EFFECT OF DESICCATION ON CALLUS CULTURES IN COTTON

THESIS

Submitted to
Dr.Panjabrao Deshmukh Krishi Vidyapeeth, Akola
in partial fulfilment of the requirements
for the Degree of

MASTER OF SCIENCE
IN
AGRICULTURE
(AGRICULTURAL BIOTECHNOLOGY)

By

ZAMBRE SUPRIYA MANOHAR

BIOTECHNOLOGY CENTRE,
DEPARTMENT OF AGRICULTURAL BOTANY

Enrolment Number - BB/660

2009

DECLARATION OF THE STUDENT

I hereby declare that the experimental work and its interpretation of the Thesis entitled **"EFFECT OF DESICCATION ON CALLUS CULTURES IN COTTON"** or part their of has neither been submitted for any other degree or diploma of any University, nor the data have been derived from any thesis / publication of any University or scientific organization. The sources of material used and all assistance received during the course of investigation have been duly acknowledged.

Place: Akola
Date: 12/06/2009

Ku. Supriya Manohar Zambre
Enrolment No. BB/660

CERTIFICATE

This is certify that thesis entitled **"EFFECT OF DESICCATION ON CALLUS CULTURES IN COTTON"** submitted in partial fulfillment of the requirement for the degree of "Master of Science in Agricultural Biotechnology" of the Dr. Panjabrao Deshmukh Krishi Vidyapeeth, Akola is a record of bonafide research work carried out by **Ku. Zambre Supriya Manohar** under my guidance and supervision.

The subject of the thesis has been approved by the Students Advisory Committee.

Place: Akola
Date : 12 / 06/ 2009

(Dr. E.R. Vaidya)
Chairman,
Advisory Committee

Countersigned

Associate Dean,
Post Graduate Institute, Akola
Dr. Panjabrao Deshmukh Krishi Vidyapeeth, Akola.

THESIS APPROVED BY THE STUDENT ADVISORY COMMITTEE
INCLUIDING EXTERNAL MEMBER (AFTER VIVA-VOCE)

1. Chairman	Dr. E. R. Vaidya	
2. Member	Dr. A. A. Akhare	
3. Member	Dr. B.R. Patil	
4. Member	Dr. M.S. Dudhare	
5. Member	Shri. A.G. Deshmukh	
6. External Member	(Dr. M.P. Mohanil)	

ACKNOWLEDGEMENT

Success is not possible lonely without involvement of many minds and hands to beauty it. Emotions cannot be adequately expressed in words because then emotions are transformed into mere formalities. Nevertheless, Formalities have to be competed. My acknowledgement is many more than what I am expressing here.

I am immensely indebted to my honorable chairman, Dr. E.R. Vaidya, Associate Professor and Head of Section Agril. Botany, Dr. Panjabrao Deshmukh Krishi Vidyapeeth, Akola for his intellectual inspiration, valuable guidance, useful suggestions, constructive kind courtesy, and interest taken during the entire course of investigation. His constant and helpful suggestions were always a source of inspiration.

I have an immense pleasure in expressing my deepest sense of gratitude and humble indebtness towards Mr. A.G. Deshmukh, Assistant Professor and Dr. M.P. Mohril, Assistant Professor, Dr. A. A. Akhare Assistant Professor of Biotechnology Center, Dr. Panjabrao Deshmukh Krishi Vidyapeeth, Akola for their valuable guidance encouragement, important suggestion, kind help from time to time and sustained interest right from suggestion of problem to completion of thesis. I shall be ever grateful to them, because of their insightful guidance I could complete my research work.

I am duly acknowledged to Dr. B.R. Patil, Senior Research Scientist, Cotton Research Unit, Dr. PDKV, Akola as an advisory member and for timely supply of seed material.

It is my great pleasure to convey thanks to Dr. D.L. Sale, Associate Dean, Post Graduate Institute, Dr. PDKV, Akola and Dr. K.B. Wanjari, Head, Department of Agricultural Botany, Akola also I convey thanks to Dr. S.J. Gahurkar, In charge, Biotechnology Centre for extending necessary facilities to carry out the research work and constructive criticism during entire period of investigation without which this work could not have been possible.

I avail of this golden opportunity to express of my cordial thanks to Dr. D.B. Dhumale, Professor, Dr. P.L. Kulwal, Assistant Professor of

Biotechnology Center, Department of Agricultural Botany, Dr. PDKV, Akola for constructive criticisms.

I am extremely grateful to Mr. S. Munje, Assistant Professor, Biotechnology Centre and all staff members of Department of Agricultural Botany, Akola specially to Miss Abhilasha Kharkar (SRF) and Thawri sir for providing guidance and encouragement during research work.

I am thankful to Mr. Jirapure and Mr. Prashant of Tissue Culture Laboratory, Biotechnology Centre, Dr. PDKV, Akola.

Indeed the words are inadequate to express my indebtedness, gratitude reverence and love to my father Shri. Manohar A. Zambre and mother Sau. Meena M. Zambre. I find no such measures adequate to quantify all that my parents have done for me. I am also thankful to my brother Shyam and sister Prajakta and Uncle Associate Prof. Rajesh Ghorpade, Associate Prof. Archana Thorat and all family members for their hard jobs of educating me and shadowing me by showing their backs towards Sun, without which this work would not have seen the light of the day at all.

I am very much thankful to my friends Darshana, Madhuri, Dipika, Shilpa, Sonali, Shraddha, Sandesh,Valmik, Ganesh, Amol,Tushar, Jagdish, Ravi and all lab members .

No less in my gratitude to my Madam Mrs. Ganga Vaidya and her son Kapil whose support helped to overcome many difficulties during my studies.

I am also thankful to my junior colleagues Mr. Navid and Miss Priyanka for helping me in my research work.

My sincere thanks to all those well wishers and who have endured their cooperation directly or indirectly in completing this research works.

(E) GLOSSARY

Agar : A polysaccharide derived from certain algae and commonly used as a gelling agent in tissue culture media.

Aseptic culture : Raising cultures from a tissue or an organ after freeing it of bacteria, fungi and other microorganisms in an environment free of these microorganisms.

Autoclave : A vessel for sterilizing with steam under pressure.

Auxins : A class of plant growth hormones which cause cell elongation, apical dominance, root initiation etc. Indole acetic acid (IAA), naphthalene acetic acid (NAA), Indolebutyric acid (IBA) and 2,4-dichlorophenoxyacetic acid (2,4-D) are some of the auxins commonly used in tissue culture.

Biotechnology: Application of techniques to modify the fundamental processes of growth and reproduction in plants, animals and microorganisms, to enhance productivity or produce new products.

Callus : A tissue arising from disorganized proliferation of cells either in cultures or in nature.

Cell culture : Culture of single cells or small groups of similar cells.

Contaminants : Inthe present context, refers to microorganisms, which may inhibit the growth of cells or tissues in culture.

Culture : Growing cells, tissues, plant organs or whole plants in nutrient medium under aseptic condition e.g. cell culture, embryo culture, shoot tip culture, anther culture, etc.

Cytokinins : A class of plant growth hormones which are adenine (e.g. kinetin, benzilaminopurine, 2-isopentenyladenine, zeatin) or urea (e.g. thidiazuron) derivates and cause cell division, cell differentiation, shoot differentiation, breaking apical dominance, etc.

Embryo : An organized structure formed following a predetermined mode of development inside the female gametophyte with or without fertilization.

Embryogenesis : The process of embryo initiation and development either in the seed or in tissue cultures.

Explant : A plant organ or piece of tissue used to initiate culture.

Genotype : The genetic make up of an individual as determined by the set of genes carried in the chromosomes.

Growth regulators : Organic compounds other than nutrient that, in small amounts, influence growth, differentiation and multiplication, such as auxins, cytokinins, ethylene and gibberellin.

Hormones : Natural or synthetic chemicals that strongly affect growth, development or metabolism at very low concentrations i.e. cytokinins, auxins and gibberellins.

Hybrid : An organism resulting from a cross between genetically unlike parents.

Hypocotyl : The portion of seedling stem below the cotyledons and above the roots.

***In vitro* :** Literally `in glass'; now applied to any process carried out in sterile culture.

***In vivo* :** Literally `in life'; applied to any process occurring in a whole organism.

Induction: To cause initiation of a process or a structure.

Micropropagation : Asexual or vegetative propagation of plants *in vitro*.

Node : A region on the stem from where a leaf bearing and axillary bud arises.

Nutrient medium : A combination of nutrients and water, usually including several salts, a carbohydrate (e.g. sucrose) and vitamins, such a medium, liquid or gelled, is often referred to as a basal medium and may be supplemented with growth hormones and occasionally, with other defined and undefined substances.

Organogenesis: Differentiation of organs from cultured cells or tissue.

pH : A measurement of the degree of acidity or alkalinity on a scale of 1-14.

Photoperiod : The length of time plants are exposed to light in an alternating light dark interval sequence.

Polysaccharide: A group of carbohydrates composed of many units of various sugars.

Proliferation : Rapid multiplication of new units (cells, embryos, shoots etc.).

Regeneration: In tissue culture, a morphogenetic response that results in the production of new organs, embryos or whole plants from cultural explants or calli derived from them.

Somatic embryogenesis : In plant tissue culture, the process of embryo initiation and development from vegetative or non-gametic cells.

Stock solutions : Concentrated solutions from which portions are used to make media.

Subculture : With respect to plant tissue culture, this is the process by which the tissue or explant is first subdivided, then transferred into fresh culture medium.

Suspension culture : A type of culture in which cells or cell aggregates are cultured in liquid medium.

Transformation : A laboratory technique for genetic modification of plants by introducing one or few selected genes into cells to change their inherited characteristics.

Abstract

Cotton is one of the world's economically important fibre crops, and is extensively cultivated as an agro-industrial cash crop. Sometimes there is a

CHAPTER I
INTRODUCTION

1.1 Background information

Cotton "King of fibre", "White Gold" being the most important commercial crop, plays a key role in socio- economic affairs of the world. It finds its mention in the "Rigveda" the oldest scripture of the Hindus. Its antiquity has been traced to the 4th millennium B.C. Despite the increasing competition from artificial fibres the cotton fibre has maintained its pristine purity and importance to this day retaining its reputation.

