numerous, conical, 2-3 in. long; bracts rounded, white, tipped with green; flowers white, projecting slightly from the cone. Hymenophyllum.

S. degeneri, New. Shrubs, 2-6 ft. high, glabrous, exserted, one to three at a time, the latter, acuminate at both ends: racemes axillary, very numerous, conical, 2-3 in. long; bracts rounded, white, tipped with green; flowers white, projecting slightly from the cone. Hymenophyllum.

S. degeneri, New. Shrubs, 2-6 ft. high, glabrous, exserted, one to three at a time, the latter, acuminate at both ends: racemes axillary, very numerous, conical, 2-3 in. long; bracts rounded, white, tipped with green; flowers white, projecting slightly from the cone. Hymenophyllum.
STROPHANTHUS (Greek, round and flower; said to allude to the form of inflorescence). Maranta. Perennial herbs grown in the warmhouse for the foliage. Stems leafy, erect, from a thick horizontal rhizome, somewhat branched, the base covered by the long leaf sheaths: lvs. short-petioled; infl. rather lax, terminal, on a long peduncle, more or less compound, rarely narrow, almost racemose-like, frequently all colored blood-red; bracts and bracteoles pubescent-like, colored; sepals 3, free, oval-oblong; petals 3, slightly narrower than the sepals; ovary 1-celled, 1-ovuled: fr. subglobose.—About 12 species, S. Amer. (Schumann, in Engler’s Das Pflanzenreich, hft. 11.—IV. 48). Closely allied to Calathea, Maranta, Phrynium and Thalia. It agrees with Maranta and Thalia in having a 1-loculed cap, and thereby differs from Calathea and Phrynium, which have 3 locules. From Maranta it differs in having a very short perianth-tube and the segments not standing opposite each other. From Thalia it differs, as does Maranta, in having 2 side staminodia rather than 1. For cult., see remarks under Callathea.

Portulacina, Griseb. (Maranta portulacina, Koern.). Two to 4 ft. high, with maranta-like lvs., the blades long-elliptic or ovate-acuminate, varying from acuminate to almost obtuse, purple beneath, bright green above with transverse stripes or bars of silvery white; fis. solitary or twin on the rachis, blood-red, the infl. simple or compound. Brazil. Lowe 26.

sanguinea, Sonder. (Thalia sanguinea, Lem.). Lvs. blades about 1 ft. long, oblong-acuminate, purple beneath and green above: scape 12-20 in. tall, red toward the top, bearing a panicle of bright red and red-bracted fls. Probably Brazilian. B.M. 4464 (as Phrynium). E.S. 19: 403.—An old garden plant.

Thrive in an intermediate house and attain a height of 5 ft. when planted in a border. Var. spectabilis, Eichler. B.M. 8494. F. TRACY HUBBARD.

STROPHOLIRION 3277

STROPHOLIRION (Greek for twisted rope and lily, referring to the twisting stem). Lilaeac. Herbaceous, with a cormed base, used for outdoor planting: lvs. few, radical: scape simple, leafless, often twining several feet lvs. rose, numerous in a terminal umbel; perianth urn-shaped, 6-lobed; stamens 3; ovary sessile, ovoid, 3-locular, ovary 1-celled, 1-ovuled: fr. subglobose. —About 40 species, Trop. and S. Afr. and Trop. Asia.

Sickle (S. dichtomus, DC.). Erect shrub with stout branches: lvs. elliptic-oblong or obovate, 3-5 x 2-3 in., obtuse, acute or apiculate, rather coriaceous; cymes more shorter than the lvs., dichtomus.
One species, Calif. Very like Brodiaea, and sometimes referred to that genus, but differing in always having 3 stamens and a perianth which is contracted at the throat and sacate at the base. \textit{S. californicum}, Fort. (Brod. \textit{californica}, Baker). Fig. 3: (adapted from Pacific R. R. Rep.). In many ways it resembles \textit{Brevvoorta Ida-Maia}, except that the scape is climbing to a height of \(3-4\) ft., and bearing an umbel of delicate rose-colored flowers. Tilly about any stick or bush that stands near it. Lvs. 1 ft. or more long, keeled, \(\frac{1}{2}\) in. or less broad: corolla 1 in. diam. Cent. Calif. B.M. 6123. \textit{C.} of \textit{Brevvoorta Ida-Maia}.

\textbf{C. Purdy.}

\textbf{STRUTHIOPTERIS:} Matteuccia.

\textbf{STRYCHNOS} (an old Greek name used by Theophrastus for some plants belonging to Solanaceae). \textit{Lopadecea.} Scendent shrubs with short tendril, or trees, of economic importance; some of the species have been introduced into the southern United States.

Leaves opposite, in scendent species some axis bear short clavate tendrils, the adjacent if. being often suppressed; cymes terminal or lateral; bracts small: fls. white to yellowish; calyx \(4-5\)-lobed; corolla \(4-5\)-cleft, tube short or long or hardly any, lobes valvate; stamens \(5\); ovary \(2\)-celled (or \(1\)-celled above): berry globose or oblong.-About 220 species, tropics of both hemispheres.

\textbf{Nux-vomica,} Linn. Tree attaining a height of \(40\) ft.: lvs. ovate, \(5\)-nerved, glabrous, \(\frac{3}{4}\) x \(\frac{3}{4}\) in.; cymes terminal, short-peduncled, \(1-2\) in. diam.; pedicels hardly any: fls. numerous; corolla-lobes glabrous: berry \(\frac{1}{2}\) in. diameter: seeds: seedcoat many-seeded. India.—The seeds yield the drugs, nux-vomica and strychnine, and the bark is somewhat used as a tonic.