Cotton is extensively cultivated as agro-industrial cash crop and also most important fibre crop amongst the fibre crops of the world. Cotton is predominantly self pollinated crop and often cross pollinated crop (Simpson, 1954). Cotton belongs to genus *Gossypium* which is one among eight genera under the tribe *Gossypieae* of family Malvaceae. This Dicotyledonous genus comprises approximately 50 species of which 45 are dipliod and five are allotetraploid (Fryxell 1992).The true lint bearing species of cotton are four, out of which two viz., *G. arboreum* and *G. herbaceum* are diploid (2n=26); commonly known as old World cotton or Deshi cotton in India, which are indigenous to Africa and Asia, and other two viz., *G. hirsutum* and *G. barbadense* L. are tetraploid (2n=52); commonly known as new World cotton or American cotton were initialy introduced in India during 17th and 18th A.D.

Cotton is big business with World production estimated at around 20 million tons. Cotton is playing a vital role in the economic, political and social affairs of the World. Chiefly a fiber crop, it has been estimated to contribute US $ 15-20 billion to the world's agriculture economy with over 180 million people depending on it for their livelihood (Benedict and Altman, 2001). Cotton is cultivated in about 70 countries of the World. The majority is produced by China, America, the Central Asian Republics, India, Pakistan, Brazil and Egypt. It provides 65 per cent raw

material to textile industry and contributed 1/3rd of total foreign exchange earning of India (Anonymous, 2006). India has a unique distinction of growing all the four spinnable lint bearing species of *Gossypium* and is one of the major producer of cotton sharing 20 per cent of world area of 93.73 lakh with production of 290 lakh bales and productivity of 562 kg lint/ha. In Maharashtra state, cotton is grown on an area of 31.33 lakh ha with production of 62 lakh bales and productivity of 336 kg/ha (CAB, 2008-09).

Vidarbha is the largest cotton growing region in Maharashtra state. It covers about 55 per cent area of Maharashtra state, which is 13.11 lakh ha with production 27 lakh bales with productivity of 350 kg lint/ha. The productivity of Maharashtra is 336 kg lint/ha (2007-08), which is lower than average productivity of India i.e. 526 kg lint/ha. (Anonymous, 2009)

Cotton has other more surprising uses from medicines and mattresses to seed oil and event sewage skins. This semi drying edible oil is used for salad or cooking oil and a non-oil residue is manufactured into a cotton cake for animal feed, fertilizer and paper. Cotton is grown chiefly for its fibre use. The production, consumption and trade of cotton based production further stimute the economy.

Regeneration of plants through tissue culture is an essential step in application of plant biotechnology for crop improvement. Cotton biotechnology hinges on two tightly interlaced processes transformation and regeneration. *Agrobacterium* mediated transformation and regeneration of cotton via somatic embryogenesis remains the preferred method of choice for generating transgenic cotton, as its advantages significantly outweigh the disadvantage relative to other methods (Wilkins *et al.*, 2000).

Plant regeneration has been achieved through organogenesis, somatic embryogenesis in *G. Klastchianum* but it failed to obtain complete plant. Plant regeneration in cotton through somatic

embryogenesis was reported by Davidonis and Hamilton (1983) in two years old calli derived from cotyledons. Since, then number of workers reported somatic embryogenesis and regeneration in cotton. However, most of successful regeneration reports were limited to Coker cultivar 201, 210, 312 and 350. *Agrobacterium* mediated method requires 10-12 months or longer to regenerate transgenic cotton plants (Firozabady *et al.*, 1987; Umberk *et al.*, 1987; Trolinder and Goodin, 1988a and 1988b; Lyon *et al.*, 1993; Thomas *et al.*, 1995), however somaclonal variation becomes problematic with such long culturing times (Stelly *et al.*, 1989; Firozabdy and DeBoer, 1993; Rajsekaran, 1996). Kumar and Pental (1998) reported regeneration of Indian cotton variety MCU-5 through somatic embryogenesis. Most of the reports indicated that regeneration response in cotton is highly cultivar dependent and Coker cultivar are highly responsive for regeneration but within the Coker cultivar there is seed to seed variation for regeneration (Gawel and Robacker, 1990; Trolinder and Xhixhian, 1989). Mathusamy and Jayabalan (2000) reported direct shoot on culture after 30 days on LRA-5166 genotype of *Gossypium hirsutum* by using leaf explant. Desiccation treatment was evaluated by Sakhanokho *et al.* (2004b) to improve the conversion efficiency of somatic embryo in diploid *Gossypium arboreum*.

Suprasanna *et al.* (2008) studied the partial desiccation for 6 h resulted in enhanced plant regeneration response from irradiated embryogenic cultures of sugarcane.

1.2 Importance of study

For transfer of desirable traits, such as fibre quality, resistance to insect, drought and diseases (Hutchinson *et.al.* 1947) the use of *in–vitro* regeneration protocol and desiccation treatment for improving the somatic embryogenesis would be more useful for the transformation technology.

Since onset of blooming in regenerated plants varies considerably seed production to produce genetically stable transgenic lines requires an additional 6-8 months, meaning that each transgenic plant may take two years or more to develop. In addition, cotton regeneration via somatic embryogenesis is highly genotype specific and highly generable lines selected from the absolute cultivar Coker 312 (Trolinder and Xhixian; 1989) serves as the industry stander at this time. Although linkage drags during introgression of transgene into elite cultivars continuous to be an issue of concern (Wilkins *et.al.* 2000).

1.3 Objectives of study

Keeping these considerations in view, the present investigation was conducted on "Effect of desiccation on callus cultures in cotton" with the following objectives,

i] To study the effect of desiccation on callus cultures, and

ii] To study the effect of desiccation on somatic embryogenesis in cotton.

The present study will be useful for developing regeneration protocol in popular cotton cultivar PKV-Rajat developed at Cotton Research unit, Dr. PDKV, Akola which is a prerequisite for transformation.

1.4 Scope and limitations of study

Callus culture study is helpful for *In-vitro* regeneration and which is basic need of genetic transformation in plants. Limited reports are available on regeneration in cotton. Despite of high commercial interest the success of biotechnological application in cotton has been limited due to genetic transformation. Major problem have been genotype dependence and low frequency of somatic embryogenesis making it difficult to regenerate plants from transgenic tissue. Therefore present study will be useful to standardize efficient regeneration protocol for transferring desirable genes.

The present study is limited to develop early stage somatic embryos in cotton, and it is needed to extend for complete regeneration of plants.

1.5 Hypothesis

The present study under taken to know the effect of desiccation on callus cultures and somatic embryogenesis in cotton cultivar PKV-Rajat developed by Cotton Research Unit, Dr. PDKV, Akola.

CHAPTER II

REVIEW OF LITERATURE

Cotton is one of the world's most economically important crop. *In vitro* cell culture techniques can provide plant breeders with new sources of genetic variation. Haploid plant production, protoplast fusion, gene transfer and exploitation of somaclonal variation techniques offer potential for crop improvement. Effective utilization of these produces ultimately hinges upon the development of efficient plant regeneration strategies.

Induction of somatic embryogenesis has been a significant achievement in plant tissue culture. Its application for mass production of plant genetic transformation and synthetic seed formation has been highlighted by Bajaj (1995). Somatic embryogenesis and plant regeneration are fundamental to the genetic improvement of cotton and desiccation treatment can also be incorporated into regeneration protocol to improved regeneration efficiency of *Gossypium* species (Sakhanokho *et al.* 2004b).

Plant tissue culture is defined as the process in which plant cell, tissue, organ or any plant part there of is grown aseptically in artificial environment (Scowcroft, 1984).

Desiccation is defined as the process of extracting moisture. Subjecting the cultured tissue to period of stress such as desiccation appears to improve the conversion of somatic embryos into mature embryos and subsequently to plants (Parrott *et al.* 1988., Yehosua *et at.* 1992).

Present review pertaining to effect of desiccation on callus cultures in cotton is presented in three parts,

2.1 General review of *in vitro* techniques

2.2 Callus induction and regeneration response in cotton.

2.3 Effect of desiccation an callus cultures and regeneration

2.3.1 Effect of desiccation on callus culture and regeneration in different plant species.

2.3.2 Effect of desiccation on callus culture and regeneration in cotton

2.1 General review on *in vitro* techniques

German botanist Gottlieb Haberlandt (1902) developed the concept of *in vitro* cell culture. He was first attempt to culture isolated, fully differentiated cells *in-vitro* on artificial media from leaves of *Lambium purpureum*. Although he failed in his goal to induce cell division, his work paved the way for development of plant tissue culture.

Winkler (1908) cultivated segment of string bean and observed some cell division but no proliferation. Kotte (1922) postulated that a true *in-vitro* culture could be made easier by using meristematic cell, such as root tip or bud. Effort to demonstrate totipotency led to development of techniques for cultivation of plant cell under controlled condition. This was made possible by the brilliant contributions form Gautheret (1939), Nobecourt (1939) and White (1939). Since then the technique of tissue culture has become an important tool for studying a wide range of basis and applied problem in biology.

The embryo culture technique was utilized by Laibach (1925) to recover hybrid progeny form an interspecific cross in *Linum species* Van Overbeek (1941) discovered the nutritional value of liquid endosperm of coconut for culture of isolated carrot embryo.

Skoog and Miller (1957) proposed the hypothesis that root-shoot differentiation in cultured Callus is regulated by auxin and cytokine ratio in the cultured medium.

The development of somatic embryo (embryoids) from carrot cells in suspension by Reinert (1959) in Germany and Steward (1958) in U.S.A. and subsequently from leaf mesophyll cells of *Malleaya cardata* by Kohlenbach (1966) were important discoveries of cell culture technology.

Morel and Martin (1952) recovered virus free Dahlia and potato plants from shoot meristem cultures to obtained disease free

The tissue and cell culture techniques provide new method for deriving variability and have a great potential for plant improvement, thus a promising tool for the plant breeders (Heinz *et al.*, 1979).

Regeneration through somatic embryogenesis is preferred over organogenesis because of a probable single cell origin of somatic embryos (Merkle *et al.*1995), thus reducing the chimeric transformation events.

Muthusamy and Jayabalan (2000) reported that the leaf bit explants derived from aseptically grown seven days old seedling of LRA-5166 were planted on MS+0.5mg/l NAA+ 0.1mg/l Kin produced direct shoot after 30 days of culture.

Hazra *et al.* (2002) was achieved plant regeneration from the seed derived decotyledonated split embryo axes of six Indian cotton cultivars viz., CNH-36, DCM-32, DHY-286, LRA-5166, LRK-516 and NHH-44 on MS medium.

Muthusamy *et al.* (2004) was obtained plantlets of *G. hirsutum* cv. MCU 5 and MCU 11 by using meristem shoot tip culture. The best shoot development was observed on media supplemented with 0.1 mg kinetin/ lit. Root development was observed on hormone free media with 0.3% cultivated charcoal.

2.2 Callus induction and regeneration response in cotton.

Callus induction and somatic embryogenesis are fundamental to cotton tissue culture biotechnology. However very few genotypes gave response to regeneration in cotton. In cotton somatic embryogenesis was first observed by Price and Smith (1979) in *G. khostzschianum* although complete plant could not be regenerated.

Royack *et al.* (1979) defined condition for suspension of two cotton G. hirsutum varieties IM 216 and Acal 44 which are resistant and susceptible, respective to the bacterial pathogen *Xanthomonus*

malvacearum (E.F.Sm) Dows A light friable callus were triedto induce root and shoot initiation were unsuccessful.

Davidonis and Hamilton (1983) subsequently described plantlet regeneration from a two-year-old callus culture of *G.hirsutum* var. Coker 310 through somatic embryogenesis. This procedure involved a lengthy culture period and was difficult to repeat.

Shoemaker *et al.* (1986) describe somatic embryogenesis and plant regeneration in *G.hirsutum* cvs. Coker 201 and 315.

Trolinder and Goodin (1987) defined the culture parameters for somatic embryogenesis in Coker varities and suggested the importance of genotype.

Trolinder and Goodin (1988) developed optimal media for induction of somatic embryogenesis from mature and immature tissue of *G. hirsutum* L. Cv. Coker 312. 100% somatic embryos was observed when culture grown on MS + 0.1 mg/l 2, 4-D + 0.5 mg/l KIN medium.

Trolinder and Xhixian (1989) screened 38 Gossypium genotype including *G.barbadense* accession for which they found a reduced level of embryogenesis compared with Coker 312.

Gawel and Robacker (1990) were tested three commercial varieties and three exotic accessions for ability to undergo somatic embryogenesis section of split petiole were cultured on three media and magnitude of embryogenesis was observed.

Firoozabady and DeBoer (1993) reported that a high 2ip: auxin ration is preferred for callus initiation and proliferation, but should be exchanged with a higher NAA: Cytokinin ration before diffentiation will occur.

Kalamani (1994) reported that hypocotyl explants of cv. MDU 9 when cultured on MS medium supplemented with 1 mg/L KIN + 1.5 mg IAA and formed callus in 20 days. The calli on subculturing to media containing BAP (2.0 mg\l) developed shoots. Multiple shoots were formed from each callus mass.

Hirimburegoma and Gamage (1994) cultured leaves, petioles, immature seeds explants of cotton cv. Coker 417 on basic MS medium supplemented with different growth regulators for 24 hours in light and dark. Callus formation was observed only on leaf and immature seed explants cultured in light with combination of 2,4-D and BAP. Callus from primary leaves was more homogeneous.

Rajasekaran (1996) observed successful regeneration of cotton (*G. hirsutum*) plants from cryopreserved embryogenic callus and cell suspension culture. Regenerated plants from cell suspension and embryogenic callus culture cryopreserved for more than four years exhibited normal morphological growth.

Rajasegar *et al.* (1996) observed the high frequency of callus induction and somatic embryogenesis on MS medium containing various concentrations and combinations of different growth regulators. Among the various explants, young leaves were found to be best for maximum frequency of callus induction on MS medium fortified with NAA (2.0mg/l) in combination with 2iP (3.0mg/l). These calli developed embryoids on MS medium containing 2iP and ABA (2.0mg/l) with 10mM glutamine. However plant regeneration frequency was low.

Gonzalez Benito *et al.* (1997) obtained callus from cotyledon and hypocotyl explants of *Gossypium hirsutum* race latifolium cv. CNPA Precoce-2 were cultured on MS media supplemented with 5 concentrations of 2,4-D and (2iP) either alone or in combination. Somatic embryos of different sizes and shapes appeared on MS medium supplemented with 2 g glutamine /l and no growth regulators. Plantlets were regenerated from these embryoids.

Cai-Xiao *et al.* (1997) cultured hypocotyls explants of cotton (*G. hirsutum*) cv. Simian 3, Glandless 2031 and Lumina 9554, on different medium. The medium containing 0.1 mg 2, 4-D, 0.1 mg IAA and 0.1 mg zeatin/l was optimum for initiation of callus from hypocotyls. Induction of embryogenic callus was achieved with 0.5 mg/l IAA and KIN.

Brar *et al.* (1998) established somatic callus tissue from immature embryos, hypocotyls, cotyledons, roots and young leaves of *G. arboretum* cv. LD-327, *G. herbaceum* cv. G. Cot.11, *G. hirsutum* cv. F-846, *G. thurberi* and *G. anomalum*. The best medium for callus initiation in diploid species was MS medium containing 0.1 mg 2,4-D + 0.1 mg KIN/l while in *G. hirsutum* MS medium containing 5.0 mg NAA + 0.1 mg KIN/l gave the best results. Among the different explants immature embryos and hypocotyls segments gave the highest amount of callus tissue, with younger explants giving better quality callus.

Kumar and Pental (1998) reported the protocol for the *in vitro* regeneration of Indian cotton cv. MCU-5 (*G. hirsutum*) Coker 201, 310, 315,312 somatic embryogenesis obtained from hypocotyl explant in 6-7 months. The highest frequency of regeneration has been reported in Coker varieties, however, even within Coker varieties there is seed to seed variation in regeneration.

Carvalho *et al.* (1998) evaluated the commercial cotton (*G. hirsutum*) cultivars CNPA process 2 and Coker 312 for somatic embryogenesis in different culture media. Calluses were induced in both varieties from hypocotyl pieces placed on MS medium supplemented with 0.1 mg 2,4-D + 0.5 mg (2ip) adenine /l.

Zhang *et al.* (1999) reported somatic embryogenesis and plant regeneration in five lines of low phenol content upland cotton (*G. hirsutum*). Grey soft and loose callus was initiated using hypocotyl segments cultured on medium containing MS inorganic and B_5 organic compounds, including kinetin and 2,4-D.

Guo-YuLong *et al.* (1999) cultured hypocotyl sections of the American variety Coker-312 and two other varieties of cotton (*G. hirsutum*) when cultured on 4 MSB based media to compare the intervarietal differences in callus induction and embryogenesis. On MSB medium containing 2, 4-D (0.05 mg/l) + kinetin (0.01 mg/l) or NAA (4.0 mg/l) +

kinetin (1.0 mg/l), callus induction rate was high for all the Coker varieties studied. Regenerated plantlets were obtained for all the Coker varieties.

Zhang *et al.* (2000) reported the regeneration protocol for elite cotton Variety Simian-3. The highest percent of callus induction on medium supplemented with Zeatin (3.0-5.0mg/L). Root was most responsive explant for production of somatic embryos the best medium for callus proliferation of embryogenic callus was MS+1.0mg/L2, 4-D+0.5mg/L Kin+0.5mg/L ZT and for diffentiation and germination of somatic embryos MS+ 0.1mg/L ZT+2gm/L activated charcoal. Plants could be regenerated within 60-80 days.

Sakhanokho *et al.* (2000) reported that callus was initiated from hypocotyl and cotyledon explants on a 1 mg/l KIN + 2 mg/l NAA. Friable embryogenic callus was selected and transferred on to MS with 0.1 mg/l KIN + 0.5 mg/l NAA. The selected callus was then transferred into a liquid embryo initiation medium. The liquid step was decreased by culturing time and increasing number of embryos per gram of cultured callus.

Zhang *et al.* (2001a) reported the direct somatic embryogenesis and plant regeneration in cotton (*G. hirsutum* cv. CCRI-12) on modified MS medium supplemented with 0.1 to 0.5 mg ZT/l, embryogenesis calluses and somatic embryos were directly induced with highest percentage induction (11.42%) at 0.1 mg/l ZT. The regenerated plants were transferred to soil.

Zhang *et al.* (2001b) reported the hypocotyls and cotyledon pieces of Coker-201 and CCRI-12 were placed on MS medium supplemented with 0.1 mg/l IAA + 0.1 mg/l ZT. The optimal medium for direct somatic embryogenesis was modified MS medium supplemented with 0.1 mg/l ZT + 2 g /l activated carbon. The somatic embryos were converted into normal plantlets when cultured on modified MS medium supplemented with 0.1 mg/l ZT. Plants could be regenerated within 60-80 days.

Nobre *et al.* (2001) described the development of a regeneration system from cotton stomata guard cells directly on epidermal strips for Coker-312 and 315. One fully developed plant was obtained from the culture of epidermal strips in both cultivars.

Sucheta Tripathy and Reddy (2002) reported the efficient plant regeneration from callus cultures of Indian cotton cultivars. Out of ten Indian cultivars, only six cultivars namely NCS-3, NA-920, NA-1325, Srisailam, LRA and PMC responded well in the plant regeneration. Only the MS media supplemented with 2 mg/l BA + 2 mg/l IAA was the best for plant regeneration.

Suresh Kumar *et al.* (2002) studied six *G. hirsutum* lines of diverse origin with two explant viz. hypocotyls and cotyledons for induction of callus. On an average over genotypic, explant and media response, highest number of callus induction on media MS+ O.1MG/L +24D+ 0.5mg/l kinetin. None of genotype showed differentiation from callus.