\textbf{Potatostrum,} Linn. f. Tree attaining a height of \(40\) ft.: lvs. elliptic, \(2\frac{1}{2}\) x \(1\) in., \(3\)-nerved, subsessile, glabrous or nearly so: cymes axillary, nearly sessile, \(1\) in. diam.: berry \(\frac{1}{2}\)-\(\frac{3}{4}\) in. diam. India and Ceylon.—The seeds are known as the clearing-nut as they have the property of clearing muddy water when they are rubbed on the inside of the vessel into which it is put.

\textbf{Spinosa,} Lam. Low tree: branchlets slender, armed with pungent spines from the nodes: lvs. obovate or suborbicular, \(5\)-nerved from near the base, glabrous, subcoriaceous: cymes terminal, short-peduncled, \(1-3\) in. diam., very compact: fls. greenish: calyx-tube very short, segms. linear: corolla-tube short, campanulate, the lobes usually \(5\): ovate: fr. the size and color of an orange, the shell leathery, the pulp abundant and edible; seeds large. Trop. and S. Afr., Madagascar, and Seychelles.—A promising fr. intro. into the U. S. 

\textbf{Staphylea.} Gilg (S. Schulmann, Hort.). Tree, \(12-22\) ft. high with axillary recurved spines: lvs. decussate, elliptical, gray-green or yellowish, \(\frac{1}{2}\) in. long: flowers yellow or white, \(\frac{1}{2}\) in. across: berries black, \(\frac{1}{2}\) in. in diameter: shrub. Australia. Gilg intro. into S. Calif. but not successful. —S. \textit{Schulmanniana}, Gilg. Tree, \(30-40\) ft. high: branchlets armed at the nodes with curved pungent spines: lvs. oblong or oblongate, glabrous; flowers yellow, from the tip of the branches: seeds ovate; corolla-lobes ovate: fr. shaped like an orange, edible. Trop. Afr. Reported as intro. into S. Calif. but not successful.

\textbf{F. Tracy Hubbard.}

\textbf{STROPHNODENDRON} (Greek, \textit{astrigend} and \textit{tree}; the bark has a puckery taste). \textit{Leguminosae.} Unarmed trees, usually small, with thick branchlets, grown in the greenhouse and also outdoors in the extreme S.: lvs. twice pinnate, lfts. small, many-paired, frequently rather broad: fls. small, hermaphrodite or polygamom, borne in short-ped-oleoed, axillary spikes, \(5\)-merous, sessile: calyx campanulate: petals obovate to the middle, finally free: stamens 10, free; ovary short-stipitate, many-ovuled: legume linear, compressed, thick.—Nine species in Trop. Amer.

\textbf{Guianense,} Benth. Branchlets subterete, they and the petioles rusty-tomentellous: pinnae \(6-12\) pairs; lfts. with \(8-10\) pairs of divisions, oblique, oval-oblong, \(4-5\) lines long, shiny above, reddish beneath: corolla smooth, about \(5\) times as long as the calyx: pod straight or slightly incurved. (Breed. & Hooker intro. into Fla.)

\textbf{S. forinandiun,} Benth. (Accacia pulcherrima, Willd.). Spines: pinnae \(13\) pairs; lfts. many-paired, oblong-linear, obtuse, pubescent beneath, petiole pubescent and Purpavus, fr. would apparently have been used twin, axillary, filiform: fls. \(5\)-parted, ptose. Brazil.

\textbf{STUIARTIA:} \textit{Steuartia.}

\textbf{Stylium} (\textit{stylis}, a column, referring to the body formed by the union of the stamens and style). \textit{Candollea} or \textit{Styliodeae}.—A woody perennial or tree of economic importance; some of the species mostly in Australia, seldom grown under glass or in the open in mild climates.

Confusion has arisen in the name of this group, and recent authorities adopt the name \textit{Candollea}, but \textit{Candollea} is itself confused. In 1805, La Billardiére founded the genus \textit{Candollea} for the plants which a few months earlier were named \textit{Stylium}, Swartz, by Wildenow (Sp. Pl. iv. 146). As the first application of the name \textit{Candollea} was that of Baker, in 1847, and \textit{Stylium} was used by Willdenow in 1805, \textit{Candollea} is a synonym for \textit{Stylium}, for the genus we are now considering, as is done by Bentham & Hooker. Schönland, however, in Engler & Prantl's Pflanzenfamilien, although kept separate by Bentham in \textit{Flora Australiensis} and by Bentham & Hooker in Genera Plantarum. Although the name \textit{Stylium}, Swartz, is antedated by \textit{Stylium}, Loureiro, founded in 1790 on a plant of the Cornaceae, Swartz's name stands, since Loureiro's \textit{Stylium} belongs as a synonym to the earlier genus \textit{Alangium} (see page 248, Vol. I). According to the International Rules, as well as on the principle of fifty years of accepted usage, it is correct to retain \textit{Candollea} for the \textit{Dilleniaceous plants} (page 653) and to use \textit{Stylium} for the genus we are now considering, as is done by Bentham & Hooker. Schönland, however, in Engler & Prantl, and, earlier, F. von Mueller, revive the \textit{Candollea} of 1805 and make \textit{Stylium} a synonym, and in this case the \textit{Candollea} of 1806 would become Eulalia of Durand if it is retained as a genus distinct from \textit{Hibbertia}. According to the Philadelphia or American Code, however, the existence of earlier homonyms, no matter whether valid names or synonyms, prevents the use of \textit{Stylium}, Swartz, and \textit{Candollea} of 1806, and it is recommended that \textit{Stylium} be the name to be used for the \textit{Stylium} of Swartz, while \textit{Eulalia} would replace \textit{Candollea}. The latest monograph, \textit{Mikr braud}, in \textit{Engler's Pflanzenreich}, art. 35 (iv. 278. 1908), adopts \textit{Stylium}, Swartz. It may be said in passing that the generic name \textit{Candollea} has also been used for plants distinct from either of the groups we are here considering, but these applications are of later origin.