Xue-Meifeng *et al.* (2002) reported the embryogenic calluses of *G. hirsutum* cv. Chuan-239 and examined the changes in colour, growth and embryogenic capability during long-term subculture. Embryogenic capability can be maintained for a long time of subculture on MSB medium containing 0.1 mg Kin/l + 1.9 g KNO_3/lit and on MSB supplemented with 0.1 mg KIN/l + 0.1 mg IAA/l. The duration of embryogenic callus subculture was recommended not to exceed 1.5 years.

Sun YuQiang *et al.* (2003) reported the high frequency somatic embryogenesis and plant regeneration from hypocotyl explant of *G. klotzschianum* Anderss. Embryogenic culture were induced on MSB medium with 0.9 mM 2, 4-D + 2.32 mM KIN. Somatic embryos cultured on MSB medium with PGR to form secondary embryo and embryo developed into normal plantlets on PGR- free MSB medium.

Kumria *et al.* (2003) initiated the embryogenic calluses, from hypocotyl or cotyledonary leaf sections on MS medium containing 0.1 mg/L 2,4-D + 0.5 mg/L KIN + 3% maltose. More than 70% of cotyledonary

embryos developed into normal plantlets when cultured on MS medium containing 0.05-mg/L gibberellic acid.

Suresh Kumar *et al.* (2002) screened twelve cotton genotypes belonging to 4 cultivated cotton species adapted to different agro climatic conditions for *in vitro* regeneration Diploid species gave higher response for *in vitro* dedifferentiation than tetraploids. Hypocotyls explants showed higher response than cotyledons for callus induction.

Mishra *et al.* (2003) suggested a step towards genotype independent regeneration of cotton (*G. hirsutum* L.) by selection for regeneration potential (RG) in commercial seed of elite cultivars. Based on the number of fertile plants regenerated on a percent seedling basis, RG was estimated as 17.4%, 44.4% and 80% in Acala cotton cultivars `Maxxa', `Ultima' and `Riata', respectively.

Aydn *et al.* (2004) developed a highly reproducible system for efficient somatic embryogenesis to regenerate plantlets from cotton (*G. hirsutum* L.) cv. (Nazilli-M-503 and Nazilli-143). Shoot apices, hypocotyls and nodes explants are used. High frequency of embryogenic calli was initiated on MS medium with 1 g/l PVP + 1 mg/l BAP + 0.5 mg/l KIN for Nazilli M-503 and 1 mg/l PVP, 2 mg/l BAP + 0.5 mg/l KIN for Nazilli-143.The germination frequency of somatic embryo (42.9%) for Nazilli-M-503 and (22-30%) for Nazilli-143.

Sakhanokho *et al.* (2004 a, b) tested 15 elite upland cotton lines from southeast germplasm. Eight lines developed by Georgia Agriculture experiment station and seven by the USDA-ARS per Dec cotton breeding programmed. Three Pee Dee Lines, PD 97019, PD 97021 and 97100 and one Georgia line, GA 98033 responded to at least one of the three medium treatments. The regeneration efficiency of the Georgia and Pee Dee lines was relatively low as compared with standard Coker 312 cultivar.

Hussain *et al.* (2004) reported an efficient *in vitro* plant regeneration system to produce somatic embryos using immature zygotic

embryos in cotton (*G. hirsutum* cv. C-312 JS). Rapid callogenesis was observed in these immature zygotic embryos. Upon the development of roots and leaves, plantlets were potted in a mixture (1:1:1) of sand, silt and peat moss under high humidity then hardened under greenhouse condition. Using this system, they were able to regenerate approximately 70% of healthy plantlets.

Kouadia *et al.* (2004) established cultures of two cultivars of cotton ISA-205 N and ISA GL7 cultivated in café `d' Ivoire from hypocotyls fragments. These fragments were excised from etiolated and non-etiolated seedlings (absence or presence of chlorophyll). The non-etiolated hypocotyls of both cultivars showed significantly higher percentage of callus induction than etiolated ones. It was shown that the darkness pre-treatment of cultured explants would be good condition to induce somatic embryogenesis of cotton.

Kumar and Tuli (2004) reported the increase in somatic embryogenesis efficiency and induction of developmental synchrony in embryogenic callus culture of cotton by single cycle of myo-inositol depletion in liquid culture. Friable callus were collected over filler mesh 40 and subjected to one cycle of myo-inositol starvation. This induced a highly synchronized embryogenesis in the culture.

Ikram-Ul-Haq and Zafar (2004) used hypocotyls explants for induction of callus through culturing on MS 1 a medium supplemented with 2,4-D and KIN. The high frequency of globular embryogenesis was achieved when well proliferating callus was cultured on MS (1/2 strength) medium for four weeks. Complete plants were regenerated through somatic embryogenesis from hypocotyls explants within 6 months.

Sakhanokho *et al.* (2005) reported the improvement in somatic embryogenesis in several cotton lines (*G. hirsutum* L.) from Georgia and Pee Dee germplasm with culture media containing various putrescine concentrations. The best results were obtained with NAA as compared to 2; 4-D based culture medium. Inclusion of 0.5 mg/l

putrescine improved somatic embryo induction for most treatments and lines tested.

Efe (2005) cultured 3,9,15 and 21 days old ovules excised from 2 different cotton species (*G. hirsutum* cv. Ersan 92 and *G. barbadense* cv. Agdas-21) on MS medium supplemented with various ingredients. To determine the effects of growth regulators on callus formation, 0.5, 1.5, 2.5, 3.5 mg/l IAA and 0.5, 1.5, 2.5, 3.5 mg KIN/l were added to the media in 16 combinations. Callus formation was 85.2% and 44.1% for *G. hirsutum* and *G. barbadense* respectively.

Ikram-Ul-Haq (2005) reported the callus proliferation was considered best on MS-1a (2.0 mg/l NAA; 0.1 mg/l ZT; 0.1 mg/l KT) when 6 weeks old callus from MS-1b (0.1 mg/l, 2,4-D; 0.5 mg/l KT) medium, there is no need to select embryogenic calluses for somatic embryogenesis, as all of them were converted to somatic embryos. When cotyledonary embryo cultured on MS with 0.05 mg/l GA3 medium were developed into normal plantlets and rooted simultaneously.

Rao *et al.* (2005) reported that wild cotton species can contribute a valuable gene pool for agronomically desirable cultivated tetraploid cultivars. Different callus induction media were tested with varying concentrations of hormones. Different stages of embryogenicity such as early torpedo stage, late torpedo stage; heart stage, globular stage and cotyledonary stage were observed in wild relatives of cotton.

Verma *et al.* (2005) reported the highest callus induction frequency (85.4%) in genotype H-771 on MS 63 medium (MS basal medium containing 0.1 mg/l ZT and 3% maltose) using hypocotyls.

2.3 Effect of desiccation on callus cultures.

2.3.1 Effect of desiccation on callus cultures and regeneration in different crop species.

Partial desiccation treatments have been reported to be beneficial for embryogenesis and plant regeneration in several plant

species. Water deficit, directly through partial desiccation, is also known to stimulate ethylene evolution (Guinn1976) that may influence morphogenetic response *in vitro*. Partial desiccation has been reported to enhance somatic embryo differentiation and development in soybean (Hammatt and Davey 1987), grapevine (Gray 1987), Cassava (Mathews et al 1993), banana (Srinivas et al 2006).

Carman (1986) improved somatic embryogenesis in wheat by partial desiccation.

Saito *et al.* (1991) have reported dehydration of the culture through filter paper improved aeration of the culture, there by probably reducing ethylene level, which might have been helpful.

Tsukahara and Hirosawa (1992) reported that dehydration of suspension culture derived calli of the Japonica variety Susanishiki enhanced the regeneration frequency from 5% up to 47%.

The desiccation treatment showed improvement in the conversion of somatic embryos into healthy plants as compared to plant obtained from the non-desiccated embryogenic calli. Slow desiccation cause stimulation of loss of turgor and substantial accumulation of starch and protein reserve in comparison with no or rapid dehydration (Etienne *et al.* 1993)

Rance *et al.* (1994) obtained 66.5%, 61.1% and 73.7% of calli that regenerated plants for the indica rice varieties TN 1, IR 72, and IR 64 by partial desiccation treatment where as in non desiccated controls only 30.0%, 15.5% and 18.7% of calli regenerated respectively.

Vertucci and Forrant (1995) and Haslekas *et al.* (1998) reported that during desiccation, free radical scavengers may provide additional protection because the development of desiccation tolerances which involves a period of water stress coincides with an increase in free radical scavengers in seeds.

Jain *et al.* (1996) also reported that 24hr partial desiccation increases three time of shoot regeneration in indica rice varities, Basmati 385 and Pusa basmati-1.

Jain *et al.* (1996)[illegible]suggested the improvement in regeneration potential has been suggested to be due to decreased water contented in dehydrated callus leading to an increase in endogenous abscisic acid level. Higuchi and Maedu (1990) and improved of oxygen supply to the callus.

Azria and Bhalla (2000) studied the plant regeneration from mature embryo derived callus of Australians rice (*Oryza sativa* L.) varieties. Partial desiccation resulting in up to 20% loss of fresh weight of callus significantly increased the regeneration frequency.

Chand and Sahrawat (2000) carried out partial desiccation of embryogenic calli prior to transfer to regeneration medium and observed increased regeneration frequency of desiccation treatment to callus culture of cv. Safari-17 and cv. Kasturi.

Desai *et al.* (2004) demonstrated that partial desiccation treatment of embryogenic callus improved plant regeneration in sugarcane.

Saharan *et al.* (2004) reported 48 hr. desiccation treatment was enhance shoot regeneration from 63 to 82% in indica rice cv. HKR-48 and HKR-125 on MS modified medium supplemented with 2 mg/lit Kin + 0.5 mg/l NAA + 30 mg/l sucrose + 6 g/l gelrite followed by MS + 1 mg/l 2 ip+ 30g/lit sucrose + 6 g/l gelrite.

Wagiran (2008) reported the plant regeneration in Japonica rice when 48 hr desiccated calli were transferred into optimal shoot regeneration media contained MS + 3 mg/l kinetin + 0.5 mg/l NAA + 3 mg/l gelrite. The regeneration frequency was highest at 76, 70 and 30% in variety Nipponbare, Hayohishikin and Fujisaka 5 respectively.

Suprasanna *et al.* (2008) reported that to stimulate regeneration response, irradiated cultures were subjected to partial

desiccation for 6 h and the treatment resulted in enhanced plant regeneration response.

Deng *et al.* (2009) reported that in four genotypes of maize calluses regenerated shoot best after 48 h of desiccation corresponding to a 23.7% average desiccation percentage and regeneration frequency reached 42.74% which increase 1.5 – 2.1 fold compared with that of non desiccated calluses.

2.3.2 Effect of desiccation on callus culture and regeneration in cotton

Voo *et al.* (1991) reported somatic embryogenesis and plant regeneration in *G.hirsutum* L. cv. coker 312 with the help of chemical and physical desiccation treatment.

Kumaria *et al.* (2003) used hypocotyls and cotyledon explants for initiation of embryogenic calli on MS medium containing 0.1mg/l2, 4 D, 0.5 mg/l Kinetin and 3% maltose produced globular- stage somatic embryos. However the frequency of globular embryos developing into normal plantlets improved considerably when culture on filter paper placed on MS medium. About 33% of globular embryos developed into cotyledonary embryos and subsequently to normal plantlets.

Sakhanokho *et al.* (2004) reported the 3-days desiccation treatment best and can be incorporated into regeneration protocol to improve the regeneration efficiency of cotton .The medium MS+0.2M glucose+ 2.6μM NAA + 0.2μM kin underwent a 3-d desiccation treatment 49 percent of these immature somatic embryos were converted into plantlets, in diploid cotton variety A-29 (PL 529722).

These improved result will helped to pave the way for future genetic transformation and can also be incorporated into regeneration protocol to improved regeneration efficiency of *Gossypium* species.

CHAPTER III

MATERIAL AND METHODS

The present *investigation was carried on* "Effect of desiccation on callus cultures in cotton *(G. hirsutum* L.)" at Plant Tissue Culture Laboratory, Biotechnology Center, Department of Agricultural Botany, Post Graduate Institute, Dr. Panjabrao Deshmukh Krishi Vidyapeeth, Akola.

3.1 Material

3.1.1 Genotypes

The experimental material of present investigation comprised of one popular variety of cotton (*G. hirsutum* L.) viz., PKV-Rajat. The seeds were obtained from Cotton Research Unit, Dr. PDKV, Akola.

3.1.2 Explants

3.1.2.1 Raising seedling in aseptic media

Explants were obtained from aseptically grown seedling at different age were used for present investigation.

Following two explants were obtained from four- five days old seedlings,

i. Hypocotyl segments

ii. Leaf bits

3.1.3 Glasswares

All the glasswares used were of 'BOROSIL' brand. For nutritional studies, culture bottles and culture tubes were used. For preparation of media and other work, Erlenmeyer flasks, beakers, measuring cylinders, petridishes, pipettes etc. were used.

3.1.4 Equipments

Equipments like LAF (Laminar Air Flow) cabinet, autoclave, growth chamber, B.O.D. incubator, weighing balance, hot air oven and pH meter were used.

3.1.5 Disinfectant and sterilizers

The chemical required for disinfection and sterilization of glasswares are given in Table 3.1.

Table 3. 1. Chemicals required for disinfection and sterilization

Particulars	Name of chemical	Conc. required
Glasswares	Potassium dichromate dissolved in conc. H_2SO_4	200 g Potassium dichromate per lit H_2SO_4
Surfactants	Mercuric chloride Ethanol	0.1% (w/v) 70% (v/v)

3.1.6 Washing glasswares

Glasswares were disinfected in solution containing potassium dichromate and concentrated H_2SO_4. To prepare the solution 60 g of pot dichromate was dissolved in 35 ml of distilled water and was heated for 2-3 minutes and final volume was made to one litre by adding conc. H_2SO_4. Glasswares were immersed for overnight in this solution. The following day, glasswares were thoroughly washed in tap water then with distilled water. They were allowed to dry on draining racks.

3.1.7 Sterilization of glasswares

Culture bottles, culture tubes were plugged with non-absorbent cotton and covered with butter paper. Petridishes, pipettes, beakers etc. were autoclaved at 1.5 p.s.i. pressure at 121^0C for an hour. They were then dried in hot air oven at 80-100^0C for two hours.

3.2 Culture media

3.2.1 Medium used for culture studies

In the present study, MS (Murashige and Skoog, 1962) medium was used. Modifications were made in this medium by adding suitable auxins and cytokinins.

3.2.2 Preparation of stock solutions

3.2.2.1 Basal media

All stock solutions were prepared in sterilized doubled distilled water, poured in well stopper bottles and stored in refrigerator. The constituents of MS media are given in the Table 3.2.

Table 3.2. Composition of Murashing and Skoog (1962) basal medium.

Ingredients	Chemical formula	Qty. (mg/l)	Conc. of stock solutions taken per litre medium
Major nutrients (stock A)			
Ammonium nitrate	NH_4NO_3	1650	50 ml
Potassium nitrate	KNO_3	1900	
Calcium chloride	$CaCl_2.2H_2O$	440	
Magnesium sulphate	$MgSO_4.7H_2O$	370	
Potassium dihydrogen orthophosphate	KH_2PO_4	170	
Minor nutrients (stock B)			
Potassium iodide	KI	0.83	5 ml
Boric acid	H_3BO_4	6.20	
Manganese sulphate	$MnSO_4.4H_2O$	22.30	
Zinc sulphate	$ZnSO_4.7H_2O$	8.60	
Sodium molybdate	$Na_2MoO_4.2H_2O$	0.25	
Copper sulphate	$CuSO_4.5H_2O$	0.025	
Cobalt chloride	$CoCl_2.6H_2O$	0.025	

Iron source (Stock C)			
Sodium EDTA	Na_2 EDTA	37.80	
Ferrous sulphate	$FeSO_4.7H_2O$	27.80	5 ml
Vitamin (stock D)			
Myoinositol		100	
Nicotic acid		0.5	
Pyridoxine HCl		0.5	5 ml
Thiamine HCl		0.1	
Glycine		2.0	

3.2.2.2. Hormones

Auxins like IAA, IBA were dissolved in few drops of NaOH and 2, 4-D in few drops of ethanol. They were heated slightly and gradually diluted to the required volume with double distilled water. Cytokinins like BAP and kinetin were dissolved in a few drops of 1 N NaOH, heated slightly and gradually diluted to required volume with double distilled water.

3.2.2.3. Carbohydrate sources

High quality sucrose was used at the concentration of 3%.

3.2.2.4. Gelling agent

i) Agar of LR grade at a conc. of 8 g per litre used for reparation of media.

ii) Phytagel (Sigma U.S.A.) at conc. of 3g per litre used for preparation of media.

3.2.3. Preparation of medium

The basal medium used for the present study was MS (Murashige and Skoog, 1962). The details of ingredients of MS media are given in Table 3.2.

For the preparation of one litre of media 50 ml of stock A solution was transformed to a clean, sterile, conical flask. To the same container 5 ml each of stock B, C and D solutions were transferred and stirred well. Growth regulators viz., IAA, 2,4-D BAP and kinetin were added to solution as per the requirement. The sucrose used at a concentration of 30 g/l (3%) or glucose was used at a conc. of 30g/l (3%) or 20g/l (2%), dissolved in water and added to the medium. The volume of solution was made up to one litre.

The pH of the medium was adjusted to 5.8. Then gelling agent such as agar or phytagel was added to the medium at 0.8 percent or 0.3 percent concentration and medium heated to dissolve the gelling agent without any clods. The medium was poured into previously sterilized bottles. The quantity of media per bottles was 30 ml. The bottles or cultures tubes were autoclaved at 121^0C at 15 lbs $inch^{-2}$ for 20 minutes.

3.2.4. pH of the medium

The pH of the medium was adjusted to 5.8 by adding 0.1 N HCl or 0.1 N NaOH before adding the solidifying agent.

3.3. Methodology

All aseptic manipulations including surface sterilization inoculation and transfer were carried out in a Horizontal Laminar Air Flow (LAF) cabinet fitted with an ultraviolet tube, which was turned on for half an hour before use. Before use of the cabinet it was smeared with ethyl alcohol (70%). All the cultures were incubated at 25 ± 2^0C under 16 hours of light (2000 Lux) and 8 hours of dark period.

3.3.1 Delinting:

Seeds were treated with commercial sulphuric acid for 5 to 10 s and then washed the seed with water and poured the seed in to lime solution for 5 min to remove excess of sulphuric acid; the seed were washed under running tap water for 10 min and dried. Before the start of experiment germination of seed was checked this is about 90 %.

3.3.2 Surface sterilization:

Delinted seed were surface sterilized by keeping the seeds water for half and hour then washed with detergent for three minute, followed by washing the seed with distilled water for three minute. Seeds were treated with 0.1% mercuric chloride for 10 minute. Seed were rinsed thrice in large volume of sterile distilled water prior to imbibitions and germination.

3.3.3 Seed germination:

Seed were germinated on full strength solid MS medium at 28±2°c with 16 hours light (1000 Lux) and eight hours dark period.

3.3.4 Explants culture:

Hypocotyls and leaf bits explants were obtained from 4 and 5 days old seedling aseptically raised on full strength MS media. Hypocotyls section of 4 mm length and leaf bits 3 mm lengths were cultured on MS medium supplemented with growth regulators.

3.3.5 Callus Induction:

To initiate the callus, explants were excised from surface sterilized seed and placed on to MS medium supplemented with growth regulators. After 4 weeks of incubation, primary callus were transferred to the fresh callus multiplication media for subculturing. Embryogenic callus was selected and maintained by subculturing once in every four week for

six month. Callus induction and subculture occurred at 25±2°C and in darkness.

The different treatment combinations of auxins and cytokinins concentrations with basal medium used for callus induction are given in Table 3.3. These were formulated on the basis of available literature.