The \textit{Stylium} are of very minor importance horticulturally and scarcely appear in the American trade, although \textit{S. adnatum} has been listed in southern California. The species are difficult of determination in Australia; \textit{Mikr braud} describes 103. Most of the species "form a spreading tuft of radical leaves from the midst of which springs the scape. Sometimes the following year the new leaves and scape are close to the old ones, forming a dense, tufted stock, the bases of the leaves sometimes assuming a bulbous appearance; in others one or two short stems or branches, may be observed." The plants are most or less lobelia-like, with pink, purplish, yellow, or white fls. in racemes, panicles, or cymes; corolla irregular, five-lobed of which four lobes ascend in pairs and the other (the lip) much smaller and deflexed or sometimes nearly as large as
the others and curved upward; calyx five-lobed, more or less two-lipped; stamens two, united with the style: fruit a capsule, two-valved from the top downward; leaves all radical, or scattered in whorl-like tufts, as described above.

*S. adnatum*, R. Br. (Candollea adnata, Muell.), has mostly very narrow or linear lvs. scattered along the st., the upper ones showed in a terminal tuft: fls. pink, nearly sessile in compound racemes or spike-like panicles: sts. 12 in. or less long.—*S. Brasunaniun*, Bentth. (Candollea Brasuniana, Muell.). Totally or rarely prolific, the radical lvs. linear to oblanceolate: scars 12-18 in. high, with whorse of narrow lvs., and bearing many small pink fls., the corolla-throat appended. B.H. 28:10. H.U. 4:72.—*S. eiliatum* Lindl. (S. sinicifragosae, Lindl. Candollea eiliata, Muell.), 8—piliferum.—*S. dodonaeum*, DC. S. nanoumifolium, Hook. (Candollea dichotoma, Muell.), low, the scars 2-4 in. high and glandular-pubescent: lvs. narrowly linear, acute, scattered between tufts at base and top: fls. yellow in a glandular-hairy compound racemes or panicle. B.M. 4386. F.S. 6:600 (as S. Hookeri). J.F. 1:59.—*S. graminidium*, Swarts (S. Armeria, Labill. Candollea graminidium, Muell.). Tufted or somewhat profloriferous, the scars 6-18 in. high, bearing a raceme or panicle of yellow or whitish or pinkish lvs., the corolla-throat not appendaged. B.R. 28:15. H.U. 4:282.—*S. Hookeri* L. H. B. Tufted, IVB.linear and hair-pointed, the plant with yellow glandular hairs; scars 6-12 in. high, bearing a raceme or panicle of yellow or whitish or pinkish lvs., the corolla-throat not appendaged. B.M. 3663 (as S. cilatum); 4629 (as S. saxifragosae). J.F. 1:34.

**STYLOPHYRUM** (Greek, style and bearing, in reference to the persistent style). *Papaveraceae.* Hardy, perennial herbs, with stout rootstocks and yellow sap: lvs. radical, pinnatifid or entire, scattered in whorl-like tufts, or cut: fls. yellow or red; peduncles elongated, solitary or aggregated between tufts at base and top; fr. yellow in a glandular-hairy compound racemes or panicle. *S. diphylum.* Nutt. (Papaver *Stylophorum*, Hort.) 3741. A hardy perennial about 1 ft. high, forming large clumps: st. with 2 lvs. at the summit: lvs. light green, pinnately parted: fls. yellow, 2 in. across, in clusters of 3-5. May, June. moist shade, W. Pa. to Wat. and Ark. B.B. 2:102. J.H. III. 34:475. Gns. 65, p. 283.—An attractive plant of easy cult. in any rich, rather loose, moist soil in either shade or open, but preferably in partial shade. It is easy to transplant. F. W. BARCLAY.

**STYRAX** (ancient Greek name of *Styrax officinalis*). *Styraceae.* *Styrax.* Ornamental woody plants chiefly grown for their handsome flowers.

Deciduous or evergreen trees or shrubs more or less stellate-pubescent: lvs. short-stalked, exstipulate, more or less covered, like the infl., with stellate hairs: fls. white; calyx campanulate, obscurely 5-toothed or truncate; petals 5, connate only at the base; stamens 10, inserted at the base of the corolla and usually somewhat connate below; ovary superior, often united at the base with the calyx, 5-lobed at the base, 1-lobed at the apex; style slender: fr. a drupe, mostly subglobose, fleshy or often dry with dehiscent pericarp, 1-2-seeded, with large, subglobose seeds.—About 100 species in the tropical, subtropical, and warmer temperate regions of Amer., Asia, and Eu. There is a monograph by Miss J. Perkins in Engler, Pflanzenreich (IV. 241). *Styraceeeae*, pp. 17-88 (1907). *S. Benzoin* yields the benzoin, a balsamic exudation of the wounded tree; styrax, a similar gum-resin, was formerly obtained from *S. officinalis*, but the styrax of today is a product of Liquidambar.

The storaxes are handsome trees of graceful, usually loose and spreading habit with numerous white and mostly fragrant, often pendulous, flowered or few-flowered clusters, followed by rather insignificant subglobose drupaceous fruits. *S. japonica* and *S. Obassia* are the hardiest and stand the winter in sheltered positions as far north as Massachusetts. *S. americana* is somewhat tender; *S. grandifolia* is hard about Philadelphia and *S. Wilsonii* is probably of the same hardiness; *S. officinalis* is hardy only South. They are well adapted for borders of shrubberies or as single specimens on the lawn, and thrive best in a light, porous soil. Propagation is by seeds which are usually profusely produced in cultivation, soon after ripening, and by layers sometimes grafted on *Halesia carolina*. *S. japonica* and *S. americana* may also be grown from cuttings, but usually only a small percentage will root.