Table 3.3. Combinations of auxins and cytokinins with basal media used for callus induction

Sr.No.	Treatment	MS (1962) basal		
		NAA mg /l	BAP mg/l	IAA mg/l
1	CM-1	3.00	0.00	0.00
2	CM-2	3.00	0.00	0.50
3	CM-3	3.00	0.00	1.00
4	CM-4	3.00	0.30	0.00
5	CM-5	3.00	0.50	0.00
6	CM-6	5.00	0.00	0.00
7	CM-7	5.00	0.00	0.50
8	CM-8	5.00	0.00	1.00
9	CM-9	5.00	0.30	0.00
10	CM-10	5.00	0.50	0.00
11	CM-11	10.0	0.00	1.0

3.3.6 Callus multiplication and proliferation.

The different treatment combinations of auxins and cytokinins concentrations with basal medium used for callus multiplication and proliferation are given in Table 3.4.

Table 3.4. Combinations of NAA and BAP with basal medium used for callus multiplication and proliferation in cotton

Sr. No.	Treatment	MS (1962) basal	
		NAA mg/l	BAP mg/l
1	M-1	5.00	
2	M-2	5.00	0.50
3	M-3	5.00	1.00
4	M-4	5.00	1.50

Observations were recorded with respect to response of two explants in different treatments combinations for

i. **Days required for callus initiation:** No. of days for initiation of callus were recorded after apparently observation of callus formation and counted in days from inoculation.

ii. **Percent callusing:** It was recorded at 45 days after inoculation of explants with one subculture at 21 days after inoculation. The frequency of callus induction was expressed in terms of percentage.

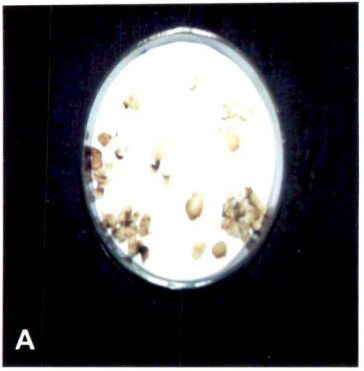
iii. **Relative growth rate of callus (%):** It was recorded at 30 DAS of 100mg callus on multiplication and proliferation medium.

3.3.7 Desiccation treatment:

Desiccation of callus was carried out at one and six month old sub cultured and was replicated in three times. Calluses around (5 gm) were treated with following two-desiccation agent and four different time duration interval under aseptic condition.

i. Filter paper 2hr, 4hr, 6hr, 8hr.

ii. Silica gel 2hr, 4hr.6hr, 8hr.



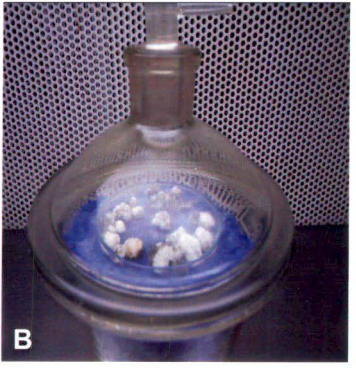


Plate 1 : Desiccators used for desiccation of callus
A - Filter paper
B - Silica gel

i) Filter paper:

Callus was carried out at one year and at six months old of subcultured and was replicated three times. Callus around five grams per treatment were transferred on to sterilized empty Petri dishes containing two dry sterilized whatman-1 filter paper. Petri dishes were sealed with Parafilm and kept at 25± 2°C in dark for 2,4,6,8 hours respectively.

ii) Silica gel:

About 5 gram per treatment of callus was desiccated using silica gel in sterilized desiccator for 2,4,6,8 hours and after desiccation, callus was transferred to regeneration medium.

Observation were be recorded after desiccation treatment

i) **Relative growth rate of callus on wt basis after desiccation:** It was recorded at 30 DAS of 100 mg desiccated callus on multiplication and proliferation medium.

a. **Fresh weight of callus (g):** Fresh weight of callus was recorded before each desiccation treatment.
b. **Weight of callus after desiccation (g):** Weight of callus after desiccation was recorded after each desiccation treatment.
c. **Moisture loss after desiccation treatment:** We used the term desiccation percentage to indicate the percent loss in callus fresh weight before and after desiccation.

$$\text{Desiccation percent (\%)} = \frac{A - B}{A} \times 100$$

Where,

A= Fresh weight of callus

B= Weight of callus after desiccation

ii) Regeneration response:

By comparing the effect different desiccation treatment, regeneration response for control calluses and desiccated calli with different media combination were recorded.

3.3.8 Somatic embryogenesis

Well-grown calli from different explants were cultured on MS medium supplemented with different levels of auxins and cytokinins. The treatment combinations of auxins and cytokinins concentrations used for regeneration study are given in Table 3.5. These were formulated on the basis of available literature (Trolinder and Goodin, 1988a and b; Kumar Shashi and Pental, 1998; Zhang *et al.* 2001; Suresh Kumar *et al.* 2002; Sakhanokho *et al.* 2004 and Verma *et al.* 2005).

Table 3.5. Combinations of auxin and cytokinins with basal medium used for somatic embryogenesis in cotton

Sr. No	Treatments	Auxin (mg/l)				Cytokinin (mg/l)	
		2,4-D	NAA	IAA	IBA	BAP	Kinetin

3.4 Statistical analysis

For recording observations on induction of callus, five aliquots of each treatment were used. For recording observation of regeneration of callus also, three aliquots were taken.

The mean and standard error were calculated as per procedure given by Panse and Sukhatme (1958).

$$X = \frac{\Sigma Xi}{N}$$

$$SD = \sqrt{\frac{\Sigma (Xi - X)^2}{N}}$$

$$SE = \frac{SD}{\sqrt{N}}$$

Where, $\bar{X}$ = Arithmetic mean

X_i = Sum of i^{th} observation

N = Number of observations

SE = Standard error

SD = Standard deviation

CHAPTER IV
RESULTS AND DISCUSSION

The present investigation was conducted on "Effect of desiccation on callus cultures in cotton". The experimental material comprised of two explants viz., hypocotyls and leaf bits of popular cotton (*G. hirsutum* L.) variety PKV– Rajat. The media treatments were formulated by using different combinations of auxins and cytokinins with Murashige and Skoog (1962) as basal medium. The observations were recorded on different aspects and the results are presented in this chapter.

4.1 Callus induction in cotton.

4.1.1 Days required for callus initiation.

The effect of different 11 media treatments for initiation of callus using two explants, hypocotyls and leaf bits of cotton variety PKV-Rajat was studied and the data are presented in Table 4.1 and Fig. 1.

It was found that minimum numbers of days (11.95±0.10) were required for initiation of callus from hypocotyls in PKV-Rajat and in leaf bits (24.34± 0.22) in CM-10 and CM-11 medium, respectively. Numbers of days required for initiation of callus were less at higher concentration of auxins as against lower concentration of auxin in both the explants.

In medium CM-2, rhizogenesis was observed within 10 to 15 days and secondary roots were also developed. For leaf bits there was higher percentage of rhizogenesis than hypocotyl. These results were comparable to earlier report given by Muthusamy and Jayabalan (2000). Callus initiation was maximum from hypocotyls within 10-11 days as compared to leaf bits. Texture of callus in leaf bits was loose friable and white in colour. Callus developed from hypocotyls was compact in texture

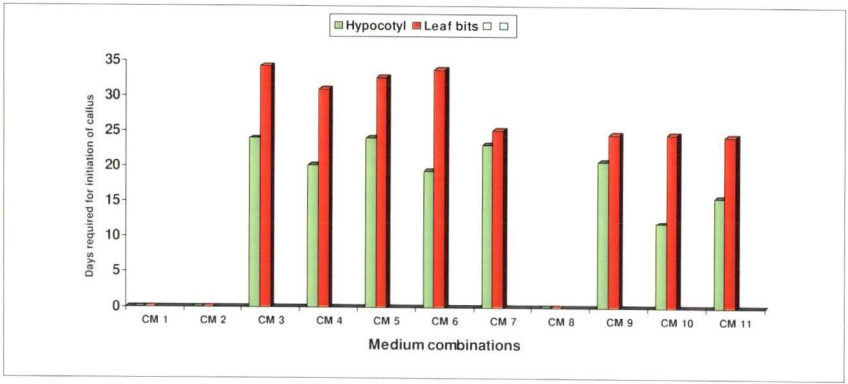

Fig. 1 Days required for initiation of callus in cotton on different medium combinations by using hypocotyls and leaf bits as explants.

similar results were also reported for hypocotyls in cotton (*Gossypium hirsutum*) by Shoemaker *et al.* (1986) and Verma *et al.* (2005).

Overall performance of hypocotyls was found to be more responsive than leaf bits for initiation of callus on different media combinations. Difference for callus initiations using different explants were also observed by Verma *et al.* (2005), Zhang *et al.* (2001) in cotton. Genotypic differences for callus initiation were also observed by Shoemaker *et al.* (1986) and Trolinder and Xhixhian (1989) in cotton.

Table 4.1 Days required for callus initiation in cotton

Sr. No.	Medium	Explants	
		hypocotyls	Leaf bits

10	CM-10	11.95±0.10	24.70±0.13
11	CM-11	15.63±0.06	24.34±0.22

4.1.2 Percent callus induction in cotton

The effect of 11 treatments on percent callusing from two explants viz., hypocotyls and leaf bits of PKV-Rajat was studied and the data are presented in Table 4.2 and Fig.2.

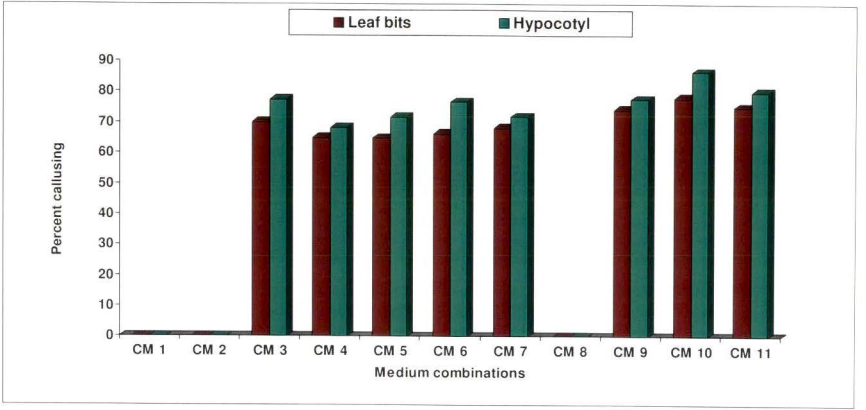

Fig. 2 Percent callus induction in cotton on different medium combinations by using leaf bits and hypocotyls as explants

Hypocotyls and leaf bits explants gave higher percent callusing on medium CM-10 and CM-11 having combination (5mg/l NAA+0.5mg/l BAP and 10mg/l NAA +1mg/l BAP). Similar results were also reported for hypocotyls by Suresh Kumar *et al.* (2003); Zhang *et al.* (2001) and Verma *et al.* (2005).