**STYRAX**

**b.** Young branchlets, petioles, and racemes soon glabrous.

**AA.** Fls. in few-fl. clusters or short racemes; lvs. ½-1 in. long.

**b.** Lvs. ½-1 in. long, serrate or denticulate, tomentose beneath.

**Wilsonii,** Rehd. Small compact shrub, to 6 ft.: lvs. rhombic-ovate or oval, obtuse or acutish, sparingly toothed or denticulate, sparingly pubescent above, white-tomentose beneath, ½-1 in. long: fls. short-stalked in 2-5-fl. clusters, ½-1 in. long; calyx stellate-pubescent; corolla-lobes oblong: fr. globose-obovoid, ½±in. long, finely velvety. May, June, W. China. B.M. 8444. G.M. 45:47. S.Z. 5:169. (The hardest species and exceedingly handsome in bloom with its profusion of gracefully drooping white fls.)

**SUCCULENTS**

- **3742. Styrax japonica.** (×½)

**SUCCULENTS**

**SCALLOPED**

- **Succisca (succise, prenmorese); cut off at the lower end, referring to the root.** *Dipsaceae.* Three or 4 herbs, by some authorities incl. in Scabiosa, of the Medit. region to Trop. Afr., marked by the soft or herbaceous scales or pales (involutiones) subtending the florets in the head, and by other technical characters. To this genus or group belongs the "teufelsabiss" of the Germans. The plants are little known in cult., but S. australis, Mert., is listed abroad among outdoor perennials. Nearly or quite glabrous: lvs. ovate-elliptic, acuminate and entire, the lower ones somewhat auriculate: heads ovate, with lilac-violet or ochroleucous fls.; scales of involucre in 2 series. **S. pratensis, Moench.** (Scabiosa Succisa, Linn.), may be cult.: root premorese (at cut off): radical lvs. ovato-lanceolate, acuminate and entire, the cuneal ones conuate; scales of involucre in 2 or 3 series.

**Succulents:** Planting, page 2672.
SUGAR-APPLE

SURINAM CHERRY

SURINAM CHERRY (Fig. 3743), Eugenia uniflora (E. Micheli) of the family Myrtaceae, is a large shrub, sometimes becoming a small tree, but commonly branching close to the ground and forming a broad compact bush 6 to 12 feet high. It is indigenous to Brazil, but has now been sufficiently collected and isolated, with two or more rows of rows, in the manner of the star dahlias. It is hoped that some very good forms of the red sunflower will be developed along these lines. A new form of the wine-red sunflower has the bicolor pattern, with the background pale (dilute) orange instead of primrose. This gives, in certain cases, an exceedingly rich and bright color. By crossing the silky-haired H. argophyllus with vinous H. annua, and again crossing the resulting plants with vinous H. annua, a very pretty new hybrid has been obtained, the rays very pale yellow, tinted with vinous or with a broad ring of color at the base. It has the H. argophyllus foliage.

As early as 1896 (Bulletin Torrey Botanical Club, vol. 23, page 357) hybrids between annual and perennial sunflowers were recorded, but without details. The hybrid H. annua X H. scaberrimus (rigidus) was listed by Thellung in 1913. In 1918, Leonard Sutton in England used the pollen of H. annua, and the red variety of H. annua, and obtained fertile seed. The F1 had the characters of the perennial parent, but Sutton reports that an F2 plant has been obtained with small streaks and splashes of red. In 1914 Mrs. Cocke used the problem, and obtained H. x pumilus, with vinous H. annua, and obtained seeds which produced plants in 1915. These resembled the perennial parent, and formed rosettes only during the first season. An attempt to force these into flower in the greenhouse in the winter of 1915-1916 totally failed; but three seeds of the original lot placed in a coldframe early in 1916 produced plants, one of which is a rosette, while the other two have formed no rosette, and have flowered the first season, like H. annua. The largest of the first lot of plants from the H. pumilus X H. annua cross flowered about the middle of July, 1916, and in its mature form showed a curious combination of characters. The rays, however, were entirely without red, and as is usual with perennials, gave a red color (Since this was written, one of the hybrids has flowered showing the collarette character, and the lobes forming the collarette are largely red.) This hybrid plant has a curiously close resemblance to the horticultural form known as Daniel Dewar. The broad leaves with perennials, gave a red color with caustic potash. It seems probable that results of considerable botanical and horticultural interest will eventually be obtained. S. Alexander of Michigan has made an elaborate study of the forms of perennial sunflowers growing in his region. He finds that only part of the species are perennial in the strictest sense, the others reproducing by underground branches, having no permanent budding crowns. He also finds that the forms are extremely diverse and has recognized over 600 minor species, differing in a variety of characters. This great diversity of character should afford the basis for many interesting hybridizations, and increased by the system of vegetative reproduction by "earth-braches," which would give us areas covered with plants of the same composition, constituting apparently fixed and constant species. Alexander finds, however, that the true stationary perennial presents a great diversity of forms, though they appear to be far less numerous than are the migrants. T. A. COCKERELL.
suberosive, opposite, entire, ovate, subacuminate at the apex and rounded to subcordate at the base, 1 to 2 inches long, glabrous, reddish when young but when mature of a deep glossy green color. When crushed they emit a pungent odor which is rather agreeable; in Brazil they are often gathered and scattered over the floors of the houses, the odor which they give off when trampled upon being appreciated and considered efficacious in driving away flies. The white slightly fragrant flowers are about \( \frac{1}{2} \) inch in diameter, solitary in the axils of the leaves on slender peduncles up to 1 inch long; the sepals are four, oblong, concave, ciliate; the petals four, oblong-obovate, cupped, ciliate. The stamens are numerous, erect in a large cluster, the filaments filiform and the anthers oval, laterally dehiscent. The style is slightly longer than the stamens, filiform, the stigma simple; ovary bicarpellary.

The plant is of very simple culture. It is usually propagated by seeds, which will germinate upon the ground beneath the bush if the fruits are allowed to fall. They can be sown in flats of light sandy loam, and cov­ally takes place within a few weeks. When a foot high, the plants may be set out in the open ground, where they are reasonably drought-resistant. Because of their attractive appearance and close, compact growth they are often used in Brazil for hedges, for which purpose they are excellent.

F. W. POPENOE.

**SUTHERLANDIA** (named for James Sutherland). *Leguminosae.* Tender canescence shrubs, hardly in the extreme S., otherwise grown in the greenhouse; lvs. unevenly pinnate; lfts. many, very entire, without stipels; stipules small, narrow: lfts. showy, scarlet, few in short axillary racemes; calyx-teeth subequal; standard erect, spreading at the top; wings small, oblong; keel erect, incurved, rather acute, exceeding the standards; stamens 1, free from the standard, the others connate in a sheath; ovary stipitate: legume ovoid, membranous, much inflated, rather indehiscent. One species, *S. afr.* Prop. by seeds and said to be easily raised from cuttings. The seeds are generally sown in June or July and the plants wintered in the greenhouse, where they should have very moderate watering and as much air and light as possible. Grown for the bloom. 

**fruitescens**, R. Br. Shrub, about 3 ft. high; lvs. with 9–11 pairs of lfts. and an odd one: fls. drooping and in the best variety 1 in. or more long, not pea-shaped: pod sometimes \( \frac{1}{2} \times \frac{1}{2} \) in., bladder-like. *S. afr.* G.W. 14, p. 383. Var. *communis,* Harv. 14, p. 383. Var. *communis,* Harv. with small, oblong; keel much longer than the standard; stamens 1, free from the standard, the others connate in a sheath; ovary stipitate: legume ovoid, membranous, much inflated, rather indehiscent.-One species, *S. afr.* Prop. by seeds and said to be easily raised from cuttings. The seeds are generally sown in June or July and the plants wintered in the greenhouse, where they should have very moderate watering and as much air and light as possible. Grown for the bloom.

**SWAINSONA** (named for Isaac Swainson, an English horticulturist of the latter part of the eighteenth century). Often incorrectly spelled *Swainsona.* Leguminosae. Glabrous or subappressed-pilose bushes or subshrubs, adapted to greenhouse culture or out-of­doors in the extreme South.

Leaves odd-pinnate; lfts. many without stipels; stipules frequently herbaceous, base broad, rarely bristle-like: lfts. blue-violet, purplish, rarely white or yellowish, in axillary, usually peduncled racemes; calyx-teeth subequal or the 2 upper shorter; standard orbicular or reniform, spreading or reflexed; wings oblong, falcate or twisted; keel broad, incurved, obtuse; stamens 9 and 1; ovary sessile or subsessile, opposite, entire, ovate, subacuminate at the apex; fruits produced in great abundance during the early spring in south Florida, with frequently a second crop later in the summer; they are subglobose, about 1 inch in diameter or somewhat less, prominently eight-ribbed longitudinally, deep crimson in color when fully ripe, each containing one large spherical seed or two hemispherical ones. The flesh is soft and melting, very juicy, of the same color as the thin skin and of an aromatic, subacid flavor. The fruit is a great favorite in parts of Brazil, where it is commonly eaten out of hand or made into jellies, preserves, and sherbets.

The plant is of very simple culture. It is usually propagated by seeds, which will germinate upon the ground beneath the bush if the fruits are allowed to fall. They can be sown in flats of light sandy loam, and covered to the depth of about an inch. Germination usually takes place within a few weeks. When a foot high, the plants may be set out in the open ground, where they require very little attention. They succeed remarkably well on the shallow sandy soils of southeast Florida, but in their native home are found upon clay or clay-loam. Their behavior in California indicates that they are reasonably drought-resistant. Because of their attractive appearance and close, compact growth they are often used in Brazil for hedges, for which purpose they are excellent.

F. W. POPENOE.
broad, attractive shrub, with long flexuous or half-climbing branches; lfts. 5-10 pairs and an odd terminal one, small, oblanceolate and obtuse or somewhat emarginate; racemes axillary and mostly exceeding the foliage, bearing rather large deep red fls.: pod 1-2 in. long, much inflated, stipitate. Austral. B.M. 792. H.F. II. 4:276. J.F. 3:394. J.H. III. 49:547. —An old-time garden plant, blooming freely in a cool or intermediate house along with carnations and roses. It thrives well either as a pot-plant or in beds. It is hardy at San Francisco. It is a nearly continuous bloomer. Cuttings taken in winter bloom in summer; these plants may then be transferred to the house for winter bloom, although maiden plants are to be preferred. By cutting back old plants, new bloom may be secured. Cuttings grow readily. The plant is easy to manage. The original form of swainsonia is little known in cult., but the advent of the white form has brought the species to the fore.