Table 4.2: Percent callus induction in hypocotyls and leaf bits explants of cotton.

Sr. No.	Medium	Explants	
		Hypocotyls	Leaf bits
1	CM-1	No callus	No callus
2	CM-2	Rooting	Rooting
3	CM-3	77.42	70.07
4	CM-4	68.10	64.91
5	CM-5	71.68	64.69
6	CM-6	76.54	66.25
7	CM-7	71.73	68.08
8	CM-8	No callus	No callus
9	CM-9	77.46	74.23
10	CM-10	86.40	78.00
11	CM-11	79.94	74.96

4.2 Callus multiplication and proliferation in cotton.

After callus induction, the whitish brown callus was transferred on callus multiplication and proliferation media. The growth rate of callus obtained from hypocotyls and leaf bits on weight basis was recorded 30 DAS and estimated in percentage in PKV-Rajat. The results are presented in Table 4.3.

Four media were tried for callus multiplication, out of which, M-3 media (5mg/l NAA and 0.5mg/ BAP) was found to be better for multiplication and proliferation of embryogenic callus. The basal media with higher concentration of NAA and lower concentrations of BAP were found to be suitable for proliferation of embryogenic callus than NAA alone. The present results were comparable to Brar *et al.* (1998).They reported (MS + 5.0 mg/l NAA + 0.1 mg/l KIN) to be the best for callus proliferation and maintenance.

The callus multiplied and proliferated faster on M-3 than other medium at 30 DAS of callus. However, friable white embryogenic callus was produced on M-1 which is primary criteria for somatic embryogenesis. These results are in agreement with results of Zhang *et al.* (2001).

Table 4.3: Callus multiplication and proliferation in cotton

Sr.No	Medium	Explant	
		Hypocotyls	Leaf bits
1	M-1	164.90±0.10	165.74±0.31
2	M-2	127.33±0.34	122.05±0.41
3	M-3	243.83±0.50	230.22±0.11
4	M-4	187.64±0.29	172.98±0.11

4.3 Effect of Desiccation on callus growth in cotton

The effect of ten media treatment on fresh weight and weight of callus after desiccation from two explants, hypocotyls and leaf bits of

each desiccation treatment in PKV Rajat were studied and the data are presented in Table 4.4, 4.5, 4.6, 4.7, and 4.8.

4.3 .1 Effect of desiccation on relative growth rate of callus

After desiccation treatment of callus for different time interval (2, 4, 6 and 8 hr) using two desiccators viz., silica gel and filter paper, the desiccated callus was transferred on callus multiplication and proliferation media. Observations were recorded for growth rate of callus on weight basis and estimated in percentage of callus multiplication 30 DAS for both explants viz., hypocotyls and leaf bits of cotton cultivar PKV-Rajat. The results are presented in Table 4.4.

The maximum growth rate of callus was observed from hypocotyls (451.33 $\pm$ 1.13) in eight hours of desiccation period using filter paper as desiccators on medium M-2 followed by (440.00 $\pm$ 0.54) medium M-3.

Two media treatments were tried out of which M2 medium was found to be better for multiplication and proliferation of desiccated callus. In desiccated callus, maximum percentage of callus multiplication than control was observed. Differences were also observed between desiccators; in silica gel desiccated callus multiplication and proliferation was lesser than filter paper desiccated callus.

Similar results were also observed by Deng *et al.* (2009) and suggested filter paper desiccation in maize. They observed that increased desiccation period resulted in increase in callus multiplication rate.

Table 4.3 Relative growth rate of callus on weight basis after desiccation treatment

Medium	Desiccation Period (hrs)	Explants	Percent increase of callus 30 DAS after desiccation (%)

HY-hypocotyls

LB –leaf bits

DAS- days after sub culture

4.3.2 Effect of two hours desiccation on callus growth

The effect of two hour desiccation using silica gel and filter paper on callus culture from two explants viz., hypocotyls and leaf bits of PKV-Rajat were studied (Table 4.5)

In case of old callus of hypocotyls, maximum weight of callus (88.48 + 0.23) was recorded with silica gel desiccation whereas in new callus it was (90.84 ± 0.24) on M4 medium.

In case of old callus of leaf bits, maximum weight (88.49 ± 0.56) was observed with silica gel desiccation on M2, whereas in new callus it was (90.68 ± 0.09) on M4 medium.

Maximum weight of callus after desiccation of hypocotyls using filter paper was 57.41 ± 0.24 whereas in new callus it was (57.45 ± 0.04) on medium M1.

Maximum weights after desiccation of old and new calli of leaf bits using filter paper was (56.58 ± 0.19) and (55.95 ± 0.22), respectively on medium M1.

In general, new callus loose higher moisture percentage as compared to old callus during desiccation. Between two desiccation, faster rate of desiccation was observed with filter paper than silica gel.

In case of silica gel, higher desiccation percentage was recorded from new callus of hypocotyls (11.78) and leaf bits (12.51) on M1 medium, whereas in case of filter paper highest desiccation percentage was recorded from old callus of hypocotyls (44.53) and leaf bits (44.92) on M2 medium. These results were also comparable to Suprasanna *et al.* (2008) in sugarcane and Rance *et al.* (1994) in rice. They dried calli sufficiently to loss 10% to 40% of their fresh weight.

Table 4.5 Effect of two-hour desiccation on callus weight in cotton

Sr. No.	Medium	Desiccators	Weight of callus after desiccation in percentage				Desiccation percentage			
			Hypocotyls		Leaf bits		Hypocotyls		Leaf bits

		FP	56.04 ±0.21	56.05 ±0.09	54.84 ±0.24	55.94 ±0.17	43.96	43.06	43.09	44.73
4	M4	SG	88.48 ±0.23	90.84 ±0.24	88.11 ±2.7	90.68 ±0.09	11.38	11.25	11.89	11.96
		FP	56.16 ±0.11	56.31 ±0.21	54.11 ±0.18	54.75 ±0.07	43.84	43.36	44.92	43.82

4.3.2 Effect of four-hour desiccation on callus weight in cotton

The effect of four-hour desiccation using silica gel and filter paper on callus culture from two explants viz., hypocotyls and leaf bits of PKV-Rajat were studied (Table 4.6).

In case of old callus of hypocotyl maximum weight (82.62 ± 0.35) was recorded using silica gel desiccated calli on M2 medium, whereas in new callus it was (81.99 ± 0.00) on M3 medium.

In case of old callus of leaf bits, maximum weight (82.84 ± 0.31) was observed using silica gel desiccated calli on M1 medium, where as in new callus it was (83.19 ± 0.16) on M4 medium.

Maximum weight of callus after desiccation of hypocotyls using filter paper was (52.13 ± 0.18) where as in new callus it was (57.45 ± 0.04) on M2 medium.

Maximum weight of callus after desiccation of old callus of leaf bits using filter paper was (53.06 ± 0.22) and in new callus it was (52.82 ± 0.11) on M3.

In case of silica gel, higher desiccation percentage was recorded from new callus of hypocotyls (19.36) and leaf bits (18.71) on M4 medium, whereas in case of filter paper, highest desiccation percentage was recorded from old callus of hypocotyls (49.82) and leaf bits (49.00) on M2 and M1 media respectively. These results are comparable to Diah and Bhalla (2000). In Australian rice variety, they observed partial desiccation resulting up to 20% loss of fresh weight of callus.

Table 4.7. Effect of four-hour desiccation on callus growth in cotton.

Sr. No.	Medium	Desiccators	Weight of callus after desiccation in percentage				Desiccation percent

4.3.3 Effect of six hours desiccation on callus weight in cotton

The effect of six-hour desiccation using silica gel and filter paper on callus culture by from two explants viz., hypocotyls and leaf bits of PKV-Rajat was studied (Table 4.7).

In case of old callus of hypocotyls, maximum weight (79.74± 0.01) was recorded using silica gel desiccated callus on M3 medium, whereas in new callus it was (78.59 ± 0.13) on M1 medium.

In case of old callus of leaf bits, maximum weight (78.28 ± 0.30) was observed using silica gel desiccated callus on M1 medium, where as in new callus it was (78.66 ± 0.52) on M4 medium.

Maximum weight of callus after desiccation of old callus of hypocotyls using filter paper was (47.85 ± 0.18) whereas in new callus it was (48.08 ±0.26) on M2 medium.

Maximum weight of callus after desiccation of old callus of leaf bits using filter paper was (47.99 ± 0.17) and in new callus it was (47.80 ± 0.61) on medium M2.

In case of silica gel, higher desiccation percentage was recorded from new callus of hypocotyls (22.85) and in leaf bits (23.00) on M3 and M4 media, whereas in case of filter paper, highest desiccation, percentage was recorded from old callus of hypocotyls (52.91) and leaf bits (53.78) on M2 and M1 media, respectively. These results obtained are in agreement with the finding of Suprasanna *et al.*, (2008) in sugarcane.

Table 4.7. Effect of six hours desiccation on callus weight in cotton.

Sr No.	Medium	Desiccators	Weight of callus after desiccation in percentage				Desiccation percent

4.3.6 Effect of eight hours desiccation on callus weight in cotton

The effect of eight hour desiccation using silica gel and filter paper on callus culture by from two explants viz., hypocotyls and leaf bits of PKV-Rajat were studied (Table 4.7).

In case of old callus of hypocotyls, maximum weight (72.64 ± 0.27 was recorded using silica gel desiccated callus on M1 medium, whereas in new callus it was (72.15 ± 0.16) on M1 media.

In case of old callus of leaf bits, maximum weight (70.02±0.12) was observed using silica gel on M1 medium, whereas in new callus it was (71.41 ± 0.21) on M4 medium.

Maximum fresh weight after desiccation of old callus of hypocotyls using filter paper was (60.34 ± 0.09) whereas in new callus it was (60.34 ±0.52) on M2 media.

Maximum fresh weight after desiccation of old callus of leaf bits by using filter paper was (47.99 ± 0.17) and in new callus it was (47.80 ± 0.61) on medium M2.

In case of silica gel, higher desiccation percentage was recorded from new callus of hypocotyl (28.36) and in leaf bits (30.94) on M4 media, whereas in case of filter paper, highest desiccation percentage was recorded from old callus of hypocotyls (61.26) and leaf bits (60.34) on M3 and M2 media, respectively. These results are comparable to Rance (1994) who reported loss of moisture up to 60 percent of fresh weight of callus in rice.

Table 4.7 Effect of eight-hour desiccation on callus weight in cotton.

C - Compact white callus
D - Yellowish green compact callus
E - Friable brownish callus
F - Yellowish green friable callus

4.5 Effect of desiccation on regeneration responses in cotton

Effect of desiccation treatment and different media combination on somatic embryogenesis in cotton was studied 30 days after desiccation callus was transferred to the regeneration media and the data was recorded (Table 4.8).

4.5.1 Effect of desiccation on somatic embryogenesis

In controlled callus somatic embryo frequency was minimum as compared to desiccated callus. It was observed that 2 and 4 hrs silica gel desiccation treatment gave better response for somatic embryo development than filter paper. In 2, 4 and 6 hrs silica gel desiccation treatments, maximum number of somatic embryos were developed on SM-27, SM-36, SM-43, SM-47, SM-53, SM-59, SM-71, SM-75 and SM-84 and SM-110, respectively after 40 days of inoculation of desiccated callus on regeneration media. These results were comparable to Deng *et al.* (2009).

Filter paper desiccation treatment for 2 and 4 h showed less somatic embryos development in SM-2, SM-3, SM-5, SM-12, SM-23, SM-27, SM-42, SM-43, SM-53, SM-59, SM-60-, SM-75 media, respectively. Somatic embryogenesis was observed from non desiccated callus on media SM-2, SM-12, SM-39 SM-47, SM-53, SM-59, SM-60 and SM-84.Similar results were also observed by Smita Shingane (2008) in cotton.

Non desiccated callus showed less response for somatic embryogenesis than desiccated callus. These results were in agreement with the finding of Wagiran (2008) in Japonica rice.

4.5.2 Colour and texture of callus after desiccation

It was apparently observed that the influence of media combinations on the expression of callus colour and texture in this case was distinct and was clearly detected at the callus formation stage.

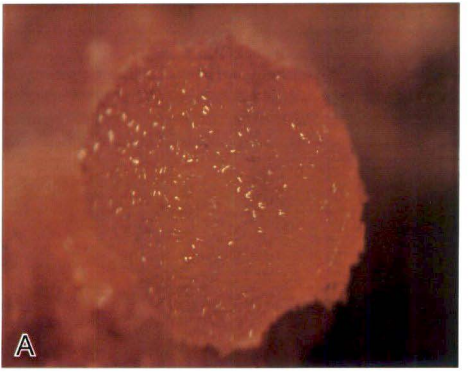

Plate 3 : Stages of somatic embryogenesis in cotton
A - Globular stage of somatic embryos
B - Heart shape stage of somatic embryos

Callus treated with filter paper desiccation treatment showed green coloured and compact white coloured callus on maximum number of media (Plate-2). Friable white callus showed maximum response to somatic embryo formation (Plate-3). Similar results were reported by Verma *et al.* (2005).Yellowish green callus, light green compact callus, friable watery callus were observed in different media treatment. The higher concentration of auxins resulted in increased friability of callus. These results are similar to the report of Trolinder and Goodin (1988) and Firozabody *et al.* (1993).

The variation with respect to colour and texture of embryogenic calli on different media combination has been observed by several authors (Finer 1988, Firozabady *et al.* 1987, Gawel *et al.* 1986, Shoemaker *et al.* 1986, Trolinder and Goodin 1988).

4.5.3 Growth Stages of somatic embryos

Globular and heart shape stages of somatic embryos were observed maximum on silica gel desiccation treatment than filter paper. (Plate 3-A and 3-B)

Desiccation also resulted in accelerated organogenesis. In some cases rhizogenesis was also observed when desiccated calli transferred to the regeneration media. Similar results were also reported by Mathusamy and Jayabalan (2000). Comparable results were also reported by Suprasanna *et al.* (2007) in sugarcane and Kumaria *et al.* (2003) in cotton.

4.5.4 Number and frequency of somatic embryos.

The maximum (13.39) percentage of globular somatic embryos were developed after 2h silica gel desiccation treatments in hypocotyls and in case of leaf bits it was (11.34) on medium SM-27 (0.75 mg/l NAA and 1.0 mg/l BAP).While heart shape stage frequency of somatic embryos was observed to be 2.99 on SM-53 (MS +0.2 mg/l Kin). Filter paper

desiccated calli beared globular stage somatic embryos up to (9.87%) in hypocotyls on medium SM-47 (2mg/l NAA+ 2mg/l BAP) and 6.67 in leaf bits on media SM-23 (0.5mg/lNAA 0.5mg/l BAP). Desiccation resulted in 12 to 20% loss of fresh weight of callus, which significantly increased the frequency of somatic embryos in *Gossypium* spp.

In non-desiccated callus, frequency of somatic embryos was minimum as compared to desiccated callus. Non desiccated calli beared globular somatic embryos up to 2.41% in hypocotyls and leaf bits1.73% on medium SM-59(MS+1mg/l BAP).Embryo initiation and maturation was also affected by media treatment. These results supported the findings of Sakhanokho *et al. (2001)* in cotton.

Several authors; Gawel *et al.* (1996), Gawel and Roback (1990), Kumar and Pental (1998), Shoemaker et al. (1986), Chand and Sahrawat (2001) have reported a low frequency of embryo maturation in cotton.

Table 4.8: Effect of desiccation treatments on somatic embryos development in cotton

CHAPTER V
SUMMARY AND CONCLUSION

In the present investigation entitled "Effect of Desiccation on Callus Cultures in Cotton". Two explants viz. hypocotyls and leaf bits of *G .hirsutum* cotton variety PKV-Rajat were used for callus induction, desiccation and somatic embryogenesis responses in cotton.

i) Minimum numbers of days (11.94 + 0.10) were recorded for callus initiation in hypocotyls and (24.74 ± 0.22) for leaf bits on medium CM10 (5 mg/l NAA + 0.5 mg/L BAP).

ii) The highest percentage of callusing (86.40%) was produced by hypocotyls and 79% for leaf bits in medium CM-11 (10 mg/l NAA + 1 mg/l BAP)

iii) Rhizogenesis was observed in both of the explants with leaf bits and hypocotyls after 15 days of inoculation on CM-2 medium (MS + 3 mg/l NAA + 0.1 mg/l IAA).

iv) In case of hypocotyls callus was multiplied maximum (243.83 ± 0.50 %), where as in case of leaf bits (230.22 ± 0.11%) on M3 (5 mg/l NAA + 0.5 mg/l BAP).

v) Desiccation percentage was recorded after two, four, six and eight hr and they were 11.78, 18, 22.85 and 28.26% respectively in silica gel. However, it was observed higher 44.53, 49.82, 52.92, and 59% in filter paper desiccation.

Higher percentage of moisture loss was also observed in the new callus as compared to old callus during desiccation treatment.

vi) The relative growth rate of callus was highest in hypocotyls (440.00 ± 0.54%) after 8 hrs desiccation on filter paper and leaf bits it was 425.67 ± 0.31 per cent. The rate of desiccation is faster in filter paper than silica gel desiccation.

vii) The maximum percentage of globular somatic embryos (13.39%) was observed in hypocotyls than leaf bits (11.34%).Heart shape

somatic embryos were also formed in hypocotyls and leaf bits explants having frequency 2.99 and 2.92% on SM-53 (MS + 0.2 mg/l kin) using silica gel desiccation.

viii) Filter paper desiccated calli beared globular stage somatic embryos up to (9.87%) in hypocotyls on medium SM-47 (2mg/l NAA+ 2mg/l BAP) and leaf bits (6.67%) on media SM-23 (0.5mg/l NAA 0.5mg/l BAP).

ix) Non desiccated calli beared globular somatic embryos up to 2.41% in hypocotyls and leaf bits 1.73% on medium SM-59(MS+1mg/l BAP).

Conclusions

i. The rate of desiccation was observed highest in filter paper than silica gel desiccation and similar trend was also observed for callus multiplication after desiccation

ii. Silica gel desiccation treatment produced more globular somatic embryos than filter paper desiccation treatment. It was also observed heart shaped somatic embryos were produced from 2h silica gel desiccation however no response in filter paper.

iii. Frequency of globular somatic embryos was more in two and four hour Silica gel desiccators than filter paper and non desiccated callus.

iv. Hypocotyl explants and silica gel desiccation was for 2 and 4 h found effective for induction of somatic embryogenesis than leaf bit explants and filter paper desiccation.

CHAPTER – VI

IMPLICATIONS

In the present investigation entitled "Effect of desiccation on callus cultures in cotton." concluded that the hypocotyls explants found suitable for callus induction. Desiccation treatment using silica gel will help to improve conversion of globular somatic embryos in to heart shaped somatic embryos. It helps to standardize protocol of somatic embryogenesis in cotton variety PKV- Rajat.

VITA

1. Name of student : **Zambre Supriya Manohar**
2. Date of Birth : **24th Sep 1985**
3. Name of College : **Post Graduate Institute, Dr. PDKV, Akola, Maharashtra.**
4. Residential address along with phone no. : **C/O Shri. Manohar A. Zambre, Raj colony Keshav nagar, Akola Dist- Akola, Pin- 4440004 Ph. No. 9922392124**

5. Academic qualifications

Sr. No.	Name of Degrees awarded	Year in which obtained	Division / Class	Name of awarding university	Subjects
1.	B.Sc. (Agriculture)	2007	Second	Dr.PDKV, Akola	Agriculture

6. Field of Interest : Research and Development

Place: Akola

Date : 12 **/ 05/ 2009**

Zambre