Var. albiflora, Lindl. (var. alba, Hort. S. albißora, Don.) Fls. pure white. B.R. 994. L.B.C. 17:1642. A.F. 8:117; 10:611; 11:1130. Eng. 5:135. —N. America. This is one of the most popular of florists' white fls. for use in winter decorations. It has been called the "winter sweet pea" because of the shape of the fls., but it has no fragrance. The delicate bright green foliage affords an excellent contrast with the pure white fls. This variety is often grown at the end of a rose- or carnation-house, or trained on a trellis. It likes abundant sunlight, rich soil, and liquid manure. When allowed too much root-room, the plants become dwarf. It is hardy at San Francisco. The former should be used. B.M. 1725.

SWEET CICELY, or SWEET-SCENTED CHERVIL (Myrrhis odorata, Scop., which see), indigenous to Europe on the banks of streams, is a graceful hardy perennial 3 feet tall, with very large downy grayish green, much-divided leaves, hair stems and leafstalks, small, fragrant white flowers, and large brown seeds of transient vitality. The leaves, which have an aromatic, anise-like, sweetish flavor and odor, characteristic of the whole plant, are still occasionally employed in flavoring soups and salads, though their use as a culinary adjunct, even in Europe, is steadily declining. In American cookery, the plant is almost confined to the unassimilated distinctly foreign population. Those lvs. 3-5 in. long, divided by division, best results are obtained from seed sown in the autumn either spontaneously or artificially; the seedlings, which appear in the following spring, are set 2 feet apart each way in
almost any ordinary garden soil. Spring-sown seed frequently fails to germinate. When once established common care will be sufficient.

M. G. KAINS.

SWEET HERBS. The term “sweet herbs” has long been applied to the fragrant and aromatic plants used in cookery to add zest to various culinary preparations, principal among which are dressings, soups, stews, and salads. At the commencement of the nineteenth century many were to be found in gardens and kitchens that now have been dropped entirely or have but very limited use. Perhaps no group of garden plants during this time has been marked by so little improvement. Except in parsley, very few distinctly new or valuable varieties have been produced or disseminated. This is mainly due to the prevailing ignorance of their good qualities, to which ignorance may be charged the improper handling, not only by the grower, but by the seller and often by the final purchaser. With the public duly awakened to the uses of herbs, improvements in growing, handling, and in the plants themselves will naturally follow, to the pleasure and profit of all.

In this country the herbs best known and appreciated are parsley, sage, thyme, savory, marjoram, spearmint, dill, fennel, tarragon, balm, and basil, arranged approximately in their order of importance. Since parsley is more extensively used as a garnish than any other garden plant, it is grown upon a larger scale than all other herbs combined. Hence some seedsmen do not rank parsley with sweet herbs. Sage is the universal flavoring for sausage and the seasoning par excellence for rich meats such as pork, goose, and duck. It is more widely cultivated than thyme, savory, and marjoram, which have more delicate flavors and are more popular for seasoning mild meats, such as turkey, chicken, and veal. With the exception of spearmint, without which spring lamb is deemed insipid and the famous mint julep a thing of little worth, the remaining herbs mentioned above are scarcely seen outside the large city markets, and even there they have only a very limited sale, being restricted mainly to the foreign population and to such restaurants and hotels as have an epicurean patronage. In many market-gardens especially near to the large cities, sweet herbs form no small source of profit, since most of them, when properly picked, can be shipped in the green state even a considerable distance, and when the market is over-supplied they can be dried by the grower and sold during the winter. Probably more than one-half the quantities used throughout the country are disposed of in the latter manner.

As a rule, the herbs are grown as annuals and are propagated from seed sown in early spring, though cuttage, layerage, and division of the perennials are in favor for home practice and to a certain extent also in the market-garden. Commercially they are most commonly grown as secondary crops to follow early cabbage, peas, beets, and the like. In the home-garden they are frequently confined to a corner easily accessible to the kitchen, where they remain from year to year. In general, herbs should be planted on good light garden soil of fine texture, kept clean by frequent cultivation, gathered on a dry day after the dew is off, dried in a current of warm, not hot air, rubbed fine and stored in air-tight vessels.

For specific information, see articles on the following: Anise, Angelica, Balm, Basil, Caraway, Coriander, Dill, Fennel, Hyssop, Mint (Marjoram), Parsley, Sage, Savory, Tarragon, also book on “Culinary Herbs,” M. G. Kains.

M. G. KAINS.

SWEET MARJORAM: Origanum.

SWEET PEA. The popular name of Lathyrus odoratus, one of the Leguminosae, grown for its handsome and fragrant flowers. See Lathyrus for botanical account of structure of the flower, see Legume; see also Orobus.

Because of its range of color, beauty of form, fragrance, and value as cut-flowers, the sweet pea is not only the queen of the large genus to which it belongs, but now ranks first among annual flowers. It has been long cultivated in gardens, and in recent years in America it has risen to a place among the five leading commercial cut-flowers.

The sweet pea is a native of the island of Sicily and was first described by Father Francisius Cupani, a devout Italian monk and an enthusiastic botanist, in a small work published at Panormi in 1695. Cupani sent seeds in 1699 to Dr. Uvedale at Enfield, England, and to Caspar Commelin at Amsterdam, Holland. The latter published a figure and description of the plant in his “Horti-Medici Anglomediterranei” (1967-1701). From this description it is learned that the flowers had purple standards and sky-blue wings, were fragrant, and that the plants were climbing in habit, as they grew to a height of 6 or 7 feet. A white-flowered variety of the sweet pea appears to have been known in 1718, and in 1737 Burmann called attention to the pink-and-white-flowered form. Although he admitted that his plant differed only in the color of the flowers from that described by Cupani, and which, he says, occurred frequently in gardens, Burmann proceeded to make a new species, Lathyrus zeilanophalus, because he received the seeds among a collection of plants from Ceylon. Later botanists have not found the sweet pea growing wild in Ceylon, from which the authorities conclude that a mistake was made. This form was named Painted Lady and was grown until about 1900, when it gave way to its improved form, Blanche Ferry.

Sweet pea seeds were offered for sale as early as 1724. The three colors mentioned above to have been the only cultivated varieties until 1793, when the black and scarlet varieties were catalogued. In 1837 the first striped variety, in 1850 a yellow-flowered and also the Blue Edged varieties, were offered. The latter was white with a distinct blue edge. Later this form was known as Butterfly, and it was the forerunner of the Picotee section. In 1855 Invincible Scarlet won the first certificate awarded a new sweet pea. Crown Princess of Prussia, the first of light pink varieties, was offered in Germany in 1858. Adonis (1882) was the first double rose-pink varieties. Until 1880 (a period of 135 years) little improvement had been made in the sweet pea, and it had not been given the attention that had been bestowed upon the dahlia, verbena, hollyhock, or the rose. There were nine distinct varieties in 1880, and although many new names appeared during the next twenty years, these mainly represented supposed improved strains of the existing colors. It is very probable that not more than fifteen distinct varieties could be found with sufficient merit to continue. In 1897 Eckford, the great specialist, began his remarkable work.

No one can understand the improvement in sweet peas within the last forty years unless one considers the form of the flowers as well as the limited number of colors which then existed. The oldest illustrations of the sweet pea show the wings to be more prominent than the standard, and although there appears to have been some improvement in the size of the standard flower, the 18th and 19th century flowers were not remarkable in any respects. The standards of most of the varieties had a tendency to reflex at the edges, and the apical notch was very prominent. Often there were side notches which caused the standard to droop forward. The natural line of improvement, aside from securing better colors or color combinations, was to round out the outline of the standard and to give it a more expanded form and greater substance.
CIX. Sweet peas of the Spencer or Waved type.
Eckford, after long experience and signal success as a breeder of florists' flowers, began his work on the sweet pea about 1876. Beginning with a few varieties, he patiently crossed and selected for several years before he began to secure results. His first notable variety, Bronze Prince, was awarded a first-class certificate by the Royal Horticultural Society in 1882. Soon he began to secure new colors and sent out the deep bronze-blue Indigo King (1885), Orange Prince (1886) and the dark maroon Boreatton (1887). Then arose a tendency year by year for new colors and improved forms of the flowers. The hooded varieties appeared and gave a new interest to sweet pea improvement. Although many of the hooded varieties that were introduced had flowers in which the standards were hooded so much as to appear triangular in outline, nevertheless many very were very beautiful. The perfection of this form was reached in the variety Dorothy Eckford (1903). The increased size of many of Eckford's varieties led to the name Grandiflora sweet pea, but this name is now used to designate all varieties which do not have flowers of the waved or "Spencer" form.

At the time of the great biennial conference on the sweet pea held in London in 1900, Eckford had introduced 115 out of the 264 varieties catalogued up to that time. Even in America the Eckford varieties constituted at least 60 per cent of all lists of selected varieties; and in 1916 the Grandiflora varieties remaining in the trade, as shown by the catalogue of the leading American dealer, more than one-half originated in Eckford's garden at Wem, in Shropshire.

Improvement in America.

The real interest in sweet peas in America began soon after the first introduction of the Eckford varieties by Breck and by Henderson in 1886. Added impetus was given by the introduction of Blanche Perry in 1889, and by Emily Henderson in 1893. As early as 1890 the sweet pea had become a popular flower in this country, and soon local sweet pea shows were held. The demand for seed greatly increased and the competition in the shows was keen enough to bring about a desire for new and better varieties. The groundwork was laid for increasing size and a greater average number of flowers to a spike. This was the introduction of the waved form, and that along with it would come increased size and a greater average number of flowers to a spike. This was the introduction of the waved or, as it is called in America, the Spencer type, in 1904. The first variety was raised by Silas Cole who named it Countess Spencer in honor of the wife of his employer. The parentage of this variety, although to be doubted by some, has been given as (Lovely x Triumph, 1888) x Prima Donna, 1899.

"Development of the waved varieties. (Fig. 3745.)"

At the time of the bicentenary conference on the sweet pea, it seemed as if the future improvement of the sweet pea would be along the line of an increase in the number of flowers to a spike or the securing of new colors or color combinations in the existing open and hooded forms of the flower. No one seemed to believe that the sweet pea was on the eve of the most remarkable improvement in the form of flower and that along with it would come increased size and a greater average number of flowers to a spike. This was the introduction of the waved or, as it is called in America, the Spencer type, in 1904. The first variety was raised by Silas Cole who named it Countess Spencer in honor of the wife of his employer. The parentage of this variety, although to be doubted by some, has been given as (Lovely x Triumph, 1888) x Prima Donna, 1899. It was shown at various English shows for three years prior to its introduction. Countess Spencer was such an improvement in size, and the form so distinctly new, that it created a sensation. The very large standard and wings were beautifully frilled and waved. The clear pink color was also especially pleasing. This variety was not entirely fixed when it was sent out and soon numerous sports were offered. Among the first of these were the orange-pink Helen Lewis and the dark maroon Boreatton. The difficulty was experienced when the seed of new waved varieties was grown in California, but from this tendency to sport have been secured many of the finest varieties.

About the time that the Countess Spencer appeared, W. J. Unwin found a sport in the variety Prima Donna which he named Gladys Unwin. It was also of the waved type of about the same shade of pink as Countess Spencer, but the flowers were not so large. Soon other
varieties appeared, and for a few years this group vied with the Spencer varieties for popular favor.

The introduction of the waved form aroused great interest and soon large numbers were growing sweet peas for exhibition. Many took up the production of new varieties, and soon new forms were offered in large numbers. In some cases the same sport had been found and given different names. It was seen that hopeless confusion would result if some means were not found to eliminate the synonyms. The English Sweet Pea Society established trial grounds, and when the American Sweet Pea Society was organized in 1909 it established trial grounds in cooperation with the Department of Floriculture of the New York State College of Agriculture at Cornell University, Ithaca, New York. These two national societies hold annual exhibitions, and the American Sweet Pea Society holds exhibitions of winter-flowering varieties at the National Flower Shows held each spring.

Classification.

More than 1,000 varieties of sweet peas have been introduced, but some of these represent strains of existing varieties or were applied to seedlings which did not present any improvement.

3746. Forms of sweet pea flowers: 1, hooded; 2, waved; 3, open. (X 1)

The modern sweet pea may be classified as follows: Climbing and dwarf types, the former being subdivided into garden and winter-flowering types. The varieties may be classified as to the form of the flower into open, hooded and waved forms (Fig. 3746).

Garden type

Winter-flowering type

Open form

Hooded form

Waved form

Dwarf type (Climbing)

Open form

Hooded form

Waved form

The open form may be further separated into notched and rounded standards; the hooded varieties according to the degree of hooding, the most extreme case being the snapdragon varieties; and the waved varieties may be classified according to the degree of waviness as it appeared to be less or greater than Countess Spencer. This latter classification would require that the flowers be taken from plants under uniform conditions of growth. The National Sweet Pea Society of England classifies sweet peas according to form of the flower into grandiflora or waved, and into thirty-seven color sections as follows: Bicolor; Bicolor (Dark); Light Blue; Dark Blue; Blush-Pink; Lilac-Blush; Carmine; Cerise (Pale); Cerise (Dark); Cream, Buff, and Ivory; Cream-Pink (Pale); Cream-Pink (Deep); Crimson; Fancy; Lavender; Lavender (Pale); Lilac; Magenta; Marbled and Watered; Maroon; Maroon-Red; Mauve (Pale); Mauve (Dark); Orange-Pink; Orange-Scarlet; Pootee-edged (Cream Ground); Pootee-edged (White Ground); Pink (Pale); Pink (Deep); Rose; Salmon; Salmon (Pink); Scarlet; Striped and Flaked (Purple and Blue); Striped and Flaked (Chocolate on Gray Ground); Striped and Flaked (Red and Rose); White.

The bright summer sun of America tends to destroy some of these fine distinctions of color, and the varieties can be grouped in about twenty-five color sections.

Garden culture.

One of the first essentials in sweet pea culture is the choice of an open sunny location, thus providing plenty of light and air. Plants grown in too much shade are weak and spindling in growth, producing few flowers. Any ordinary garden soil is suitable for sweet peas, provided it is sufficiently drained so that in periods of excessive rains the water will not lie on the surface, causing the plants to become yellow and the roots to decay. A heavy soil usually gives better results than a light one as it holds moisture better.

A preparation of the soil as is usually made for the growing of vegetables will give fairly good results; but extra care in the selection and preparation of the soil will be required for larger flowers, longer stems, better colors, and a longer blooming-period.

The sweet pea is a deep-rooting plant, and in order to provide suitable conditions so that the effects of drought are overcome, the preparation must be deep and thorough. Deep preparation not only gives better results than a light one as it holds moisture better, but also increases the area in which moisture and nourishment may be found, and the plant responds by sending feeding-roots in all directions.

The preparation of the soil should be made in autumn by trenching at least 2 feet in depth. Since this is an expensive operation, it is advisable instead to dig a trench 16 inches wide and 2 feet deep for each row of peas. If the subsoil is poor or of unsuitable character, it should be removed and replaced with good soil. If the subsoil is very heavy, coarse stable-manure should be mixed with it. A good dusting of air-slaked lime, applied while working the soil in the autumn, is very beneficial. Many soils that have been cultivated for a long time are acid, so that leguminous plants, such as clover or sweet peas, will not grow, or at least do not thrive. Lime corrects this acid condition and, furthermore, it releases plant-food that would not otherwise be available in soils which are not acid. Clay soils are made more open and porous by the use of lime. Half-decayed stable-manure should be mixed with the top soil. Bone-meal applied at the rate of one-quarter to one-half pound to a lineal yard of trench will prove beneficial. The trenches should be filled more than level full, and left rough. During the winter the soil settles, but if in spring the ridges can yet be seen, it will be found that these dry rapidly and thus favor early planting.

Sweet peas for the garden are either sown where the plants are to be grown or are sown in pots and transplanted. Sowing in the open ground may be done either in autumn or spring. South of the latitude of New York, sweet peas may be successfully grown from fall sowings. North of this line the practice is not always successful unless they are planted in a well-drained situation in a sandy loam. The general conditions requisite to success are to plant late so that the seed does not germinate and appear above the surface. If any top growth is made, the plants will be killed in sections where the ground freezes. The rows should be slightly ridged up to prevent water standing over the row. After the ground freezes, a mulch of manure is
SWEET PEA

applied. Fall-sown sweet peas bloom ten days to two weeks earlier than the spring-sown, and usually produce better flowers.

Sweet peas planted in the spring should be sown early. As soon as the soil is dry enough, the rows should be sown over the trellises prepared in the fall. If the ridges remain, they will dry earlier than level soil. These may be raked level and a drill opened so that the seed may be sown 2 to 4 inches apart. After the plants have started, but before they begin to stool, the plants should be thinned so that the plants stand 3 to 4 inches apart. As soon as the tendrils appear, small twigs should be thrust in the ground to support the plants and prevent their injury by the wind.
